Abstract

For a positive integer k , we say that a graph is k -existentially complete if for every $0 \leq a \leq k$, and every tuple of distinct vertices $x_1, \dots, x_a, y_1, \dots, y_{k-a}$, there exists a vertex z that is joined to all of the vertices x_1, \dots, x_a and none of the vertices y_1, \dots, y_{k-a} . While it is easy to show that the binomial random graph $G_{n,1/2}$ satisfies this property with high probability for $k \sim c \log n$, little is known about the “triangle-free” version of this problem; does there exist a finite triangle-free graph G with a similar “extension property”. This question was first raised by Cherlin in 1993 and remains open even in the case $k = 4$.

We show that there are no k -existentially complete triangle-free graphs with $k > \frac{8 \log n}{\log \log n}$, thus giving the first non-trivial, non-existence result on this “old chestnut” of Cherlin. We believe that this result breaks through a natural barrier in our understanding of the problem.

1 Introduction

We define an *embedding* of a graph H into a graph G to be a graph isomorphism from H to an induced subgraph of G .¹ Let a *partial embedding* of a graph H into G be a graph isomorphism between an induced subgraph of H and an induced subgraph of G . Say that an embedding $\tilde{\theta} : H \rightarrow G$ *extends* a partial embedding θ of H into G if $\tilde{\theta}$ is identically θ , when $\tilde{\theta}$ is restricted to the domain of θ .

The Rado graph R , an interesting and important object in its own right [1, 6, 4, 10], is the unique countable graph, up to isomorphism, with the property that every partial embedding of

¹Often this is called an *isomorphic embedding*, but as all embeddings that we consider will be isomorphic embeddings, we drop the extra qualifier.

a countable graph G may be extended to a complete embedding of G . Interestingly, there exist many examples of finite graphs that “approximate” the Rado graph in this sense. For example, the binomial random graph $G_{n,1/2}$ has the property that every partial embedding of a graph on $c \log n$ vertices extends to a complete embedding.

It is not hard to see that there is a natural analogue of the Rado graph for the class of triangle-free graphs. That is, there is a *countable*, triangle-free graph G so that every partial embedding of an arbitrary, countable, triangle-free graph H extends to a complete embedding of H . The question of whether there exist *finite* graphs with a similar property was raised and studied by Cherlin [2, 3] in the context of logic and model theory and has recently made its way over to combinatorics by way of Even-Zohar and Linial [8]. This is the question that we pursue in this paper.

To be more precise, let us fix some terms. We call a graph *k-existentially complete* if every partial embedding of a graph on $k + 1$ vertices extends to a complete embedding. We call a graph *k-existentially complete triangle-free* (Henceforth *k-ECTF*) if G is triangle-free and every partial embedding of a triangle-free, $(k + 1)$ -vertex graph extends to a complete embedding. Equivalently, a graph is *k-ECTF* if for every $0 \leq a \leq k$ and every tuple of distinct vertices $x_1, \dots, x_a, y_1, \dots, y_{k-a}$ there exists a vertex adjacent to all of x_1, \dots, x_a and none of y_1, \dots, y_{k-a} , *provided* x_1, \dots, x_a form an independent set.

In 1993, Cherlin asked [2] if there exist finite *k-ECTF* graphs for every fixed $k \in \mathbb{N}$. To date this problem remains poorly understood [3] and the state-of-the-art can be summarized as follows. The case $k = 1$ is trivial; a graph is 2-ECTF if and only if it is maximal triangle-free, twin-free and not a C_5 or a single edge; there are various (non-trivial) constructions for 3-ECTF graphs [9, 2, 3, 8]; and the case $k = 4$ is open.

Our belief is along the lines of Even-Zohar and Linial, who have conjectured that no such graphs exist for $k \geq k_0$, where $k_0 \in \mathbb{N}$. In the present paper we take a step towards this conjecture by giving a non-trivial restriction on the maximum possible value of k , relative to n . Let $f(n)$ be the largest integer k for which there exists a *k-ECTF* graph on n vertices. While an easy argument gives that $f(n) \leq c \log n$, our main result gives an asymptotic improvement over this estimate, thereby giving a first non-trivial restriction on $f(n)$.

Theorem 1. *Let $n \in \mathbb{N}$ be sufficiently large. There do not exist *k-ECTF* graphs on n vertices, with $k > \frac{8 \log n}{\log \log n}$. That is, $f(n) = O\left(\frac{\log n}{\log \log n}\right)$.*

One might interpret Theorem 1 as giving the first concrete evidence that the triangle-free version of the problem is substantially different than the problem without the restriction on triangles. Indeed, with high probability, $G_{n,1/2}$ is *k-existentially complete* with $k \sim c \log n$ and thus essentially matches the trivial bound.

We point out that a closely related question on triangle-free graphs was raised and studied by Erdős and Fajtlowicz [5] and later by Pach [9]; for $k \in \mathbb{N}$, what is the smallest maximum degree in a triangle-free graph G with the property that every independent set of size at most k has a common neighbour. Little is known about this question except in this case where k is large: Pach [9] gave a classification of graphs where $k \geq n$, that is where *all* independent sets have a common neighbour. This was later later strengthened for $k \geq c \log n$ by Erdős and Pach [7].

2 Proof of Main Theorem

Given a finite set X , we say that μ is a *probability measure on X* if μ is a probability measure on the power set of X . Of course, μ is determined by the values $\mu(\{x\})$ for $x \in X$. For a graph $G = (V(G), E(G))$, and disjoint subsets $X, Y \subseteq V(G)$, let $G[X, Y]$ denote the *induced bipartite graph* on vertex set $X \cup Y$, with bipartition $\{X, Y\}$, and $x \in X$ joined to $y \in Y$ if and only if $xy \in E(G)$.

Let G be a bipartite graph with vertex partition $\{A, B\}$. For $s, t \in \mathbb{N}$, we say G is (s, t) -*separating for A* if, for every pair of disjoint subsets $S, T \subseteq A$ with $|S| \leq s$ and $|T| \leq t$, there exists a vertex $v \in B$ so that v is joined to all of S and none of T .

It is easy to see that if $k \in \mathbb{N}$ and $G = (A, B, E)$ is a bipartite graph which is (k, k) -separating for A , then $|B| \geq 2^k$. The following lemma, gives a strengthened bound when we impose a restriction on the neighbourhoods of vertices in B .

Lemma 2. *For $k \in \mathbb{N}$, let G be a bipartite graph with bipartition $\{A, B\}$ with $|A| \geq 2k$, and let μ be a probability measure on A . If G is $(k, 0)$ -separating for A and $\mu(N(x)) < \varepsilon$ for each $x \in B$, then $|B| > 1/\varepsilon^k$.*

Proof. Sample the points $x_1, \dots, x_k \in A$ independently at random and according to the distribution μ . Then

$$\begin{aligned} 1 &= \mathbb{P}(x_1, \dots, x_k \in N(x) \text{ for some } x \in B) \\ &\leq \sum_{x \in B} \mathbb{P}(x_1, \dots, x_k \in N(x)) \\ &= \sum_{x \in B} \mu(N(x))^k \leq |B| \varepsilon^k, \end{aligned}$$

thus completing the proof. □

For, $s, t \in \mathbb{N}$, let $G = (A, B, E)$ be a bipartite graph that is (s, t) -separating for A . We now define a measure on B that measures how well a given subset of B covers the s -tuples of A . In particular, define the *covering measure* $\mu_{G,s,A}$, with respect to G , by defining a way of sampling it: first sample $X_1, \dots, X_s \in A$ independently and uniformly from A . Then, uniformly at random, choose a vertex among all vertices $v \in B$ so that $X_1, \dots, X_s \in N(v)$. A key property of this measure is that for every $B' \subseteq B$, we have that

$$\mu_{G,s,A}(B') \leq \mathbb{P}(X_1, \dots, X_s \in N(x), \text{ for some } x \in B'). \quad (1)$$

Here \mathbb{P} denotes the uniform measure on A for the X_1, \dots, X_s . The following lemma says that if $G = (A, B, E)$ is $(s, 0)$ -separating for A and a set $B' \subset B$ is given large mass by $\mu_{G,s,A}$, then the neighbourhoods of $x \in B'$ “expand” and collectively cover many vertices of A .

Lemma 3. *For $k \in \mathbb{N}$, let $G = (A, B, E)$ be a bipartite graph which is $(k, 0)$ -separating for A and let $\mu = \mu_{G,k,A}$ be the covering measure defined on B . If $B' \subseteq B$ has $\mu(B') > \varepsilon$ for some $\varepsilon > 0$, then*

$$\left| \bigcup_{x \in B'} N(x) \right| \geq \left(1 - \frac{1}{k} \log(\varepsilon^{-1}) \right) |A|.$$

Proof. Write $|\bigcup_{x \in B'} N(x)| = (1 - \eta)|A|$ for some $0 < \eta < 1$. Then if X_1, \dots, X_k are sampled independently and uniformly from A , we have

$$\begin{aligned} & \mathbb{P}(X_1, \dots, X_k \in N(x) \text{ for some } x \in B') \\ & \leq \mathbb{P}(X_1, \dots, X_k \in \bigcup_{x \in B'} N(x)) \\ & \leq (1 - \eta)^k \leq e^{-k\eta}. \end{aligned} \quad (2)$$

Now apply the observation at (1) to (2) to obtain the inequality

$$\varepsilon < \mu(B') \leq \mathbb{P}(X_1, \dots, X_k \in N(x) \text{ for some } x \in B') \leq e^{-k\eta}.$$

Taking logarithms gives $\eta < \frac{1}{k} \log(\varepsilon^{-1})$, as desired. \square

We also require a basic fact about triangle-free graphs.

Lemma 4. *A triangle-free graph on n vertices contains an independent set of size $\geq \lfloor \sqrt{n} \rfloor$*

Proof. If G contains a vertex of degree at least $\lfloor \sqrt{n} \rfloor$ then the neighbourhood of this vertex is an independent set and we are done. Otherwise, all neighbourhoods are of size at most $\lfloor \sqrt{n} \rfloor - 1$. In

this latter case we may greedily construct a proper colouring of G with at most \sqrt{n} colours. There will be a colour-class of size at least \sqrt{n} . \square

We are now in a position to give the proof of our main theorem.

Proof of Theorem 1. Suppose that G is a $2k$ -ECTF graph on n vertices with $k \geq \frac{4 \log n}{\log \log n}$. To reduce clutter, let $\varepsilon = 4(\log \log n)^{-1}$ so that $k \geq \varepsilon \log n$. Fix an independent set $I \subseteq V(G)$ with $|I| \geq \lfloor \sqrt{n} \rfloor$ and choose $x_0 \in I$. Then set $J = I \setminus \{x_0\}$. We define a procedure that will discover a collection of more than n distinct vertices in G , thus giving a contradiction. Let us set $\alpha = \frac{3}{k} \log(\varepsilon^{-2})$ and note the inequalities

$$\alpha^{-k/2} > n, \tag{3}$$

and

$$\frac{2}{k} \log(\varepsilon^{-2}) + \frac{k}{\sqrt{n} - 2} \leq \frac{3}{k} \log(\varepsilon^{-2}) = \alpha, \tag{4}$$

which hold for n sufficiently large.

We prove the following statement by induction on $t \in [0, n + 1]$: for each $t \in [0, n + 1]$ we may find a vertex $w_t \in V(G)$, and a set $L_t \subseteq J^{\frac{k}{2}}$ so that the following conditions hold.

1. The vertices w_1, \dots, w_t are distinct.
2. If $(v_1, \dots, v_{k/2}) \in L_t$, then $v_1, \dots, v_{k/2}$ are not all contained in any of the neighbourhoods $\{N(w_i)\}_{i=1}^t$. That is,

$$(v_1, \dots, v_{k/2}) \notin \bigcup_{i=1}^t (N(w_i))^{k/2}.$$

3. We have $|L_t| \geq (1 - t\alpha^{k/2}) |J|^{k/2}$.

For the basis step, set $L_0 = J^{k/2}$. Now assume that we have defined distinct vertices w_1, \dots, w_{t-1} and a set L_{t-1} satisfying the above. We show that we may find appropriate w_t and L_t .

Note that $|L_{t-1}| \geq 1$, as $|L_{t-1}| \geq |J|^{k/2}(1 - (t-1)\alpha^{k/2}) \geq |J|^{k/2}(1 - n\alpha^{k/2}) > 0$, as $\alpha^{-k/2} > n$, by the inequality at (3). So we may fix $y_1, \dots, y_{k/2} \in J$ so that $(y_1, \dots, y_{k/2}) \in L_{t-1}$. Define $B \subseteq V(G)$ to be the collection of vertices in G that are adjacent to x_0 and not adjacent to any of $y_1, \dots, y_{k/2}$. Note that since each vertex in B joins to x_0 , B is an independent set. Now put $A = I \setminus \{x_0, y_1, \dots, y_{k/2}\}$ and consider $G[A, B]$. Observe that $G[A, B]$ is $(k/2, k/2 - 1)$ -separating for A and therefore $|B| \geq 2^{k/2-1}$, by the trivial bound. Let $\mu = \mu_{G[A, B], k/2, A}$ be the covering measure defined on B , with respect to the bipartite graph $G[A, B]$.

Define Y to be the set of vertices in G that are joined to all of $y_1, \dots, y_{k/2}$. Note that the graph $G[B, Y]$ is $(k/2, k/2)$ -separating for B , as there are no edges between $y_1, \dots, y_{k/2}$ and B and B is an independent set in G . We now claim that there exists a vertex $w \in Y$ with $\mu(N_B(w)) > \varepsilon^2$. Suppose to the contrary that $\mu(N_B(x)) < \varepsilon^2$ for all $x \in Y$. Since $G[B, Y]$ is $(k/2, k/2)$ -separating for B , we may apply Lemma 2 to learn that $|Y| > \frac{1}{\varepsilon^k} = n$, which is a contradiction.

So we may choose some $w \in Y$ with $\mu(N_B(w)) \geq \varepsilon^2$ and apply Lemma 3 to learn that

$$\left| \bigcup_{x \in N_B(w)} N_A(x) \right| \geq \left(1 - \frac{2}{k} \log(\varepsilon^{-2}) \right) |A|. \quad (5)$$

The key here is that w is not adjacent to any of the vertices in the union on the left hand side of (5), as this would create a triangle. Thus, (5) tells us that w is adjacent to at most $\frac{2|A|}{k} \log(\varepsilon^{-2})$ vertices in A and thus w is adjacent to at most $\frac{2|A|}{k} \log(\varepsilon^{-2}) + k/2$ vertices in J . As $|A| < |J|$, w covers at most

$$|J|^{k/2} \left(\frac{2}{k} \log(\varepsilon^{-2}) + \frac{k}{2|J|} \right)^{k/2} \leq |J|^{k/2} \alpha^{k/2} \quad (6)$$

$k/2$ -tuples in $J^{k/2}$. Here we have used the inequality $|J| = |I| - 1 \geq \lfloor \sqrt{n} \rfloor - 1$ and the inequality at (4). So we define $w_t = w$ and set

$$L_t = L_{t-1} \setminus \{(v_1, \dots, v_{k/2}) : v_1, \dots, v_{k/2} \in N(w) \cap J\}.$$

By induction and the bound at (6) we have $|L_t| \geq |J|^{\frac{k}{2}} (1 - t\alpha^{k/2})$. Finally, we note that w_t must be distinct from w_1, \dots, w_{t-1} as w_t is joined to all of $y_1, \dots, y_{k/2}$ which is not true of any of the w_1, \dots, w_{t-1} , by the induction hypothesis.

So, by induction, we have constructed $n+1$ distinct vertices in a n -vertex graph; a contradiction. This implies that there are no l -ECTF graphs with $l = 2k \geq \frac{8 \log n}{\log \log n}$, thus completing the proof of Theorem 1. \square
