#### Abstract

We discovered a simple quadratic equation, which relates scattering phases of particles on Fermi surface. We consider one dimensional Bose gas and $X X Z$ Heisenberg spin chain.

[^0]
## 1 Introduction

To define everything precisely we consider a specific model. Let us concentrate our attention on Bose gas with delta interaction (quantum Nonlinear Schrödinger equation).

The Hamiltonian of the model is

$$
\begin{equation*}
H=\int d x\left(\partial_{x} \Psi^{\dagger}(x) \partial_{x} \Psi(x)+c \Psi^{\dagger}(x) \Psi^{\dagger}(x) \Psi(x) \Psi(x)-h \Psi^{\dagger}(x) \Psi(x)\right) \tag{1.1}
\end{equation*}
$$

Here $0<c<\infty, h>0$ are the coupling constant and the chemical potential respectively. The canonical Bose fields $\Psi(x, t), \Psi^{\dagger}(x, t),(x, t \in \mathbf{R})$ obey the standard commutation relations

$$
\begin{equation*}
\left[\Psi(x, t), \Psi^{\dagger}(y, t)\right]=\delta(x-y) \tag{1.2}
\end{equation*}
$$

and act in the Fock space with the vacuum vector $|0\rangle$, which is characterized by the relation:

$$
\begin{equation*}
\Psi(x, t)|0\rangle=0 \tag{1.3}
\end{equation*}
$$

Alternatively the model can be formulated on the language of many-body quantum mechanics system, containing $N$ identical particles. In this case the Hamiltonian of the Bose gas can be represented as

$$
\begin{equation*}
\mathcal{H}_{N}=-\sum_{j=1}^{N} \frac{\partial^{2}}{\partial x_{j}^{2}}+2 c \sum_{N \geq j>k \geq 1} \delta\left(x_{j}-x_{k}\right)-h N \tag{1.4}
\end{equation*}
$$

For nonzero value of the coupling constant the Pauli principal is valid (chapter VII of 且).

The model was solved by Bethe Ansatz [2]. The ground state is a Fermi sphere. In order to describe it precisely it is convenient to introduce spectral parameter $\lambda$ (similar to rapidity). The derivative of the momentum of the particle with respect to the spectral parameter is

$$
\begin{equation*}
\frac{\partial k(\lambda)}{\partial \lambda}=2 \pi \rho(\lambda) \tag{1.5}
\end{equation*}
$$

where the function $\rho(\lambda)$ is defined by an integral equation

$$
\begin{equation*}
\rho(\lambda)-\frac{1}{2 \pi} \int_{-q}^{q} K(\lambda, \mu) \rho(\mu) d \mu=\frac{1}{2 \pi} . \tag{1.6}
\end{equation*}
$$

Here $q$ is the value of the spectral parameter on the Fermi surface, and

$$
\begin{equation*}
K(\lambda, \mu)=\frac{2 c}{c^{2}+(\lambda-\mu)^{2}} \tag{1.7}
\end{equation*}
$$

One can prove that the integral operator $\hat{I}-\frac{1}{2 \pi} \hat{K}$ is not degenerated, and hence, the equation (1.6) has unique solution (3], chapter I of [1]). The density of the gas is given by

$$
\begin{equation*}
D=\int_{-q}^{q} \rho(\lambda) d \lambda . \tag{1.8}
\end{equation*}
$$

There is one particle in the model. It is defined at $\lambda \geq q$ or $\lambda \leq-q$. The energy of the particle $\varepsilon(\lambda)$ is

$$
\begin{equation*}
\varepsilon(\lambda)-\frac{1}{2 \pi} \int_{-q}^{q} K(\lambda, \mu) \varepsilon(\mu) d \mu=\lambda^{2}-h . \tag{1.9}
\end{equation*}
$$

It vanishes on the Fermi surface $\varepsilon( \pm q)=0$. The momentum is

$$
\begin{equation*}
k(\lambda)=\lambda+\int_{-q}^{q} \theta(\lambda-\mu) \rho(\mu) d \mu \tag{1.10}
\end{equation*}
$$

Here

$$
\begin{equation*}
\theta(\lambda)=i \ln \left(\frac{i c+\lambda}{i c-\lambda}\right) \tag{1.11}
\end{equation*}
$$

One can calculate a scattering matrix of particle with spectral parameter $\lambda$ on another particle with spectral parameter $\mu$ (chapter I of [1]). There is no multi-particle production or reflection. Transition coefficient is

$$
\begin{equation*}
\exp \{2 \pi i F(\lambda \mid \mu)\} \tag{1.12}
\end{equation*}
$$

The phase $F(\lambda \mid \mu)$ is defined by an integral equation

$$
\begin{equation*}
F(\lambda \mid \mu)-\frac{1}{2 \pi} \int_{-q}^{q} K(\lambda, \nu) F(\nu \mid \mu) d \nu=\frac{1}{2 \pi} \theta(\lambda-\mu) \tag{1.13}
\end{equation*}
$$

The most important are scattering phases of particles on the Fermi edges $F(q \mid q)$ and $F(q \mid-q)$. In this paper we prove the identity

$$
\operatorname{det}\left(\begin{array}{cc}
1-F(q \mid q) & F(q \mid-q)  \tag{1.14}\\
-F(-q \mid q) & 1+F(-q \mid-q)
\end{array}\right)=1
$$

This is the main result of the paper. Another way to rewrite this identity is

$$
\begin{equation*}
(1-F(q \mid q))^{2}-F^{2}(q \mid-q)=1 \tag{1.15}
\end{equation*}
$$

Here we have used the property $F(-\lambda \mid-\mu)=-F(\lambda \mid \mu)$, which follows immediately from the antisymmetry of $\theta(\lambda-\mu)=-\theta(\mu-\lambda)$.

This identity also permit us to relate "fractional" charge to the phase shift on the Fermi surface. Fractional charge $\mathcal{Z}$ appears in formulæ for finite size corrections (chapter I of [1]). This value is necessary for conformal description of the model (chapter XVIII of [1]) and it is equal to

$$
\begin{equation*}
\mathcal{Z}=2 \pi \rho(q) \tag{1.16}
\end{equation*}
$$

Using the equations (1.6), (1.13) for $\rho(\lambda)$ and $F(\lambda \mid \mu)$, one can find the relationship between the fractional charge and the scattering phase on the Fermi surface

$$
\begin{equation*}
\mathcal{Z}=1+F(q \mid-q)-F(q \mid q) . \tag{1.17}
\end{equation*}
$$

Indeed, it follows from (1.6) that

$$
\begin{equation*}
[2 \pi \rho(\lambda)-1]-\frac{1}{2 \pi} \int_{-q}^{q} K(\lambda, \mu)[2 \pi \rho(\mu)-1] d \mu=\frac{1}{2 \pi}[\theta(\lambda+q)-\theta(\lambda-q)] \tag{1.18}
\end{equation*}
$$

Comparing this equation with (I.13) we find

$$
\begin{equation*}
2 \pi \rho(\lambda)=1+F(\lambda \mid-q)-F(\lambda \mid q), \tag{1.19}
\end{equation*}
$$

what, in turns, implies (1.17). The identity (1.15) allows us to find new relation

$$
\begin{equation*}
\mathcal{Z}^{-1}=1-F(q \mid-q)-F(q \mid q) . \tag{1.20}
\end{equation*}
$$

## 2 The proof of the main identity

In this section we give the proof of the identity (1.14). In order to do this, one should calculate the derivatives of the function $F(\lambda \mid \mu)$ with respect to $\lambda, \mu$ and $q$. Using the basic equation (1.13), we have

$$
\begin{align*}
& \frac{\partial F(\lambda \mid \mu)}{\partial \lambda}-\frac{1}{2 \pi} \int_{-q}^{q} K(\lambda, \nu) \frac{\partial F(\nu \mid \mu)}{\partial \nu} d \nu=\frac{1}{2 \pi} K(\lambda, \mu) \\
& -\frac{1}{2 \pi} K(\lambda, q) F(q \mid \mu)+\frac{1}{2 \pi} K(\lambda,-q) F(-q \mid \mu), \tag{2.1}
\end{align*}
$$

$$
\begin{gather*}
\frac{\partial F(\lambda \mid \mu)}{\partial \mu}-\frac{1}{2 \pi} \int_{-q}^{q} K(\lambda, \nu) \frac{\partial F(\nu \mid \mu)}{\partial \mu} d \nu=-\frac{1}{2 \pi} K(\lambda, \mu)  \tag{2.2}\\
\frac{\partial F(\lambda \mid \mu)}{\partial q}-\frac{1}{2 \pi} \int_{-q}^{q} K(\lambda, \nu) \frac{\partial F(\nu \mid \mu)}{\partial q} d \nu \\
\quad=\frac{1}{2 \pi} K(\lambda, q) F(q \mid \mu)+\frac{1}{2 \pi} K(\lambda,-q) F(-q \mid \mu) \tag{2.3}
\end{gather*}
$$

Here we have used that $\frac{\partial}{\partial \lambda} \theta(\lambda-\mu)=K(\lambda, \mu)$.
As we have mentioned already, the resolvent of the operator $\hat{I}-\frac{1}{2 \pi} \hat{K}$ exists and it is equal to

$$
\begin{equation*}
\hat{R}=\left(\hat{I}-\frac{1}{2 \pi} \hat{K}\right)^{-1} \cdot \frac{1}{2 \pi} \hat{K} \tag{2.4}
\end{equation*}
$$

The derivatives of the function $F(\lambda \mid \mu)$ can be expressed in terms of the resolvent

$$
\begin{align*}
& \frac{\partial F(\lambda \mid \mu)}{\partial \lambda}=R(\lambda, \mu)-R(\lambda, q) F(q \mid \mu)+R(\lambda,-q) F(-q \mid \mu) \\
& \frac{\partial F(\lambda \mid \mu)}{\partial \mu}=-R(\lambda, \mu)  \tag{2.5}\\
& \frac{\partial F(\lambda \mid \mu)}{\partial q}=R(\lambda, q) F(q \mid \mu)+R(\lambda,-q) F(-q \mid \mu)
\end{align*}
$$

Using these equations one can find the complete derivatives with respect to $q$ of functions $F(q \mid q), F(q \mid-q)$ etc.:

$$
\begin{align*}
& \frac{d}{d q} F(q \mid \pm q)=\left.\left(\frac{\partial}{\partial \lambda} \pm \frac{\partial}{\partial \mu}+\frac{\partial}{\partial q}\right) F(\lambda \mid \mu)\right|_{\substack{\lambda=q \\
\mu= \pm q}},  \tag{2.6}\\
& \frac{d}{d q} F(-q \mid \pm q)=\left.\left(-\frac{\partial}{\partial \lambda} \pm \frac{\partial}{\partial \mu}+\frac{\partial}{\partial q}\right) F(\lambda \mid \mu)\right|_{\substack{\lambda=-q \\
\mu= \pm q}}
\end{align*}
$$

Substituting here equations (2.5) we find

$$
\begin{align*}
& \frac{d}{d q} F(q \mid-q)=2 R(q,-q)(1+F(-q \mid-q)) \\
& \frac{d}{d q} F(-q \mid q)=-2 R(-q, q)(1-F(q \mid q)) \\
& \frac{d}{d q} F(q \mid q)=2 R(q,-q) F(-q \mid q)  \tag{2.7}\\
& \frac{d}{d q} F(-q \mid-q)=2 R(-q, q) F(q \mid-q)
\end{align*}
$$

Now it is sufficient to take the derivative with respect to $q$ of the l.h.s. of the equation (1.14):

$$
\begin{align*}
& \frac{d}{d q} \operatorname{det}\left(\begin{array}{cc}
1-F(q \mid q) & F(q \mid-q) \\
-F(-q \mid q) & 1+F(-q \mid-q)
\end{array}\right) \\
& =-\frac{d F(q \mid q)}{d q}(1+F(-q \mid-q))+(1-F(q \mid q)) \frac{d F(-q \mid-q)}{d q} \\
& \quad+\frac{d F(q \mid-q)}{d q} F(-q \mid q)+F(q \mid-q) \frac{d F(-q \mid q)}{d q} \\
& =-2 R(q,-q) F(-q \mid q)(1+F(-q \mid-q)) \\
& \\
& \quad+2 R(-q, q) F(q \mid-q)(1-F(q \mid q)) \\
& \quad+2 R(q,-q) F(-q \mid q)(1+F(-q \mid-q))  \tag{2.8}\\
& \quad-2 R(-q, q) F(q \mid-q)(1-F(q \mid q))=0 .
\end{align*}
$$

On the other hand, it is clear that for $q=0$ we have

$$
\left.\operatorname{det}\left(\begin{array}{cc}
1-F(q \mid q) & F(q \mid-q)  \tag{2.9}\\
-F(-q \mid q) & 1+F(-q \mid-q)
\end{array}\right)\right|_{q=0}=1
$$

Thus, the identity (1.14) is proved.
We would like to emphasize the we did not use the explicit expressions for the kernel $K(\lambda, \mu)$ and the function $\theta(\lambda-\mu)$. In fact, we have used only three properties:
a) the existence of the resolvent of the operator $\hat{I}-\frac{1}{2 \pi} \hat{K}$;
b) the kernel $K(\lambda, \mu)$ and the function $\theta(\lambda-\mu)$ depend on the difference;
c) the derivative of $\theta(\lambda-\mu)$ is equal to the kernel $K(\lambda, \mu)$.

In order to reduce (1.14) to the identity (1.15) one should use also the antisymmetry property $\theta(\lambda-\mu)=-\theta(\mu-\lambda)$.

Thus, the quadratic identity for the scattering phase is valid for a wide class of completely integrable models, but not only for the one-dimensional Bose gas. In particular, it is valid for scattering phases of elementary particles (spin waves) of $X X Z$ Heisenberg spin chain in a magnetic field (chapter II of [1]).
