## $Q$ uantum $m$ echanics of $m$ easurem ent

N. J. Cerf and C.A dam iniz<br>${ }^{1}$ W . K . K ellogg Radiation Laboratory and ${ }^{2} \mathrm{C}$ om putation and N eural System S , C aliformia Institute of Technology, P asadena, C alifomia 91125<br>(R eceived 6 M ay 1996, revised January 1997)

A $n$ analysis of quantum $m$ easurem ent is presented that relies on an inform ation-theoretic description of quantum entanglem ent. In a consistent quantum inform ation theory of entanglem ent, entropies (uncertainties) conditionalon $m$ easurem ent outcom es can be negative, im ply ing that $m$ easurem ent can be described via unitary, entropy-conserving, interactions, while still producing random ness in a $m$ easurem ent device. In such a fram ew ork, quantum $m$ easurem ent is not accom panied by a w ave-function collapse, or a quantum jump. The theory is applied to them easurem ent of incom patible variables, giving rise to a stronger entropic uncertainty relation than heretofore known. It is also applied to standard quantum $m$ easurem ent situations such as the Stem-G erlach and double-slit experim ents to illustrate how random ness, inherent in the conventionalquantum probabilities, arises in a unitary fram ew ork. Finally, the present view clari es the relationship between classical and quantum concepts.

## I. IN TRODUCTION

For seventy years it has rem ained a $m$ ystery how quantum $m$ easurem ent can be probabilistic in nature, and thus be accom panied by the creation of random ness or uncertainty, while at the sam e tim e being described by unitary evolution. This apparent contradiction has cast serious doubts on the very foundations of quantum me chanics. M eanw hile, the equations and predictions of the purportedly awed theory en joy unbridled, unequivocal success. In this paper, we present an inform ationtheoretic description of quantum $m$ easurem ent which sheds new light on this long-standing question. This description, in term s of the quantum in form ation theory (Q IT ) introduced by us recently [7, 2], im plies that the (conditional) quantum entropy of an entangled subsystem can be negative, in contrast to its classical counterpart. As we outline below, this allows for the creation of entropy in the $m$ easurem ent device which is counterbalanced by the negative entropy of the quantum system itself, resulting in the conservation ofentropy in the m easurem ent process. C onsequently, the probabilistic nature of quantum $m$ echanics can be show $n$ to follow from a com pletely consistent, unitary, description of $m$ easurem ent.

O urm odeldoes not require the quantum system to be coupled to a m acroscopic|uncontrollable| environm ent, and is therefore distinct from the environm ent-induced decoherence m odel, one of the prevalent contem porary view s of quantum $m$ easurem ent 3]. A s show $n$ below, the view advocated here only insists on the \self-consistency" of the $m$ easurem ent device while abandoning the $100 \%$ correlation betw een the device and the $m$ easured quantum system which is a comerstone ofdecoherencem odels. A lso, while the inform ation-theoretic interpretation suggests that the universe exists in a supenposition of quantum states, all of quantum phenom enology is explained arm ed only with one, rather than $m$ any, such universes.

A m ore detailed investigation of the $m$ easurem ent process reveals that the collapse of the wavefunction is an illusion, brought about by the observation of part of a com posite system that is quantum entangled and thus inseparable. $R$ ather than collapsing, the w avefunction of a $m$ easured system becom es entangled $w$ th the wavefunction of the $m$ easurem ent device. If prepared in a superposition of eigenstates, the $m$ easured system is not reduced to one of its eigenstates. In other w ords, a quantum jump does notoccur. That thism ust be the case has of course been suspected for a long tim e, and it certainly is implicit in the quantum eraser experim ents on which we shall com $m$ ent below. H ere we show that this feature em erges naturally if quantum entanglem ent is properly described in the language of Q IT. Furthem ore, due to the absence of a collapse of the w avefunction, our unitary description im plies that quantum $m$ easurem ent is inherently reversible, overtuming the com $m$ on view. H ow ever, in an experim ent where quantum entanglem ent is trans-
ferred to a m acroscopic \pointer" variable (as is essential for classical observers) the reversibility is obscured by the practical im possibility of keeping track of all the atom $s$ involved in the unitary transform ation, rendering the $m$ easurem ent as irreversible as the them odynam ics of gasen. Thus, as suggested earlier by Peres 团], the apparent irreversibility of quantum $m$ easurem ent can be understood entirely in classical term s.

In the next section, we brie y review the current state of quantum $m$ easurem ent theory, $w$ ith em phasis on the standard von $N$ eum ann theory of $m$ easurem ent. In Section III, we outline those features of the quantum infor$m$ ation theory introduced in [7] $\sqrt{2}$ ] which apply to quantum $m$ easurem ent, and point out the singular im portance of negative entropy in quantum entanglem ent. W e also focus on the relation betw een entanglem ent and inseparability in this theory. In Section IV we then proceed w ith a $m$ icroscopic description of the unitary physical $m$ easurem ent process as anticipated by von $N$ eum ann, but properly interpreted within Q IT.We focus on the measurem ent of incom patible variables in Section $V$ and show how one of the $m$ ilestones of quantum physics, the uncertainty relation, em erges naturally from our construction. A ltematively, this Section can be read as describing unitary quantum $m$ easurem ent $m$ ore form ally, im plying som e of the well-know n relations of conventional quantum m echanics. Section $V$ discusses new insights into the interpretation of quantum $m$ echanics brought about by this inform ation-theoretic analysis. T here, we investigate the relationship betw een classical and quantum variables and propose a simple resolution to the \Schrodinger-cat" paradox. A lso, we com m ent on the origin of the com plem entarity principle and the duality betw een w aves and particles. W eo er our conclusions in Section VI. F inally, A ppendix A illustrates the interpretation of standard experim ents of quantum mechanics within our fram ew ork. There, we consider the basic Stem-G erlach setup and \quantum erasure" in the standard double-slit experim ent.

## II. THEORY OFMEASUREMENT

The theory of $m$ easurem ent occupies a central role in quantum physics and has undergone a num ber of conceptual revolutions. Those range from the probabilistic interpretation of quantum $m$ echanics by Bom and the C openhagen interpretation cham pioned by B ohr (see e.g. [5]), over von $N$ eum ann's sem inalcontribution in the \G rundlagen" 目] to m ore m odem interpretations such as

[^0]Everett＇s［友］，c ram er＇s 冝］，and Zurek＇s 目］．
C entral to all these treatm ents is the problem of the collapse of the w avefunction，or state vector．To illustrate this process，consider for exam ple the $m$ easurem ent of an electron，described by the wavefunction（q）where $q$ is the coordinate of the electron．Further，let the $m$ easure－ $m$ ent device be characterized intially by its eigenfunc－ tion 0() ，where $m$ ay sum $m$ arize the coordinates of the device．B efore $m$ easurem ent，i．e．，before the electron interacts $w$ ith the $m$ easurem ent device，the system is de－ scribed by the wavefunction

$$
\begin{equation*}
\text { (q) } 0 \text { ( ): } \tag{2.1}
\end{equation*}
$$

A fter the interaction，the w avefunction is a superposition of the eigenfunctions of electron and $m$ easurem ent devioe

X

$$
\begin{equation*}
\mathrm{n}(\mathrm{q})_{\mathrm{n}}(\mathrm{)}: \tag{22}
\end{equation*}
$$

Follow ing orthodox $m$ easurem ent theory，the classicalna－ ture of the $m$ easurem ent apparatus im plies that after $m$ easurem ent the \pointer＂variable takes on a well－ de ned value at each point in tim $e$ ；the wavefunction，as it tums out，is thus not given by the entire sum in 2．2） but rather by the single term

$$
\begin{equation*}
\mathrm{n}(\mathrm{q}) \mathrm{n}(\mathrm{l}): \tag{2.3}
\end{equation*}
$$

$T$ he w avefunction 2．2）is said to have collapsed to 2．3）．
A comerstone of the Copenhagen interpretation of $m$ easurem ent w asprecisely this collapse，due to the inter－ action of a quantum ob ject w ith a m acroscopic，classical， $m$ easurem ent device．T he crucial step to describe the $m$ easurem ent process as an interaction of two quantum system $s$［as is im plicit in（22）］was $m$ ade by von Neu － m ann［6］，who recognized that an interaction betw een a classical and a quantum system cannot be part of a con－ sistent quantum theory．In his G rundlagen，he therefore proceeded to decom pose the quantum $m$ easurem ent into two fundam ental stages．The rst stage（term ed \von N eum ann $m$ easurem ent＂）gives rise to the wavefunction 2．2）．The second stage（which von $N$ eum ann term ed （observation＂of the $m$ easurem ent）involves the collapse described above，i．e．，the transition from 2．2．）to 2．3）．

W e now proceed to describe the rst stage in $m$ ore de－ tail．For ease of notation，let us recast this problem into the language of state vectors instead．T he rst stage in－ volves the interaction of the quantum system $Q w$ th the $m$ easurem ent device（or \ancilla＂）A．B oth the quantum system and the ancilla are fiully determ ined by their state vector，yet，let us assum e that the state of Q（described by state vector $\dot{x i}$ ）is unknown whereas the state of the ancilla is prepared in a special state j0i，say．T he state vector of the com bined system $\$ \mathrm{~A}$ i before $m$ easurem ent then is

$$
\begin{equation*}
j \mathrm{t}=0 \mathrm{i}=\dot{\mathrm{x}} \mathrm{ij} 0 \mathrm{i} \quad \dot{\mathrm{j}} ; 0 \mathrm{i}: \tag{2.4}
\end{equation*}
$$

$T$ he von $N$ eum ann $m$ easurem ent is described by the uni－ tary evolution of QA via the interaction $H$ am iltonian

$$
\begin{equation*}
\hat{H}=\hat{x_{Q}} \hat{\mathrm{P}_{\mathrm{A}}} ; \tag{2.5}
\end{equation*}
$$

operating on the product space of Q and $\mathrm{A} . \mathrm{Here}, \hat{\mathrm{X}_{Q}}$ is the observable to be m easured，and $\hat{P_{A}}$ the operator con－ jugate to the degree of freedom of $A$ that will re ect the result of the $m$ easurem ent．$W$ e now obtain for the state vector $\mathbb{D} A$ i after $m$ easurem ent（e．g．at $t=1$ ，putting $\mathrm{h}=1$ ）

$$
\begin{equation*}
j t=1 i=e^{i \hat{X} \hat{X}_{Q} \hat{P_{A}}} \dot{j} ; 0 i=e^{i x \hat{P_{A}}} \dot{y} ; 0 i=\dot{x} ; x i: \tag{2.6}
\end{equation*}
$$

Thus，the pointer in A that previously pointed to zero now also points to the position $x$ that $Q$ is in．A ccording to von $N$ eum ann，this sim ple operation re ects the corre－ lation betw een $Q$ and $A$ introduced by the $m$ easurem ent． In general，this unitary operation rather introduces en－ tanglem ent，which is beyond the classical concept of cor－ relations．In fact，the creation of entanglem ent in a von $N$ eum ann m easurem ent is generic．This is illustrated for typicalm easurem ent situations in A ppendix A．
$T$ he second stage in von $N$ eum ann＇s theory of $m$ ea－ surem ent，the observation of the pointer variable by a conscious observer（or a mechanical device with mem － ory），is the key problem ofm easurem ent theory and the centralob ject of th is paper． H istorically，th is conundrum is usually couched into the question：$\backslash A$ t w hat point does the possibility of an outcom e change into actuality？＂In the interpretation of this stage，von $N$ eum ann nally con－ ceded to B ohr，who m aintained that the \observing＂op－ eration（stage two），now distinct from the \m easuring＂ process（stage one），is irreversible and non－causal．At rst glance，there appears to be no escape from this con－ clusion，as a pure state（a superposition）seem s to evolve into a m ixed state（describing all possible outcom es），a process that cannot be described by a unitary operation． This becom es m ore evident if we apply the unitary oper－ ation described above to an initial quantum state which is in a quantum superposition：

$$
\begin{equation*}
j \mathrm{t}=0 \mathrm{i}=\mathrm{j}+\mathrm{y} \text {;0i: } \tag{2.7}
\end{equation*}
$$

$T$ hen，the linearity of quantum $m$ echanics im plies that

$$
\begin{equation*}
j \mathrm{t}=1 \mathrm{i}=\mathrm{e}^{\mathrm{ix} \hat{X}_{Q} \hat{\mathrm{P}_{M}}} \quad \dot{\mathrm{x}} ; 0 \mathrm{O}+\dot{\mathrm{y}} ; 0 \mathrm{i}=\hat{\mathrm{x}} ; \mathrm{xi}+\dot{\mathrm{y}} ; \mathrm{yi} \tag{2.8}
\end{equation*}
$$

[^1]which is still a pure state．H ow ever，it does not re ect classical correlations betw een $Q$ and $A$（as would the state $\mathrm{x}+\mathrm{y} \boldsymbol{j} \mathrm{x}+\mathrm{yi}$ ）but rather quantum entanglem ent． $T$ his realization is the content of the celebrated quan－ tum non－cloning theorem 11］．Just like the w avefunction （2．2），the state vector（2．8）cannot describe the result of the observation of the pointer，as the pointer is classical and takes on de nite values．Thus，a m easurem ent w ill revealA to be in the state $\dot{x} i$ or jyi，the sum（2．8）w illap－ pear to have collapsed，and a \com pletely known＂（fully described）quantum ob ject seem $s$ to have evolved into one of severalpossible outcom es． T h is recurrent problem froced von $N$ eum ann to introduce a process di erent from unitary evolution to describe the second stage in quan－ tum $m$ easurem ent，the observation of $A$ in the entangled system QA．W hile he show ed that the boundary betw een the observed system QA and the observer can be placed arbitrarily，he still concluded that \observation＂m ust ul－ tim ately take place．R eluctantly，he suggested that the collapse of the w avepacket had to occur in the observer＇s brain，thereby allow ing the concept of consciousness to enter in his description of $m$ easurem ent［6，12，13］．

To this date，there is no unanim ous agreem ent on a solution to this problem．A prom ising attem pt at un－ raveling the $m$ ystery was presented by Everett 7］．In his intenpretation，$m$ easurem ent is described exactly as outlined above，only the second stage never takes place． $R$ ather，the di erent term $s$ in the sum（2．2）or（2．8）are interpreted as the \records＂of（conscious or m echani－ cal）observers，each recording possible versions of reality， while only one particular term is available for one ob－ server in a particular instantiation．The sum has been intenpreted by $D$ eW itt $\mathbb{Z}]$ as the wavefunction of a uni－ verse constantly branching at each quantum event．W hile intemally consistent，the E verett\｛D eW itt interpretation su ers from the burden of unprovable ad hoc assum p－ tions．Interesting from the point of view advanced here are the form ulations of Peres［目］and Zurek 目］，gen－ erally referred to as environm ent－induced decoherence m odels．In their approach， m ixed states are obtained from pure states by tracing over either the $m$ easurem ent apparatus（for exam ple because it has $m$ any uncontrol－ lable degrees of freedom ）or a m acroscopic environm ent （which absorbs the quantum phases because it involves enorm ously num erous random degrees of freedom ）．The underlying idea thus is that the loss of inform ation in a m acroscopic system is responsible for the creation of entropy in a measurem ent．W hile accounting for the apparently irreversible character of quantum $m$ easure－ $m$ ent，this approach does not address the issue of the collapse，nor does it provide a satisfying explanation for the Schrodinger－cat paradox（see，e．g．，14］）．A nother in－ teresting attem pt is due to $C$ ram er 0$]$ ，who invokes the exchange of retarded and advanced w aves betw een ele－ $m$ ents of a $m$ easurem ent situation in the second stage of $m$ easurem ent．The di culty to describe quantum $m$ ea－ surem ent as unitary evolution is a ecting areas ofphysics as diverse as black holes and quantum optics．Attem pts
at tackling the problem range from giving up unitarity in quantum $m$ echanics to understand the production ofen－ tropy in H aw king radiation［15］，to describing quantum decoherence via a non－屯iouvillian equation 16］．M ost re－ cently，it w as suggested that using D N A as a m icroscopic $m$ easuring devioe 14］（to record the absorption of ultra－ violet photons）would reveal that $\backslash[. .$.$] even the most$ prom inent nonorthodox $m$ odels of quantum $m$ echanics have nontrivialdi culties＂if no essential role is ascribed to a conscious observer！

H istorically，it appears that the failure to understand von $N$ eum ann＇s second stage is rooted in a m isunder－ standing of the correlations introduced by the rst stage． In fact，it was only three years after the appearance of the G rundlagen that E instein，Podolsky，and R osen （EPR）［17］pointed out the peculiarities of a wavefinc－ tion such as（2．8），now known as the wavefunction of an EPR entangled state．As we shall see in the next Section，correlations inherent in such a state cannot be understood via classical concepts，as the state so cre－ ated is not separable．The observation of only a part of such a system e ects the appearance of probabilities （in a subsystem）when in fact none such are present（in the com bined system ）．T he second stage ofm easurem ent can be understood w ithout recourse to non－unitary tim e－ evolution or the intervention of consciousness，w ith in the language of the quantum inform ation theory introduced recently［1］］．

## III．QUANTUM INFORMATION THEORY

In the standard inform ation theoretical treatm ent of quantum m easurem ent，classical（Shannon）inform ation theory［18］is applied to probabilities derived from quan－ tum mechanics．M ore precisely，the quantum probabil－ ities of the di erent outcom es of the $m$ easurem ent of a quantum state are used to calculate the tradeo betw een entropy and inform ation that accom panies the $m$ easure－ $m$ ent 19］．H ow ever，this treatm ent is incom plete，as the quantum probabilities entering Shannon theory are de－ void of the phase inform ation which characterizes quan－ tum mechanical superpositions．To be consistent，quan－ tum inform ation theory needs to be based on density $m$ atrioes only，rather than on probability distributions．

Let us sum $m$ arize the uni ed inform ation－theoretical description of correlation and entanglem ent that was introduced in Ref．［1，园］．This theory parallels classi－ cal（Shannon）inform ation theory，but extends it to the quantum regim e．A quantum system A，described by a density $m$ atrix $A$ ，has von $N$ eum ann entropy

$$
S(A)=T_{A}\left[\begin{array}{ll}
A  \tag{3.1}\\
A
\end{array}\right]
$$

$w$ here $T r_{A}$ denotes the trace over the degrees of freedom associated with A ．If A is expressed in a diagonal ba－ sis，i．e．，$A={ }_{a} p(a)$ jihaj the von $N$ eum ann entropy
is equal to the classical (Shannon-B oltzm ann-G ibbs) entropy

$$
H(A)={ }_{a}^{X} p(a) \log p(a):
$$

An im portant property of the von Neum ann entropy $S(A)$ is that it rem ains constant when the system $A$ undergoes a unitary transform ation. This is analogous to the Boltzm ann entropy rem aining constant under a reversible transform ation in classical them odynam ics. A s quantum m echanics only allow s unitary tim e-evolution, the von $N$ eum ann entropy of any isolated system rem ains constant in tim e.

T he substitution of probabilities (in classical in form ation theory) by density $m$ atrices (in quantum inform ation theory) becom es crucialw hen considering com posite system s , such as a bipartite system AB. Indeed, the density $m$ atrix $A B$ of the entire system can in general not be w ritten as a diagonalm atrix, if changes of basis are perform ed on the variables associated to A and B separately. ( $O$ f course, A B can always be diagonalized by applying a change of variables to a joint basis.) The com posite system AB is associated with a von $N$ eum ann entropy

$$
\begin{equation*}
S(A B)=T_{\AA_{B}}\left[A B \log _{A B}\right] \tag{3.3}
\end{equation*}
$$

N ow, in order to analyze a m easurem ent situation, we need to consider a conditionalquantum entropy $S(A-B)$, which describes the entropy of $A$ know ing $B$. Let $S(A-B)$ therefore denote the von $N$ eum ann entropy of $A$ conditionalon B, and be given by

$$
\begin{equation*}
S(A \not B)=T_{\AA_{B}}\left[A_{B} \log _{A \mathcal{B}}\right] \tag{3.4}
\end{equation*}
$$

w ith

$$
\begin{equation*}
\lim _{\mathrm{A} \mathcal{B}}=\lim _{\mathrm{AB}}^{\mathrm{h}} \mathrm{i=n}\left(1_{\mathrm{A}} \quad \mathrm{~B}\right)^{1=n} \mathrm{i}_{\mathrm{n}} \tag{3.5}
\end{equation*}
$$

the \conditional" density matrix de ned in [1]. Here, stands for the tensor product in the joint $H$ ilbert space and ${ }_{\mathrm{B}}=\mathrm{T} r_{\mathrm{A}}\left[{ }_{\mathrm{A}}\right.$ ] denotes a $\backslash \mathrm{m}$ arginal" (or reduced) density $m$ atrix, obtained by a partial trace over the variables associated with A only. The conditional density $m$ atrix de ned here is just the quantum analogue of the conditional probability $p(a+b)=p(a ; b)=p(b)$ in classical inform ation theory and reduces to it in a classical situation (i.e., when the density $m$ atrix is diagonal). In the case that $A B$ and ( $1_{A} \quad$ B ) comm ute, Eq. (3.5) sim ply reduces to

$$
\begin{equation*}
A j B=A B\left(1_{A} \quad B\right)^{1}: \tag{3.6}
\end{equation*}
$$

U sing Eqs. 3.5) and 3.5), it can be checked that the total entropy decom poses as

$$
\begin{equation*}
S(A B)=S(A)+S(B \not \subset A)=S(B)+S(A \not B) ; \tag{3.7}
\end{equation*}
$$

in perfect analogy w ith the equations relating classical entropies. W e also de ne a quantum $m$ utualentropy

FIG.1. (a) G eneral entropy diagram for a quantum com posite system AB. (b) Entropy diagram s for three cases of tw o spin-1/2 particles: (I) independent, (II) classically correlated, and (III) quantum EPR-entangled.
(a)

(b)

$$
\begin{equation*}
S(A: B)=T_{\AA_{B}}\left[A B \log _{A: B}\right] \tag{3.8}
\end{equation*}
$$

w ith

$$
\begin{equation*}
A: B=\lim _{n!1}^{h}(A \quad B)^{1=n} \operatorname{lin}_{A B}^{i_{n}} ; \tag{3.9}
\end{equation*}
$$

which reduces to

$$
A: B=\left(\begin{array}{ll}
A & B \tag{3.10}
\end{array}\right)_{A B}^{1}
$$

for com $m$ uting $m$ atrices. $U$ sing $E$ qs. (3.8) and (3.9), the quantum $m$ utual entropy can be written as

$$
\begin{equation*}
S(\mathbb{A}: B)=S(\mathbb{A})+S(B) \quad S(\mathbb{A}) \tag{3.11}
\end{equation*}
$$

and is interpreted as the \shared" entropy betw een A and B. Eqs. 3.7) and 3.11) precisely parallel the classical relations, and validate the de nitions (3.5) and (3.9) . The relations between $S(A), S(B), S(A B), S(A-B)$, $S(B \neq A)$, and $S(A: B)$ are conveniently sum $m$ arized by a Venn-like entropy diagram, as show $n$ in $F$ ig. 1 a.

A sm entioned earlier, in spite of the apparent sim ilarity betw een the quantum de nitions for $S(A-B)$ or $S(A: B)$ and their classical countenparts, dealing $w$ ith $m$ atrices (rather than scalars) opens up a quantum realm for inform ation theory that is inacoessible to classical physics. $T$ he crucial point is that, while a conditional probabil-止y is a probability distribution (i.e., $0 \quad p(a b) \quad 1)$, its quantum analogue $A_{B}$ is not a density $m$ atrix. In general, $A$ 位 is a positive $H$ erm itian $m$ atrix in the joint H ilbert space, but it can have eigenvalues exceeding one, and consequently, the associated conditionalentropy
$S(A-B)$ can be negative. In classical inform ation theory, a conditional entropy $H(A-B)$ is always non-negative. $T$ his is in agreem ent $w$ ith com $m$ on sense, since the classical entropy of a com posite system AB cannot be lower than the entropy of any subsystem A or B. M ore precisely, for classicalentropies, w e have the basic inequality,

$$
\max \left[\begin{array}{l}
(\mathrm{A}) ; \mathrm{H}(\mathrm{~B})] \quad \mathrm{H}(\mathrm{AB}) \quad H(\mathrm{~A})+H(\mathrm{~B}) \tag{3.12}
\end{array}\right.
$$

where the upper bound is reached for independent subsystem s, while the lower bound corresponds to maxi$m$ ally correlated subsystem $s$ and implies $H(A-B) \quad 0$, H ( $\mathrm{B}_{3} \mathrm{~A}$ ) 0 . In contrast, the equivalent inequality (due to A rakiand Lieb 20]) for quantum entropies becom es

$$
\begin{equation*}
j(A) \quad S(B) j \quad S(A B) \quad S(A)+S(B) \tag{3.13}
\end{equation*}
$$

where the lower bound can be lower than the classical one, im plying that $S(A \beta)$ or $S(B A)$ can be negative. $T$ his well-know $n$ non-m onotonicity of quantum entropies follow s naturally in ourm atrix-based form alism from the fact that $A_{A} B$ can have eigenvalues larger than one. T he situation where $S(A)>S(A B)$ or $S(B)>S(A B)$ occurs in the case of quantum entanglem ent.

As an illustration, it is instructive to consider three simple cases of two spin-1/2 particles with entropy $]^{3} S(A)=S(B)=1$. In our nst case $I$, let the particles be independent, each one being described by the density $m$ atrix

$$
\begin{equation*}
A=B=\frac{1}{2}(j " i h " j+j \# i h \# j) \tag{3.14}
\end{equation*}
$$

Then, the entire system has ${ }_{A B}=A \quad B$, so that the totalentropy is $S(A B)=2$, while each system carries one bit ofentropy (seeF ig. [1b). A lso, we have AjB $=A_{B}$ and ${ }_{B j A}=1_{A} \quad B$, implying that $S(A \beta)=S(A)$ and $S(B \neq A)=S(B)$. In our next case II, let the tw o particles be fully (classically) correlated, so that

$$
\begin{equation*}
A B=\frac{1}{2}(j " \text { "ih" " j+ j\#\#ih\#\# }): \tag{3.15}
\end{equation*}
$$

$T$ his is a uniform $m$ ixture, $w$ th the tw o particles alw ays in the sam e state (i.e., classically correlated). The respective entropies are shown in $F$ ig. 117. O ur last case III is quantum entanglem ent, and corresponds physically to the situation which appears when a singlet state is created by the decay of a spin-0 particle into two spin1/2 particles (creating an \EPR-pair"). Such a system is described by the EPR w ave function $4^{4 /}$

$$
\begin{equation*}
j_{A B} i=\frac{1}{P_{\overline{2}}}(j " " i+j \# \# i): \tag{3.16}
\end{equation*}
$$

[^2]Here, ${ }_{\text {A }}=j_{A B}$ ih $_{\text {Ab }} j$ so thatwe have $S(A B)=0$, as expected for a pure quantum state. By taking a partial trace of $A B$, we see that both subsystem sA and B are in a $m$ ixed state

$$
\begin{equation*}
A=B=\frac{1}{2}(j " i h " j+j \# i n \# j) ; \tag{3.17}
\end{equation*}
$$

as in cases I and II. Such m ixed states have positive entropy, yet, the combined entropy is zero in this case. $T$ hen, the conditional entropies are foroed to be negative, $S(A \not B)=S(B \not A)=1$, whereas the mutual entropy $S(A: B)=2$ (this is illustrated in $F$ ig. Tho). This can be veri ed by straightforw ard evaluation. In general, conditional entropies are negative for any isolated ( $\mathrm{S}=0$ ) entangled quantum system. N ote further that the EPR entanglem ent constraint $[S(A B)=0]$ for an EPR pair arises from the fact that it is created via a unitary transform ation from a system initially in a zero entropy pure state (the decay of the spin-0 particle). This constraint im plies that only one of the three entropies $S(A \not B), S(B \neq A)$, and $S(A: B)$, is an independent variable. In other words, the entropy diagram of any pure entangled bipartite system can only be a multiple of that of case III in F ig. T1b. T his situation violates the classicalinequalities $\mathbb{E}$. (3.12)] that relate Shannon entropies, and therefore corresponds to a purely quantum situation, while cases I and II are classically allow ed [1/2]. In this sense, the $m$ atrix-based fram ew ork presented above m ust be seen as an extension of Shannon theory: it describes all the situations allow ed classically (from case I to case II), but extends to entanglem ent (case III).

The appearance of \unclassical" (> 1) eigenvalues in the conditionaldensity $m$ atrix ofentangled states can be related to quantum non-separability and the violation of entropic B ell inequalities, as show $n$ elsew here 21]. A s far as the separability of a pure state is concemed, it is straighforw ard to check that the non-negativity of the conditional entropy is a necessary and su cient condition for separability. T he separability ofm ixed states, on the other hand, presents a $m$ ore di cult problem. $F$ irst, the concavity of $S(A-B)$ in $A B$, a property related to strong subadditivity of quantum entropies, im plies that any separable state 22]

is associated with a non-negative conditional entropy $S(A \beta)$. (T he converse is not true.) Indeed, each product com ponent ${ }_{A}^{(k)}{ }_{B}^{(k)}$ of a separable state is associated w th the conditional density m atrix

$$
\begin{equation*}
{ }_{A j B}^{(k)}={ }_{A}^{(k)} \quad 1_{B} \tag{3.19}
\end{equation*}
$$

so that we have

$$
\begin{equation*}
S(A-B) \quad X \quad w_{k} S\left({ }_{A}^{(k)}\right) \quad 0: \tag{320}
\end{equation*}
$$

This shows that the non-negativity of conditional entropies is a necessary condition for separability. This condition is show $n$ to be equivalent to the non-violation of entropic Bell inequalities in Ref. 21]. Secondly, it is easy to check from Eq. (3.4) that, if $S(A-B)$ is negative, A jß m ust adm it at least one \non-classical" eigenvahue, i.e., an eigenvalue exceeding one. $T$ his results from the fact that $\operatorname{Tr}($ ) 0 if and are positive (Herm itian) $m$ atrices. W e have checked that all the eigenvalues of $A j B$ and $B j_{A}$ are 1 for random ly generated separable density $m$ atrioes [of the form Eq. 3.18)], which suggests the con jecture that the \classicality" of the spectrum of
$A$ $j B$ is a (strong) necessary condition for separability 5 .
For exam ple, this criterion can be applied to two spin$1 / 2$ particles in a $W$ emer state, that is a mixture of a singlet fraction $x$ and a random fraction ( $1 \quad x$ ), as recently exam ined by $P$ eres 23]. T he density $m$ atrix ofthis state is given by

| ${ }_{A} B=\stackrel{\mathrm{B}}{\mathrm{Q}}$ | (1 | $\mathrm{x})=4$ | 0 | 0 |  | $0 \quad 1$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | 0 | $(1+x)=4$ | $\mathrm{x}=2$ |  | 0 C |
|  |  | 0 | $\mathrm{x}=2$ | $(1+x)=4$ |  | 0 |
|  |  | 0 | 0 | 0 | (1 | $\mathrm{x})=4$ |

A sim ple calculation show sthat $A_{j B}$ adm its three eigenvalues equalto ( $1 \quad x$ ) $=2$, and a fourth equalto $(1+3 x)=2$. T he above separability criterion is thus ful lled when th is fourth eigenvalue does not exceed 1 , that is for $x \quad 1=3$. $T$ herefore, for this particular case, our condition sim ply reduces to P eres' condition based on the positivity of the partial transpose of $A B{ }^{6}$ (It happens to be a su cient condition for a 22 H ilbert space.) W e have checked, how ever, that our criterion is distinct from Peres' in general, opening the possibility that it could be a stronger necessary (or perhaps su cient) condition for separability in a H ibert space of arbitrary dim ensions. Further work w ill be devoted to this question.
$T$ he description of quantum entanglem ent $w$ ith in this inform ation-theoretic fram ework tums out to be very pow erfulw hen considering tripartite \{ or $m$ ore generally multipartite\{ quantum system s. Indeed, it is possible to extend to the quantum regim e the various classical entropies that are de ned in the Shannon inform ationtheoretic treatm ent of a $m$ ultipartite system. This accounts for exam ple for the em ergence of classical cor-

[^3]FIG.2. Temary entropy Venn-diagram for a general tripartite system ABC. The com ponent entropies are de ned in the text.

relation from quantum entanglem ent in a tripartite (or larger) system . A lso, the quantum analogues of all the fundam ental relations betw een classical entropies (such as the chain rules for entropies and $m$ utual entropies) hold in quantum inform ation theory and have the sam e intuitive interpretation. Let us rst consider a sim ple diagram $m$ atic $w$ ay of representing quantum entropies involved in a tripartite system ABC, as shown in Figure $Z$.
$T$ he conditional entropies $S(A \not B C), S(B \not \subset C)$, and $S(C$ iAB) are a straightforw ard generalization of conditionalentropies in a bipartite system, that is $S(A-B C)=$ $S(A B C) \quad S(B C)$, etc. The entropies $S(A: B)$, $S(A: C \not B)$, and $S(B: C A)$ correspond to conditionalm utual entropies, i.e. the $m$ utual entropy betw een two of the subsystem $s w$ hen the third is know $n$. In perfect analogy w ith the classical de nition, one can w rite,

$$
\begin{align*}
S(A: B) & =S(A \mathbb{C}) \quad S(A \not B C) \\
& =S(A C)+S(B C) \quad S(C) \quad S(A B C) \tag{322}
\end{align*}
$$

which illustrates that the conditional mutual entropies are alw ays non-negative as a consequence of the strong subadditivity property of quantum entropies. The entropy in the center of the diagram is a ternary mutual entropy, de ned as

$$
\begin{align*}
S(A: B)= & S(A: B) \quad S(A: B X) \\
= & S(A)+S(B)+S(C) \quad S(A B) \\
& S(A C) \quad S(B C)+S(A B C) \tag{323}
\end{align*}
$$

and corresponds to the entropy shared by the three subsystem $\mathrm{s} A, B$, and $\mathrm{C} . \mathrm{N}$ ote that for any tripartite system in a pure state, we have $S(A B)=S(C), S(A C)=S(B)$, and $S(B C)=S(A)$, so that the temary m utual entropy vanishes. M ore generally, for a m ultipartite system, relations betw een quantum entropies can be written which parallelthe classicalrelations and have the sam e intuitive interpretation.

As an ilhustration, let us consider a tripartite system ABC in a G reenberger $H$ ome-Zeilinger (G H Z) state (which will.becom e crucial in the quantum $m$ easurem ent process), described by the wave function

$$
\begin{equation*}
j_{A B C} i=p_{\frac{1}{2}}(j " n " i+j \# \# \# i): \tag{3.24}
\end{equation*}
$$

FIG.3. (a) Temary entropy diagram for a GHZ state (an \EPR -triplet"). (b) Entropy diagram for subsystem AB, unconditional on C. The entropy of Conditional on AB is negative, and com pensates the positive entropy of $A B$ unconditional on C .
(a)

(b)

A $s$ it is a pure state, 迆s quantum entropy is $S(A B C)=0$. W hen tracing over any degree of freedom (for instance the one associated w ith C ), we obtain

$$
\begin{equation*}
\text { AB }=\frac{1}{2}(j " " i h " " j+j \# \# i h \# \#) \tag{3,25}
\end{equation*}
$$

corresponding to a classically correlated system of type II (see $F$ ig. 1 H 0 ). We thus nd $S(A)=S(B)=S(C)=$ $S(A B)=S(A C)=S(B C)=1$, allow ing us to 11 in the entropy diagram for the G H Z state in Fig. 3 Ba . T he im portant feature of the G H Z state is that it entails quantum entanglem ent between any part (e.g., C ) and the rest of the system (A B ). Even m ore im portant, ignoring (that is, tracing over) a part of it (C ) creates classical correlation betw een the two rem aining parts ( $A$ and $B$ ), as shown in Fig . 3 b b . In other words, the subsystem A B unconditional on $C$, i.e., $W$ thout considering the state of $C$, is indistinguishable from a type II system. This property is central to the understanding of the quantum $m$ easurem ent process, and willbe em phasized throughout the

[^4]follow ing section. It is generalized w ithout di culty to the case of an \EPR-nplet":
\[

$$
\begin{equation*}
j \text { i }=\frac{1}{P} \frac{1}{2}(j " " \quad \text { "i+ j\#\# } \quad \text { \#i): } \tag{326}
\end{equation*}
$$

\]

Ignoring (tracing over) any degree of freedom creates classical correlations betw een all the rem aining degrees of freedom.

W e can see now how an EPR entangled system (an EPR pair) plays a special role in quantum mechanics. $T$ he correlation betw een the elem ents of the pair [described by the $m$ utualentropy $S(A: B)$ ] goes beyond anything classically achievable ( $\backslash$ super-correlation"). A classicalapproach to understanding the correlations suggests that $m$ easuring half of an EPR pair im m ediately a ects the other half, which $m$ ay be arbitrarily far aw ay. C lassical thinking of this sort applied to an EPR pair is m isleading, how ever. Indeed, a carefiul investigation of the inform ation ow in EPR pair experim ents reveals that causality is never violated. In Ref. [1]] we suggest that EPR pairs are better understood in term sof qubit $\{$ antiqubit pairs, where the qubit (antiqubit) carries plus ( $m$ inus) one bit of inform ation, and antiqubits are interpreted as qubits traveling backw ards in tim eq. In anticipation of the discussion in the follow ing section, let usm ention (as advertised earlier) that the von $N$ eum ann $m$ easurem ent [see Eq. 2.8)] creates just such EPR entanglem ent (not classical correlation) betw een the quantum system and the $m$ easurem ent device. T he key realization will be that the quantum von $N$ eum ann entropy rather than Shannon Boltzm ann-G ibbs entropy is in fact the physicalentropy [1] 2 ]. T his explains the observation that entropy is created in the $m$ easurem ent of the spin of, say, an electron, in spite of the fact that the von $N$ eum ann entropy is zero for a pure state, independently of the choice of basis. A s we outline below, the apparent entropy created in a spin m easurem ent (if the spin is not aligned $w$ th the $m$ easurem ent axis) is actually the quantum entropy of part of an entangled system, and is cancelled by the negative conditional entropy of the (non-observed) rem ainder.
IV.MEASUREMENTPROCESS
A. Second stage: observation

W e have now prepared the ground to understand von N eum ann's second stage. The crucial observation was

[^5]touched upon brie y above: von $N$ eum ann entangle$m$ ent (2.8) creates super-correlations (a type III EPRentangled state) betw een $Q$ ( $m$ easured quantum system ) and A (ancilla), rather than correlations. The system QA thus created is inherently quantum, and cannot reveal any classical inform ation. To obtain the latter, we need to create classical correlations betw een part of the $E P R-$ pair QA and another ancilla A ${ }^{0}$, i.e., we need to observe the quantum observer. No new ingredients are needed for this. R ather, we sim ply allow the EPR entangled system QA to come into contact with a system $A^{0}$, building the system $Q A A^{0}$. Subsequently, we apply a unitary transform ation $w$ ith an interaction H am iltonian of the type 2.5), only that now it is de ned on the com bined H ibert space of QA and $A^{0}$. C learly, this is just a repetition of the rst stage, but now leading to a G H Z-like state ${ }^{9}$
\[

$$
\begin{equation*}
\text { QAA }{ }_{i}=\dot{x} ; x ; x i+\dot{y} ; y ; y i: \tag{4.1}
\end{equation*}
$$

\]

A lloperations have been unitary, and QAA ${ }^{0}$ is described by the pure state

$$
\begin{equation*}
Q A A^{0}=\$ A A^{0} \mathrm{ih} Q A A^{0} j: \tag{42}
\end{equation*}
$$

Experim entally, how ever, we are only interested in the correlationsbetw een $A$ and $A{ }^{0}$, and not in correlations.betw een A and Q (which are unobservable anyw ay). Luckily, there is no obstacle to obtaining such classical (type II) correlations now (unlike in the case where only two particles were quantum entangled). Indeed, it is now im $m$ ediately obvious that when ignoring the quantum state Q itself, as paradoxically as it $m$ ay appear at rst sight, $A$ and $A^{0}$ nd them selves classically correlated and in a $m$ ixed state:

$$
\begin{equation*}
A A O_{A}=T r_{Q}(Q A A 0)=j x ; x i h x ; x j+\dot{y} ; y i h y ; y j: \tag{4.3}
\end{equation*}
$$

W ew ill show that ignoring $Q$ tums out to be unavoidable $w$ hen $m$ easuring $Q$. $T$ his is the basic operation (ignoring part of an $\backslash E P R$-nplet") that was alluded to in the previous section, and which we w ill encounter again below.

In general, for the $m$ easurem ent of any quantum system in an N -dim ensionaldiscrete H ilbert space we obtain after tracing over Q

$$
\begin{equation*}
A A^{\circ}=\mathrm{X}_{\mathrm{i}=1}^{\mathrm{N}} \mathrm{P}_{\mathrm{i}} \text { 苂ihiij} \tag{4.4}
\end{equation*}
$$

$w$ here the $p_{i}$ are the probabilities to nd $A$ (or $A^{0}$ ) in one of its eigenstates $\ddot{\mu}$. $T$ his com pletes the second stage of the quantum $m$ easurem ent. A state $w$ as form ed ( $A A^{\circ}$ ) which appears to be mixed,

$$
\begin{equation*}
S\left(A^{0}\right)>0 ; \tag{4.5}
\end{equation*}
$$

[^6]while $A, A^{0}$ and $Q$ were pure to begin with. Yet, this $m$ ixed state is quantum entangled $w$ th $Q$, which carries negative conditional entropy
\[

$$
\begin{equation*}
S\left(Q \Rightarrow A A^{0}\right)<0 \tag{4.6}
\end{equation*}
$$

\]

such that the com bined system QAA ${ }^{0}$ is still pure:

$$
\begin{equation*}
S\left(Q A A^{0}\right)=S\left(A^{0}\right)+S\left(Q A^{0}\right)=0: \tag{4.7}
\end{equation*}
$$

C learly therefore, a transition from a pure state to a $m$ ixed state (for the entire isolated system QAA ${ }^{0}$ ) did not take place, whereas the quantum probabilities in the $m$ ixed state $A A^{0}$ correspond precisely to the square of the am plitudes ofquantum $m$ echanicalm easurem ent (see Section V ). Q uantum probabilities arise in unitary tim e developm ent, thanks to the negative entropy of the \unobserved" quantum system $Q$.

Let us em phasize now the fact that this view of $m$ easurem ent im plies that conceptually three rather than just two system smust be involved. The \observation" of the $m$ easurem ent is possible only when a third system $A^{0}$ (a quantum particle or set of particles w ith a H ilbert space dim ension at least equal to the dim ension of the $H$ ibert space of $Q$ ) interacts $w$ ith $A$ (the ancilla which $\backslash m$ easured" Q through von $N$ eum ann entanglem ent). Indeed, the classicalintuition ofm easurem ent is built upon correlations, which can only em erge in the presence of a third system $A{ }^{0}$. The fact that $A{ }^{0}$ need not be a $m$ icroscopic object is an issue which w illbecom e im portant when wew ill be concemed with the am pli cation of the $m$ easurem ent. But, conœeptually speaking, it is enough to say that A ${ }^{0}$ is a particle that \observes" the $m$ easurem ent $m$ ade by A on $Q$. Because classical observers are necessarily $m$ ade out of a $m$ acroscopic num ber of particles, it is in practioe necessary to have a large num ber of correlated particles $\mathrm{A}^{0} ; \mathrm{A}^{\infty}$; in order to achieve a m acroscopic $m$ easure$m$ ent. H ow ever, this is com pletely arbitrary: wem ay say that a $m$ easurem ent has been perform ed as long as the result is recorded on any kind of storage device ${ }^{10}$, in which case the size of $A^{0}$; $A^{\infty}$; $\quad$ simply depends on the num ber of particles in the $m$ easurem ent apparatus. A s a $m$ atter of fact, just one particle living in the sam e H ilbert space as $Q$ and $A$ is enough to com plete a conceptual $m$ easurem ent, so that the description of the system $Q A A^{0}$ is enough to com pletely $m$ odelquantum $m$ easurem ent.

O ur model does therefore not fall in the class of environm ent-induced decoherence models, sim ply because inform ation is not lost to an environm ent. $W$ e have a quantum state $Q$ and an ancilla $A$ (w hich $m$ ay be com posed of very few degrees of freedom, and does not have to be \large"). W e suggest that a m easurem ent sim ply

[^7]im plies ignoring the quantum system $Q$, which forces the ancilla $A$ to appear in a $m$ ixed state. O ur m odel does not predict the quantum system $Q$ to be classically correlated w ith the ancilla A after the $m$ easurem ent, the cornerstone of standard environm ent-induced decoherence $m$ odels. $R$ ather, we argue that the classical correlations that em erge from the $m$ easurem ent (by tracing over $Q$ ) concem the intemal degrees of freedom of A only. The ancilla is therefore \self-consistent", since arbitrarily dividing A into tw o halves alw ays provides tw o classically correlated subsystem s . In other words, A is never correlated w ith Q ; correlations only appear inside A. T hus, our description appears to be $m$ ore fundam ental, as it can account for a $m$ easurem ent situation where the degrees of freedom of A are few and totally controllable (they are not traced over). In contrast, environm entinduced decoherence m odels cannot explain the appearance ofm ixed states in such system s (see, e.g., 14]). O f course, our m odel does not prechude a m ore com plex situation where a m acroscopic uncontrollable environm ent is coupled w th $Q$ and A, but we believe such an environm ent is not conceptually necessary to interpret a $m$ easurem ent. The apparent irreversibility (creation of entropy) is traced to the \hidden" negative entropy inside the $m$ easured quantum system itself, not to the large environm ent.

A s w ill be em phasized in Section $V$, the ilhusion of a w ave-function collapse can be understood by considering consecutive $m$ easurem ents. A subsequent observation of Q (which is now part of an entangled system $Q A A^{\circ}$ ) w ith another ancilla, say $B B^{0}$, w ill result in $B B^{0}$ show ing the sam e intemal correlations as AA ${ }^{0}$. M ore im portantly, the second ancilla w illibe 100\% correlated w ith the rst, im plying that it re ects the sam e exact outcom e. This leaves the observerw ith the illusion that one de nite outcom ew as recorded by the rst ancilla and that any subsequent $m$ easurem ent sim ply con $m s$ that $Q$ is in that state. In other words, it appears as if the rst m easure$m$ ent pro jected the quantum state onto an eigenstate, as re ected by any subsequent $m$ easurem ent. Yet, the only $e$ ect of the $m$ easurem ent on the quantum state is entanglem ent with the devices, and all am plitudes of the quantum system are unchanged. Partial observation of the entangled state leads to all the devioes being 100\% correlated.

> B.Ampli cation and reversibility

A sm entioned above, inducing classicalcorrelationsbetw een the quantum variables $A$ and $A{ }^{0}$ does not lead to a m acroscopically observable pointer. $R$ ather, the basic unitary operation

$$
\begin{equation*}
(\mathrm{QA})+\mathrm{A}^{0}{ }^{\mathrm{U}}!\mathrm{QA} A^{0} \tag{4.8}
\end{equation*}
$$

m ust be \repeated" $\mathrm{O}\left(10^{23}\right)$ tim es until a m acroscopic

F IG . 4. D iagram $m$ atic representation of the tw o-stage unitary $m$ easurem ent. EPR -entanglem ent between $m$ easured quantum system $Q$ and ancilla $A$ ( rst stage, $U_{1}$ ) and entanglem ent betw een $Q A$ and $m$ acroscopic system $A^{0} A{ }^{\infty}$ (second stage, observation $\mathrm{U}_{2}$ ). The m acroscopic ancilla $A A^{0} A^{\infty} \quad$ unconditional on $Q$ is a mixed state describing classical correlation. H ow ever, $Q$ and $A A^{0} A{ }^{\infty}$ still form an EPR-pair.

w ith A, such that the result can be observed and recorded. The quantum state of the joint system $Q A A{ }^{0} A^{\infty}$
akin to an entangled EPR -nplet $w$ ith vanishing entropy. A $n$ experim ental setup allow s the observation of the correlations betw een $A$ and $A{ }^{0} A{ }^{\infty}$ unconditionalon $Q$ noring the quantum state itself), and results in all of the $10^{23}$ particles reproducing (being classically correlated $w$ ith) the quantum state of A. This process is usually called the am pli cation, or \classicization", of the quantum state A. T he two-stagem easurem ent process inchuding entanglem ent and am pli cation is pictured in F ig. 4.

Before tuming to the question of reversibility, let us stress the fact that the creation of entropy (in a subsystem ) depends on the initialstate of w ith respect to the observable under consideration. T he fact that an arbitrary state cannot be duplicated (or cloned) plays a crucial role in the ampli cation process: the quantum noncloning theorem 11] states that it is possible to am plify a quantum state (e.g. the state ofA) only if it belongs to a set of orthogonal states. M ore precisely, w hen a quantum system $Q$ is allow ed to interact w ith an ancilla $A$ in order to $m$ easure an observable $O_{A}$, the eigenstates jai of $O_{A}$ de ne the set of orthogonalstates that can be am plied (and which lead to a m acroscopic devige that re ects the $m$ icroscopic state). An attem pt at am plifying an arbitrary quantum state will generate entanglem ent betw een the particles constituting the $m$ acroscopic ob ject. $T$ his entanglem ent then is responsible for the generation of random ness in the outcom e. A ccordingly, subsystem ( $A A^{0} A^{\infty}$ ) carries positive unconditional entropy, w hile the unobserved Q (which is traced over) carries the com $m$ ensurate negative conditional entropy to allow for the zero entropy pure state of the entire entangled system QAA ${ }^{0}{ }^{\infty}$

Let us close this section by stressing that, while quantum $m$ easurem ent is conceptually reversible, its irreversible appearance has the sam e roots as irreversibility in classical m echanics, as suggested earlier by P eres 4]. A s explained previously, the am pli cation consists in renum ber of quantum particles ( $A^{0} ; A^{\infty}$; are correlateqeating the basic von $N$ eum ann $m$ easurem ent a large
num ber of tim es, until a m acroscopic num ber of quantum particles are correlated w th A. The whole (isolated) system is in a pure entangled state, but ignoring (tracing over) $Q \mathrm{~m}$ akes the rest of the system appear classically correlated. Y et, no irreversible process takes place. R andom ness the probabilities $p_{n}$ in 4.4)] is generated because A already appears to be random if one fails to take into account $Q$. This is the $m$ easurem ent analogue of the random orientation ofhalfofan EPR pair in an otherw ise fully determ ined ( $\mathrm{S}=0$ ) system. N othing new happens by introducing correlationsbetw een A and a m acroscopic num ber of quantum particles ( $\mathrm{A}^{0} \mathrm{~A}^{\infty}$ ). H ow ever, reversing the \observation" operation [applying a sequence of inverse unitary transform ations of the type 4.8)] tums out to be exceedingly di cult in practice. Indeed, one would have to reverse every one of the $\mathrm{O}\left(10^{23}\right)$ unitary operations that introduced the correlations betw een the m acroscopic set of particles. W hile this is possible in principle, it is practically not so because $m$ issing a single particle that w as involved in the $m$ easurem ent w ould result in the incorrect unitary (inverse) transform ation, thus failing to restore the initial quantum state. The root for the practical irreversibility is thus the same for the quantum $m$ easurem ent as for the physics of $m$ acroscopic classical system s. The tem poral developm ent is irreversible only because of the practical im possibility to control a m acroscopic num ber of initial conditions, while the $m$ icroscopic interactions are all reversible.

As a consequence, we see that only those quantum $m$ easurem ents can be reversed for which the ancilla A is not correlated w ith a m acroscopic num ber of particles, i.e., when A is not explicitly observed by a m acroscopic observer. H ow ever, the reversibility of the rst stage of the $m$ easurem ent, the quantum entanglem ent, can, and has been, achieved. Com m on lore of double-slit experi$m$ ents holds that just providing the possibility ofperform ing a $m$ easurem ent (providing the opportunity to obtain \which-path" inform ation, for exam ple) is irreversible. A s illustrated by the so-called \quantum -eraser" experi$m$ ents, this is incorrect 25]. Indeed, providing the possibility of observation (rather than $m$ easurem ent itself) is, according to the unitary quantum $m$ easurem ent theory outlined here, just the von $N$ eum ann $m$ easurem ent (the rst stage, or EPR entanglem ent), and is therefore com pletely reversible. In A ppendix A, we analyse the quantum eraser setup w ithin our fram ew ork.

## V. IN COMPATIBLEMEASUREMENTSAND UNCERTAINTYRELATIONS

W ew ill now show that the uncertainty principle which characterizes the $m$ easurem ent of two incom patible observables arises naturally from our unitary description of the $m$ easurem ent process. W e also derive a new bound for the entropic uncertainty relation for consecutive $m$ easurem ents which is stronger than the one in the literature to date.

Let us perform two consecutive $m$ easurem ents on the quantum system $Q$. First, we m easure the observable $\mathrm{O}_{\mathrm{A}}$ by allowing Q to interact w ith a (rst) ancilla A . ( $T$ he am pli cation stage of the $m$ easurem ent is ignored here for the sake of sim plicity). Subsequently, we let the system $Q$ interact with an ancilla $B$ in order to $m$ easure observable $O_{B}$. For illustrative punposes, we assum e that $Q$ is a discrete system which is initially described by the state vector

$$
\begin{equation*}
\mathscr{Q} i=X_{i=1}^{X^{N}} \quad i \dot{\beta}_{i} i \tag{5.1}
\end{equation*}
$$

where $\dot{p}_{i} i$ are the eigenstates of $O_{A}$ and $N$ is the di$m$ ension of the $H$ ilbert space associated $w$ th $Q$ (or A, or B). T he unitary transform ation associated w ith the $m$ easurem ent of $O_{A}$ creates an entangled state for the joint system Q A

$$
\begin{equation*}
\text { XA } i=X_{i=1}^{X^{N}} i \dot{\beta}_{i} ; i i \tag{52}
\end{equation*}
$$

where $\mathbb{j i}$ are the basis states of $A$, which label the di erent outcom es of the rst $m$ easurem ent. In other words, if $Q$ is in state $\dot{A}_{i} i$, the ancilla $A$ ends up in state $\ddot{j}$ i. As explained previously, if $Q$ is intially not in one of the eigenstates of $O_{A}, Q A$ will be entangled. Of course, $S(Q A)=0$, since it evolved unitarily from the pure state Q ; 0i. The $m$ arginal density $m$ atrix of $A$ is obtained by tracing the density $m$ atrix $Q A=$ Q A ind $A$ jover $Q$, yielding

$$
\begin{equation*}
A=\mathrm{X}_{\mathrm{i}} \mathrm{j}_{\mathrm{i}}{ }^{\jmath} \text { jihij}: \tag{5.3}
\end{equation*}
$$

C onsequently, the quantum entropy of A is given by

$$
\begin{equation*}
S(A)=H\left[p_{i}\right] \tag{5.4}
\end{equation*}
$$

where $H\left[p_{i}\right]$ denotes the classical (Shannon) entropy

$$
\begin{equation*}
H\left[p_{i}\right]={ }_{i}^{X} p_{i} \log p_{i} \tag{5.5}
\end{equation*}
$$

associated with the probability distribution $p_{i}=j i f$. $T$ his is in perfect agreem ent w th the standard description of a m easurem ent, which states that the outcom e i
 is simply the square of the quantum amplitude ${ }_{i}$. Re$m$ arkably thus, the physical (von $N$ eum ann) entropy of A reduces precisely to the Shannon entropy for the outcom e of the $m$ easurem ent, which is the one predicted by standard quantum $m$ echanics. Yet, since A is entangled with $Q$, the physicalentropy of the com bined system rem ains zero.
$W$ e now consider the $m$ easurem ent of the second observable $O_{B}$, by letting $Q$ interact $w$ ith $B$. First, we dene the unitary operator $U$ which transform $s$ the eigen-
states $\dot{\mu}_{\mathrm{i}} i$ of $O_{A}$ into the eigenstates $\mathrm{p}_{\mathrm{j}} \mathrm{i}$ of $\mathrm{O}_{\mathrm{B}}$ : its m atrix elem ents are

$$
\begin{equation*}
\mathrm{U}_{\mathrm{ij}}=\mathrm{hb} \dot{j}_{j} \dot{\exists}_{\mathrm{i}} \mathrm{i}: \tag{5.6}
\end{equation*}
$$

O bviously, if $O_{A}$ and $O_{B}$ commute, $U$ is the identity $m$ atrix. Expressing $i d$ in the $b_{j} i$ basis and entangling it $w$ ith $B$ in order to $m$ easure $O_{B}$, we obtain the nal state of the system

$$
\begin{equation*}
\text { X A B } i={ }_{i ; j=1}^{\mathrm{X}^{\mathrm{N}}}{ }_{i} U_{i j} D_{j} ; i ; j i \tag{5.7}
\end{equation*}
$$

$w$ here $\ddot{j} i$ are the basis states of $B$ (again, this $m$ eans that if $B$ is in state $j$ then $Q$ was initially in $b_{j}$ ). This is also an entangled state, w th zero entropy [S (Q AB) = 0] since it was obtained by evolying a pure state using two unitary transform ations. The $m$ arginal density $m$ atrix describing A B (ignoring the system $Q$ ) is given by

$$
\begin{equation*}
A B={\underset{i ; i^{0} ; j}{ }}_{i}^{i} i^{0} U_{i j} U_{i^{0} j} \not \ddot{H} ; j i h i^{0} ; j j: \tag{5.8}
\end{equation*}
$$

Note that AB cannot be diagonalized by applying a change of variable of the product form ( $U_{A} \quad U_{B}$ ), except in the case where $O_{A}$ and $O_{B}$ commute. The $m$ arginal density $m$ atrioes for $A$ and $B$ are given by

$$
\begin{align*}
& \text { X } \\
& { }_{A}={ }^{X} \quad{ }_{i}{ }^{2} \text { 关ihij; }  \tag{5.9}\\
& X^{i} \tag{5.10}
\end{align*}
$$

$$
\begin{aligned}
& \text { i;j }
\end{aligned}
$$

The quantum entropies of $A$ and $B$ then read

$$
\begin{array}{ll}
S(A)=H\left[p_{i}\right] & \text { with } p_{i}={\underset{X}{i}}_{i}^{j} ; \\
S(B)=H\left[q_{j}\right] & w \text { th } q_{j}=p_{i} p_{i} q_{j j i}: \tag{5.12}
\end{array}
$$

$w$ here $q_{j j i}=j J_{i j}{ }^{\rho}$ and $H\left[q_{j}\right]$ is the classical (Shannon) entropy associated $w$ ith the probability distribution $q_{j}$. Here, $q_{j j i}$ can be understood as the conditional probability to obtain the outcom $e j$ for the second $m$ easurem ent, after having obtained outcom e i for the rst one.

Rem arkably, the entropy of the second $m$ easurem ent $\mathrm{H}\left[\mathrm{q}_{\mathrm{j}}\right]$ is com pletely com patible w ith the standard assum ption of a collapse of the wave function in the rst $m$ easurem ent. Indeed, it corresponds exactly to what would be predicted in conventional quantum $m$ echanics, by assum ing that the wave function was projected on $\dot{\beta}_{i} i \mathrm{w}$ th a probability $\mathrm{p}_{\mathrm{i}}=j_{i}{ }^{\mathrm{j}}$ after the rst mea surem ent, and interpreting $\mathrm{j}_{\mathrm{ij}}{ }^{\rho}$ as the probability of

[^8]FIG.5. (a) Temary entropy diagram for the system $Q A B$ (quantum system $Q$, and ancillae A and B). (b) Entropy diagram of the system $A B$ unconditional on $Q$, describing the sequentialm easurem ent of $O_{A}$ and $O_{B}$.

$m$ easuring $j$ on an eigenstate $\dot{\mu}_{i} i$ of the rst observable. $T$ his reveals how the standard assum ption of w ave function collapse in $m$ easurem ent can be operationally correct, although we show here that it is not the actual physical process. N ote that the rst $m$ easurem ent can be view ed as inducing a \loss of coherence", as the second $m$ epasurem ent yields $q_{j}={ }_{i} j_{i} U_{i j}{ }^{\rho}$ rather than
 there was no rst $m$ easurem ent. For the com bined system QAB on the other hand, there is of course no loss of coherence.

The entropy diagram corresponding to the state Q AB is shown in $F$ igure 5a. The entropy of $A$ (resulting from the rst $m$ easurem ent) is $S(A)=H\left[p_{i}\right]$, whereas the entropy of $B$ (resulting from the second $m$ easurem ent) is

$$
\begin{equation*}
S(B)=H\left[q_{j}\right]=H\left[p_{i}\right]+H\left[q_{j j}\right] ; \tag{5.13}
\end{equation*}
$$

where we de ned the (classical) conditionalentropy

$$
\begin{equation*}
H\left[q_{j j i}\right]=\sum_{i ; j}^{X} p_{i} q_{j j i} \log q_{j j i}: \tag{5.14}
\end{equation*}
$$

This last quantity represents the additional am ount of entropy that appears due to the second $m$ easurem ent. $F$ igure 5 fo depicts the apparent entropy diagram of $A B$ unconditional on $Q$, illustrating the basic equation

$$
\begin{equation*}
S(A)+S(B \nmid \nexists A)=H\left[p_{i}\right]+H\left[q_{j j_{j}}\right]=H\left[q_{j}\right] \tag{5.15}
\end{equation*}
$$

relating the entropy of the rst and the second $m$ easure$m$ ent. $N$ ote that, despite the asym $m$ etry betw een $A$ and $B\left(O_{A}\right.$ is $m$ easured rst), Eq. 5.15) can be rew ritten in sym $m$ etric form

$$
\begin{equation*}
S(A)+S(B) \quad H \quad[q] \tag{5.16}
\end{equation*}
$$

since the mutual entropy $S(A: B)$ is alw ays positive. Equation 5.15) plays the role of an uncertainty relation for entropies, expressing the fact the the sum of the entropies resulting from the $m$ easurem ent of $O_{A}$ and $O_{B}$ is constant. If we were to try to reduce the entropy associated with one of them, then the other entropy would increase. In order to have a genuine \entropic uncertainty relation" for consecutive $m$ easurem ents, independent of the in itial state of $Q$, it is necessary to $m$ in im ize the right-hand side of Eq. 5.15) over to i (i.e., over the
$i_{i}$ 's). The convexity of Shannon entropy implies that $H\left[q_{j}\right]$ is $m$ in im ized in the case where the $p_{i}$ distribution is $m$ axim ally peaked, that is, when the initial state of $Q$ is an eigenstate $\dot{\mu}_{i} i$ of the rst observable. In this case, $S(A: B)=H\left[p_{i}\right]=0$, and therefore, assum ing $\mathbb{X} i=\dot{\beta}_{i} i$ (for instance) yields

$$
S(A)+S(B) \quad H\left[q_{j i}\right]_{i} \text { xed } \quad \begin{array}{lll} 
& X & q_{j i j}  \tag{5.17}\\
& \log q_{j j i}
\end{array}
$$

Then, m inim izing over i, we obtain the entropic uncertainty relation

$$
\begin{equation*}
S(A)+S(B) \quad \min _{i}^{\operatorname{in} H}\left[q_{j j i}\right]_{i} \text { xed }=\underset{i}{\operatorname{in} H}\left[j J_{i j} \int_{i}^{2}\right. \text { xed } \tag{5.18}
\end{equation*}
$$

Physically, this $m$ eans that the sum of the entropies is bounded from below by the Shannon entropy corresponding to the expansion of an eigenstate of $O_{A}$ into the basis ofeigenstates ofO ${ }_{B}$ ( $m$ ore precisely, the eigenstate which $m$ inim izes the Shannon entropy). N ote that our entropic uncertainty relation 5.18) is stronger than the D eutschK raus exclusion principle 26,28$]$, which states that

$$
\begin{equation*}
S(A)+S(B) \quad \log c \tag{5.19}
\end{equation*}
$$

where $\mathrm{c}=\mathrm{max}_{\mathrm{i} ; \mathrm{j}} \mathrm{jJ}_{\mathrm{ij}} \mathrm{J}^{\text { }}$. Indeed, it is easy to see that $m$ in $_{i} H\left[j J_{i j} \stackrel{?}{\rho}\right]_{i}$ xed $\quad \log c$.

In the case of com plem entary observables (i.e., if the distribution of $O_{A}$ values is uniform for any eigenstate of $O_{B}$ and vige versa), one obtains the sim ple entropic uncertainty relation 27,29]

$$
\begin{equation*}
S(A)+S(B) \quad \log N \tag{5,20}
\end{equation*}
$$

where N is the dim ension of the H ilbert space, as expected. This bound just corresponds to the situation where the conditional entropy $S(Q \nmid A)$ takes on the largest negative value com patible w ith the dim ension of the $H$ ibert space ofQ. This is for instance the case if one

FIG.6. Lower bound for the entropic uncertainty relation in a spin $-1 / 2$ H ilbert space. The solid line represents our bound Eq. 5.23) ], while the dashed line stands for the $D$ eutsch $K$ rausbound Eq. 522) ], for betw een 0 and $=2$.

$m$ easures any tw o spin-pro jections of a spin-1/2 particle. In this case, we obtain

$$
\begin{equation*}
S(x)+S(y) \quad 1: \tag{5,21}
\end{equation*}
$$

For the case of two commuting observables $\left(\left[O_{A} ; O_{B}\right]=\right.$ 0 ), we nd $U_{i j}=i_{i}$ and therefore $S(A)+S(B) \quad 0$, reecting that they can be $m$ easured sim ultaneously $w$ ith arbitrarily high accuracy. In situations that are inter$m$ ediate betw een com patible and com plem entary ( m axim ally incom patible) observables, our bound is dem onstrably m ore constraining than the one of Deutsch and $K$ raus. Let us show this for the simple case of a twodim ensionalH ilbert space.

For a general2 2 unitary $m$ atrix $U_{i j}$, w ith $\mathrm{j}_{11} \jmath=$
 param eter, the $D$ eutsch $-K$ raus uncertainty relation is

$$
S(A)+S(B) \quad \operatorname{logmax} \cos ^{2} \quad ; \sin ^{2} \quad ; \quad(5.22)
$$

whereas we nd

$$
\begin{equation*}
S(A)+S(B) \quad H \quad \cos ^{2} \quad ; \sin ^{2} \quad: \tag{5.23}
\end{equation*}
$$

In $F$ ig. 1 , we com pare the right-hand sides of E qs. 522) and 523), illustrating that the bounds are equal only for com pletely com patible ( $=0$; $=2$ ) or maxim ally incom patible ( $==4$ ) observables.

## VI. IN TERPRETATION

In this section we com $m$ ent on the im plications of unitary quantum $m$ easurem ent and the concept of quantum entanglem ent for the foundations and the interpretation of quantum $m$ echanics.
The inability to consistently describe the measure$m$ ent process in quantum $m$ echanics\{the quantum $m$ easurem ent paradox \{has seriously discredited the foundations of a theory that otherw ise describes the $m$ icroscopic world succinctly, e ortlessly, and correctly. The questions that we would like to address anew here concem
the relation betw een quantum and classicalconcepts, the Schrodinger \cat paradox", as well as the intenpretation of the com plem entarity principle.

In standard quantum $m$ echanics, the criterion to decide whether a classicalor a quantum picture is m ore adequate generally involves com paring a representative unit of action of the system under consideration $S_{\text {typ }} w$ th the unit $h$. Such a criterion suggests that any $m$ acroscopic system that ful lls $S_{\text {typ }} \quad h$ behaves classically. Yet, the present paper proposes that EPR -entangled system $S$, $w$ hether m icroscopic or m acroscopic, are fundam entally quantum and can in no lim it be understood classically. W e would like to suggest here that a degree of freedom appears classical if it is com posed ofm any $\left[0\left(10^{23}\right)\right]$ classically correlated intemal variables. This occurs precisely when part of an entire isolated system which is in a pure quantum state is ignored (i.e., unobserved and traced over). N ote that tracing over just one degree of freedom that is entangled is enough to prom ote the classical appearance! Tracing over an unobserved degree of freedom is not a physical process, and is thu not described by any tim e evolution. R ather, a quantum $m$ easurem ent forces the observation of correlations unconditional on part of a (quantum inseparable) system. T hus, any classical degree offreedom has a \classicalappearance" only because it is part ofa largerquantum inseparable system in a pure state.

Let us consider this in $m$ ore detail, as it suggests a very sim ple and satisfying explanation for the Schrodinger cat paradox. In this, perhaps the $m$ ost well-know $n$ and $m$ ost puzzling of all gedankenexperim ente, the rst stage of the $m$ easurem ent concems a decaying atom and its em itted particle (say, a photon). Let us assum $e$, as is usual, that the w avefunction (after som e tim e) is a supenposition of an lexcited" atom A? and the vacuum, and a decayed atom A w ith one photon:

$$
\begin{equation*}
j \text { oi }=\frac{1}{P_{\overline{2}}} \not A^{?} ; 0 i+A ; 1 i ; \tag{6.1}
\end{equation*}
$$

i.e., both atom and photon form an entangled state $w$ ith vanishing overall entropy. Then, in the second stage of the $m$ easurem ent, the $O\left(10^{23}\right)$ atom $s$ form ing the cat interact w ith the photon, form ing an EPR-nplet for the entire quantum state $\{$ of course still a pure state. If we sim plify the problem by assum ing that the cat's quantum variable is dichotom ic, $w$ ith live and dead cat eigenstates与i and $\ddagger i$, the $w$ ave function becom es

$$
\begin{equation*}
j_{1} i=\frac{1}{P_{2}} \quad \not A^{?} ; 0 ; L i+\nexists ; 1 ; D i: \tag{6.2}
\end{equation*}
$$

Tracing over the initial atom (the experim ent after all involves $m$ onitoring the cat, not the atom ), one obtains a m ixed state w here all the $10^{23}$ atom sare correlated with the em itted particle, i.e., they are arranged in such a w ay that the cat is either dead or alive (w th probabilities 1/2) :

$$
\begin{equation*}
\text { ;cat }=\frac{1}{2} \quad j 0 ; L \text { ih0 } ; L j+1 / j ; D i h 1 ; D j \text { : } \tag{6.3}
\end{equation*}
$$

This m acroscopic system has an entropy of 1 bit, that is, random ness has been created. M ore im portantly, the density $m$ atrix is equal to that of a statistical ensem ble prepared w ith equal num bers of dead and living cats, $m$ aking both situations (the experim ent and the preparation) physically indistinguishable. T he random ness created in the cat- subsystem is com pensated by a conditionalentropy of $\{1$ bit for the decaying atom. Since the entire system has vanishing entropy, it is still com pletely determ ined. M oreover, no such thing as a collapse of the cat $w$ ave function happens w hen the box is opened to an observer; w hat happens is sim ply that now all the atom $s$ of the observer becom e also entangled w ith those of the cat:

$$
\begin{equation*}
j_{2} i=\frac{1}{P^{\prime}} \not A^{?} ; 0 ; L ; l i+\not A ; 1 ; D ; d i \quad: \tag{6.4}
\end{equation*}
$$

where we introduced the dichotom ic observer states and jdi describing the observation of the live or dead cat. $T$ he corresponding $m$ arginaldensity $m$ atrix is

$$
\begin{equation*}
\text { ;cat;obs }=\frac{1}{2} \quad j \text {; } \mathrm{L} ; \mathrm{llh} 0 ; L ; 1 j+\operatorname{lj} ; \mathrm{D} ; \mathrm{dih1} ; \mathrm{D} ; \mathrm{dj}: \tag{6.5}
\end{equation*}
$$

T he observer notioes that the cat is either dead or alive, and thus the observer's ow n state becom es classically correlated w ith that of the cat, although, in reality, the entire system (including the atom, the , the cat, and the observer) is in a pure entangled state. It is practically im possible, although not in principle, to undo this observation, i.e., to resuscitate the cat, or, $m$ ore precisely, to com e back to the initial decaying atom, w ith a living cat and an ignorant observer

$$
\begin{equation*}
j_{2 i}{ }^{U_{2}}!j_{1} i^{U_{1}}!j_{0 i}{ }^{1} \tag{6.6}
\end{equation*}
$$

since it requires to enact the inverse unitary transform ations on all the atom $s$ form ing the observer and the cat. This irreversibility is com pletely equivalent to the irreversibility in classicalm echanics. Indeed, classically, to reverse the $m$ icroscopic tim e evolution, it is necessary to invert the velocity ofall the particles, the practicalim possibility of which gives a m acroscopic irreversible aspect to tim e evolution. In quantum $m$ echanics, it is necessary to undo any unitary evolution associated $w$ ith allinteractions that particles have undergone, so that reversibility is practically im possible if a m acroscopic num ber of particles have been involved. W e are led to conclude that irreversibility is not an inherent feature of quantum me chanics.

Finally, the present approach sheds light on the origins of the com plem entarity principle, or wave-particle duality. On the one hand, we see that the w ave function
com pletely describes a quantum state, a fact eloquently argued forby B ohr. O n the other hand, we cannot escape the appearance of random ness in quantum $m$ easurem ent. $T$ hese facts w ere interpreted by B ohr to be \com plem entary" to each other, much as the wave nature of quantum ob jects was view ed as \com plem entary" to its particle nature. O ur identi cation of von N eum ann entropy as the real, physical, entropy of a system corroborates that the quantum wave function does indeed provide a com plete description of the quantum state, since the von Neum ann entropy of a pure state is zero. Yet, we nd that random ness is not an essential comerstone of quantum $m$ easurem ent, but rather an illusion created by it. Thus, we are led to conclude that com plem entarity is a working concept, but has no ontologicalbasis as a principle. The sam e appears to be true for the w ave-particle duality. On the one hand we agree that quantum system s , due to the superposition principle, are w ave-like in nature. This is inherent in the \com pleteness postulate of the density m atrix" (see, e.g., [10]), which im plies that tw o system s prepared in the sam e density $m$ atrix, but by $m$ aking di erent $m$ ixtures of pure states, are com pletely indistinguishable. On the other hand, the particle aspect of a quantum object em erges sim ply from the $m$ easure$m$ ent process, when a wavefunction interacting $w$ ith a $m$ easurem ent device appears as a $m$ ixed state. $T$ hus, as we unm ask the particle-like behavior ofquantum system $s$ to be an illusion created by the incom plete observation of a quantum (entangled) system $w$ ith a $m$ acroscopic num ber of degrees of freedom, we are led to conchide once $m$ ore that the wave-nature of quantum system $s$ is funda$m$ ental, and that there is no particle-w ave duality, only an apparent one.

## V II. C O N C LU S IO N

In conclusion, we are able to reconcile unitary evolution of quantum states and the apparent creation of random ness in a $m$ in im alm odelofthe $m$ easurem ent process. $T$ his is achieved via the introduction of an elem entary quantum $m$ easurem ent process (the EPR entanglem ent) in which entropy is conserved by balancing random ness w ith negative entropy. W e show how the usual probabilistic results of quantum $m$ echanics arise naturally in this description, paving the way for a fully consistent description of quantum $m$ echanics in which the $m$ easurem ent device is not accorded a privileged role. This description does not require the concept of wave function collapse or the presence of a m acroscopic environm ent in order to predict the results of quantum experim ents, thereby rem oving the special status of quantum $m$ echanics as far as irreversibility is concemed. In addition, our analysis show sthat, in spite of its appearance, any classical system is in fact an entity which is part of a larger quantum system. W e believe this answers the question about the location of the frontier betw een the quantum
and the classical world, $w$ ith respect to $m$ easurem ent. W e answ er that there is no classicalw orld, only the classical appearance of part of a quantum world. This view is especially satisfying as m easurem ent, bereft of its special status outside of quantum $m$ echanics (which it had been accorded to by the C openhagen interpretation) and unencum bered by extemal notions such as consciousness (as advocated by von $N$ eum ann) is now part of a consistent theory de ned w thout recourse to classical notions which, after all, should appear as a lim it of a quantum theory only.

## ACKNOW LEDGMENTS

W e would like to express our deepest gratitude to P rof. $H$ ans $B$ ethe, who after reading $R$ ef. [1] in form ed us that \negative [...] entropy solves the problem of the reduction of the wave packet" and encouraged us to pursue this avenue. W e are also grateful for $m$ any enlightening discussions on this topic while he was visiting the K ellogg Lab in the spring of 1996. Finally, we thank A. Peres and M JW . Hall for usefiul comments on the $m$ anuscript. This work was supported in part by NSF G rant Nos. PHY 94-12818 and PHY 94-20470.

## APPENDIX A: STANDARD QUANTUM EXPERIMENTS

In this appendix we apply our quantum $m$ easurem ent theory to standard experim ents, in order to illustrate how the usualquantum probabilistic results em erge in a unitary treatm ent.

## 1. Stern-G erlach experim ent

In the Stem-G erlach experim ent, a beam of atom $s$ is guided through an inhom ogeneousm agnetic eld $B_{z}$ nor$m$ alto the direction ofm otion of the atom $s$ (see Fig. Ta). In this eld, the atom s experience a force de ecting them out of the beam, depending on the orientation of their $m$ agnetic $m$ oments $w$ th respect to the $m$ agnetic eld axis. The beam s are collected a distance aw ay on a screen. Let us assum e here for sim plicity that the m agnetic $m$ om ents of the atom $s$ take on only two di erent values ( $s=1=2$ ), and de ne $z$ eigenstates $j " i$ and j\#i. If the incident beam consists out of atom s prepared in a x (say) eigenstate, the in itial state is a quantum superposition

$$
\begin{equation*}
j \text { beam } i=P_{\overline{2}}^{1} j " i+j \# i: \tag{A1}
\end{equation*}
$$

The auxiliary variable, or ancilla, is in this case a spatial location, say left or right ( $L$; $R$ ). A pplying the $m$ agnetic eld then com pletes the von $N$ eum ann $m$ easurem ent

FIG.7. (a) Setup of the Stem-G erlach experim ent. (b) \C onsistency" requirem ent for two sequential Stem-G erlach experim ents illustrating the appearance of classical correlation.
(a)

(b)

$$
\begin{equation*}
j i=\frac{1}{\overline{2}} j " ; L i+j \# ; R i \text { : } \tag{A2}
\end{equation*}
$$

Through this operation, the di erent spin-orientations have been \tagged" (the " spin is tagged w ith a left location, and conversely), but it is incorrect to assum e that spin-orientations and locations are now correlated. M uch m ore than that, they are entangled: locations and spin-orientations form EPR pairs. T he second stage of $m$ easurem ent (am pli cation) occurs on the screen. C ollecting the particles ignores the spin-orientation entirely such that the particles of the screen becom e classically correlated w ith the location variable, form ing a type II classically correlated system carrying one bit of entropy. Let us em phasize here that the m easurem ent of the $10-$ cation variable ( $L ; R$ ) does not allow us to infer the spin orientation of the atom. Thus, even though the particle beam $w$ as de ected in the $z$-direction (as if the beam $w$ as com posed of atom $s w$ ith $m$ agnetic $m$ om ents quantized in the $z$-direction), such a classical description is m isleading.

D enoting as usual the system (atom) with $Q$, the ancilla (location) $w$ ith $A$ and the screen $w$ ith $A^{0}$ (w ith eigenstates $7 \mathrm{j} i$ and jri), we obtain

$$
\begin{equation*}
A A 0=T \check{L}_{Q}(Q A A 0)=\frac{1}{2} \leftrightarrows ; l i h L ; l j+\underset{\jmath}{ } ; \operatorname{rihR} ; r j \tag{A3}
\end{equation*}
$$

which is the standard result: the spot on the screen reects the $L \quad R$ variable (classical correlation). Yet, the entropy of the com bined system Q A A ${ }^{0}$ has not changed, stillbeing zero. T he random ness in the m easurem ent result (the bit of entropy in the $A A^{0}$ system) is cancelled by the negative entropy of the unobserved quantum state Q,

$$
\begin{equation*}
S\left(Q \nexists A^{0}\right)=1: \tag{A4}
\end{equation*}
$$

It is im portant to observe that the random ness which $m$ ay appear in the $m$ easurem ent of the position (collecting the particles on a screen or a detector) does not occur because there w ere unknow intemal degrees of freedom, which along w th the w ave function, w ould be needed to com pletely describe the particle (cf. hidden-variable theory). The wave function entirely de nes the state (it is indeed of zero entropy).

It is well-know $n$ that if a second $m$ agnetic eld gradient is used in order to perform a second Stem-G erlach $m$ easurem ent (foregoing the collection on the screen) as depicted in Fig. 7b, one obtains tw o correlated variables: the position x after the rst, and y after the second eld gradient. The standard interpretation is that, once the wave function has been projected (via the rst eld gradient), only positive (negative) spin-projection particles are left in the $L(\mathbb{R})$ beam, so that the second $m$ easure$m$ ent is incapable of splltting the beam again. This is a basic requirem ent for consecutive $m$ easurem ents of the sam e observable on a quantum system. In reality, this is nothing else than the classical correlation which appears when a pure quantum state is observed only partially. The tw o position variables $x$ and $y$ are classically correlated ( $m$ ixed state) since one is ignoring the spin orientation (x;y; z form an EPR-triplet). This experi$m$ ent is practically irreversible since the second stage of the $m$ easurem ent (classicization) occurs when detecting the particle after the second eld gradient. W henever no detector is placed after the eld gradient, the \m easure$m$ ent" is easily reversible, but in that case it has not been observed by a m acroscopic observer.

## 2. Q uantum eraser

The quantum eraser experim ent (see 25]) provides a nice dem onstration of how the rst stage (von $N$ eum ann $m$ easurem ent, or \tagging") can be reversed. Severalversions of this experim ent have been perform ed. H ow ever, we restrict ourselves here to an idealized such experim ent for convenience.

A $n$ eraser experim ent can be visualized as a tw o-slit experim ent using a beam of horizontally polarized photons (see Fig. 8). This beam is subsequently split in a crystal. $W$ hen the split beam s recom bine, they produce the well-know $n$ interference pattem. H ow ever, a polarization rotator placed on, say, the left path (so that the polarization of one of the split beam s\{the left one $\{$ is changed from horizontal to vertical) w ill cause the interference pattem to vanish. This is in agreem ent w th Feynm an's rule: the paths are distinguishable since a photon traveling via the left path is vertically polarized at the screen, while a photon traveling along the right one rem ains horizontal. The standard explanation is that providing the \which-path" inform ation precludes the existence of interference. The quantum eraser idea is that this whichpath inform ation can be erased, by inserting a polar-

FIG.8. Setup for the \quantum eraser" in the two-slit experim ent. The detector in front of the eraser is not part of the standard setup, and illustrates the im possibility of storing the inform ation before erasure.

ization lter aligned on the diagonal direction betw een the recom bined beam s and the screen. Such a procedure $m$ akes it im possible to tell whether a photon was horizontally or vertically polarized beforehand. A ccordingly, the interference pattem on the screen is resurrected.

W e start w ith a pure beam of horizontally polarized photons (see Fig. (8). A fter the splitting of the beam, the quantum state of the photon is described by the state vector

$$
\begin{equation*}
j_{1} i=P_{\overline{2}}^{1} \text { Ji+ Ri } \mathcal{H} i ; \tag{A5}
\end{equation*}
$$

a function of two dichotom ic variables: a location variable = L (left) orR (right), and a polarization variable
$=H$ (horizontal) or $V$ (vertical). This describes a superposition of a left-photon and a right-photon after the splitting of the beam s. The polarization rotator placed on the left path represents the rst stage of the $m$ easure$m$ ent: it can be viewed as a ltagging" operation (the left path is tagged w ith a vertically polarized photon and conversely) resulting in the state

$$
\begin{equation*}
j_{2} i=\frac{1}{P^{2}} \text { It; Vi+ } \mathcal{R} ; \mathrm{Hi} \text { : } \tag{A6}
\end{equation*}
$$

$T$ he crucial point is that, after tagging, the location and polarization variables are entangled and form an EPRpair. Assum ing, as is usually done, that the photon is either on the left path (w ith a vertical polarization) or on the right path (w ith a horizontal polarization) is classical intuition but decidedly w rong. We cannot w itness classical correlation betw een location (L or R) and polarization ( $H$ or V); rather, the variables are entangled (or super-correlated) carrying negative conditional entropies ensuring that the total entropy vanishes. Indeed, the state $j{ }_{2} i$ is still a pure state, since it evolved from $j$ ii by a unitary transform ation. At this stage, $m$ easuring the location of the photon (ignoring its polarization ) yields a random variable (ignoring half of the EPR-pair gives a $m$ ixed state $w$ ith positive entropy).

Equivalently, $m$ easuring the polarization of the photon after recom bining the beam $s$ (ignoring the phase hidden in the location variable ) also yields a random variable. H ow ever, in both cases, this positive entropy is exactly com pensated by a negative conditional entropy such as to preserve an overall vanishing entropy. Location and polarization play the role of con jugate (or incom patible) variables that cannot be $m$ easured sim ultaneously. T he entanglem ent in $j_{2} i$ is responsible for the loss of coherence in the location variable (them arginaldensity $m$ atrix of is a m ixture) which results in the disappearance of the interference pattem. T his is obvious since the crossterm $s$ in the square of $j{ }_{2} i$ vanish because $j v i$ and $j H i$ are orthogonal.

Yet, it can be seen easily that the eraser (the diagonally oriented polarization lter placed in front of the screen) reverses the \tagging" operation, so that the quantum state j $2^{i}$ evolves back to a pure state

$$
\begin{equation*}
j 3_{3} i=\frac{1}{2^{2}} \overline{2} \text { ji+ Ri } \quad j i+j V i \tag{A7}
\end{equation*}
$$

proportionalto j 1 i, up to a trivialrotation of the polarization vector. T his resuscitates the interference pattem as the location variable is now unentangled. Indeed, the square of the $w$ avefiunction at position $x$ on the screen is

$$
\begin{equation*}
j_{3} \jmath^{2}=\frac{1}{4} j_{L}(x) \jmath{ }_{j}^{f}+j_{R}(x) \jmath+2 \operatorname{Re}\left[\underset{L}{?}(x)_{R}(x)\right] \tag{A8}
\end{equation*}
$$

where $\mathrm{L}(\mathrm{x})=\mathrm{hx} \mathrm{f} \mathrm{i}$ for exam ple. The quantum eraser experim ent only concems the rst stage of the $m$ easure$m$ ent, that is the possibility of observing a $m$ easurem ent. As explained earlier, only the latter can be reversed in practioe, whereas the $m$ acroscopic recording of the polarization is (practically) irreversible. A n attem pt at recording the polarization of the photon after recom bination but before erasure (see Fig. 8) to cheat the eraser into delivering an interference pattem and which-path inform ation, involves entangling the polarization $w$ ith an ancilla A w ith eigenstates hi and jvi:

$$
\begin{equation*}
j{ }_{2}^{0} i=P_{\overline{2}}^{1} \text { I ; V;vi+R;H;hi : } \tag{A9}
\end{equation*}
$$

Such an action is enough to thw art any attem pt at recovering the interference pattem. Indeed, the action of the eraser on $j{ }_{2}^{0} i$ yields

$$
\begin{equation*}
j{ }_{3}^{0} i=\frac{1}{2^{P}} \overline{2} \text { 出;vi+ R;hi fi+ JVi ; } \tag{A10}
\end{equation*}
$$

leaving the location variable entangled w ith A (which is typically a m acroscopic num ber of intemal variables which are classically correlated when ignoring ). In contrast with $j$ 3i, $j{ }_{3}^{0} i$ does not give rise to an interference pattem, as it is com pletely analogous to Eq. A 6).

T he present discussion illustrates Feynm an's rule stating that, in the case of a double-slit experim ent, a quantum state behaves as a particle whenever which-path inform ation is extracted, and as a wave otherw ise. A s we saw above, which-path inform ation is obtained by entangling the location variable. This operation by itself generates the appearance of a m ixed state (and com $m$ ensurate particle-like behavior) from a pure state (w ith w ave-like behavior).

[^0]:    ${ }^{1} \mathrm{~T}$ his last conclusion is reached in environm ent-induced decoherence models as well, since there is no qualitative di erence betw een an environm ent and a large num ber of degrees of freedom belonging to a $m$ acroscopic $m$ easurem ent device.

[^1]:    ${ }^{2}$ A generalm easurem ent can be described using a positive－ operator－valued $m$ easure（ $\mathrm{P} O \mathrm{~V}$ ），based on the decom posi－ tion of the identity operator into positive operators on the H ilbert space 10］．The von $N$ eum ann $m$ easurem ent is a spe－ cial case in which the positive operators are the orthogonal projection operators $\mathrm{X}_{Q}$ ihX $\mathrm{Q}_{\mathrm{j}} \mathrm{j}$（which sum to identity be－ cause of the closure relation）．The restriction to a sim ple von N eum ann m easurem ent，however，is su cient for our pur－ poses since a POVM can alw ays be described as a von Neu － $m$ ann $m$ easurem ent in an extended $H$ ilbert space．

[^2]:    ${ }^{3}$ Throughout th is paper we take logarithm $s$ to the base tw o , such that entropies are expressed in bits.
    ${ }^{4} \mathrm{~T}$ he state in (3.16) is in fact one of the Bell states, which are a generalization of the EPR state.

[^3]:    ${ }^{5} \mathrm{~N}^{2}$ ote that the spectrum of ${ }_{A B} j_{B}$ and ${ }_{B j A}$ is invariant under local transform ations of the form $U_{A} \quad U_{B}$.
    ${ }^{6}$ P eres' criterion of separability 23] is that none of the eigenvalues of the partial transpose of $A_{B}$ is negative. For the W emer state, three eigenvalues are equalto $(1+x)=4$ and the fourth one is equal to ( $1 \quad 3 x$ ) $=4$. This low est eigenvalue is non-negative if $x \quad 1=3$. Thus, expressing that these eigenvalues are non-negative is sim ply equivalent to expressing that the eigenvalues of A jB $^{\prime}$ do not exceed one.

[^4]:    ${ }^{7}$ The negative conditional entropies in this diagram betray that this state is purely quantum, unobtainable in classical physics. A smentioned earlier, the fact that the ternary mu tual entropy $S(A: B: C)$ is zero is generic of the description of any three-body system in a pure state [it follows from the constraint $S(A B C)=0$, i.e., that A B C has been form ed by applying a unitary transform ation on a pure state].

[^5]:    ${ }^{8}$ T he term qubit denotes the quantum unit of inform ation, which is the quantum analog to the classical unit of inform ation), see, e.g. 24].

[^6]:    ${ }^{9} \mathrm{~W}$ e dispense w th norm alizations.

[^7]:    ${ }^{10} \mathrm{~T}$ h is is the content of the so-called $\backslash$ psychophysical parallelism " hypothesis, that a m easurem ent is achieved whether or not a conscious observer is involved 6].

[^8]:    ${ }^{11} \mathrm{~T}$ his unitary operation is unique up to a perm utation of eigenstates which is unim portant in this discussion.
