CONTINUOUS DEPENDENCE ON THE COEFFICIENTS 
AND GLOBAL EXISTENCE FOR STOCHASTIC 
REACTION DIFFUSION EQUATIONS

MARKUS KUNZE AND JAN VAN NEERVEN

Abstract. We prove convergence of the solutions $X_n$ of semilinear stochastic evolution equations on a Banach space $B$, driven by a cylindrical Brownian motion in a Hilbert space $H$,
$$
\begin{align*}
    dX_n(t) &= (A_n X(t) + F_n(t, X_n(t))) \, dt + G_n(t, X_n(t)) \, dW_H(t), \\
    X_n(0) &= \xi_n,
\end{align*}
$$
assuming that the operators $A_n$ converge to $A$ and the locally Lipschitz functions $F_n$ and $G_n$ converge to the locally Lipschitz functions $F$ and $G$ in an appropriate sense. Moreover, we obtain estimates for the lifetime of the solution $X$ of the limiting problem in terms of the lifetimes of the approximating solutions $X_n$.

We apply the results to prove global existence for reaction diffusion equations with multiplicative noise and a polynomially bounded reaction term satisfying suitable dissipativity conditions. The operator governing the linear part of the equation can be an arbitrary uniformly elliptic second order elliptic operator.

1. Introduction

The aim of this paper is to address the problem of continuous dependence upon the ‘data’ $A$, $F$, $G$, and $\xi$, of the solutions of semilinear stochastic evolution equations of the form
$$
\begin{align*}
    dX(t) &= (AX(t) + F(t, X(t))) \, dt + G(t, X(t)) \, dW_H(t), \\
    X(0) &= \xi,
\end{align*}
$$
where $A$ is an unbounded linear operator on a Banach space $E$, $W_H$ is a cylindrical Brownian motion in a Hilbert space $H$, and $F$ and $G$ are locally Lipschitz continuous coefficients. This continues a line of research initiated in [12] where the case of globally Lipschitz continuous coefficients was considered. Convergence of solutions in the locally Lipschitz case considered in the present article was posed as an open problem in [2].

In order to outline our approach, we start by briefly recalling how a solution $X = \text{sol}(A, F, G, \xi)$ of equation (SCP) may be found in the case of locally Lipschitz continuous coefficients (see [2] [13] [16]).

For each $r > 0$ one picks functions $F^{(r)}$ and $G^{(r)}$ which are globally Lipschitz continuous and of linear growth and which coincide with $F$ and $G$ on the ball $B^{(r)} = \{x \in E : \|x\| \leq r\}$. Then, denoting by $X^{(r)}$ the solution of equation (SCP) with $F$ and $G$ replaced with $F^{(r)}$ and $G^{(r)}$ respectively, one proves that with
$$
\tau^{(r)} := \inf\{t > 0 : \|X_n(t)\| > r\}
$$

one has $X^{(r)} = X^{(s)}$ on $[0, \tau^{(r)}]$ for all $0 < s \leq r$. In particular, $\tau^{(r)}$ increases with $r$. One then defines $\sigma := \lim_{r \to \infty} \tau^{(r)}$ and, for $t \in [0, \tau^{(r)}]$, $X(t) = X^{(r)}(t)$. It is then shown that $X$ is the maximal solution of the original problem \( \text{SCP} \). The stopping time $\sigma$ is called the lifetime of $X$.

Suppose now that we approximate the operator $A$ by a sequence of operators $A_n$, the coefficients $F$ and $G$ by a sequence of coefficients $F_n$ and $G_n$, and the initial value $ξ$ by a sequence $ξ_n$. For each $r > 0$ this gives rise to processes $X^{(r)}_n$ from which the solution $X_n = \text{sol}(A_n, F_n, G_n, ξ_n)$ is constructed. By the above, one expects convergence $X^{(r)}_n \to X^{(r)}$ as $n \to \infty$ for each $r > 0$, and hence $X^{(r)}_n \to X$ as $n \to \infty$ up to suitable stopping times. The aim of this paper is to describe a general procedure which allows one to deduce that, in these circumstances, one indeed obtains convergence $X_n \to X$ and the lifetime of $X$ can be computed explicitly in terms of the stopping times

$$
\tau^{(r)}_n := \inf\{t > 0 : \|X_n(t)\| > r\}.
$$

This follows from a general convergence result for processes defined up to stopping times presented in Section 2.

Applications to stochastic evolution equations are presented in Section 3. In particular, we are able to identify situations in which the limiting process $X$ is globally defined when the processes $X_n$ have this property.

An example where this happens arises in the theory of stochastic reaction diffusion equations. In Section 4 we prove global existence for such equations assuming that the nonlinearity $F$ is of polynomial growth and satisfies suitable dissipativity assumptions and that $G$ is locally Lipschitz and of linear growth. This improves previous results due to Brzeźniak and Gątarek [3] and Cerrai [4] in various ways. Indeed, in our framework, the operator $A$ governing the linear part of the equations can be an arbitrary uniformly elliptic second-order operator. For such operators $A$, martingale solutions were obtained in [3] for polynomially bounded $F$ and uniformly bounded $G$. Assuming rather restrictive simultaneous diagonisability conditions on $A$ and the driving noise, in [4] global mild solutions were obtained for polynomially bounded $F$ and certain unbounded nonlinearities $G$.

In Section 3 and 4 we extend these results by proving global existence of mild solutions under the same growth assumptions on $F$ and $G$ as in [4] but without any diagonisability assumptions on $A$ and the noise process whatsoever. Although our approach combines certain essential features of [4] with a Gronwall type lemma in the spirit of [3], the the abstract results of Section 2 streamline the proof considerably. In the final section 5 we write out our results for the special case of a 1D stochastic reaction diffusion equations driven by white noise and comment on possible variations in higher dimensions.

Notations and terminology are standard and follow those of [12]. Throughout this article we fix probability space $(\Omega, \mathcal{F}, \mathbb{P})$ endowed with a filtration $\mathbb{F} = \{\mathcal{F}_t\}_{t \in [0, T]}$, where $0 < T < \infty$ is a finite time horizon. Unless stated otherwise, all processes considered are defined on this probability space, and adaptedness is understood relative to $\mathbb{F}$. We work over the real scalar field, but occasional sectoriality arguments require passage to complexifications; this will be done without further notice.

2. Convergence of locally defined processes

We begin by proving a general convergence result for sequences of processes defined up to certain stopping times. For each $n \in \mathbb{N} := \mathbb{N} \cup \{\infty\}$, a continuous adapted process $X_n = (X_n(t))_{t \in [0, \sigma_n]}$ with values in a Banach space $E$ is given. Here, $\sigma_n : (0, T] \to (0, T]$ denotes the explosion time of $X_n$, i.e., on the set $\{\sigma_n < T\}$ we have $\limsup_{t \to \sigma_n} \|X_n(t)\| = \infty$. For each $r > 0$ we set

$$
\rho^{(r)}_n := \inf\{t \in (0, \sigma_n) : \|X_n(t)\| > r\}
$$

...
with the convention \( \inf(\emptyset) = T \). Furthermore, we assume that for each \( r > 0 \) we are given a globally defined, continuous, adapted process \( X_n^{(r)} = (X_n^{(r)}(t))_{t \in [0,T]} \) such that the following conditions are satisfied:

(a) For all \( n \in \mathbb{N} \) and \( r > 0 \), almost surely

\[
X_n^{(r)} 1_{[0,\rho_n^{(r)}]} = X_n 1_{[0,\rho_n^{(r)}]} \quad \text{on} \quad [0,T],
\]

(b) For all \( r > 0 \),

\[
\lim_{n \to \infty} X_n^{(r)} = X^{(\varepsilon)} \quad \text{in} \quad L^0(\Omega; C([0,T]; E)).
\]

Note that in (a), on the set \( \{\rho_n^{(r)} = 0\} \) we do require \( X_n^{(r)}(0) = X_n(0) \) almost surely. In the applications below, the processes \( X_n \) are obtained by solving certain stochastic evolution equations with locally Lipschitz continuous coefficients, and the processes \( X_n^{(r)} \) are obtained as the solutions of the equations with the same initial condition but with coefficients ‘frozen’ outside the ball of radius \( r \).

In the proofs of Theorem 2.1 and Lemma 2.3 we shall work with versions of \( \{X_n^{(r)}\} \) where \( n \to \infty \) holds:

(1) For all \( r > 0 \) and \( \varepsilon > 0 \) we have, almost surely,

\[
\liminf_{n \to \infty} \rho_n^{(r)} \leq \rho^{(r)} \leq \limsup_{n \to \infty} \rho_n^{(r+\varepsilon)}.
\]

Moreover, along every subsequence \( n_k \) we can find a further subsequence \( n_{k_j} \), for which we have, almost surely,

\[
\limsup_{j \to \infty} \rho_{n_{k_j}}^{(r)} \leq \rho^{(r)} \leq \liminf_{j \to \infty} \rho_{n_{k_j}}^{(r+\varepsilon)}.
\]

(2) For all \( r > 0 \) and \( \varepsilon > 0 \) we have

\[
X_n 1_{[0,\rho_n^{(r)} \wedge \rho_n^{(r+\varepsilon)}]} \to X^{(\varepsilon)} 1_{[0,\rho^{(r)}]} \quad \text{in} \quad L^0(\Omega; B_0([0,T]; E)).
\]

(3) We have

\[
X_n 1_{[0,\rho^{(r+\varepsilon)} \wedge \rho^{(r)}}] \to X^{(\varepsilon)} 1_{[0,\rho^{(r)}]} \quad \text{in} \quad L^0(\Omega \times [0,T]; E).
\]

Remark 2.2. Note that the inequalities in (1) involve the whole sequences \( \{\rho_n^{(r)}\}_{n \in \mathbb{N}} \) and \( \{\rho_n^{(r+\varepsilon)}\}_{n \in \mathbb{N}} \). For this reason we cannot pass to an almost surely uniformly convergent subsequence in (b) and thereby reduce the theorem to a statement about individual trajectories (and hence to a theorem on deterministic functions). Limes inferior and limes superior are highly unstable with respect to passing to a subsequence; for example, the Haar functions \( h_n \) on the unit interval satisfy \( \liminf_{n \to \infty} h_n = -1 \) and \( \limsup_{n \to \infty} h_n = 1 \), but each subsequence has a further subsequence converging to 0 pointwise almost everywhere.

In the proof of Theorem 2.1 we shall use the following lemma.

Lemma 2.3. For all \( n \in \mathbb{N} \), \( r > 0 \), \( \varepsilon > 0 \), and \( \tau \in (0,T] \) the following holds. If, for some \( \omega \in \Omega \), \( \|X_n^{(r+\varepsilon)}(t,\omega)\| \leq r \) for all \( t \in [0,\tau] \), then at least one of the following holds:

(i) \( X_n^{(r+\varepsilon)}(t,\omega) = X_n(t,\omega) \) for all \( t \in [0,\tau] \);

(ii) \( \rho_n^{(s)}(\omega) = 0 \) for all \( s \in [0,r+\varepsilon] \).

Proof. We distinguish two cases.

Case 1: If \( \rho_n^{(r+\varepsilon)}(\omega) \geq \tau \), then \( X_n^{(r+\varepsilon)}(t,\omega) = X_n(t,\omega) \) for all \( t \in [0,\tau] \) by assumption (a).
Case 2: Suppose that $\rho_{n}^{(r+\varepsilon)}(\omega) < \tau$ and let $s \in (r, r + \varepsilon)$. Assume that $\rho_{n}^{(s)}(\omega) > 0$. By path continuity, $0 < \rho_{n}^{(s)} < \rho_{n}^{(r+\varepsilon)} < \tau$ and $\|X_{n}(\rho_{n}^{(s)}(\omega), \omega)\| = s$. By (a) the contradiction $s = \|X_{n}(\rho_{n}^{(s)}(\omega), \omega)\| = \|X_{n}(\rho_{n}^{(r+\varepsilon)}(\rho_{n}^{(s)}(\omega), \omega)\| \leq r$ follows. Hence we must have $\rho_{n}^{(s)} = 0$. Since $\rho_{n}^{(s)} = 0$ for $s \in (r, r + \varepsilon)$, we obviously have $\rho_{n}^{(s)} = 0$ for all $s \in [0, r + \varepsilon)$.

Proof of Theorem 2.1

Proof of (1) – We begin with the proof of the left-hand side inequality in first assertion.

Fix $r > 0$. By (b) we may pass to a subsequence which satisfies $X_{n_{k}}^{(4r)} \rightarrow X_{\infty}^{(4r)}$ in $C([0, T]; E)$ almost surely, say for all $\omega$ is a set $\Omega'$ of full probability. Our first aim is to prove that

$$\limsup_{k \rightarrow \infty} \rho_{n_{k}}^{(r)} \leq \rho_{\infty}^{(r)}$$

on $\Omega'$; noting that we could also have started from an arbitrary subsequence, this will also give the left-hand side estimate in the second assertion of (1).

Fix an $\omega \in \Omega'$. We may assume that $\rho_{\infty}^{(r)}(\omega) < T$, since otherwise (2.1) holds trivially. Likewise we may assume that $\limsup_{k \rightarrow \infty} \rho_{n_{k}}^{(2r)}(\omega) > 0$. For if we had $\limsup_{k \rightarrow \infty} \rho_{n_{k}}^{(r)}(\omega) = 0$, then certainly $\limsup_{k \rightarrow \infty} \rho_{n_{k}}^{(r)}(\omega) = 0$ and again (2.1) holds trivially.

We claim that in this situation $\rho_{\infty}^{(2r)}(\omega) > 0$. To prove the claim, observe that since we have $\limsup_{k \rightarrow \infty} \rho_{n_{k}}^{(2r)}(\omega) > 0$, there is a $\delta = \delta(\omega) > 0$ so that, passing to a further subsequence $\rho_{n_{k}}^{(2r)} = \rho_{n_{k}}^{(2r)}(\omega)$ possibly depending on $\omega$, we have $\rho_{n_{k}}^{(2r)}(\omega) \geq \delta$ for all $j$. It follows from (a) that $X_{n_{k}}^{(r)}(\omega) = X_{n_{k}}^{(4r)}(\omega)$ on $[0, \delta]$. Moreover, $X_{n_{k}}^{(4r)}$ converges to $X_{\infty}^{(4r)}(\omega)$, uniformly on $[0, \delta]$. Hence also $X_{n_{k}}^{(r)}(\omega)$ converges to $X_{\infty}^{(r)}(\omega)$, uniformly on $[0, \delta]$. Now, since $\|X_{n_{k}}^{(r)}(t, \omega)\| \leq 2r$ for $t \in [0, \delta]$, it follows that $\|X_{n_{k}}^{(4r)}(t, \omega)\| \leq 2r$ for $t \in [0, \delta]$ which, by Lemma 2.3 implies that $X_{n_{k}}^{(4r)}(t, \omega) = X_{n_{k}}^{(4r)}(t, \omega)$ for such $t$. By passing to the limit $j \rightarrow \infty$ we find $\|X_{\infty}(t, \omega)\| \leq 2r$ for $t \in [0, \delta]$ and thus $\rho_{\infty}^{(2r)}(\omega) \geq \delta > 0$. This proves the claim.

We can now choose a sequence $t_{j}(\omega) \downarrow \rho_{\infty}^{(r)}(\omega)$ such that $t_{1}(\omega) < \rho_{\infty}^{(2r)}(\omega)$ and $\|X_{\infty}(t_{j}(\omega), \omega)\| > r$ for all $j$. Such a sequence exists by our assumption that $\rho_{\infty}^{(r)}(\omega) < T$, the definition of $\rho_{\infty}^{(r)}(\omega)$, and path continuity. For each $j$ there is an index $k_{0}(\omega, j)$ such that

$$\|X_{n_{k}}^{(4r)}(\omega) - X_{\infty}^{(4r)}(\omega)\|_{C([0, T]; E)} < \min \left\{ \|X_{\infty}(t_{j}(\omega), \omega)\| - r, r \right\}$$

for all $k \geq k_{0}(\omega, j)$. For such $k$ we have

$$\|X_{n_{k}}^{(4r)}(t, \omega)\| < 3r \quad \text{for all } 0 \leq t \leq \rho_{\infty}^{(2r)}(\omega).$$

To see this, note that if $0 \leq t \leq \rho_{\infty}^{(2r)}(\omega)$, then $\|X_{n_{k}}^{(4r)}(t, \omega)\| = \|X_{\infty}(t, \omega)\| \leq 2r$. Also, for all such $k$ we have

$$\|X_{n_{k}}^{(4r)}(t_{j}(\omega), \omega)\| > r.$$

By Lemma 2.3 either $\|X_{n_{k}}^{(r)}(t_{j}(\omega), \omega)\| > r$ or $\rho_{n_{k}}^{(r)}(\omega) = 0$. Note that in both cases, $\rho_{n_{k}}^{(r)}(\omega) \leq t_{j}(\omega)$. This being true for all $k \geq k_{0}(\omega, j)$, it follows that $\limsup_{k \rightarrow \infty} \rho_{n_{k}}^{(r)}(\omega) \leq t_{j}(\omega)$.
Now fix $\eta > 0$. On the set $\bigcup_{m \in \mathbb{N}} \cap_{n \geq m} \{ \rho_n^{(r)} \geq \rho_{\infty} + \eta \}$, the above subsequence certainly satisfies $\limsup_{k \to \infty} \rho_{nk}^{(r)} \geq \limsup_{r \to \infty} \rho_{\infty} + \eta$. But since (2.1) holds on a set of full probability, this implies that $\mathbb{P}(\bigcup_{m \in \mathbb{N}} \cap_{n \geq m} \{ \rho_n^{(r)} \geq \rho_{\infty} + \eta \}) = 0$. It follows that

$$\mathbb{P}(\liminf_{n \to \infty} \rho_n^{(r)} \leq \rho_{\infty} + \eta) = 0 \mathbb{P}(\bigcap_{m \in \mathbb{N}} \bigcup_{n \geq m} \{ \rho_n^{(r)} \leq \rho_{\infty} + \eta \}) = 1.$$ 

Upon letting $\eta \downarrow 0$, we have $\liminf_{n \to \infty} \rho_n^{(r)} \leq \rho_{\infty} + \eta$, which, together with the above, implies that $\mathbb{P}(\liminf_{n \to \infty} \rho_n^{(r)} \leq \rho_{\infty} + \eta) = 1$.

Next we prove the right-hand side inequality of the first assertion in (1).

Fix $r > 0$ and $\varepsilon > 0$. By (b) we may pass to a subsequence such that $X_{nk}^{(r+2\varepsilon)} \to X_{\infty}^{(r+2\varepsilon)}$ in $C([0,T]; E)$ almost surely, say on the set $\Omega'$ of full probability. Our first aim is to prove that

$$\liminf_{k \to \infty} \rho_{nk}^{(r+\varepsilon)} \geq \rho_{\infty}^{(r)}$$

on $\Omega'$; noting that we could also have started from an arbitrary subsequence, this will also give the right-hand side estimate in the second assertion of (1).

Fix an $\omega \in \Omega'$. We may assume that $\rho_{\infty}^{(r)}(\omega) > 0$, for otherwise (2.2) trivially holds.

The next step is to prove that $X_{nk}(\omega) \to X_{\infty}(\omega)$ uniformly on $[0, \rho_{\infty}^{(r)}(\omega)]$. On this interval we know that $\|X_{nk}(\omega)\| \leq r$. Hence, by (a), $X_{\infty}(\omega) = X_{\infty}^{(r+2\varepsilon)}(\omega)$ on $[0, \rho_{\infty}^{(r)}(\omega)]$. Since $X_{nk}^{(r+2\varepsilon)}(\omega) \to X_{\infty}^{(r+2\varepsilon)}(\omega)$ uniformly, it follows that, for large enough $k$, say for all $k \geq k_1(\omega)$,

$$\|X_{nk}^{(r+2\varepsilon)}(\omega)\| \leq r + \varepsilon \text{ on } [0, \rho_{\infty}^{(r)}(\omega)].$$

By (2.3) and Lemma 2.3, for each $k \geq k_1(\omega)$ we are in at least one of the following two cases: either we have $\|X_{nk}(\omega)\| \leq r + \varepsilon$ on $[0, \rho_{\infty}^{(r)}(\omega)]$ and thus $\rho_{nk}^{(r+\varepsilon)}(\omega) \geq \rho_{\infty}^{(r)}(\omega)$, or else $\rho_{nk}^{(r+\varepsilon)}(\omega) = 0$.

Suppose the latter happens for infinitely many $k$ (the set of these $k$ may depend on $\omega$). Then $\|X_{nk}(0, \omega)\| \geq r + \varepsilon$ for infinitely many $k$. Since

$$X_{nk}(0, \omega) = X_{nk}^{(r+2\varepsilon)}(0, \omega) \to X_{\infty}^{(r+2\varepsilon)}(0, \omega) = X_{\infty}(0, \omega)$$

this implies $\|X_{\infty}(0, \omega)\| \geq r + \varepsilon$. But then $\rho_{\infty}^{(r)}(\omega) = 0$ by path continuity, and this contradicts our previous assumption. Thus, for all but finitely many $k$ we must have the first alternative. This proves (2.2).

Fix $\eta > 0$. Arguing as above, $\mathbb{P}(\bigcup_{m \in \mathbb{N}} \cap_{n \geq m} \{ \rho_n^{(r+\varepsilon)} \leq \rho_{\infty}^{(r)} - \eta \}) = 0$ and thus $\mathbb{P}(\limsup_{n \to \infty} \rho_n^{(r+\varepsilon)} \geq \rho_{\infty}^{(r)} - \eta) = 0$. Upon letting $\eta \downarrow 0$ we see that $\mathbb{P}(\limsup_{n \to \infty} \rho_n^{(r+\varepsilon)} \geq \rho_{\infty}^{(r)}) = 1$.

Proof of (2) – Fix $r > 0$ and $\varepsilon > 0$. Since convergence in probability is metrizable, it suffices to prove that every subsequence of $(X_n 1_{[0,\rho_{\infty}^{(r)}] \land \rho_{\infty}^{(r+\varepsilon)}})_{n \in \mathbb{N}}$ has a further subsequence for which the claimed convergence holds.

Given a subsequence, we may pass to a further subsequence (which, for ease of notation, we index by $n$ again) such that

$$X_{n}^{(r+2\varepsilon)} \to X_{\infty}^{(r+2\varepsilon)}$$

in $C([0,T]; E)$ almost surely.

Fix an $\omega$ from the set of convergence. If $\rho_{\infty}^{(r)}(\omega) = 0$, then it is trivial that $X_n 1_{[0,\rho_{\infty}^{(r)}] \land \rho_{\infty}^{(r+\varepsilon)}}(\omega) \to X_{\infty} 1_{[0,\rho_{\infty}^{(r)}] \land \rho_{\infty}^{(r+\varepsilon)}}(\omega)$, and therefore we may assume that $\rho_{\infty}^{(r)}(\omega) > 0$. Then, as we have seen in the proof of the second assertion of (1), for all $n \geq n_0(\omega)$ we have $\|X_n(t, \omega)\| \leq r + \varepsilon$ for all $0 \leq t \leq \rho_{\infty}^{(r)}(\omega)$. For these $n$ we see that $\rho_{nk}^{(r+\varepsilon)}(\omega) \geq \rho_{\infty}^{(r)}(\omega)$ and therefore $X_n 1_{[0,\rho_{\infty}^{(r)}] \land \rho_{\infty}^{(r+\varepsilon)}}(\omega) = X_n 1_{[0,\rho_{\infty}^{(r)}]}(\omega)$. 

Also, \( X_n(t, \omega) = X_n^{(r+2\varepsilon)}(t, \omega) \) and \( X_{\infty}(t, \omega) = X_{\infty}^{(r+2\varepsilon)}(t, \omega) \) for \( 0 \leq t \leq \rho_{\infty}^{(r+\varepsilon)}(\omega) \). Combining these observations with (2.4) we find, for \( n \geq n_0(\omega) \),

\[
X_n \mathbb{1}_{[0, \rho_{\infty}^{(r)} \wedge \rho_{n}^{(r+\varepsilon)}]}(\omega) = X_n \mathbb{1}_{[0, \rho_{n}^{(r)}]}(\omega) = X_n^{(r+2\varepsilon)} \mathbb{1}_{[0, \rho_{\infty}^{(r)}]}(\omega) \\
\rightarrow X_{\infty}^{(r+2\varepsilon)} \mathbb{1}_{[0, \rho_{\infty}^{(r)}]}(\omega) = X_{\infty} \mathbb{1}_{[0, \rho_{\infty}^{(r)}]}(\omega)
\]

in \( B_b([0, T]; E) \).

Proof of (3) – Again, we will show that every subsequence has a subsequence for which the claimed convergence holds.

Let a subsequence be given. By the proof of (2), this subsequence has a further subsequence \( n_{k, l} \) such that

\[
X_{n_{k, l}} \mathbb{1}_{[0, \rho_{\infty}^{(1)} \wedge \rho_{n_{k, l}}^{(r+2\varepsilon)}]}(\omega) \rightarrow X_{\infty} \mathbb{1}_{[0, \rho_{\infty}^{(1)}]}(\omega)
\]

in \( B_b([0, T]; E) \) as \( k \to \infty \), for all \( \omega \) outside a set null set \( N_1 \).

Suppose we have already constructed a subsequence \( n_{k, l} \) such that

\[
X_{n_{k, l}} \mathbb{1}_{[0, \rho_{\infty}^{(j)} \wedge \rho_{n_{k, l}}^{(r+2\varepsilon)}]}(\omega) \rightarrow X_{\infty} \mathbb{1}_{[0, \rho_{\infty}^{(j)}]}(\omega)
\]

in \( B_b([0, T]; E) \) as \( k \to \infty \), for all \( j \in \{1, \ldots, l\} \) and all \( \omega \) outside a null set \( N_l \). By the proof of (2), we can extract a further subsequence \( n_{k, l, l+1} \) such that

\[
X_{n_{k, l}} \mathbb{1}_{[0, \rho_{\infty}^{(j)} \wedge \rho_{n_{k, l}}^{(r+2\varepsilon)}]}(\omega) \rightarrow X_{\infty} \mathbb{1}_{[0, \rho_{\infty}^{(j)}]}(\omega)
\]

in \( B_b([0, T]; E) \) as \( k \to \infty \), for all \( j \in \{1, \ldots, l, l+1\} \) and all \( \omega \) outside a null set \( N_{l+1} \). We continue this procedure inductively.

Now put \( N := \bigcup_{l \geq 1} N_l \). Setting \( n_l := n_{l, l} \), it follows that

\[
(2.5) \quad X_{n_l} \mathbb{1}_{[0, \rho_{\infty}^{(j+1)} \wedge \rho_{n_{l}}^{(r+2\varepsilon)}]}(\omega) \rightarrow X_{\infty} \mathbb{1}_{[0, \rho_{\infty}^{(j)}]}(\omega)
\]

in \( B_b([0, T]; E) \) as \( l \to \infty \), for all \( j \geq 1 \) and \( \omega \) outside the null set \( N \).

By the second part of (1), upon replacing \( N \) by some larger null set and passing to a further subsequence of \( n_l \) if necessary, we may assume that outside \( N \) we also have

\[
(2.6) \quad \liminf_{l \to \infty} \rho_{n_{l}}^{(j+1)}(\omega) \geq \rho_{\infty}^{(j)}(\omega) \quad \text{for all} \quad j \geq 1.
\]

Now let \((t, \omega) \in [0, T] \times (\Omega \setminus N)\). We claim that

\[
X_{n_l}(t, \omega) \mathbb{1}_{[0, \sigma_{\infty} \wedge \sigma_{n_l}]}(t, \omega) \rightarrow X_{\infty}(t, \omega) \mathbb{1}_{[0, \sigma_{\infty}]}(t, \omega)
\]

in \( E \) as \( l \to \infty \).

We distinguish two cases. First, if \( t \geq \sigma_{\infty}(\omega) \), then

\[
X_{n_l}(t, \omega) \mathbb{1}_{[0, \sigma_{\infty} \wedge \sigma_{n_l}]}(t, \omega) = 0 = X_{\infty}(t, \omega) \mathbb{1}_{[0, \sigma_{\infty}]}(t, \omega)
\]

for all \( l \in \mathbb{N} \) and there is nothing to prove.

Second, suppose that \( t < \sigma_{\infty}(\omega) \). Pick an integer \( j \) such that \( \|X_{\infty}(s, \omega)\| < j \) for all \( 0 \leq s \leq t \). Then \( t < \rho_{\infty}^{(j)}(\omega) \). By (2.6), for all large enough \( l \) we have \( t < \rho_{n_{l}}^{(j+1)}(\omega) \leq \sigma_{n_l}(\omega) \). Hence, for all large \( l \),

\[
X_{n_l}(t, \omega) \mathbb{1}_{[0, \sigma_{\infty} \wedge \sigma_{n_l}]}(t, \omega) = X_{n_l}(t, \omega) = X_{n_l}(t, \omega) \mathbb{1}_{[0, \rho_{\infty}^{(j)} \wedge \rho_{n_{l}}^{(r+2\varepsilon)}]}(t, \omega).
\]

By (2.5), the right-hand side converges to

\[
X_{\infty}(t, \omega) = X_{\infty}(t, \omega) \mathbb{1}_{[0, \rho_{\infty}^{(j)}]}(t, \omega) = X_{\infty}(t, \omega) \mathbb{1}_{[0, \rho_{\infty}^{(j)}]}(t, \omega).
\]

This proves the claim. \( \square \)
Corollary 2.4. Under the above assumptions we have
\[ \sigma_\infty \geq \lim_{r \to \infty} \liminf_{n \to \infty} \rho_n^{(r)} \]
almost surely. Furthermore, every subsequence \( n_k \) has a further subsequence \( n_{kj} \), for which
\[ \sigma_\infty = \lim_{r \to \infty} \liminf_{j \to \infty} \rho_{n_{kj}}^{(r)} \]
almost surely.

Proof. The first assertion follows from the first assertion in Theorem 2.1(1) upon letting \( r \to \infty \). To obtain the second assertion, given a subsequence \( n_k \) let \( n_{kj} \) be a subsequence for which the second assertion in Theorem 2.1(1) holds. Then \( \sigma_\infty \leq \lim_{r \to \infty} \liminf_{j \to \infty} \rho_{n_{kj}}^{(r)} \) almost surely. The reverse inequality follows from the first part of Theorem 2.1(1) applied to this subsequence. \( \square \)

Corollary 2.5. Under the above assumptions, suppose that \( \sigma_n = T \) almost surely for all \( n \in \mathbb{N} \), and suppose furthermore that for some \( p \geq 1 \) we have
\[ \sup_{n \in \mathbb{N}} \| X_n \|_{L^p(\Omega; C([0,T];E))} < \infty. \]

Then:
1. Almost surely, \( \sigma_\infty = T \);
2. We have \( X_\infty \in L^p(\Omega; C([0,T];E)) \);
3. If \( p > 1 \), then, for all \( 1 < q < p \),
\[ X_n \to X_\infty \text{ in } L^q(\Omega; C([0,T];E)). \]

Proof. (1) From Theorem 2.1(2) and Fatou’s lemma we infer, for \( r > 0 \) and \( \varepsilon > 0 \),
\[ E[\| X_\infty \mathbb{1}_{[0,\rho_n^{(r)}]} \|_{B_h([0,T];E)}^p] \leq \lim_{n \to \infty} E[\| X_n \mathbb{1}_{[0,\rho_n^{(r)}]} \|_{B_h([0,T];E)}^p] \]
\[ \leq \lim_{n \to \infty} E[\| X_n \mathbb{1}_{[0,\rho_n^{(r)}]} \|_{C([0,T];E)}] \leq C, \]
where \( C := \sup_{n \in \mathbb{N}} \| X_n \|_{L^p(\Omega; C([0,T];E))} \). Employing Fatou’s lemma a second time, we see that
\[ E[\| X_\infty \mathbb{1}_{[0,\sigma_\infty]} \|_{B_h([0,T];E)}^p] = E \lim_{r \to \infty} E[\| X_\infty \mathbb{1}_{[0,\rho_n^{(r)}]} \|_{B_h([0,T];E)}^p] \]
\[ \leq \lim_{r \to \infty} E[\| X_\infty \mathbb{1}_{[0,\rho_n^{(r)}]} \|_{B_h([0,T];E)}] \leq C. \]
In particular, we infer that \( X_\infty \) is almost surely bounded on \( (0, \sigma_\infty) \). Since \( \sigma_\infty \) is an explosion time, this is only possible if \( \sigma_\infty = T \).

(2) From what we have proved so far it follows that \( X_\infty \in L^p(\Omega; C_b([0,T];E)) \) and thus \( \sup_{t \in [0,T]} \| X_\infty(t, \omega) \| < \infty \) for almost all \( \omega \in \Omega \). This implies that \( \bigcup_{k \in \mathbb{N}} \{ \rho_n^{(k)} = T \} \) has full measure and hence, by (a), \( X(\omega) \in C([0,T];E) \) almost surely. By continuity, \( \sup_{t \in [0,T]} \| X_\infty(t, \omega) \| = \sup_{t \in [0,T]} \| X_\infty(t, \omega) \| \) almost surely and now \( X_\infty \in L^p(\Omega; C([0,T];E)) \) follows.

(3) Fix \( 1 < q < p \) and write, for \( r > 0 \) and \( \varepsilon > 0 \),
\[ E[\| X_n - X_\infty \|_{C_{B_h([0,T];E)}^q}^q] \leq E[\| X_n \mathbb{1}_{[0,T]} - \mathbb{1}_{[0,\rho_n^{(r)}]} \|_{B_h([0,T];E)}^q] \]
\[ + E[\| X_n \mathbb{1}_{[0,\rho_n^{(r)}]} - \mathbb{1}_{[0,\rho_n^{(r,\varepsilon)}]} \|_{B_h([0,T];E)}^q] \]
\[ + E[\| X_\infty \mathbb{1}_{[0,\rho_n^{(r)}]} - \mathbb{1}_{[0,T]} \|_{B_h([0,T];E)}^q]. \]

From \( \{ \rho_n^{(r)} \land \rho_n^{(r,\varepsilon)} < T \} \subseteq \{ \| X_n \|_{B_h([0,T];E)} \geq r \} \cup \{ \| X_\infty \|_{B_h([0,T];E)} \geq r + \varepsilon \} \),
it follows that
\[(2.8)\]
\[
\left\|X_n \left( \mathbb{I}_{[0,T]} - \mathbb{I}_{[0,R_n^+(r+\varepsilon)]} \right) \right\|_{B_b([0,T];E)} \\
\leq \mathbb{I}\{\left\|X_\infty\right\|_{B_b([0,T];E)} \geq r\} \left\|X_n\right\|_{B_b([0,T];E)} \vee \mathbb{I}\{\left\|X_\infty\right\|_{B_b([0,T];E)} \geq r + \varepsilon\} \left\|X_n\right\|_{B_b([0,T];E)}.
\]

Since the \(X_n\) form a bounded sequence in \(L^p(\Omega; C([0,T]; E))\), the random variables \(\left\|X_n\right\|_{\infty}^p\) are uniformly integrable. Using this to handle the second term on the right-hand side of (2.8) and Hölder’s inequality (with exponents \(p\) and \(p'\), \(\frac{1}{p} + \frac{1}{p'} = 1\)) to handle the first, (2.8) implies that the first term on the right-hand side of (2.7) converges to 0 as \(r \to \infty\).

For fixed \(r > 0\) and \(\varepsilon > 0\), convergence of the middle term on the right-hand side of (2.7) follows from Theorem 2.1 (2) and the uniform integrability of the \(\left\|X_n\right\|_{\infty}^p\).

As for the third term, arguing as before we have
\[
\left\|X_\infty \left( \mathbb{I}_{[0,T]} - \mathbb{I}_{[0,R_n^+(r+\varepsilon)]} \right) \right\|_{B_b([0,T];E)} \\
\leq \mathbb{I}\{\left\|X_\infty\right\|_{B_b([0,T];E)} \geq r\} \left\|X_\infty\right\|_{B_b([0,T];E)}.
\]

and therefore the third term on the right-hand side of (2.7) tends to 0 as \(r \to \infty\).

It thus follows that \(X_n \to X_\infty\) in \(L^q(\Omega; C_b([0,T]; E))\). \(\square\)

3. Application to semilinear stochastic equations

We shall now apply the abstract results of the previous section to prove convergence of approximate solutions of stochastic evolution equations of the form
\[
(\text{SCP})\ \
\begin{align*}
\text{d}X(t) &= \left[AX(t) + F(t, X(t))\right] \text{d}t + G(t, X(t)) \text{d}W(t) \\
X(0) &= \xi.
\end{align*}
\]
The driving noise process \(W\) is assumed to be a cylindrical Brownian motion in some Hilbert space \(H\).

3.1. Stochastic evolution equations in UMD spaces. Under the assumptions stated below, existence and uniqueness of maximal solutions for (SCP) in UMD spaces \(E\) was proved in \([13]\), and convergence of the solutions in the case of globally Lipschitz continuous coefficients was established in \([12]\).

Continuing the notations of the previous section we shall write \(A = A_\infty\), \(F = F_\infty\), \(G = G_\infty\) and \(\xi = \xi_\infty\) when we thinks of these objects as the limits of sequences of approximating objects \(A_n\), \(F_n\), \(G_n\), \(\xi_n\).

(A1) For \(n \in \mathbb{N}\), the operators \(A_n\) are densely defined, closed and uniformly sectorial on \(E\) in the sense that there exist numbers \(M \geq 1\) and \(w \in \mathbb{R}\) such that each \(A_n\) is sectorial of type \((M,w)\).

(A2) The operators \(A_n\) converge to \(A_\infty\) in the strong resolvent sense:
\[
\lim_{n \to \infty} R(\lambda, A_n)x = R(\lambda, A_\infty)x
\]
for some (equivalently, all) \(\text{Re} \lambda > w\) and all \(x \in E\).

Assumptions (A1) and (A2) coincide with those made in \([12]\). Assuming (A1), the strongly continuous analytic semigroups \(e^{-w t S(t)}\) are uniformly bounded, uniformly in \(n\). Therefore, for \(w' > w\) the fractional powers \((w' - A_n)^\alpha\) are well defined for all \(\alpha \in (0, 1)\). In particular, the fractional domain spaces
\[
E_{n,\alpha} := D((w' - A_n)^\alpha)
\]
are Banach spaces with respect to the norm
\[
\left\|x\right\|_{E_{n,\alpha}} := \left\|(w' - A_n)^\alpha x\right\|.
\]
Up to equivalent norms, these spaces are independent of the choice of \(w'\). It may happen, however, that these spaces vary with \(n\). This may cause problems, and to avoid these we make the following assumption.
We then set $E := E_{\infty, \alpha}$ as linear subspace of $E$. Moreover, there exist constants $c_\alpha > 0$ and $C_\alpha > 0$ such that
\[ c_\alpha \|x\|_{E_{\infty, \alpha}} \leq \|x\|_{E_{\alpha}} \leq C_\alpha \|x\|_{E_{\infty, \alpha}} \quad \forall x \in E_\alpha, \ n \in \mathbb{N}. \]

We then set $E_\alpha := E_{\infty, \alpha}$ and $\| \cdot \|_\alpha := \| \cdot \|_{E_{\infty, \alpha}}$. We complete the scale $E_\alpha$ by setting $E_0 := E$ and $\| \cdot \|_0 := \| \cdot \|$.

It is immediate from assumption (A3) that for each $0 < \alpha < \frac{1}{2}$, the operators $(u' - A_n)^\alpha$ are uniformly bounded in $\mathcal{L}(E_\alpha, E)$ and that the operators $(u' - A_n)^{-\alpha}$ are uniformly bounded in $\mathcal{L}(E_\alpha, \mathbb{R})$.

For $0 < \alpha < \frac{1}{2}$ we define the extrapolation spaces $E_{n, \alpha}$ as the completion of $E$ under the norms $\|x\|_{E_{n, \alpha}} := \|(u' - A_n)^{-\alpha}x\|_E$. For fixed $n$, these spaces are independent of $w'$ up to an equivalent norm, and for each fixed $w' > w$ these spaces are independent of $n$ with equivalence constants independent of $n$. Accordingly, we set $E_{\alpha} := E_{\infty, \alpha}$ and $\| \cdot \|_{- \alpha} := \| \cdot \|_{E_{\infty, -\alpha}}$. Then for all $0 \leq \alpha, \beta < \frac{1}{2}$, the operators $(u' - A_n)^{\alpha + \beta}$ and $(u' - A_n)^{-2\alpha + \beta}$ are uniformly bounded in $\mathcal{L}(E_{\alpha}, E_{-\beta})$ and $\mathcal{L}(E_{-\beta}, E_{\alpha})$, respectively.

Concerning the coefficients $F_\alpha$ and $G_\alpha$, we shall assume that the hypotheses of [13] Section 8 are satisfied, uniformly with respect to $n$, and with exponents
\[ 0 \leq \theta < \frac{1}{2}, \quad 0 \leq \kappa_F, \kappa_G < \frac{1}{2}, \]
and we add the assumptions concerning their convergence of [12]. The precise assumptions are as follows. Recall that $\gamma(H, F)$ denotes the operator ideal of all $\gamma$-radonifying operators from $H$ into the Banach space $F$ (see [13] for further explanations of the hypotheses involving these spaces).

(F1) The maps $F_\alpha : [0, T] \times \Omega \times E_\theta \to E_{-\kappa_F}$ are uniformly locally Lipschitz continuous, i.e., for all $r > 0$ there exists a constant $L_F^{(r)} \geq 0$ such that
\[ \|F_\alpha(t, \omega, x) - F_\alpha(t, \omega, y)\|_{E_{-\kappa_F}} \leq L_F^{(r)} \|x - y\|_\theta \]
for all $t \in [0, T]$, $\omega \in \Omega$ and $x, y \in E_\theta$ of norm $\|x\|_\theta, \|y\|_\theta \leq r$. Moreover, for all $x \in E_\theta$ the map $(t, \omega) \mapsto F_\alpha(t, \omega, x)$ is strongly measurable and adapted and there exists a constant $C_{F, 0}$ such that
\[ \|F(t, \omega, 0)\|_{E_{-\kappa_F}} \leq C_{F, 0}. \]

(F2) For all $r > 0$ and almost all $(t, \omega) \in [0, T] \times \Omega$ we have
\[ F_\alpha^{(r)}(t, \omega, x) \to F_\alpha^{(r)}(t, \omega, x) \] in $E_{-\kappa_F}$ for all $x \in E_\theta$.

(G1) The maps $G_\alpha : [0, T] \times \Omega \times E_\theta \to E_{\gamma(H, E_{-\kappa_G})}$ are uniformly locally $\gamma$-Lipschitz continuous, i.e., for all $r > 0$ there exist maps $G_\alpha^{(r)} : [0, T] \times \Omega \times E_\theta \to \gamma(H, E_{-\kappa_G})$ such that
\[ G_\alpha^{(r)}(t, \omega, x) = G_\alpha(t, \omega, x) \quad \gamma(H, E_{\kappa_G}) \] on $[0, T] \times \Omega \times \{x \in E_\theta : \|x\|_\theta \leq r\}$.

Moreover, there there exist constants $L_G^{(r)}$ such that for all Borel probability measures $\mu$ on $[0, T]$, all $\omega \in \Omega$, all $\phi_1, \phi_2 \in L^2([0, T], \mu; E_\theta) \cap \gamma(L^2([0, T], \mu; E_\theta) \cap \gamma(L^2([0, T], \mu; E_\theta), and all $n \in \mathbb{N}$ we have
\[ \|G_\alpha^{(r)}(\cdot, \omega, \phi_1) - G_\alpha^{(r)}(\cdot, \omega, \phi_2)\|_{\gamma(L^2([0, T], \mu; E_{-\kappa_G})} \leq L_G^{(r)} \|\phi_1 - \phi_2\|_{L^2([0, T], \mu; E_\theta)}. \]
For all $x \in E_\theta$, $h \in H$, and $n \in \mathbb{N}$ there exists a constant $C_{G, 0}$ such that for all Borel probability measures $\mu$ on $[0, T]$
\[ \|G_\alpha^{(r)}(\cdot, \omega, 0)\|_{\gamma(L^2([0, T], \mu; E_{-\kappa_G})} \leq C_{G, 0}. \]
Finally, we assume that for all $n \in \mathbb{N}$, $x \in E_\theta$ and $h \in H$ the map $(t, \omega) \mapsto G_n(t, \omega, x)h$ is strongly measurable and adapted. We also assume this measurability and adaptedness of the maps $G^{(r)}_n$.

(G2) For all $r > 0$ and almost all $(t, \omega) \in [0, T] \times \Omega$ we have

$$G^{(r)}_n(\cdot, \omega, x) \rightarrow G^{(r)}_\infty(\cdot, \omega, x)$$

in $\gamma(L^2(0, T, \mu; H), E_{-\kappa_G})$ for all $x \in E_\theta$ and all Borel probability measures $\mu$ on $[0, T]$.

Examples where these assumptions are satisfied have been presented in [12, 13].

When $E$ also has type 2, then the conditions (G1) and (G2) are implied by the ‘classical’ notions of Lipschitz continuity and convergence assumptions, respectively, with respect to the norm of $\gamma(H, E_{-\kappa_G})$; see [13, Lemma 5.2] (cf. the statement of Proposition 3.3).

For UMD spaces $E$, under the above assumptions the existence of a unique maximal solution $(X_n(t))_{t \in [0, \sigma_n)}$ of (SCP) with coefficients $A_n$, $F_n$, $G_n$ was proved in [13, Theorem 8.1] for initial data $\xi_n \in L^p(\Omega, \mathcal{F}_0, \mathbb{P}; E_\theta)$ with $2 < p < \infty$. Moreover, it was shown that $\sigma_n$ is an explosion time for $X_n$. In this context we shall write

$$X_n = \text{sol}(A_n, F_n, G_n, \xi_n).$$

In the special case when the coefficients $F_n$ and $G_n$ are of linear growth and satisfy global Lipschitz assumptions (so that $\sigma_n \equiv T$), the convergence results proved in [12, Theorems 4.3, 4.7] for the case $\theta = \kappa_F = \kappa_G = \delta = 0$ can be extended mutatis mutandis to yield the following result.

**Proposition 3.1.** Let $E$ be a UMD space, assume (A1), (A2), (A3), suppose the mappings $F_n : [0, T] \times \Omega \times E_\theta \rightarrow E_{-\kappa_F}$ and $G_n : [0, T] \times \Omega \times E_\theta \rightarrow \gamma(H, E_{-\kappa_G})$ satisfy the global Lipschitz counterparts of (F1), (G1) with linear growth assumptions, and assume that they satisfy (F2), (G2). Let $2 < p < \infty$, $0 \leq \theta < \frac{1}{2}$, $0 \leq \kappa_F, \kappa_G < \frac{1}{2}$ satisfy

$$\theta + \kappa_F < \frac{3}{2} - \frac{1}{p}, \quad \theta + \kappa_G < 1 - \frac{1}{p} - \frac{1}{q},$$

where $\tau \in (1, 2]$ denotes the type of $E$. If $\xi_n \rightarrow \xi_\infty$ in $L^p(\Omega, \mathcal{F}_0, \mathbb{P}; E_\theta)$, then the global solutions $(X_n(t))_{t \in [0, T]}$ of (SCP) satisfy

$$X_n \rightarrow X_\infty \quad \text{in} \quad L^q(\Omega; C([0, T]; E_\theta)).$$

If $\lambda, \delta \geq 0$ satisfy

$$\lambda + \delta < \frac{1}{2} - \frac{1}{p} - \kappa_G,$$

then for all $1 \leq q < p$,

$$X_n - S_n(\cdot)\xi_n \rightarrow X_\infty - S_\infty(\cdot)\xi_\infty \quad \text{in} \quad L^q(\Omega; C^\lambda([0, T]; E_\theta)).$$

The approximation of $A$ by the operators $A_n$ with respect to the fractional domain norms is handled by using Lemma A.1 for the rest the proofs of [12, Theorems 4.3, 4.7] carry over almost word for word.

**Remark 3.2.** In situations where one has $\theta = \kappa_F = \kappa_G = \delta = 0$ with $F$ and $G$ not necessarily globally Lipschitz continuous, Assumption (A3) is not needed in Proposition 3.1 and also not in the following results.

Combining this result with Theorem 2.1 we obtain the following extension of Proposition 3.1 to the locally Lipschitz case.

**Theorem 3.3.** Let $E$ be a UMD space, assume (A1), (A2), (A3), (F1), (F2), (G1), (G2), and let (3.1) hold. Suppose that $\xi_n \rightarrow \xi_\infty$ in $L^p(\Omega, \mathcal{F}_0, \mathbb{P}; E_\theta)$. Let $(X_n(t))_{t \in [0, \sigma_n]} = \text{sol}(A_n, F_n, G_n, \xi_n)$ and define

$$\rho_n^{(r)} := \inf \{t \in (0, \sigma_n) : \|X_n(t)\|_\theta > r\}.$$

Then,
Corollary 3.4. If, in addition to the assumptions of the previous theorem, we have

\[ \lim_{n \to \infty} \rho^{(r)}_n \leq \rho^{(r)}_\infty \leq \lim_{n \to \infty} \rho^{(r+\varepsilon)}_n ; \]

(2) For all \( r > 0 \) and \( \varepsilon > 0 \) we have

\[ X_n \mathbb{1}_{[0,\rho^{(r)}_\infty \wedge \rho^{(r+\varepsilon)}_\infty)} \rightarrow X_\infty \mathbb{1}_{[0,\rho^{(r)}_\infty)} \text{ in } L^0(\Omega; B_b([0,T]; E_\delta)) ; \]

(3) We have

\[ X_n \mathbb{1}_{[0,\sigma_\infty \wedge \sigma_n]} \rightarrow X_\infty \mathbb{1}_{[0,\sigma_\infty)} \text{ in } L^0(\Omega \times [0,T]; E_\delta) . \]

**Proof.** For \( r > 0 \), define

\[ F_n^{(r)}(t, \omega, x) := \begin{cases} F_n(t, \omega, x) \, \frac{\|x\|_\rho}{r} & \text{if } \|x\|_\rho \leq r \\ F_n(t, \omega, \|x\|_\rho) & \text{otherwise.} \end{cases} \]

For each \( r > 0 \), the maps \( F_n^{(r)} \) and \( G_n^{(r)} \) are uniformly \((\gamma-)\)Lipschitz continuous and of linear growth. In particular, the processes \( X_n^{(r)} := \text{sol}(A_n, F_n^{(r)}, G_n^{(r)}, \xi_n) \) exist globally. Then the processes \( X_n \) together with the processes \( X_n^{(r)} \) satisfy the hypotheses of Theorem 2.1. Indeed, (a) follows from the maximality of \( X_n \), cf. [13, Lemma 8.2], and (b) follows from the convergence \( X_n \rightarrow X_\infty \) in \( L^q(\Omega; C([0,T]; E_\delta)) \) of Proposition 3.3. \( \square \)

Concerning the initial data, it actually suffices to assume that \( \xi_n \) converges to \( \xi \) in \( L^0(\Omega; \mathcal{F}_0, P; E_\delta) \); see Subsection 3.3.

**Corollary 3.4.** If, in addition to the assumptions of the previous theorem, we have \( \sigma_n = T \) almost surely for all \( n \in \mathbb{N} \) and \( \sup_{n \in \mathbb{N}} \mathbb{E}\|X_n\|_{C([0,T]; E_\delta)}^p < \infty \), then:

(1) \( \sigma_\infty = T \) almost surely;
(2) For all \( 1 \leq q < p \),

\[ X_n \rightarrow X_\infty \text{ in } L^q(\Omega; C([0,T]; E_\delta)) ; \]

(3) For \( 0 \leq \delta < \frac{1}{2} - \frac{1}{p} - \kappa_G \) we have

\[ X_n - S_n(\cdot)\xi_n \rightarrow X_\infty - S_\infty(\cdot)\xi_\infty \text{ in } L^0((0,T) \times \Omega; E_\delta) ; \]

(4) If, in addition, (3.2) holds and \( \sup_n \mathbb{E}\|X_n - S_n(\cdot)\xi_n\|_{L^\infty([0,T]; E_\delta)}^p < \infty \), then

\[ X_n - S_n(\cdot)\xi_n \rightarrow X_\infty - S_\infty(\cdot)\xi_\infty \text{ in } L^q(\Omega; C^\mu([0,T], E_\delta)) \]

for all \( 1 \leq q < p \) and \( 0 \leq \mu < \lambda \).

**Proof.** (1) and (2) follow from Corollary 2.3.

(3) Before we start the proof we note that the result follows trivially (with convergence in a stronger sense) from (2) when \( \delta \leq \theta \). The point of (3) is that we might have \( \delta > \theta \), and this is what we shall assume in the rest of the proof.

The processes \( Y_n := X_n - S_n(\cdot)\xi_n \) belong to \( L^0(\Omega; C_b([0,T]; E_\delta)) \) in view of \( \sigma_n = T \) and [13, Theorem 8.1].

We first additionally assume that the initial values \( \xi_n \) are uniformly bounded in \( L^\infty(\Omega, \mathcal{F}_0, P; E_\delta) \) and put

\[ C := \sup_{t \in [0,T], n \in \mathbb{N}} \|S_n(t)\xi_n\|_{L^\infty(\Omega; E_\delta)} . \]

Put \( Z_n^{(r)} := \text{sol}(A_n, F_n^{(r+C)}, G_n^{(r+C)}, \xi_n) \), where \( F_n^{(r)} \) is as in the proof of Theorem 3.3 and \( Y_n^{(r)} := Z_n^{(r)} - S_n(\cdot)\xi_n \). If we put \( \varphi_n^{(r)} := \inf\{t > 0 : \|Y_n(t)\|_\delta > r \} \), then

\[ Y_n \mathbb{1}_{[0,\varphi_n^{(r)}]} = Y_n^{(r)} \mathbb{1}_{[0,\varphi_n^{(r)}]} \]

Indeed, if \( t \leq \varphi_n^{(r)} \), then \( \|Y_n(t)\|_\delta \leq r \) and

\[ \|Z_n^{(r)}(t)\|_\theta \leq \|Y_n^{(r)}(t)\|_\theta + \|S_n(t)\xi_n\|_\theta \leq \|Y_n^{(r)}(t)\|_\delta + C \leq r + C \]
almost surely. By the maximality of $X_n$, $X_n I_{[0,E^n(\cdot)]} = Z_n^{(r)} I_{[0,E^n(\cdot)]}$. Subtracting $S_n(\cdot) \xi_n$, it follows that $Y_n I_{[0,E^n(\cdot)]} = Y_n^{(r)} I_{[0,E^n(\cdot)]}$ as claimed.

This proves that Hypothesis (a) preceding the statement of Theorem 2.5 is satisfied. Hypothesis (b) follows from Proposition 3.3. Thus the assertion follows from Theorem 2.5(3).

It remains to remove the additional boundedness assumption. To that end, fix $K \in \mathbb{N}$. From any given subsequence of $\xi_n$ we can extract a further subsequence, relabeled with indices $n$, such that $\xi_n \to \xi_\infty$ almost surely and $\|\xi_n - \xi_\infty\|_{L^p(\Omega;E_\theta)} \leq 2^{-n}$. By the Chebyshev inequality, $P(\|\xi_n - \xi_\infty\|_\theta > 1) \leq 2^{-np}$.

Now define $\Omega^N_K := \{\|\xi_n\|_\theta \leq K + 1 \forall n \geq N\}$. Then

$$P(\Omega^N_K) \leq P(\|\xi_\infty\|_\theta > K) + 2^{-np}.$$ Setting $\xi_n^{(K)} := \xi_n 1_{\{\|\xi_n\|_\theta \leq K + 1\}}$, it follows that $\xi_n^{(K)} \to \xi_\infty^{(K)}$ in $L^p(\Omega;E_\theta)$ and $\xi_n^{(K)}$ is bounded in $L^\infty(\Omega;E_\theta)$. By the above, the claim holds true for the processes $Y_n^{(K)}$, which are defined as the processes $Y_n$, but starting the uncompensated solution at the modified initial data $\xi_n^{(K)}$.

By [13] Lemma 8.2, almost surely on $\Omega^N_K$, we have $Y_n^{(K)} = Y_n$. Thus along our subsequence, (2) hold with $\Omega$ replaced with $\Omega^N_K$ for all $K, N \in \mathbb{N}$. Writing $\Omega$ as a countable union of such sets, it follows that (2) holds as stated.

(4) is immediate from (2) and [12] Lemma 4.2. □

Example 3.5. The condition $\sup_{n \in \mathbb{N}} E\|X_n\|_{C([0,T];E_\theta)}^p < \infty$ is satisfied if, in addition to the assumptions in Theorem 3.3, $F_n$ and $G_n$ are uniformly of linear growth. For $\lambda, \delta \geq 0$ with $\lambda + \delta < \frac{1}{2} - \frac{1}{p} - r_C$, we also have $\sup_n E\|X_n - S_n(\cdot)\xi_n\|_{C([0,T];E_\theta)}^p < \infty$; see [13] Theorem 8.1. Hence, in this situation, Corollary 2.5(4) applies.

3.2. Stochastic evolution equations on general Banach spaces. Reaction diffusion type equations with nonlinearities of polynomial growth are usually considered in spaces of continuous functions. This is essential in order to verify the assumptions posed on the nonlinearities. As far as we know, there is no satisfying theory of stochastic integration available in spaces of continuous functions. We get around this by assuming that the Banach space $B$ in which we seek the solutions is sandwiched between $E_\theta$ and $E$. We then assume that $E$ is a UMD Banach space as in the previous section and carry out all stochastic integrations in the interpolation scale of $E$. In order to be able to handle initial values with values in $B$ without losing regularity due to the various embeddings, however, we need to carry out all fixed point arguments in the space $L^p(\Omega;C([0,T];B))$.

In applications, typical choices are $B = C(\partial)$ and $E = L^p(\partial)$ for some large $p \geq 2$, with $\partial$ a domain in $\mathbb{R}^d$. This motivates us to work in UMD spaces $E$ with type 2 from the onset (these include the spaces $L^p(\partial)$ for $2 \leq p < \infty$). Accordingly we shall assume:

(E) $E$ is a UMD Banach space with type 2.

In addition to (A1) – (A3) we shall assume:

(A4) The semigroups $S_n$ restrict to strongly continuous semigroups $S_n^B$ on $B$ which are uniformly exponentially bounded in the sense that, for certain constants $M \geq 1$ and $\bar{\omega} \in \mathbb{R}$ we have $\|S_n(t)\|_{L^\infty(B)} \leq Me^{\bar{\omega}t}$ for all $t \geq 0$ and $n \in \mathbb{N}$.

(A5) We have continuous, dense embeddings $E_\theta \hookrightarrow B \hookrightarrow E$.

Strong resolvent convergence of the parts $A_n|_B$ of $A_n$ in $B$ follows from (A1) – (A4); see Lemma A.2.

In the applications we have in mind, the operators $A_n$ are second order elliptic differential operators on $E := L^p(\partial)$ subject to suitable boundary conditions (b.c.),
where $\mathcal{O} \subseteq \mathbb{R}^d$ is some domain, and $E_0 = H^{20,p}_0(\mathcal{O})$ is the corresponding Sobolev space. If $p \geq 2$ and $\theta \geq 0$ are chosen appropriately in relation to the dimension $d$, then $E_0$ is continuously and densely embedded into $B := C_{b.c.}(\mathcal{O})$.

In the present framework we can repeat the procedure of the previous subsection to obtain convergence to maximal solutions of \( \text{SCP} \) with nonlinearities $F$ and $G$ which are locally Lipschitz continuous from a corresponding convergence result for globally Lipschitz continuous coefficients. In particular, the results of Theorem 3.3 and Corollary 2.5(1) and (2) generalise \textit{mutatis mutandis} to the situation considered here. Instead of spelling out the details we content ourselves with the statement of the convergence result for the globally Lipschitz case.

**Proposition 3.6.** Let $B$ be a Banach space, assume (E) and (A1)--(A5), and assume that (3.1) holds with $\tau = 2$, i.e., $2 < p < \infty$, $0 \leq \theta < \frac{1}{2}$, $0 \leq \kappa_G < \frac{1}{2}$ satisfy

$$\theta + \kappa_G < \frac{1}{2} - \frac{1}{p}.$$ 

Moreover, let $F_n : [0,T] \times \Omega \times B \to E_{-\kappa_F}$ and $G_n : [0,T] \times \Omega \times B \to \gamma(H,E_{-\kappa_G})$ be strongly measurable, adapted, and globally Lipschitz continuous in the third variable, uniformly with respect to the first and second variables. If

$$\lim_{n \to \infty} F_n(t,\omega,x) = F_\infty(t,\omega,x) \quad \text{and} \quad \lim_{n \to \infty} G_n(t,\omega,x) = G(t,\omega,x)$$

for all $(t,\omega,x) \in [0,T] \times \Omega \times B$ and $\xi_n \to \xi_\infty$ in $L^p(\Omega;\mathcal{F}_0;B)$, then:

1. For each $n \in \mathbb{N}$, the problem \( \text{SCP} \) with coefficients $(A_n,F_n,G_n)$ and initial datum $\xi_n$ has a unique mild solution $X_n$ in $L^p(\Omega;C([0,T];B))$;

2. For all $1 \leq q < p$,

$$X_n \to X_\infty \quad \text{in} \quad L^q(\Omega;C([0,T];B)).$$

3. If $\lambda, \delta \geq 0$ satisfy $\lambda + \delta < \frac{1}{2} - \frac{1}{p} - \kappa_G$ then

$$X_n - S_n(\cdot)\xi_n \to X_\infty - S(\cdot)\xi_\infty \quad \text{in} \quad L^q(\Omega;C^\lambda([0,T];E_0))$$

for all $1 \leq q < p$.

Note that the condition $\theta + \kappa_F < 1$, which also results from (3.1) if we take $\tau = 2$, is automatically satisfied in view of the standing assumptions $0 \leq \theta, \kappa_F < \frac{1}{2}$.

**Sketch of proof.** Towards (1), let $V_T := L^p_\theta(\Omega;C([0,T];B))$ denote the space of continuous, adapted $B$-valued processes $\phi$ such that $\|\phi\|_{V_T} := \mathbb{E}\|\phi\|_{C([0,T];B)} < \infty$. By (A4), $S_n(\cdot)\xi_n \in V_T$.

Consider the fixed point operators $\Lambda_n,\xi_n,T$ from $V_T$ into itself defined by

$$[\Lambda_n,\xi_n,T\phi](t) := S_n(t)\xi_n + \int_0^t S_n(t-s)F_n(s,\phi(s))ds + \int_0^t S_n(t-s)G_n(s,\phi(s))ds.$$ 

Using [13] Lemma 3.4, we see that $S_n \ast F_n(\cdot,\phi)$ is in $L^p_\theta(\Omega;C([0,T];E_\theta))$, and hence in $V_T$, for all $\phi \in V_T$. Moreover, by the assumptions on $G_n$, we see that $s \mapsto S_n(t-s)G_n(s,\phi(s))$ is in $L^p(\Omega;L^2(0,t;\gamma(H,E_\theta)))$. Since $E_\theta$, being isomorphic to $E$, is UMD with type 2, this function is stochastically integrable in $E_\theta$. In fact, using [13] Proposition 4.2 one finds that the stochastic convolution defines an element of $L^p_\theta(\Omega;C([0,T];E_\theta))$, and hence of $V_T$.

Standard arguments show that for each $n$, $\Lambda_n,\xi_n,T$ is Lipschitz continuous on $V_T$ and the Lipschitz constants of $\Lambda_n,\xi_n,T$ converge to 0 as $T \downarrow 0$. Hence, for small enough $T$, solutions of \( \text{SCP} \) can be obtained from Banach’s fixed point theorem and global solutions of \( \text{SCP} \) can be ‘patched together’ inductively from solutions on smaller time intervals.

(2) As in the proof of [12] Theorem 4.3 it suffices to prove that $\Lambda_n,\xi_n,T\phi \to \Lambda_\infty,\xi_\infty,T\phi$ in $V_T$ for all $\phi \in V_T$ with $T$ small. Convergence of $S_n(\cdot)\xi_n \to S_\infty(\cdot)\xi_\infty$ follows from Lemma A.2. As for the stochastic and deterministic convolutions, as
in [12] Lemma 4.5 one sees that they actually converge in $L^p(\Omega; C([0, T]; E_0))$, and hence in $L^p(\Omega; C([0, T]; B))$ by (A5).

(3) follows similarly as in the proof of [12] Theorem 4.7. □

3.3. Extension to measurable initial values. In our results so far, we have assumed that $\xi_n \to \xi_\infty$ in a suitable $L^p$-space. It is routine to extend these results to initial data $\xi_n$ which are merely assumed to be strongly measurable (but no integrability assumption is imposed) and convergent in measure.

Given a strongly $\mathcal{F}_0$-measurable initial value $\xi$, a maximal solution of (SCP) is constructed as follows; cf. [13] Section 7. For $K \in \mathbb{N}$, we put $\xi^{(K)} := \xi\mathbb{1}_{\{\|\xi\| \leq K\}}$. If $(X^{(K)}(t))_{t \in [0,\sigma(K))]$ denotes the maximal solution of (SCP) with initial datum $\xi^{(K)}$, then one sees that on the set $\{\|\xi\| \leq K\}$ we have $X^{(K)}\mathbb{1}_{\{t \in [0,\sigma(K))\}} = X^{K'}\mathbb{1}_{\{t \in [0,\sigma(K'))\}}$ for all $K' \geq K$, see [13] Lemma 8.2. Hence a maximal solution of (SCP) can be constructed from the solution $X^{(K)}$.

Now suppose that for $n \in \mathbb{N}$ we are given a measurable $\xi_n$ such that $\xi_n \to \xi_\infty$ in measure. Then for fixed $K$ the truncated random variables $\xi_n^{(K)}$ converge to $\xi^{(K)}$ in measure and are uniformly bounded, hence uniformly $p$-integrable for all $1 \leq p < \infty$. It follows that $\xi^{(K)}_n \to \xi^{(K)}_\infty$ in every $L^p$. Hence, cutting off the nonlinearities $F_n$ and $G_n$ as well as the initial data and arguing as before, we obtain convergence results for solutions of (SCP) with measurable initial data. We leave the details to the reader.

4. Global existence for reaction diffusion type equations

In this section, we shall make additional assumptions on the coefficients similar to those considered by Brzec\'dziak and Gatarek [3] and Cerrai [4].

Throughout this section we shall assume that $B$ is a Banach space and that $E$ is a UMD space with type 2. Unless explicitly stated otherwise all norms $\| \cdot \|$ are taken in $B$.

Let us first recall that in a Banach space $B$, the subdifferential of the norm at $x$ is given by

$$\partial \|x\| := \{x^* \in B^* : \|x^*\| = 1 \text{ and } \langle x, x^* \rangle = 1\}.$$

We recall, see [6] Proposition D.4, that if $u : I \to B$ is a differentiable function, then $\|u(\cdot)\|$ is differentiable from the right and from the left with

$$\frac{d^+}{dt}\|u(t)\| = \max \{\langle u'(t), x^* \rangle : x^* \in \partial \|u(t)\|\},$$

$$\frac{d^-}{dt}\|u(t)\| = \min \{\langle u'(t), x^* \rangle : x^* \in \partial \|u(t)\|\}.$$
(F′) The map $F : [0, T] \times \Omega \times B \to B$ is locally Lipschitz continuous in the sense that for all $r > 0$, there exists a constant $L_F^{(r)}$ such that

$$
\|F(t, \omega, x) - F(t, \omega, y)\| \leq L_F^{(r)} \|x - y\|
$$

for all $\|x\|, \|y\| \leq r$ and $(t, \omega) \in [0, T] \times \Omega$ and there exists a constant $C_{F,0} \geq 0$ such that

$$
\|F(t, \omega, 0)\| \leq C_{F,0}
$$

for all $t \in [0, T]$ and $\omega \in \Omega$. Moreover, for all $x \in B$ the map $(t, \omega) \mapsto F(t, \omega, x)$ is strongly measurable and adapted.

For suitable constants $a', b' \geq 0$ and $N \geq 1$ we have

$$
\langle Ax + F(t, x + y), x' \rangle \leq a'(1 + \|y\|)^N + b'\|x\|
$$

for all $x \in D(A|_B)$, $y \in B$, and $x^* \in \partial\|x\|$.

(G′) The map $G : [0, T] \times \Omega \times B \to \gamma(H, E_{-\kappa G})$ is locally Lipschitz continuous in the sense that for all $r > 0$ there exists a constant $L_G^{(r)}$ such that

$$
\|G(t, \omega, x) - G(t, \omega, y)\|_{\gamma(H, E_{-\kappa G})} \leq L_G^{(r)} \|x - y\|
$$

for all $\|x\|, \|y\| \leq r$ and $(t, \omega) \in [0, T] \times \Omega$ and there exists a constant $C_{G,0} \geq 0$ such that

$$
\|G(t, \omega, 0)\|_{\gamma(H, E_{-\kappa G})} \leq C_{G,0}
$$

for all $t \in [0, T]$ and $\omega \in \Omega$. Moreover, for all $x \in B$ and $h \in H$ the map $(t, \omega) \mapsto G(t, \omega, x)h$ is strongly measurable and adapted.

Finally, for suitable constants $c \geq 0$ and $\varepsilon > 0$ we have

$$
\|G(t, \omega, x)\|_{\gamma(H, E_{-\kappa G})} \leq c'(1 + \|x\|)^{\frac{1}{2} + \varepsilon}
$$

for all $(t, \omega, x) \in [0, T] \times \Omega \times B$.

Remark 4.1. In the results to follow, the constant $\varepsilon$ in (G′) has to be sufficiently small.

Example 4.2. Let $B = C(\overline{\mathcal{O}})$ for some bounded domain $\mathcal{O} \subset \mathbb{R}^d$. Let $F : [0, T] \times \Omega \times B \to B$ be given by

$$
(F(t, \omega, x))(s) = f(t, \omega, s, x(s)),
$$

where

$$
f(t, \omega, s, \eta) = -a(t, \omega, s)\eta^{2k+1} + \sum_{j=0}^{2k} a_j(t, \omega, s)\eta^j, \quad \eta \in \mathbb{R}.
$$

We assume that there are constants $0 < c \leq C < \infty$ such that (cf. [3])

$$
c \leq a(t, \omega, s) \leq C, \quad |a_j(t, \omega, s)| \leq C, \quad (j = 0, \ldots, 2k + 1)
$$

for all $(t, \omega, s) \in [0, T] \times \Omega \times \overline{\mathcal{O}}$. It is easy to see that, in this situation, for a suitable constant $a' \geq 0$ we have

$$
-a'(1 + |\eta|^{2k+1}\mathbb{1}_{\{\eta \geq 0\}}) \leq f(t, \omega, s, \eta) \leq a'(1 + |\eta|^{2k+1}\mathbb{1}_{\{\eta \leq 0\}})
$$

for all $t \in [0, T], \omega \in \Omega, s \in \mathcal{O}, \eta \in \mathbb{R}$. This, in turn, yields that

$$
f(t, \omega, s, \eta + \zeta) \cdot \text{sgn} \eta \leq a'(1 + |\zeta|^{2k+1})
$$

for all $(t, \omega, s) \in [0, T] \times \Omega \times \overline{\mathcal{O}}$ and $\eta, \zeta \in \mathbb{R}$. By the results of [3] Section 4.3] this implies

$$
\langle F(t, \omega, x + y), x' \rangle \leq a'(1 + \|y\|^{2k+1})
$$

for all $t \in [0, T], \omega \in \Omega, x, y \in B$, and $x^* \in \partial\|x\|$. Since $A_B$ is dissipative, it follows that (F′) holds.

The first main result of this section reads as follows.
Theorem 4.3. Let $B$ be a Banach space, assume (E), (A1), (A4), (A5), (F'), and (G') with $\varepsilon > 0$ sufficiently small, and assume that $2 < p < \infty$, $0 \leq \theta < \frac{1}{2}$, $0 \leq \kappa_F, \kappa_G < \frac{1}{2}$, and
\[ \theta + \kappa_G < \frac{1}{2} - \frac{1}{Np}. \]
For all $\xi \in L^p(\Omega, \mathcal{F}_0, \mathbb{P}; B)$, the maximal solution $(X(t))_{t \in [0, \sigma)}$ of (SCP) is global, i.e., we have $\sigma = T$ almost surely. Moreover,
\[ E\|X\|^p_{C([0,T];B)} \leq C(1 + E\|\xi\|^p), \]
where the constant $C$ depends on the coefficients only through the sectoriality constants of $A$ and the constants $a', b', c'$ and the exponent $N$.

This result improves corresponding results in [3, 4] under similar assumptions on $F$ and $G$. In [3], global existence of a martingale solution was obtained for uniformly bounded $G$; in [4], rather restrictive simultaneous diagonalisability assumptions on $A$ and the noise were imposed.

In the proof of Theorem 4.3 we will use the following lemma, which is a straightforward generalisation of [3, Lemma 4.2]. For the reader’s convenience we include the short proof.

Lemma 4.4. Let $A$ be the generator of a strongly continuous contraction semigroup $S$ on $B$, $x \in B$ and $F : [0, T] \times B \to B$ satisfy condition (F'). If for some $\tau > 0$ two continuous functions $u, v : [0, \tau) \to B$ satisfy
\[ u(t) = S(t)x + \int_0^t S(t-s)F(s, u(s) + v(s)) \, ds \quad \forall t \in [0, \tau), \]
then
\[ \|u(t)\| \leq e^{b't}\left(\|x\| + \int_0^t a'(1 + \|v(s)\|)^N \, ds\right). \]

Proof. For $n \in \mathbb{N}$, put $u_n(t) := nR(n,A)u(t)$, $x_n := nR(n,A)x$ and $F_n(t,y) := nR(n,A)F(t,y)$. Then
\[ u_n(t) = S(t)x_n + \int_0^t S(t-s)[F(s, u_n(s) + v(s)) + r_n(s)] \, ds \]
where $r_n(s) = F_n(s, u_n(s) + v(s)) - F(s, u_n(s) + v(s))$. It follows that $u_n$ is differentiable with
\[ u'_n(t) = Au_n(t) + F(t, u_n(t) + v(t)) + r_n(t). \]
By the observations at the beginning of this section, for almost all $t \in (0, T)$ we have, for all $x^* \in \partial\|u_n(t)\|$,\[ \frac{d}{dt}\|u_n(t)\| = \langle A(t)u_n(t) + F(s, u_n(t) + v(t)) + r_n(t), x^* \rangle \]
\[ \leq a'(1 + \|v(t)\|)^N + b'\|u_n(t)\| + \|r_n(t)\|. \]
Thus, by Gronwall’s lemma,
\[ \|u_n(t)\| \leq e^{b't}\left(\|x_n\| + \int_0^t a'(1 + \|v(s)\|)^N + \|r_n(s)\| \, ds\right). \]
Since $\|nR(n,A)\| \leq 1$ and $nR(n,A) \to I$ strongly as $n \to \infty$, the assertion follows upon letting $n \to \infty$. \qed

Proof of Theorem 4.3. Let us first assume that (G') is satisfied with $\varepsilon = 0$; in the proof we indicate the reason why a small $\varepsilon > 0$ can be allowed.

We define
\[ F_n(t, \omega, x) := \begin{cases} F(t, \omega, x) & \text{if } \|x\| \leq n, \\ F(t, \omega, \frac{x}{\|x\|}) & \text{otherwise.} \end{cases} \]
We also set $X_n := \text{sol}(A, F_n, G, \xi)$. 

MARKUS KUNZE AND JAN VAN NEERVEN
Let us first note that for $x \in \mathcal{D}(A|B)$, $y \in B$, and $x^* \in \partial \|x\|$, we have

$$\langle Ax + F_n(t, \omega, x + y), x^* \rangle \leq a'(1 + \|y\|)^N + b\|x\|$$

for all $(t, \omega) \in [0, T] \times \Omega$. If $\|x + y\| \leq n$, then this follows directly from (F'). If $\|x + y\| > n$, then

$$\langle Ax + F_n(t, \omega, x + y), x^* \rangle = \langle Ax + F(t, \omega, \frac{nx}{\|x + y\|} + \frac{ny}{\|x + y\|}), x^* \rangle$$

$$= \langle A\frac{nx}{\|x + y\|} + F(t, \omega, \frac{nx}{\|x + y\|} + \frac{ny}{\|x + y\|}), x^* \rangle$$

$$+ (1 - \frac{n}{\|x + y\|})\langle Ax, x^* \rangle$$

$$\leq a'(1 + \frac{n\|y\|}{\|x + y\|})^N + b\|\frac{n\|y\|}{\|x + y\|}\|$$

$$\leq a'(1 + \|y\|^N) + b\|x\|$$

where we have used (F') and the dissipativity of $A$ in $B$ in the third step and $\|x + y\| > n$ in the fourth.

Trivially,

$$\mathbb{E}\|X_n\|_{C[0,T];B}^p \leq \mathbb{E}\|S(\cdot)\xi + S \ast F_n(\cdot, X_n)\|_{C[0,T];B}^p + \mathbb{E}\|S \circ G(\cdot, X_n)\|_{C[0,T];B}^p.$$  

By (4.2) and Lemma 4.4 applied with

$$u_n := X_n - S \circ G(\cdot, X_n), \quad v_n = S \circ G(\cdot, X_n),$$

we obtain

$$\mathbb{E}\|S(\cdot)\xi + S \ast F_n(\cdot, X_n)\|_{C[0,T];B}^p$$

$$= \mathbb{E} \sup_{t \in [0,T]} \mathbb{E}\|S(\cdot)\xi + \int_0^t S(t - s)F_n(s, u_n(s) + v_n(s)) ds\|^p$$

$$\leq e^{b'pT} \mathbb{E} \sup_{t \in [0,T]} \left(\|\xi\| + \int_0^t a'(1 + \|v_n(s)\|)^N ds\right)^p$$

$$\leq e^{b'pT} \mathbb{E}(1 + \|\xi\|^p + \|S \circ G(\cdot, X_n)\|_{C[0,T];B}^N)^p$$

$$\leq e^{b'pT} (1 + \mathbb{E}\|\xi\|^p + \mathbb{E}\|S \circ G(\cdot, X_n)\|_{C[0,T];B}^N).$$

Since $\theta + \kappa G < \frac{1}{2} - \frac{1}{Np}$, we may pick $\alpha \in (0, \frac{1}{2})$ such that $\theta + \kappa G < \alpha - \frac{1}{Np}$. Then, for some $\varepsilon > 0$,

$$\mathbb{E}\|S \circ G(\cdot, X_n)\|_{C[0,T];B}^{Np}$$

$$\leq e^{Np} \mathbb{E}\|S \circ G(\cdot, X_n)\|_{C[0,T];E_\alpha}^{Np}$$

$$\leq T^{\varepsilon Np} \mathbb{E}\int_0^T \|s \mapsto (t - s)^{-\alpha} G(s, X_n)\|_{L^2(0, t; H, E_{-\varepsilon G})}^{Np} dt$$

$$\leq T^{\varepsilon Np} \mathbb{E}\int_0^T \|s \mapsto (t - s)^{-\alpha} G(s, X_n)\|_{L^2(0, t; \gamma(0, H, E_{-\varepsilon G}))}^{Np} dt$$

$$= T^{\varepsilon Np} \mathbb{E}\int_0^T \left(\int_0^t (t - s)^{-2\alpha} \|G(s, X_n(s))\|_{\gamma(0, H, E_{-\varepsilon G})}^2 ds\right)^{\frac{Np}{2}} dt$$

$$\leq T^{\varepsilon Np} \left(\int_0^T t^{-2\alpha} dt\right)^{\frac{Np}{2}} \mathbb{E}\int_0^T \|G(t, X_n(t))\|_{\gamma(0, H, E_{-\varepsilon G})}^{Np} dt$$

$$\leq T^{\frac{1}{2} - \alpha + \varepsilon} Np (c')^{Np} \mathbb{E}\int_0^T (1 + \|X_n(t)\|)^p dt$$

$$\leq T^{\frac{1}{2} - \alpha + \varepsilon} Np + 1 (c')^{Np} (1 + \mathbb{E}\|X_n\|_{C[0,T];B}^p).$$
In this computation we used the following facts. The first inequality follows from the continuity of the embedding $E_0 \hookrightarrow B$, the second from [13, Proposition 4.2] (here the condition on $a$ is used), the third uses the fact that if $(S, \mu)$ is a $\sigma$-finite measure space, $H$ a Hilbert space and $F$ a Banach space with type $2$, then we have a continuous embedding $L^2(S, \mu; \gamma(H, F)) \hookrightarrow \gamma(L^2(S, \mu; H), F)$ of norm less than or equal to the type $2$ constant of $F$, in the next inequality we used Young’s inequality, and in the sixth step the assumptions on $G$.

Because of the strict inequality $\alpha < \frac{1}{2}$, in step $(\star)$ we can apply Young’s inequality with slightly sharper exponents. This creates room (explicitly computable in terms of the other exponents involved) for a small $\varepsilon > 0$ in Hypothesis $(G')$.

Combining these estimates we obtain

\[
\mathbb{E}\|S(\cdot)\xi + S \ast F_n(\cdot, X_n)\|^p_{C([0,T]; B)} \lesssim e^{b'pT}p\left(1 + \mathbb{E}\|\xi\|^p + T^{(\frac{1}{2} - \alpha - \varepsilon)Np + 1}\left(1 + \mathbb{E}\|X_n\|^p_{C([0,T]; B)}\right)\right).
\]

Next,

\[
\mathbb{E}\|S \circ G(\cdot, X_n)\|^p_{C([0,T]; B)} \lesssim (\mathbb{E}\|S \circ G(\cdot, X_n)\|^N_{C([0,T]; B)})^{\frac{1}{N}} \lesssim T^{(\frac{1}{2} - \alpha + \lambda)Np + 1}\left(1 + \mathbb{E}\|X_n\|^p_{C([0,T]; B)}\right).
\]

Substituting these estimates into [13] we obtain

\[
\mathbb{E}\|X_n\|^p_{C([0,T]; B)} \leq C_0 + C_1 \mathbb{E}\|\xi\|^p + C_2(T)\mathbb{E}\|X_n\|^p_{C([0,T]; B)}
\]

for a certain constants $C_0$, $C_1$ and a function $C_2(T)$ which does not depend on $\xi$ and converges to 0 as $T \downarrow 0$. Hence, if $T > 0$ is small enough, we obtain

\[
\mathbb{E}\|X_n\|^p_{C([0,T]; B)} \leq (1 - C_2(T))^{-1}(C_0 + C_1 \mathbb{E}\|\xi\|^p).
\]

Iterating this procedure a finite number of times, it follows that given $T > 0$, there exists a constant $C$ as in the statement such that $\sup_n \mathbb{E}\|X_n\|^p_{C([0,T]; B)} \leq C(1 + \mathbb{E}\|\xi\|^p) < \infty$. By Corollary [2.3] the lifetime of $X$ equals $T$ almost surely and we have $X_n \rightarrow X$ in $L^q(\Omega, C([0,T]; B))$ for all $1 \leq q < p$. □

Our next aim is to prove a version of Theorem [4.4] (Theorem [4.9] below) which, in return for an additional assumption on $F$, allows nonlinearities $G$ of linear growth. For this purpose we introduce the following hypotheses.

- \text{(F'') There exist constants $a''$, $b''$, $m > 0$ such that the function $F : [0, T] \times \Omega \times B \rightarrow B$ satisfies}

\[
(F(t,w,y+x) - F(t,w,y), x^*) \leq a''(1 + \|y\|^m - b''\|x\|^m)
\]

for all $t \in [0,T]$, $\omega \in \Omega$, $x, y \in B$, and $x^* \in \partial\|x\|$, and

\[
\|F(t,y)\| \leq a''(1 + \|y\|^m)
\]

for all $y \in B$.

- \text{(G'') The function $G : [0, T] \times \Omega \times B \rightarrow \gamma(H, E_{-\kappa G})$ satisfies the measurability and adaptedness assumption of (G') and is locally Lipschitz continuous and of linear growth. Moreover, we have}

\[
\|G(t,\omega, 0)\|_{\gamma(H, E_{-\kappa G})} \leq C_{G,0}
\]

for all $(t, \omega) \in [0,T] \times \Omega$ and a suitable constant $C_{G,0} > 0$.

\text{Example 4.5. The map $F$ described in Example [4.2] also satisfies condition (F''). Indeed, for the function $f$ as in Example [4.2] it is easy to see that for certain constants $a_1, a_2 \in \mathbb{R}$ and $b_1, b_2 > 0$ we have}

\[
a_1 - b_1 \eta^{2k+1} \leq f(t,\omega, s, \eta) \leq a_2 - b_2 \eta^{2k+1}
\]
for all \((t, \omega, s, \eta) \in [0, T] \times \Omega \times \mathcal{F} \times \mathbb{R}\). But this yields that
\[
(4.4) \quad W := \left| f(t, \omega, s, \eta + \zeta) - f(\zeta) \right| \cdot \text{sgn} \eta \leq a - b|\eta|^{2k+1} + c|\zeta|^{2k+1}
\]
for certain positive constants \(a, b, c\) and all \((t, \omega, s) \in [0, T] \times \Omega \times \mathcal{F}\) and \(\eta, \zeta \in \mathbb{R}\).

To see this, we distinguish several cases.

- \(\eta, \zeta \geq 0\). In this case,
  \[
  W \leq a_2 - b_2(\eta + \zeta)^{2k+1} - a_1 + b_1\zeta^{2k+1}
  \leq a_2 - a_1 - b_2|\eta|^{2k+1} + b_1|\zeta|^{2k+1}
  \]
since \(\eta + \zeta \geq \eta = |\eta|\).
- \(\eta, \zeta \leq 0\). In this case,
  \[
  W \leq a_2 - b_2\zeta^{2k+1} - a_1 + b_1(\eta + \zeta)^{2k+1}
  = a_2 - a_1 + b_2|\eta|^{2k+1} - b_2(|\eta| + |\zeta|)^{2k+1}
  \leq a_2 - a_1 + b_2|\zeta|^{2k+1} - b_2|\eta|^{2k+1}.
  \]
- \(\eta \leq 0 \leq \zeta\). In this case,
  \[
  W \leq a_2 - b_2\zeta^{2k+1} - a_1 + b_1(\eta + \zeta)^{2k+1}
  = a_2 - a_1 + b_2|\zeta|^{2k+1} - a_1 + b_1(|\zeta| - |\eta|)^{2k+1}.
  \]
If \(|\zeta| \geq |\eta|\), then this can be estimated by
\[
a_2 - a_1 - b_2|\eta|^{2k+1} + b_1|\zeta|^{2k+1}.\]
If \(0 \neq |\zeta| \leq |\eta|\), then
\[
W \leq a_2 - a_1 + b_1|\zeta|^{2k+1}\left(1 - \left(\frac{|\eta|}{|\zeta|}\right)^2k+1\right)
\leq a_2 - a_1 + b_1|\zeta|^{2k+1}\left(1 - \left(\frac{|\eta|}{|\zeta|}\right)^{2k+1} + \sum_{j=1}^{2k} \left(2k + 1\right)\right).
\]
- The case where \(\zeta \leq 0 \leq \eta\) can be handled similarly.

This shows that (4.4) holds for \(a = a_2 - a_1, b = \min\{b_1, b_2\}\) and \(c = \max\{b_1, b_2\}\left(1 + \sum_{j=1}^{2k} \left(2k + 1\right)\right)\). Now, with the same strategy as in [3], one infers \(F''\) from (4.4).

Following the ideas of [3], we proceed through the use of a comparison principle. For the reader’s convenience we include the proof, which is similar to that of [17, §9 Satz IX].

**Lemma 4.6.** Let \(f : (a, b) \times (c, d) \to \mathbb{R}\) be continuous and uniformly locally Lipschitz continuous in the second variable, i.e., for all compact \(K \subseteq (c, d)\) there exists a constant \(L = L(K)\) such that
\[
|f(t, x) - f(t, y)| \leq L|x - y| \quad \forall x, y \in K, \ t \in (a, b).
\]
Suppose the functions \(u^+, u^- : [\alpha, \beta] \to (c, d)\) are absolutely continuous functions and satisfy, for almost all \(t \in (\alpha, \beta),\)
\[
\frac{d}{dt} u^+(t) \geq f(t, u^+(t)), \quad \frac{d}{dt} u^-(t) \leq f(t, u^- (t)).
\]
If \(u^+(t_0) > u^-(t_0)\) for some \(t_0 \in [\alpha, \beta]\), then \(u^+(t) > u^-(t)\) for all \(t \in [t_0, \beta]\).

**Proof.** We may of course assume that \(t_0 \in [\alpha, \beta]\).

Put \(d(t) := u^+(t) - u^-(t)\) for \(t \in [\alpha, \beta]\). Suppose that \(A := \{t \in (t_0, \beta) : d(t) \leq 0\}\) is nonempty. Then, by continuity, \(t_1 := \inf A > t_0\). Moreover, \(d(t) > 0\) on \([t_0, t_1)\) and \(d(t_1) = 0\).
Let $K = K^+ \cup K^-$ with $K^\pm := \{ u^\pm(t) : t \in [\alpha, \beta] \}$ and denote by $L$ the corresponding Lipschitz constant from the hypothesis. For almost all $s \in (t_0, t_1)$ we have
\[ d'(s) = \frac{d}{ds}(u^+(s) - u^-(s)) \geq f(s, u^+(s)) - f(s, u^-(s)) \]
\[ \geq -L|u^+(s) - u^-(s)| = -Ld(s) \]

since $s < t_1$. It follows that $\frac{d'}{L} \geq -L$ almost everywhere on $(t_0, t_1)$ and hence, by integration, $d(t) \geq d(t_0)e^{-L(t-t_0)}$ for all $t \in (t_0, t_1)$. By continuity, $d(t_1) \geq d(t_0)e^{-L(t-t_0)} > 0$, which contradicts $d(t_1) = 0$. Hence we must have $A = \emptyset$ and thus $u^+(t) > u^-(t)$ for all $t \in (t_0, \beta]$ as claimed. \[ \square \]

**Corollary 4.7.** Let $f$ and $u^+, u^-$ be as in Lemma 4.6 but assume now that $u^+(t_0) \leq u^-(t_0)$ for some $t_0 \in [\alpha, \beta]$. Then $u^+(t) \leq u^-(t)$ for all $t \in [\alpha, t_0]$.

**Proof.** If $u^+(t_1) > u^-(t_1)$ for some $t_1 \in [\alpha, t_0)$, then Lemma 4.6 would imply that $u(t_0) > u^-(t_0)$. \[ \square \]

The next lemma should be compared with Lemma 4.3.

**Lemma 4.8.** Let $A$ be the generator of a strongly continuous contraction semigroup $S$ on $B$ and let $F : [0, T] \times B \to B$ satisfy conditions $(F')$ and $(F'')$. If $u, v \in C([0, T]; B)$ satisfy
\[ u(t) = \int_0^t S(t-s)F(s, u(s) + v(s)) \, ds, \]
for all $t \in [0, T]$, then
\[ \sup_{t \in [0, T]} \|u(t)\| \leq \left( \frac{4a''}{b'} \right) \left( 1 + \sup_{t \in [0, T]} \|v(t)\| \right). \]

**Proof.** To simplify notations we write $a = a''$ and $b = b''$, where $a''$, $b''$ are as in $(F'')$.

**Step 1** – First we assume that $A$ is bounded. Then $u$ is continuously differentiable and
\[ u'(t) = Au(t) + F(t, u(t) + v(t)), \quad t \in [0, T]. \]

By the remarks at the beginning of the section, for almost all $t \in (0, T)$ we have, for all $x^* \in \partial\|u(t)\|$,\[
\frac{d}{dt}\|u(t)\| = \langle Au(t), x^* \rangle + \langle F(t, u(t) + v(t)) - F(t, v(t)), x^* \rangle + \langle F(t, v(t)), x^* \rangle \\
\leq 0 + 2a(1 + \|v(t)\|^m) - b\|u(t)\|^m \\
\leq 2a\left( 1 + \sup_{s \in [0, T]} \|v(s)\| \right)^m - b\|u(t)\|^m.
\]

In the second estimate we have used the dissipativity of $A$ and our assumptions.

Setting $\varphi(t) := \|u(t)\|$ and $\gamma := (2a)^{\frac{1}{m}}(1 + \sup_{s \in [0, T]} \|v(s)\|)$, it follows that $\varphi$ is absolutely continuous with
\[ \varphi'(t) \leq -b\varphi(t)^m + \gamma^m \]

almost everywhere. We have to prove that $\varphi(t) \leq \left( \frac{\varphi(0)}{2} \right)^{\frac{1}{m}} \gamma$ for all $t \in [0, T]$. Assume to the contrary that $\varphi(t_0) > \left( \frac{\varphi(0)}{2} \right)^{\frac{1}{m}} \gamma$ for some $t_0 \in [0, T]$. Clearly $\varphi(0) = 0$, so $t_0 \in (0, T)$. Let $\psi : I \to \mathbb{R}$ be the unique maximal solution of
\[
\begin{cases}
\psi'(t) = -b\psi(t)^m + \gamma^m, \\
\psi(t_0) = \varphi(t_0).
\end{cases}
\]

By Corollary 4.7 $\psi(t) \leq \varphi(t)$ for all $t \in I \cap [0, t_0]$. 

20 MARKUS KUNZE AND JAN VAN NEERVEN
We claim that $\psi(t) > (\frac{1}{b})^\frac{1}{p} \gamma$ for all $t \in I \cap [0, t_0]$. If the claim was false, noting that $\psi(t_0) = \varphi(t_0) > (\frac{1}{b})^\frac{1}{p} \gamma$, we would have $\psi(t_1) = (\frac{1}{b})^\frac{1}{p} \gamma$ for some $t_1 \in I \cap [0, t_0]$. By uniqueness, this would imply that $\psi \equiv (\frac{1}{b})^\frac{1}{p} \gamma$, a contradiction to $\psi(t_0) > (\frac{1}{b})^\frac{1}{p} \gamma$. This proves the claim.

We have proved that $(\frac{1}{b})^\frac{1}{p} \gamma < \psi \leq \varphi$ on $I \cap [0, t_0]$. It follows that $0 \in I$ since otherwise $\psi$, and hence $\varphi$, would blow up at some point in $[0, t_0]$.

Consequently, $(\frac{1}{b})^\frac{1}{p} \gamma < \psi$ on $I \cap [0, t_0]$, which implies that $\psi'(t) < 0$ and hence that $\psi$ is decreasing. It follows that

$$0 = \varphi(0) \geq \psi(0) \geq \psi(t_0) = (\frac{2}{b})^\frac{1}{p} \gamma,$$

a contradiction.

Step 2 - In order to remove the assumption that $A$ is bounded, we approximate $A$ with its Yosida approximands $A_n := nAR(n, A) = n^2R(n, A) - n$. We note that if $A$ is dissipative, then so are all $A_n$. We denote the (contraction) semigroup generated $A_n$ by $S_n$. Let $u_n$ be the unique fixed point in $C([0, T]; B)$ of

$$w \mapsto \left[ t \mapsto \int_0^t S_n(t-s)F(s, w(s) + v(s)) \, ds \right].$$

We note that, by the local Lipschitz assumption on $F$, there always exists a unique maximal solution of this equation. By Theorem 4.3 with $G \equiv 0$ this solution is global. Assumption (A3) is not needed for this part of the argument; cf. Remark 3.2.

By the above,

$$\sup_{t \in [0, T]} \|u_n(t)\| \leq \left( \frac{4a}{b} \right)^\frac{1}{p} \left( 1 + \sup_{t \in [0, T]} \|v(t)\| \right)$$

for all $n \in \mathbb{N}$. Since $u_n \to u$ in $C([0, T]; B)$, this gives the desired result.

We can now extend Theorem 4.3 assuming that $G$ is of linear growth.

**Theorem 4.9.** Assume (A1), (A4), (A5), (F'), (F''), (G'') and let $p > 2$ satisfy $\theta + \kappa_G < \frac{1}{2} - \frac{1}{p}$.

Then for all $\xi \in L^p(\Omega, \mathcal{F}_0, \mathbb{P}; B)$ the maximal solution $(X(t))_{t \in [0, \sigma)}$ of (SCP) is global. Moreover,

$$\mathbb{E}\|X\|^p_{C([0, T]; B)} \leq C(1 + \mathbb{E}\|\xi\|^p),$$

where the constant $C$ depends on the coefficients only through the sectoriality constants of $A$ and the constants $a', b'', c''$ and the exponent $N$.

**Proof.** For $n \in \mathbb{N}$ we put

$$G_n(t, \omega, x) := \begin{cases} G(t, \omega, x), & \|x\| \leq n \\ G(t, \omega, \frac{n}{\|x\|}) & \text{otherwise.} \end{cases}$$

Since $G$ is of linear growth, $G_n$ is bounded. In particular, $A, F$ and $G_n$ satisfy the Hypotheses (F') and (G') uniformly with respect to $n$. Hence, by Theorem 4.3 $X_n := \text{sol}(A, F, G_n, \xi)$ exists globally.

Proceeding as in the proof of Theorem 4.3, we have

$$(4.5) \quad \mathbb{E}\|X_n\|^p_{C([0, T]; B)} \leq \mathbb{E}\|\xi\|^p + \mathbb{E}\|S * F(\cdot, X_n)\|^p_{C([0, T]; B)} + \mathbb{E}\|S \circ G(\cdot, X_n)\|^p_{C([0, T]; B)}.$$

Using Lemma 4.8 with $u_n = X_n - S(\cdot)\xi - S \circ G(\cdot, X_n)$ and $v_n = S(\cdot)\xi + S \circ G(\cdot, X_n)$

\footnote{In the published version of the paper (J. Differential Equations 253 (2012), no. 3, 1036–1068), it was incorrectly stated that $p > 2$ should satisfy $\theta + \kappa_G < \frac{1}{2} - \frac{1}{p}$. We thank Carlo Marinelli for kindly pointing this out.}
we obtain
\[ \mathbb{E}\|S \ast F(\cdot, X_n)\|_{C([0,T]; B)}^p \leq \left( \frac{4n^{''}}{b''} \right)^{\frac{1}{p}} \left( 1 + \mathbb{E}\|\xi\|_p + \mathbb{E}\|S \circ G(\cdot, X_n)\|_{C([0,T]; B)}^p \right). \]

Moreover, a computation similar as in the proof of Theorem 4.3 yields
\[ \mathbb{E}\|S \circ G_n(\cdot, X_n)\|_{C([0,T]; B)}^p \leq C(T)(\alpha + \beta \mathbb{E}\|X_n\|_{C([0,T]; B)}^p) \]
where \( C(T) \to 0 \) as \( T \to 0 \) and \( \alpha, \beta \) only depend on the constants in the linear growth assumption on \( G \). Substituting this back into (4.23), it follows that
\[ \mathbb{E}\|X_n\|_{C([0,T]; B)}^p \leq C_0 + C_1 \mathbb{E}\|\xi\|_p + C_2(T) \mathbb{E}\|X_n\|_{C([0,T]; B)}^p \]
and the proof can be finished as that of Theorem 4.3 \( \square \)

In combination with our earlier results, it can be seen that the solution \( X \) in Theorem 4.3 depends continuously on the data \( A, F, G, \) and \( \xi \) in the sense discussed in Section 8. We leave the precise statement of this result to the reader.

5. 1D Reaction Diffusion Equations with Space-Time White Noise

In this section, we apply our results to stochastic reaction diffusion equations in dimension 1 with multiplicative space-time white noise. The restriction to the 1-dimensional situation is made so that space-time white noise can be considered. However, it is possible to extend our results also to higher space dimensions, provided that (i) white noise is replaced with either coloured or finite-dimensional noise (ii) appropriate regularity assumptions are made on the domain. For ease of notation, we will also only consider coefficients \( f \) and \( g \) which do not depend on \( \omega \).

We consider the stochastic partial differential equation
\[
\begin{cases}
\frac{\partial}{\partial t} u(t, x) = \mathcal{A} u(t, x) + f(t, x, u(t, x)) + g(t, x, u(t, x)) \frac{\partial w}{\partial t}(t, x), \\
u(0, x) = \xi(x),
\end{cases}
\]
for \((t, x) \in [0, T] \times [0, 1] \). We complement (5.1) with either Dirichlet or Neumann boundary conditions. Here, \( \mathcal{A} \) is a second-order elliptic operator, formally given by
\[ \mathcal{A} u = (au')' + bu' + c \]
where the coefficients \( a, b, c \) are real-valued and belong to \( L^\infty(0, 1) \), and
\[ \inf_{x \in (0, 1)} a(x) > 0. \]
The nonlinearity \( f : [0, T] \times [0, 1] \times \mathbb{R} \to \mathbb{R} \) is as in Example 4.2 and \( g : [0, T] \times [0, 1] \times \mathbb{R} \to \mathbb{R} \) is locally Lipschitz continuous and of linear growth in the third variable, uniformly with respect to the first two variables. Finally, \( w \) is a space-time white noise on \([0, 1]\).

Let us rewrite equation (5.1) in our general abstract framework. We set
\[ H = L^2(0, 1), \quad E = L^q(0, 1) \]
with \( 2 \leq q < \infty \). Then \( E \) is a UMD Banach space with type 2. On \( H \) we consider the closed sectorial form
\[ a[u, v] := \int_0^t a(x)u'(x)v'(x) - b(x)u'(x)v(x) - c(x)u(x)v(x) \, dx \]
defined on the domain \( D(a) := H^1_0(0, 1) \) or \( D(a) := H^1(0, 1) \), depending on whether we impose Dirichlet or Neumann boundary conditions. The operator \((A, D(A))\) is defined as usual by defining \( D(A) \) as the subspace of all \( u \in D(a) \) such that there exists a unique element \( w \in H \) such that
\[ -[w, v]_H = a[u, v] \quad \forall v \in D(a). \]
We then set \( Au := w \) for \( u \in \mathcal{D}(A) \). It is well known (see [15]) that \( A \) generates a strongly continuous, analytic semigroup \( S \) on \( L^2(0,1) \). Moreover, \( S \) is positive and, replacing \( a \) with \( a - c_0 \) for some \( c_0 \geq 0 \) if necessary, we may assume that \( S \) is sub-Markovian. In particular, \( S \) extends to a strongly continuous semigroup \( S^E \) on \( E = L^q(0,1) \), and, as a consequence of the Stein interpolation theorem (see [15, Proposition 3.12]), this semigroup is analytic on \( E \). By rescaling we may assume that \( S^E \) is uniformly exponentially stable on \( E \) (we may replace \( A^E \) and \( f \) with \( A^E - c_0 \) and \( f + c_0 \)).

Since \( \mathcal{D}(A) \subseteq \mathcal{D}(a) \subseteq C([0,1]) \) and \( S(t)f \in \mathcal{D}(A) \) for all \( f \in E \) and \( t > 0 \) by the analyticity of \( S \), it follows that \( C([0,1]) \) is invariant under \( S \). Moreover, if \( B \) denotes the closure of \( \mathcal{D}(a) \) in \( C([0,1]) \) (i.e., \( B = C_0([0,1]) \) in the case of Dirichlet boundary conditions and \( B = C([0,1]) \) in the case of Neumann boundary conditions) then \( S \) restricts to a strongly continuous contraction semigroup \( S^B \) on \( B \).

The next lemma identifies the associated fractional domain spaces.

**Lemma 5.1.** The fractional domain spaces associated to \( A^E \) are given, for \( 0 < \theta < \frac{1}{2} \), by \( E_\theta = W_0^{2,\theta}(0,1) \) and \( E_{\theta} = W^{2,\theta}(0,1) \) depending on whether the boundary conditions are Dirichlet or Neumann.

**Proof.** By [7], the semigroup associated to \( A^E \) satisfies Gaussian upper bounds. Hence, by the results of [3], (a suitable translate of) \( A^E \) has a bounded \( H^\infty \)-calculus and thus, in particular, bounded imaginary powers. Therefore, see [10, Theorem 6.6.9], we have \( \mathcal{D}(w' - A)^{\theta}' = [E, \mathcal{D}(A)]_{\theta} \).

Next observe that by [11, Theorem 7.1] the fractional domain space \( E_{\frac{1}{2}} \) is given as \( \mathcal{D}(a) \cap W^{1,q}(0,1), \) i.e. \( W_0^{1,q}(0,1) \) or \( W^{1,q}(0,1) \), depending on the boundary conditions. Employing [10, Theorem 6.6.9] a second time, it follows that for \( \theta \in (0, \frac{1}{2}) \) we have \( \mathcal{D}(w' - A)^{\theta} = [E, \mathcal{D}(w' - A)^{\theta}]_{2\theta} \).

In either case, the Sobolev embedding implies that \( E_{\theta} \) is continuously embedded in \( B \) for \( 2\theta > \frac{1}{q} \). Hence the conditions (A1), (A4) and (A5) are satisfied for \( \theta \in (\frac{1}{2}, \frac{1}{q}) \).

The nonlinearity \( F \) is modeled as in the previous section, where it was seen that \((F') \) and \((F'') \) hold. Concerning \( G \), we first pick \( \kappa_G \in (\frac{1}{2}, \frac{1}{q}) \). Following [13, Section 10.2] we define the multiplication operator \( \Gamma : [0,T] \times B \to \mathcal{L}(H) \) by

\[
[\Gamma(t,u)h](s) := g(t,s,u(s))h(s), \quad s \in [0,1],
\]

and then define \( G : [0,T] \times B \to \gamma(H, E_{-\kappa_G}) \) by

\[
(-A)^{-\kappa_G}G(t,u)h := \iota(-A)^{-\kappa_G} \Gamma(t,u)h,
\]

where \( \iota : H^{2\kappa_G}(0,1) \to L^q(0,1) = E \). As in [13, Section 10.2] one sees that \( G \) takes values in \( \gamma(H, E_{-\kappa_G}) \) is locally Lipschitz continuous as a map from \( [0,T] \times B \to \gamma(H, E_{-\kappa_G}) \). It follows easily that \( G \) satisfies assumption (G'').

From Theorem 4.9 we obtain:

**Theorem 5.2.** Let \( \frac{q}{p} > 2k + 1 \), where \( k \) is the exponent in the reaction term \( F \). Under the assumptions above, for every \( \xi \in L^p(\Omega, \mathcal{F}_0, \mathbb{P}; B) \) the solution \( X \) of equation (5.1) exists globally and belongs to \( L^p(\Omega; C([0,T]; B)) \).

**Proof.** The condition \( \frac{q}{p} > N \), with \( N = 2k + 1 \), allows us to choose \( 2 \leq q < \infty \), \( \theta \in (0, \frac{1}{2}) \) and \( \kappa_G \in (\frac{1}{2}, \frac{1}{q}) \) such that, with \( E = L^q(0,1) \), we have \( E_{\theta} \hookrightarrow B \) and \( 0 \leq \theta + \kappa_G < \frac{1}{2} - \frac{1}{p^*} \). By the above discussion, the assumptions of Theorem 4.9 are then satisfied.

Let us end this article by discussing the dependence of the solution upon the coefficients \( A, F \) and \( G \). Suppose for every \( n \in \mathbb{N} \) we are given an operator \( \chi_n \), determined through its coefficients \( a_n, b_n \) and \( c_n \), and functions \( f_n, g_n : [0,T] \times B \to \mathcal{L}(H), \).
B. Let $A_n, F_n$ and $G_n$ be defined by replacing $\mathcal{A}, f$ and $g$ with $\mathcal{A}_n, f_n$ and $g_n$, respectively.

Then we have $F_n(t, u) \to F(t, u)$ in $B$, if $f_n(t, \cdot, \cdot) \to f(t, \cdot, \cdot)$ for all $t \in [0, 1]$, uniformly on compact subsets of $[0, 1] \times \mathbb{R}$. This is a stronger assumption than in [12], where only pointwise convergence was required. However, for reaction diffusion equations we need convergence in $C([0, 1])$.

To infer convergence $G_n(t, u) \to G(t, u)$ for all $t \in [0, 1], u \in B$, it is sufficient to have convergence $g_n(t, x, s) \to g(t, x, s)$ for all $(t, x, s) \in [0, T] \times [0, 1] \times \mathbb{R}$. Instead, under this assumption we clearly have $\Gamma_n(t, u)h \to \Gamma(t, u)h$ in $L^2(0, 1)$ for all $t \in [0, T]$ and $u \in B$. Hence, by ‘convergence by right multiplication’, see [14, Proposition 2.4], convergence of $G_n(t, u) \to G(t, u)$ in $\gamma(H, E_{-\kappa g})$ follows.

Finally, let us address conditions (A1) – (A3). If the coefficients $a_n, b_n$ and $c_n$ are uniformly bounded and elliptic then the forms $a_n$ are uniformly sectorial. This immediately yields (A1), cf. [12, Lemma 5.1].

Lemma A.1. Assume (A1) – (A3). Then the constants may be chosen independently of $n$.

Proof. For notational convenience, we will assume that $\mathcal{A}, f$ and $g$ are given. For $x \in E_{\theta}$ we have $S_n(t)x \to S_\infty(t)x$ in $E_\theta$, uniformly on compact time intervals in $[0, \infty)$.

(1) Let $\theta \in (0, \frac{1}{2})$ and $x \in E_\theta$, then $S_n(t)x \to S_\infty(t)x$ in $E_\theta$, uniformly on compact time intervals in $[0, \infty)$.

(2) Let $\theta \in (0, \frac{1}{2})$ and $x \in E_{-\kappa}$, then $A_nS_n(t)x \to A_\infty S_\infty(t)x$ in $E_\theta$, uniformly on compact time intervals in $[0, \infty)$.

(3) Let $\theta \in (0, \frac{1}{2})$ and $\lambda, \delta \geq 0$ satisfy $\lambda + \delta < \theta$. If $x_n \to x_\infty$ in $E_\theta$, then $S_n(t)x_n \to S_\infty(t)x_\infty$ in $C^2([0, T], E_\delta)$.

Appendix A. Convergence of analytic semigroups

In this appendix we prove some convergence results for analytic semigroups under assumptions (A1) – (A3). The lemmas [A.1] and [A.2] may be known to specialists, but since we could not find these results in the literature we include proofs for reasons of completeness.

The first lemma is used in the proof of Proposition 3.1.

Lemma A.1. Assume (A1) – (A3). Then

(1) For all $0 \leq \theta < \frac{1}{2}$ and $x \in E_\theta$ we have $S_n(t)x \to S_\infty(t)x$ in $E_\theta$, uniformly on compact time intervals in $[0, \infty)$.

(2) For all $0 \leq \theta, \kappa < \frac{1}{2}$ and $x \in E_{-\kappa}$ we have $A_nS_n(t)x \to A_\infty S_\infty(t)x$ in $E_\theta$, uniformly on compact time intervals in $[0, \infty)$.

(3) Let $\theta \in (0, \frac{1}{2})$ and $\lambda, \delta \geq 0$ satisfy $\lambda + \delta < \theta$. If $x_n \to x_\infty$ in $E_\theta$, then $S_n(t)x_n \to S_\infty(t)x_\infty$ in $C^2([0, T], E_\delta)$.

Proof. For notational convenience, we will assume that $w < 0$. For $x \in E_{\theta}$ we have

$$
\|S_n(t)x - S_\infty(t)x\| \leq \|(-A_n)^\theta S_n(t)x - (-A_\infty)^\theta S_\infty(t)x\|_E
$$

for $0 \leq t \leq T$.

(A.1)

where the implied constants in the first line may be chosen independently of $n$ by (A3). Now observe that for $0 \leq t \leq T$,

$$
\|(A_n)^\theta S_n(t)x - (A_\infty)^\theta S_\infty(t)x\|_E \leq C_T \|(-A_n)^\theta x - (-A_\infty)^\theta x\|_E + \|S_n(t)(-A_\infty)^\theta x - S_\infty(t)(-A_\infty)^\theta x\|_E,
$$

where $C_T := \sup \{\|S_n(t)\| \mid t \in [0, T], n \in \mathbb{N} \} < \infty$ as a consequence of (A1).

We now prove that, given a compact set $K \subseteq E_{\theta}$, we have $(-A_n)^\theta x \to (-A_\infty)^\theta x$ in $E$, uniformly for $x \in K$. This proves that also the first term on the right-hand side of (A.2) converges to 0, hence the first term on the right-hand side of (A.1) converges to 0 uniformly for $x \in K$.
Lemma A.2. Assume (A1) − (A4). For all \( 0 \leq \theta < \frac{1}{2} \) and \( x \in B \) we have
\[
S_n(t)x \to S(x) \in C[[0, T]; B).
\]

**Proof.** By Lemma A.1 we have \( S_n(t)x \to S(x) \in C([0, T]; E_\theta) \to C([0, T]; B) \) for all \( x \in E_\theta \). By the density of \( E_\theta \) in \( B \) and the uniform exponential boundedness of \( S_n^\theta \), this extends to all \( x \in B \).
