Duality in Entanglement-Assisted Quantum Error Correction

Ching-Yi Lai, Todd A. Brun, and Mark M. Wilde

Abstract—The dual of an entanglement-assisted quantum error-correcting (EAQEC) code is defined from the orthogonal group of a simplified stabilizer group. From the Poisson summation formula, this duality leads to the MacWilliams identities and linear programming bounds for EAQEC codes. We establish a table of upper and lower bounds on the minimum distance of any maximal-entanglement EAQEC code with length up to 15 channel qubits.

Index Terms—entanglement-assisted quantum error correction, quantum dual code, MacWilliams identity, linear programming bound

I. INTRODUCTION

The theory of quantum error correction underpins the practical realization of quantum computation and quantum communication [1], [2], [3], [4], [5], [6]. Quantum stabilizer codes are an extensively analyzed class of quantum error-correcting codes because their encoding, decoding, and recovery are straightforward to describe using their algebraic properties [7], [8], [9], [10].

Entanglement-assisted quantum error correction is a paradigm in which the sender and receiver share entanglement before quantum communication begins [11]. An \( [n, k, d; c] \) EAQEC code encodes \( k \) information qubits into \( n \) channel qubits with the help of \( c \) pairs of maximally-entangled Bell states. The code can correct up to \( \frac{d-1}{2} \) errors acting on the \( n \) channel qubits, where \( d \) is the minimum distance of the code. Standard stabilizer codes are a special case of EAQEC codes with \( c = 0 \), and we use the notation \([n, k, d]\) for such codes.

Bowen proposed the first EAQEC code [12], which is equivalent to the well-known five-qubit code [13]. Fattal et al. established a technique for handling entanglement in the stabilizer formalism [14]. Brun, Devetak, and Hsieh then devised the entanglement-assisted stabilizer formalism and showed how to transform any \([n, k, d]\) classical quaternary code\(^1\) into an \([n, 2k - n + c, d; c]\) EAQEC code, where \( c \) depends on the properties of the classical code [15]. Lai and Brun further explored the properties of EAQEC codes and proposed an optimization method to find optimal EAQEC codes that cannot be obtained by the aforementioned construction [16]. By optimal, we mean that \( d \) is the highest achievable minimum distance for given parameters \( n, k, \) and \( c \).

In classical coding theory, a well-established notion is that of a dual code. Suppose that \( C \) is an \([n, k]\) linear code over an arbitrary field \( \mathbb{F}(q) \) with a generator matrix \( G \) and a corresponding parity check matrix \( H \) such that \( HG^T = 0 \). The dual code of \( C \) is the \([n, k' = n - k]\) linear code \( C^\perp \) with \( H \) as a generator matrix and \( G \) as a parity check matrix. The dimensions of the code \( C \) and its dual code \( C^\perp \) satisfy the relation \( k + k' = n \). It is well known that the MacWilliams identity gives a relationship between the weight enumerator of \( C \) and the weight enumerator of its dual code \( C^\perp \) [17], which can be used to determine the minimum distance of the dual code \( C^\perp \), given the weight enumerator of \( C \).

The MacWilliams identity for quantum codes connects the weight enumerator of a classical quaternary self-orthogonal code associated with the quantum code to the weight enumerator of its dual code [18], [19], [20], [21]. This leads to the linear programming bounds (upper bound) on the minimum distance of quantum codes. We will show that this type of the MacWilliams identity for quantum stabilizer codes can be directly obtained by applying the Poisson summation formula from the theory of orthogonal groups. However, the orthogonal group of a stabilizer group with respect to the symplectic inner product (which will be defined later) does not define another quantum stabilizer code. So this is not a duality between codes in the usual quantum case.

In this paper, we define a notion of duality in entanglement-assisted quantum error correction based on the theory of orthogonal groups, and this notion of duality bears more similarity to the classical notion of duality because the orthogonal group of an entanglement-assisted code forms a nontrivial entanglement-assisted quantum code. We then show how the quantum analog of the MacWilliams identity and the linear programming bound for EAQEC codes follow in a natural way. We apply the EAQEC code constructions in [11], [16], [22] to find good EAQEC codes with maximal entanglement for \( n \leq 15 \). Combining the results of the linear programming bounds, we give a table of upper and lower bounds on the highest achievable minimum distance of any

\(^1\)An \([n, k, d]\) classical linear code over a certain field encodes \( k \) information digits into \( n \) digits, where \( d \) is its minimum distance.
We organize this paper as follows. We first review some basics of entanglement-assisted quantum codes in the following section. In Section [III] we define the dual of an EAQEC code. The MacWilliams identity for EAQEC codes and the linear programming bound for EAQEC codes are derived in Section [IV], followed by a table of upper and lower bounds on the minimum distance of any EAQEC code with maximal entanglement and \( n \leq 15 \). The final section concludes with a summary and future questions.

II. REVIEW OF EAQEC CODES

We begin with some notation. The Pauli matrices

\[
I = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}, \quad X = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}, \quad Y = \begin{bmatrix} 0 & -i \\ i & 0 \end{bmatrix}, \quad Z = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}
\]

form a basis of the space of linear operators on a two dimensional single-qubit state space \( \mathcal{H} \). Let

\[
\mathcal{G}_n = \{ eM_1 \cdots \cdots M_n : M_j \in \{ I, X, Y, Z \}, e \in \{ \pm 1, \pm i \} \}
\]

be the \( n \)-fold Pauli group. We use the subscript \( X_j, Y_j, \) or \( Z_j \) to denote a Pauli operator on qubit number \( j \). We define \( X^u = \prod_{i:n_i = 1} X_i \) for some binary \( n \)-tuple \( u = (u_1 \cdots u_n) \) and similarly \( Z^v = \prod_{j:v_j = 1} Z_j \) for some binary \( n \)-tuple \( v = (v_1 \cdots v_n) \). Any element \( g = eM_1 \cdots \cdots M_n \in \mathcal{G}_n \) can be expressed as \( g = e'X^{u'}Z^{v'} \) for some \( e' \in \{ \pm 1, \pm i \} \) and two binary \( n \)-tuples \( u \) and \( v \). The weight \( w(t) \) of \( g \) is the number of \( M_j \)'s that are not equal to the identity operator \( I \).

Since the overall phase of a quantum state is not important, we consider the quotient of the Pauli group by its center \( \mathcal{G}_n = \mathcal{G}_n/\{ \pm 1, \pm i \} \), which is an Abelian group and can be generated by a set of \( 2n \) independent generators. For \( g_1 = X^{u_1}Z^{v_1}, g_2 = X^{u_2}Z^{v_2} \in \mathcal{G}_n \), the symplectic inner product \( \ast \) in \( \mathcal{G}_n \) is defined by

\[
g_1 \ast g_2 = u_1 \cdot v_2 + u_2 \cdot v_1 \mod 2,
\]

where \( \cdot \) is the usual inner product for binary \( n \)-tuples. Note that \( \ast \) is commutative. We define a map \( \phi : \mathcal{G}_n \rightarrow \mathcal{G}_n \) by \( \phi(eX^uZ^v) = X^uZ^v \). For \( g, h \in \mathcal{G}_n \), \( \phi(g) \ast \phi(h) = 0 \) if they commute, and \( \phi(g) \ast \phi(h) = 1 \), otherwise. The orthogonal group of a subgroup \( V \) of \( \mathcal{G}_n \) with respect to \( \ast \) is

\[
V_{\perp} = \{ g \in \mathcal{G}_n : g \ast h = 0, \forall h \in V \}.
\]

For example, consider a stabilizer group \( S \), which is an Abelian subgroup of \( \mathcal{G}_n \) and does not contain the negative identity operator \(-I\). Then the orthogonal group of \( \phi(S) \) is \( \phi(S)^{\perp} = \phi(N(S)) \), where \( N(S) \) is the normalizer of \( S \).

An \([n, k, d] \) stabilizer code is a \( 2^k \)-dimensional subspace of the \( n \)-qubit Hilbert space \( \mathcal{H}^{\otimes n} \), which is the joint \(+1\)-eigenspace of \( n-k \) independent generators of a stabilizer subgroup \( S \) of \( \mathcal{G}_n \). The minimum distance \( d \) is the minimum weight of any element in \( \phi(N(S)) \setminus \phi(S) \).

In the scheme of EAQEC codes [11], [16], Alice and Bob share \( c \) maximally-entangled pairs \( \Phi_{+}^{c}AB = \frac{1}{\sqrt{c}} (|00\rangle + |11\rangle) \). Suppose Alice tries to send a \( k \)-qubit state \( |\phi\rangle \) to Bob through a noisy channel, using an additional \( n-k-c \) ancilla qubits in the state \( |0\rangle \). We assume that Bob’s qubits suffer no errors since they do not pass through the noisy channel. Let \( J = (J^i, J^c, J^n) \) be the set of positions of the information qubits, the entangled pairs, and the ancilla qubits on Alice’s side, respectively. For example, if the initial state is \( |\phi\rangle|\Phi_{+}^{c}AB\rangle|0\rangle^{\otimes n-k-c} \), we have \( J^i = \{ 1, \cdots, k \}, J^c = \{ k+1, \cdots, k+c \}, \) and \( J^n = \{ k+c+1, \cdots, n \} \). Then Alice applies a Clifford encoder \( U \) on her \( n \) qubits to protect the information qubits. A Clifford encoder is a unitary operator that maps elements \( G_n \) to elements of \( \mathcal{G}_n \) under unitary conjugation. An \([n, k, d; c] \) EAQEC code is defined by the pair \((U, J)\), where \( d \) is the minimum distance and will be defined later. For convenience, let \( g_j = UZ_jU^\dagger \) and \( h_j = UX_jU^\dagger \) for \( j = 1, \cdots, n \). The encoded state associated with the pair \((U, J)\) of \( \mathcal{G}_n \) is

\[
\mathcal{S}' = \langle g_j^1, \cdots, g_j^c, h_j^1, \cdots, h_j^c, g_j^c, \cdots, g_j^{n-k-c} \rangle.
\]

Note that the commutation relations are as follows:

\[
\begin{align*}
g_i \ast g_j &= 0 \text{ for all } i \text{ and } j, \\
h_i \ast h_j &= 0 \text{ for all } i \text{ and } j, \\
g_i \ast h_j &= 0 \text{ for } i \neq j, \\
g_i \ast h_i &= 1 \text{ for all } i.
\end{align*}
\]

We say that \( g_j \) and \( h_j \) are symplectic partners for \( j \in J^i \cup J^c \).

The logical subgroup \( \mathcal{L} \) associated with the pair \((U, J)\) of the encoded state is

\[
\mathcal{L} = \langle g_j, h_j, j \in J^i \rangle.
\]

The symplectic subgroup \( \mathcal{S}' \) associated with the pair \((U, J)\) of \( \mathcal{S}' \) is the subgroup generated by the \( c \) pairs of symplectic partners of \( \mathcal{S}' \):

\[
\mathcal{S}' = \langle g_j, h_j, j \in J^c \rangle.
\]

The isotropic subgroup \( \mathcal{S}_I \) associated with the pair \((U, J)\) of \( \mathcal{S}' \) is the subgroup generated by the generators \( g_j \) of \( \mathcal{S}' \). Therefore
\[ g_i * g = 0 \text{ for all } g \text{ in } \mathcal{S}' \]

\[ \mathcal{S}_I = \langle g_j, j \in J^a \rangle. \]

Notice that \( \mathcal{S}' = \mathcal{S}_S \times \mathcal{S}_I \) in \( \mathcal{G}_n \). The minimum distance \( d \) of the EAQEC code is the minimum weight of any element in \( \mathcal{S}' \setminus \mathcal{S}_I \).

### III. Duality in EAQEC Codes

Observe that the orthogonal group of \( \mathcal{S}' = \mathcal{S}_S \times \mathcal{S}_I \) associated with the pair \((U, J = (J^I, J^a))\) in \( \mathcal{G}_n \) is \( \mathcal{L} \times \mathcal{S}_I \). That is,

\[ \mathcal{L} \times \mathcal{S}_I = (\mathcal{S}_S \times \mathcal{S}_I) \perp. \]

We can define another EAQEC code with logical subgroup \( \mathcal{S}_S \), symplectic subgroup \( \mathcal{L} \) and isotropic subgroup \( \mathcal{S}_I \) associated with the pair \((U, J^I = (J^I, J^a, J^a))\).

The number of a set of independent generators of \( \mathcal{S}_S \times \mathcal{S}_I \) is \( K = 2c + (n - k - c) = n - k + c \), and the number of a set of independent generators of its orthogonal group \( \mathcal{L} \times \mathcal{S}_I \) is \( K' = 2k + (n - k - c) = n + k - c \). These parameters satisfy the following relation:

\[ K + K' = 2n = N, \]

where \( N \) is the number of a set of independent generators of the full Pauli group \( \mathcal{G}_n \). This equation is parallel to the classical duality between a code and its dual code, which motivates the definition of the dual code of an EAQEC code as follows.

**Definition 1.** The dual of an \([[n, k, d, c]]\) EAQEC code, defined by a simplified stabilizer group \( \mathcal{S}' = \mathcal{S}_S \times \mathcal{S}_I \) and a logical group \( \mathcal{L} \) associated with the pair \((U, J = (J^I, J^a))\), is the \([[n, c, d', k]]\) EAQEC code associated with the pair \((U, J^I = (J^I, J^a, J^a))\) where \( \mathcal{L} \times \mathcal{S}_I \) is the simplified stabilizer group and \( \mathcal{S}_S \) is the logical group for some minimum distance \( d' \).

When \( c = n - k \), we call such a code a maximal-entanglement EAQEC code. In this case, \( \mathcal{S}_I \) is the trivial group that contains only the identity, and the simplified stabilizer group is \( \mathcal{S}_S \). Its dual code is a maximal-entanglement EAQEC code defined by the logical group \( \mathcal{L} \).

When \( c = 0 \), the code is a standard stabilizer code, with a stabilizer group \( \mathcal{S} = \mathcal{S}_I = \langle g_j, j \in J^a \rangle \), and a logical group \( \mathcal{L} = \langle g_j, h_j, j \in J^I \rangle \). \( \mathcal{S}_S \) is the trivial group in this case. The simplified stabilizer group \( \mathcal{L} \) defines an \([[n, 0, d', k]]\) EAQEC code—that is, a single entangled stabilizer state that encodes no information.

### IV. The MacWilliams Identity and the Linear Programming Bounds

The MacWilliams identity for general quantum codes can be obtained from the general theory of classical additive codes as indicated in [8] or by applying the Poisson summation formula from the theory of orthogonal groups [27].

**Theorem 2.** Suppose \( W_V(x, y) = \sum_{w=0}^{n} a_w x^{n-w} y^{w} \) and \( W_{V^\perp}(x, y) = \sum_{w=0}^{n} a_{w} x^{n-w} y^{w} \) are the weight enumerators of a subgroup \( V \) of \( \mathcal{G}_n \) and its orthogonal group \( V^\perp \) in \( \mathcal{G}_n \). Then

\[ W_V(x, y) = \frac{1}{|V^\perp|} W_{V^\perp}(x + 3y, y - x), \]

or equivalently

\[ B_w = \frac{1}{|V^\perp|} \sum_{w'=0}^{n} P_w(w', n) a_{w'}, \quad \text{for } w = 0, \ldots, n, \]

where \( P_w(w', n) = \sum_{w=0}^{n} (-1)^{n-w} u(w')(n-w') \) is the Krawtchouk polynomial [17].

Applying Theorem 2 to the simplified stabilizer group \( \mathcal{S}_S \times \mathcal{S}_I \) and the isotropic subgroup \( \mathcal{S}_I \), respectively, we obtain the MacWilliams Identity for EAQEC codes.

**Corollary 3.** The MacWilliams identities for EAQEC codes are as follows:

\[ W_{\mathcal{L} \times \mathcal{S}_I}(x, y) = \frac{1}{|\mathcal{S}_S \times \mathcal{S}_I|} W_{\mathcal{S}_S \times \mathcal{S}_I}(x + 3y, y - x), \]

\[ W_{\mathcal{S}_I}(x, y) = \frac{1}{|\mathcal{L} \times \mathcal{S}_S \times \mathcal{S}_I|} W_{\mathcal{L} \times \mathcal{S}_S \times \mathcal{S}_I}(x + 3y, y - x). \]

The significance of the MacWilliams identities is that linear programming techniques can be applied to find upper bounds on the minimum distance of EAQEC codes. For an \([[n, k, d, n - k]]\) EAQEC code, \( \mathcal{S}_I \) is trivial and the minimum distance is the minimum weight of any element in the logical subgroup \( \mathcal{L} \). We must have \( B_w = 0 \) for \( w = 1, \ldots, d - 1 \). If we cannot find any solutions to an integer program with the following constraints:

\[ A_0 = B_0 = 1; \]
\[ A_w \geq 0, B_w \geq 0, \quad \text{for } w = 1, \ldots, n; \]
\[ A_w \leq |\mathcal{S}_S|, B_w \leq |\mathcal{L}|, \quad \text{for } w = 1, \ldots, n; \]
\[ \sum_{w=0}^{n} A_w = |\mathcal{S}_S|, \quad \sum_{w=0}^{n} B_w = |\mathcal{L}|; \]
\[ B_w = \frac{1}{|\mathcal{S}_S|} \sum_{w'=0}^{n} P_w(w', n) a_{w'}, \quad \text{for } w = 0, \ldots, n; \]
\[ B_w = 0, \quad \text{for } w = 1, \ldots, d - 1; \]

for a certain \( d \), this result implies that there is no \([[n, k, d, n - k]]\) EAQEC code. If \( d^* \) is the smallest of such \( d \)'s, then \( d^* - 1 \) is an upper bound on the minimum distance of an \([[n, k, d, n - k]]\) EAQEC code. This bound is called the linear programming bound for EAQEC codes.

For \( 0 < c < n - k \), both \( \mathcal{S}_I \) and \( \mathcal{S}_S \) are nontrivial. The minimum distance is the minimum weight of any element in \( \mathcal{S}_I \times \mathcal{L} \setminus \mathcal{S}_I \). We need constraints on both the weight enumerators of \( \mathcal{S}_I \times \mathcal{S}_S \) and \( \mathcal{S}_I \) from equations (7) and (8).

For \( c = 0 \), \( V^\perp \) is the stabilizer group \( \mathcal{S} \), \( V \) is the normalizer group of \( \mathcal{S} \) and [5] gives the MacWilliams Identity for stabilizer codes [18, 9].

Now we can establish a table of upper and lower bounds on the minimum distance of maximal-entanglement EAQEC codes for \( n \leq 15 \). The upper bounds for \( n \leq 15 \) and \( k \geq 2 \) are from the linear programming bound, which is generally tighter than the singleton bound [11] and the Hamming bound for...
nondegenerate EAQEC codes [12]. The linear programming bounds are not necessarily tight, however. In some cases, they can be improved by other arguments. For instance, it can be proved that \([n, 1; n−1]\) and \([n, n−1, 1]\) EAQEC codes do not exist for even \(n\) [28].

Lai and Brun proposed a construction of \([n, 1, n; n−1]\) entanglement-assisted (EA) repetition codes for \(n\) odd in [16]. By slightly modifying that construction, we construct \([n, 1, n−1; n−1]\) EA repetition codes for \(n\) even [28], which are optimal.

The following codes are obtained by applying the the EAQEC code construction from classical codes in [11]: \([7, 2, 5; 5]\), \([9, 4, 5; 5]\), \([9, 5, 4; 4]\), \([10, 4, 6; 6]\), \([11, 5, 6; 6]\), \([11, 4, 6; 7]\), \([11, 6, 5; 5]\), \([12, 2, 9; 10]\), \([12, 8, 4; 4]\), \([12, 5, 6; 7]\), \([13, 2, 10; 11]\), \([13, 3, 9; 10]\), \([13, 6, 6; 7]\), \([14, 7, 6; 7]\), \([14, 8, 5; 6]\), \([15, 9, 5; 6]\), \([15, 8, 6; 7]\). The following codes are from the circulant code construction in [10]: \([7, 3, 4; 4]\), \([8, 2, 6; 6]\), \([10, 3, 6; 7]\), \([11, 3, 7; 8]\), \([15, 5, 8; 10]\), \([15, 6, 7; 9]\). The following codes are obtained by transforming standard stabilizer codes into EAQEC codes in [22]: \([6, 2, 4; 5]\), \([8, 4, 4; 4]\), \([9, 6, 3; 3]\), \([10, 6, 4; 4]\), \([10, 7, 3; 3]\), \([11, 8, 3; 3]\), \([12, 6, 5; 6]\), \([12, 7, 4; 5]\), \([12, 9, 3; 3]\), \([13, 5, 6; 8]\), \([13, 9, 4; 4]\), \([13, 10, 3; 3]\), \([14, 11, 3; 3]\), \([15, 4, 8; 11]\), \([15, 10, 4; 5]\). These codes give lower bounds on the achievable distance for many values of \(n\) and \(k\).

If an \([n, k, d; c]\) code exists, it can be shown that both an \([n+1, k, d; c+1]\) and an \([n, k−1, d′ ≥ d; c+1]\) code exist [28], which proves the existence of the following codes: \([14, 3, 9; 11]\), \([14, 9, 4; 5]\), \([13, 8, 4; 5]\), \([14, 10, 3; 4]\), \([14, 6, 6; 8]\), codes. We used MAGMA [29] to find the optimal quantum stabilizer codes, and then applied the encoding optimization algorithm in [10] to obtain the other lower bounds.

V. DISCUSSION

In this paper, we defined the dual code of an EAQEC code and derived the MacWilliams identities for EAQEC codes. Based on these identities, we found a linear programming bound on the minimum distance of a EAQEC code. We provided a table of upper and lower bounds on the minimum distance of maximal-entanglement EAQEC codes for \(n ≤ 15\). Most lower bounds in Table I are from the optimization algorithm [16]. To make the bounds in Table I tighter, we need to consider other code constructions to raise the lower bounds. We also plan to explore the existence of other \([n, k, d; n−k]\) codes to decrease the upper bound. Similar tables for EAQEC codes with \(0 < c < n−k\) can be constructed by the same techniques.

Rains introduced the idea of the shadow enumerator of a quantum stabilizer code [30], which can be related to the weight enumerator of the stabilizer group similar to the MacWilliams identity. This relation provides additional constraints on the linear programming problem and can improve the linear programming bound for quantum codes. To introduce the “shadow enumerator” of an EAQEC code may be a potential way to improve on the linear programming bound.

\begin{table}[h]
\centering
\begin{tabular}{|c|c|c|c|c|c|c|}
\hline
\(n\) & \(k\) & 8 & 9 & 10 & 11 & 12 & 13 & 14 \\
\hline
