#### Abstract

We discovered a simple quadratic equation, which relates scattering phases of particles on Fermi surface. We consider one dimensional Bose gas and XXZ Heisenberg spin chain.

<sup>&</sup>lt;sup>1</sup>Dedicated to J. Zittartz on the occasion of his 60th birthday

# 1 Introduction

To define everything precisely we consider a specific model. Let us concentrate our attention on Bose gas with delta interaction (quantum Nonlinear Schrödinger equation).

The Hamiltonian of the model is

$$H = \int dx \left( \partial_x \Psi^{\dagger}(x) \partial_x \Psi(x) + c \Psi^{\dagger}(x) \Psi^{\dagger}(x) \Psi(x) \Psi(x) - h \Psi^{\dagger}(x) \Psi(x) \right).$$
(1.1)

Here  $0 < c < \infty$ , h > 0 are the coupling constant and the chemical potential respectively. The canonical Bose fields  $\Psi(x,t)$ ,  $\Psi^{\dagger}(x,t)$ ,  $(x,t \in \mathbf{R})$  obey the standard commutation relations

$$[\Psi(x,t),\Psi^{\dagger}(y,t)] = \delta(x-y).$$
(1.2)

and act in the Fock space with the vacuum vector  $|0\rangle$ , which is characterized by the relation:

$$\Psi(x,t)|0\rangle = 0. \tag{1.3}$$

Alternatively the model can be formulated on the language of many-body quantum mechanics system, containing N identical particles. In this case the Hamiltonian of the Bose gas can be represented as

$$\mathcal{H}_N = -\sum_{j=1}^N \frac{\partial^2}{\partial x_j^2} + 2c \sum_{N \ge j > k \ge 1} \delta(x_j - x_k) - hN.$$
(1.4)

For nonzero value of the coupling constant the Pauli principal is valid (chapter VII of [1]).

The model was solved by Bethe Ansatz [2]. The ground state is a Fermi sphere. In order to describe it precisely it is convenient to introduce spectral parameter  $\lambda$  (similar to rapidity). The derivative of the momentum of the particle with respect to the spectral parameter is

$$\frac{\partial k(\lambda)}{\partial \lambda} = 2\pi\rho(\lambda), \qquad (1.5)$$

where the function  $\rho(\lambda)$  is defined by an integral equation

$$\rho(\lambda) - \frac{1}{2\pi} \int_{-q}^{q} K(\lambda, \mu) \rho(\mu) \, d\mu = \frac{1}{2\pi}.$$
 (1.6)

Here q is the value of the spectral parameter on the Fermi surface, and

$$K(\lambda, \mu) = \frac{2c}{c^2 + (\lambda - \mu)^2}.$$
 (1.7)

One can prove that the integral operator  $\hat{I} - \frac{1}{2\pi}\hat{K}$  is not degenerated, and hence, the equation (1.6) has unique solution ([3], chapter I of [1]). The density of the gas is given by

$$D = \int_{-q}^{q} \rho(\lambda) \, d\lambda. \tag{1.8}$$

There is one particle in the model. It is defined at  $\lambda \ge q$  or  $\lambda \le -q$ . The energy of the particle  $\varepsilon(\lambda)$  is

$$\varepsilon(\lambda) - \frac{1}{2\pi} \int_{-q}^{q} K(\lambda, \mu) \varepsilon(\mu) \, d\mu = \lambda^2 - h.$$
(1.9)

It vanishes on the Fermi surface  $\varepsilon(\pm q) = 0$ . The momentum is

$$k(\lambda) = \lambda + \int_{-q}^{q} \theta(\lambda - \mu)\rho(\mu) \, d\mu.$$
(1.10)

Here

$$\theta(\lambda) = i \ln\left(\frac{ic+\lambda}{ic-\lambda}\right).$$
(1.11)

One can calculate a scattering matrix of particle with spectral parameter  $\lambda$  on another particle with spectral parameter  $\mu$  (chapter I of [1]). There is no multi-particle production or reflection. Transition coefficient is

$$\exp\{2\pi i F(\lambda|\mu)\}.\tag{1.12}$$

The phase  $F(\lambda|\mu)$  is defined by an integral equation

$$F(\lambda|\mu) - \frac{1}{2\pi} \int_{-q}^{q} K(\lambda,\nu) F(\nu|\mu) \, d\nu = \frac{1}{2\pi} \theta(\lambda-\mu).$$
(1.13)

The most important are scattering phases of particles on the Fermi edges F(q|q) and F(q|-q). In this paper we prove the identity

$$\det \begin{pmatrix} 1 - F(q|q) & F(q|-q) \\ -F(-q|q) & 1 + F(-q|-q) \end{pmatrix} = 1.$$
 (1.14)

This is the main result of the paper. Another way to rewrite this identity is

$$\left(1 - F(q|q)\right)^2 - F^2(q|-q) = 1.$$
(1.15)

Here we have used the property  $F(-\lambda | -\mu) = -F(\lambda | \mu)$ , which follows immediately from the antisymmetry of  $\theta(\lambda - \mu) = -\theta(\mu - \lambda)$ .

This identity also permit us to relate "fractional" charge to the phase shift on the Fermi surface. Fractional charge  $\mathcal{Z}$  appears in formulæ for finite size corrections (chapter I of [1]). This value is necessary for conformal description of the model (chapter XVIII of [1]) and it is equal to

$$\mathcal{Z} = 2\pi\rho(q). \tag{1.16}$$

Using the equations (1.6), (1.13) for  $\rho(\lambda)$  and  $F(\lambda|\mu)$ , one can find the relationship between the fractional charge and the scattering phase on the Fermi surface

$$\mathcal{Z} = 1 + F(q|-q) - F(q|q).$$
(1.17)

Indeed, it follows from (1.6) that

$$[2\pi\rho(\lambda)-1] - \frac{1}{2\pi} \int_{-q}^{q} K(\lambda,\mu) [2\pi\rho(\mu)-1] \, d\mu = \frac{1}{2\pi} [\theta(\lambda+q) - \theta(\lambda-q)].$$
(1.18)

Comparing this equation with (1.13) we find

$$2\pi\rho(\lambda) = 1 + F(\lambda|-q) - F(\lambda|q), \qquad (1.19)$$

what, in turns, implies (1.17). The identity (1.15) allows us to find new relation

$$\mathcal{Z}^{-1} = 1 - F(q|-q) - F(q|q).$$
(1.20)

# 2 The proof of the main identity

In this section we give the proof of the identity (1.14). In order to do this, one should calculate the derivatives of the function  $F(\lambda|\mu)$  with respect to  $\lambda, \mu$  and q. Using the basic equation (1.13), we have

$$\frac{\partial F(\lambda|\mu)}{\partial \lambda} - \frac{1}{2\pi} \int_{-q}^{q} K(\lambda,\nu) \frac{\partial F(\nu|\mu)}{\partial \nu} d\nu = \frac{1}{2\pi} K(\lambda,\mu)$$
$$-\frac{1}{2\pi} K(\lambda,q) F(q|\mu) + \frac{1}{2\pi} K(\lambda,-q) F(-q|\mu), \quad (2.1)$$

$$\frac{\partial F(\lambda|\mu)}{\partial \mu} - \frac{1}{2\pi} \int_{-q}^{q} K(\lambda,\nu) \frac{\partial F(\nu|\mu)}{\partial \mu} d\nu = -\frac{1}{2\pi} K(\lambda,\mu), \qquad (2.2)$$

$$\frac{\partial F(\lambda|\mu)}{\partial q} - \frac{1}{2\pi} \int_{-q}^{q} K(\lambda,\nu) \frac{\partial F(\nu|\mu)}{\partial q} d\nu$$
$$= \frac{1}{2\pi} K(\lambda,q) F(q|\mu) + \frac{1}{2\pi} K(\lambda,-q) F(-q|\mu). \quad (2.3)$$

Here we have used that  $\frac{\partial}{\partial \lambda} \theta(\lambda - \mu) = K(\lambda, \mu)$ . As we have mentioned already, the resolvent of the operator  $\hat{I} - \frac{1}{2\pi}\hat{K}$ exists and it is equal to

$$\hat{R} = \left(\hat{I} - \frac{1}{2\pi}\hat{K}\right)^{-1} \cdot \frac{1}{2\pi}\hat{K}.$$
(2.4)

The derivatives of the function  $F(\lambda|\mu)$  can be expressed in terms of the resolvent

$$\frac{\partial F(\lambda|\mu)}{\partial \lambda} = R(\lambda,\mu) - R(\lambda,q)F(q|\mu) + R(\lambda,-q)F(-q|\mu)$$

$$\frac{\partial F(\lambda|\mu)}{\partial \mu} = -R(\lambda,\mu)$$

$$\frac{\partial F(\lambda|\mu)}{\partial q} = R(\lambda,q)F(q|\mu) + R(\lambda,-q)F(-q|\mu)$$
(2.5)

Using these equations one can find the complete derivatives with respect to q of functions  $F(q|q),\,F(q|-q)$  etc.:

$$\frac{d}{dq}F(q|\pm q) = \left(\frac{\partial}{\partial\lambda} \pm \frac{\partial}{\partial\mu} + \frac{\partial}{\partial q}\right)F(\lambda|\mu)\Big|_{\substack{\lambda=q\\\mu=\pm q}},$$

$$\frac{d}{dq}F(-q|\pm q) = \left(-\frac{\partial}{\partial\lambda} \pm \frac{\partial}{\partial\mu} + \frac{\partial}{\partial q}\right)F(\lambda|\mu)\Big|_{\substack{\lambda=-q\\\mu=\pm q}}.$$
(2.6)

Substituting here equations (2.5) we find

$$\frac{d}{dq}F(q|-q) = 2R(q,-q)\left(1+F(-q|-q)\right),$$

$$\frac{d}{dq}F(-q|q) = -2R(-q,q)\left(1-F(q|q)\right),$$

$$\frac{d}{dq}F(q|q) = 2R(q,-q)F(-q|q),$$

$$\frac{d}{dq}F(-q|-q) = 2R(-q,q)F(q|-q).$$
(2.7)

Now it is sufficient to take the derivative with respect to q of the l.h.s. of the equation (1.14):

$$\frac{d}{dq} \det \left( \begin{array}{cc} 1 - F(q|q) & F(q|-q) \\ -F(-q|q) & 1 + F(-q|-q) \end{array} \right) \\
= -\frac{dF(q|q)}{dq} \left( 1 + F(-q|-q) \right) + \left( 1 - F(q|q) \right) \frac{dF(-q|-q)}{dq} \\
+ \frac{dF(q|-q)}{dq} F(-q|q) + F(q|-q) \frac{dF(-q|q)}{dq} \\
= -2R(q,-q)F(-q|q) \left( 1 + F(-q|-q) \right) \\
+ 2R(-q,q)F(q|-q) \left( 1 - F(q|q) \right) \\
+ 2R(q,-q)F(-q|q) \left( 1 + F(-q|-q) \right) \\
- 2R(-q,q)F(q|-q) \left( 1 - F(q|q) \right) = 0. \quad (2.8)$$

On the other hand, it is clear that for q = 0 we have

$$\det \left( \begin{array}{cc} 1 - F(q|q) & F(q|-q) \\ -F(-q|q) & 1 + F(-q|-q) \end{array} \right) \Big|_{q=0} = 1.$$
 (2.9)

Thus, the identity (1.14) is proved.

We would like to emphasize the we did not use the explicit expressions for the kernel  $K(\lambda, \mu)$  and the function  $\theta(\lambda - \mu)$ . In fact, we have used only three properties:

a) the existence of the resolvent of the operator  $\hat{I} - \frac{1}{2\pi}\hat{K}$ ;

- b) the kernel  $K(\lambda, \mu)$  and the function  $\theta(\lambda \mu)$  depend on the difference;
- c) the derivative of  $\theta(\lambda \mu)$  is equal to the kernel  $K(\lambda, \mu)$ .

In order to reduce (1.14) to the identity (1.15) one should use also the antisymmetry property  $\theta(\lambda - \mu) = -\theta(\mu - \lambda)$ .

Thus, the quadratic identity for the scattering phase is valid for a wide class of completely integrable models, but not only for the one-dimensional Bose gas. In particular, it is valid for scattering phases of elementary particles (spin waves) of XXZ Heisenberg spin chain in a magnetic field (chapter II of [1]).
