ON SOLUBILITY OF GROUPS WITH FINITELY MANY CENTRALIZERS

MOHAMMAD ZARRIN

Communicated by

ABSTRACT. For any group \( G \), let \( C(G) \) denote the set of centralizers of \( G \). We say that a group \( G \) has \( n \) centralizers (\( G \) is a \( C_n \)-group) if \( |C(G)| = n \). In this note, we prove that every finite \( C_n \)-group with \( n \leq 21 \) is soluble and this estimate is sharp. Moreover, we prove that every finite \( C_n \)-group with \( |G| < \frac{20n+15}{19} \) is non-nilpotent soluble. This result gives a partial answer to a conjecture raised by A. Ashrafi in 2000.

1. Introduction

For any group \( G \), let \( C(G) \) denote the set of centralizers of \( G \). We say that a group \( G \) has \( n \) centralizers (\( G \in C_n \), or \( G \) is a \( C_n \)-group) if \( |C(G)| = n \). Also we say that \( G \) has a finite number of centralizers, written \( G \in \mathcal{C} \), if \( G \in C_n \) for some \( n \in \mathbb{N} \). Indeed \( \mathcal{C} = \bigcup_{i \geq 1} C_i \). It is clear that a group is a \( C_1 \)-group if and only if it is abelian. Belcastro and Sherman in [5], showed that there is no finite \( C_n \)-group for \( n \in \{2, 3\} \) (while Ashrafi in [2], showed that, for any positive integer \( n \neq 2, 3 \), there exists a finite group \( G \) such that \( |C(G)| = n \)). Also they characterized all finite \( C_n \)-groups for \( n \in \{4, 5\} \). Tota (see Appendix of [10]) proved that every arbitrary \( C_4 \)-group is soluble. The author in [11] showed that the derived length of a soluble \( C_n \)-group (not necessarily finite) is \( \leq n \).
For more details concerning $C_n$-groups see [1, 2, 3, 4, 11, 12]. In this paper, we obtain a solubility criteria for $C_n$-groups in terms of $|G|$ and $n$.

Our main results are:

**Theorem A.** Let $G$ be a finite $C_n$-group with $n \leq 21$, then $G$ is soluble.

**Theorem B.** If $G$ is a finite $C_n$-group, then the following hold:

1. $|G| < 2n$, then $G$ is a non-nilpotent group.
2. $|G| < \frac{30n+15}{19}$, then $G$ is a non-nilpotent soluble group.

Let $G$ be a finite $C_n$-group. In [5], Belcastro and Sherman raised the question whether or not there exists a finite $C_n$-group $G$ other than $Q_8$ and $D_{2p}$ ($p$ is a prime) such that $|G| \leq 2n$. Ashrafi in [2] showed that there are several counterexamples for this question and then Ashrafi raised the following conjecture (conjecture 2.4): If $|G| \leq 3n/2$, then $G$ is isomorphic to $S_3, S_3 \times S_3$, or a dihedral group of order 10. Now by Theorem A, we can obtain that if $|G| \leq 3n/2$, then $G$ is soluble. Therefore Theorem A give a partial answer to the conjecture put forward by Ashrafi.

2. **Proofs**

Let $n > 0$ be an integer and $\mathcal{X}$ be a class of groups. We say that a group $G$ satisfies the condition $(\mathcal{X}, n)$ ($G$ is a $(\mathcal{X}, n)$-group) whenever in every subset with $n + 1$ elements of $G$ there exist distinct elements $x, y$ such that $\langle x, y \rangle$ is in $\mathcal{X}$. Let $\mathcal{A}$ and $\mathcal{N}$ be the classes of nilpotent groups and abelian groups, respectively. Indeed, in a group satisfying the condition $(\mathcal{A}, n)$, the largest set of non-commuting elements (or the largest set of elements in which no two generate an abelian subgroup) has size at most $n$.

Here we give an interesting relation between groups that have $n$ centralizers and groups that satisfy the condition $(\mathcal{A}, n - 1)$.

**Proposition 2.1.** Let $n$ be a positive integer and $G$ be a $C_n$-group (not necessarily finite). Then $G$ satisfies the condition $(\mathcal{A}, n - 1)$.

**Proof.** Suppose, for a contradiction, that $G$ does not satisfy the condition $(\mathcal{A}, n - 1)$. Therefore there exists a subset $X = \{a_1, a_2, \cdots, a_n\}$ of $G$
such that \( \langle a_i, a_j \rangle \) is not abelian, for every \( 1 \leq i \neq j \leq n \). This follows that \( C_G(a_i) \neq C_G(a_j) \) for every \( 1 \leq i \neq j \leq n \). Now since \( C_G(e) = G \), where \( e \) is the trivial element of \( G \), we get \( n = |C(G)| \geq n + 1 \), which is impossible. \( \square \)

Note that by easy computation we can see that the symmetric group of degree 4, \( S_4 \), satisfies the condition \( (A, 10) \), but \( S_4 \) is not a \( C_{11} \)-group (in fact, \( S_4 \) is a \( C_{14} \)-group). That is, the converse of the above Proposition is not true.

We can now deduce Theorem A.

**Proof of Theorem A.** Clearly every group satisfies the condition \( (A, n) \) also satisfies the condition \( (N, n) \). Thus, by Proposition 2.1, \( G \) satisfies the condition \( (N, n) \) for some \( n \leq 20 \). Now this statement follows from the main result of [6]. By easy computation we can obtain that the alternating group of degree 5, has 22 centralizers.

Note that Ashrafi and Taeri in [4], proved that, if \( G \) is a finite simple group and \( |C(G)| = 22 \), then \( G \cong A_5 \). Then they, by this result, claimed that, if \( G \) is a finite group and \( |C(G)| \leq 21 \), then \( G \) is soluble. Therefore, in view of Theorem A, we gave positive answer to their claim.

Tota in [10, Theorem 6.2]) showed that a group \( G \) belongs to \( C \) if and only if it is center-by-finite. Therefore it is natural problem to obtain bounds for \( |G : Z(G)| \) in terms of \( n \).

**Theorem 2.2.** There is some constant \( c \in \mathbb{R}_{>0} \) such that for any \( C_n \)-group \( G \)

\[
 n \leq |G : Z(G)| \leq c^{n-1}.
\]

*Proof.* First, by the main result of [9] and Proposition 2.1 we have \( |G : Z(G)| \leq c^{n-1} \), for some constant \( c \). To remain the prove we may assume that \( Z(G) \neq 1 \). Since elements in the same coset modulo \( Z(G) \) have the same centralizer, it follows that \( n \leq |G : Z(G)| \). \( \square \)

For the proof of Theorem B, we need the following lemma.

**Lemma 2.3.** Let \( G \) be a finite \( C_n \)-group. Then

\[
 n \leq \frac{|G| + |I(G)|}{2},
\]

where \( I(G) = \{a \in G \mid a^2 = 1\} = \{a \in G \mid a = a^{-1}\} \).
Proof. Since $C_G(a) = C_G(a^{-1})$, we can obtain that
\[ n \leq |I(G)| + \frac{|G - I(G)|}{2} \leq \frac{|G| + |I(G)|}{2}, \]
as wanted. \hfill \Box

**Corollary 2.4.** Let $G$ be a finite simple $C_n$-group. Then $3n/2 < |G|$.  

**Proof.** It is well known that for every simple group we have $I(G) < |G|/3$. Now the result follows from Lemma 2.3. \hfill \Box

Here we show that a semi-simple $C_n$-group has order bounded by a function of $n$. (Recall that a group $G$ is semi-simple if $G$ has no non-trivial normal abelian subgroups.)

**Proposition 2.5.** Let $G$ be a semi-simple $C_n$-group. Then $G$ is finite and $|G| \leq (n - 1)!$.

**Proof.** The group $G$ acts on the set $A := \{ C_G(x) \mid a \in G \setminus Z(G) \}$ by conjugation. By assumption $|A| = n - 1$. Put $B = \bigcap_{x \in G} N_G(C_G(x))$. The subgroup $B$ is the kernel of this action and so
\[ G/B \hookrightarrow S_{n-1}. \]

By definition of $B$, the centralizer $C_G(a)$ is normal in $B$ for any element $a \in G$. Therefore $a^{-1}ab \in C_G(a)$ for any two elements $a, b \in B$. So $B$ is a 2-Engel group (see [7]). Now it is well known that $B$ is a nilpotent group of class at most 3. Now as $G$ is a semi-simple group, we can obtain that $B = 1$. It follows from (*) that $G$ is a finite group and $|G| \leq (n - 1)!$, as wanted. \hfill \Box

We need the following result, for the proof of Theorem B.

**Theorem 2.6.** (Potter, 1988) Suppose $G$ admits an automorphism which inverts more than $4|G|/15$ elements. Then $G$ is soluble.

**Proof of Theorem B.** (1). Suppose, for a contradiction, that $G$ is nilpotent group, so in particular $Z(G) \neq 1$. Now it follows from Theorem 2.2 that $2n \leq |G|$, which is contradiction.

(2). From part (1) we obtain that $G$ is not nilpotent. Since $|G| < \frac{30n + 15}{19}$ and so $2n > \frac{19|G| - 15}{19}$, Lemma 2.3 implies that
\[ |I(G)| \geq 2n - |G| > \frac{4|G|}{15} - 1. \]

On the other hand, since $I(G)$ is the set of all elements of $G$ that inverted by the identity automorphism, Theorem 2.6 completes the proof.
