Abstract

We prove the following quantitative hardness results for the Shortest Vector Problem in the ℓ_p norm (SVP_p), where n is the rank of the input lattice.

1. For “almost all” $p > p_0 \approx 2.1397$, there no $2^{n/C_p}$ -time algorithm for SVP_p for some explicit constant $C_p > 0$ unless the (randomized) Strong Exponential Time Hypothesis (SETH) is false.
2. For any $p > 2$, there is no $2^{o(n)}$ -time algorithm for SVP_p unless the (randomized) Gap-Exponential Time Hypothesis (Gap-ETH) is false. Furthermore, for each $p > 2$, there exists a constant $\gamma_p > 1$ such that the same result holds even for γ_p -approximate SVP_p .
3. There is no $2^{o(n)}$ -time algorithm for SVP_p for any $1 \leq p \leq 2$ unless either (1) (non-uniform) Gap-ETH is false; or (2) there is no family of lattices with exponential kissing number in the ℓ_2 norm. Furthermore, for each $1 \leq p \leq 2$, there exists a constant $\gamma_p > 1$ such that the same result holds even for γ_p -approximate SVP_p .

1 Introduction

A lattice \mathcal{L} is the set of all integer combinations of linearly independent basis vectors $\mathbf{b}_1, \dots, \mathbf{b}_n \in \mathbb{R}^d$,

$$\mathcal{L} = \mathcal{L}(\mathbf{b}_1, \dots, \mathbf{b}_n) := \left\{ \sum_{i=1}^n z_i \mathbf{b}_i : z_i \in \mathbb{Z} \right\}.$$

We call n the *rank* of the lattice \mathcal{L} and d the *dimension* or the *ambient dimension* of the lattice \mathcal{L} .

The Shortest Vector Problem (SVP) takes as input a basis for a lattice $\mathcal{L} \subset \mathbb{R}^d$ and $r > 0$ and asks us to decide whether the shortest non-zero vector in \mathcal{L} has length at most r . Typically, we define length in terms of the ℓ_p norm for some $1 \leq p \leq \infty$, defined as

$$\|\mathbf{x}\|_p := (|x_1|^p + |x_2|^p + \dots + |x_d|^p)^{1/p}$$

for finite p and

$$\|\mathbf{x}\|_\infty := \max |x_i|.$$

In particular, the ℓ_2 norm is the familiar Euclidean norm, and it is the most interesting case from our perspective. We write SVP_p for SVP in the ℓ_p norm (and just SVP when we do not wish to specify a norm).

Starting with the breakthrough work of Lenstra, Lenstra, and Lovász in 1982 [LLL82], algorithms for solving SVP in both its exact and approximate forms have found innumerable applications, including factoring polynomials over the rationals [LLL82], integer programming [Len83, Kan87, DPV11], cryptanalysis [Sha84, Odl90, JS98, NS01], etc. More recently, many cryptographic primitives have been constructed whose security is based on the (worst-case) hardness of SVP or closely related lattice problems [Ajt04, Reg09, GPV08, Pei10, Pei16]. Such lattice-based cryptographic constructions are likely to be used on massive scales (e.g., as part of the TLS protocol) in the not-too-distant future [ADPS16, BCD+16, NIS16].

Most of the above applications rely on approximate variants of SVP with rather large approximation factors (e.g., the relevant approximation factors are polynomial in n for most cryptographic constructions). However, the best known algorithms for the approximate variant of SVP use an algorithm for exact SVP_2 over lower-rank lattices as a subroutine [Sch87, GN08, MW16]. So, the complexity of the exact problem is of particular interest. We briefly discuss some of what is known below.

Algorithms for SVP. Most of the asymptotically fastest known algorithms for SVP are variants of the celebrated randomized sieving algorithm due to Ajtai, Kumar, and Sivakumar [AKS01], which solved SVP_p in $2^{O(d)}$ time for $p = 2$ and $p = \infty$. This was extended to all ℓ_p norms [BN09], then to SVP in all norms [AJ08], and then even to “norms” whose unit balls are not necessarily symmetric [DPV11]. These $2^{O(d)}$ -time algorithms that work in all norms in particular imply $2^{O(n)} \cdot \text{poly}(d)$ -time algorithms for SVP_p , by taking the ambient space to be the span of the lattice. We are therefore primarily interested in the running time of these algorithms as a function of the rank n . (Notice that, in the ℓ_2 norm, we can always assume that $n = d$.)

In the special case of $p = 2$, quite a bit of work has gone into improving the constant in the exponent in these $2^{O(n)}$ -time algorithms [NV08, PS09, MV10, LWXZ11]. The current fastest known algorithm for SVP_2 runs in $2^{n+o(n)}$ time [ADRS15, AS17]. But, this is unlikely to be the end of the story. Indeed, there is also a $2^{n/2+o(n)}$ -time algorithm that approximates SVP_2 up to a small

constant factor,¹ and there is some reason to believe that this algorithm can be modified to solve the exact problem [ADRS15, AS17]. Further complicating the situation, there exist even faster “heuristic algorithms,” whose correctness has not been proven but can be shown under certain heuristic assumptions [NV08, WLTB11, Laa15]. The fastest such heuristic algorithm runs in time $(3/2)^{n/2+o(n)} \approx 2^{0.29n}$ [BDGL16].

Hardness of SVP. Van Emde Boaz first asked whether SVP_p was NP-hard in 1981, and he proved NP-hardness in the special case when $p = \infty$ [van81]. Despite much work, his question went unanswered until 1998, when Ajtai showed NP-hardness of SVP_p for all p [Ajt98]. A series of works by Cai and Nerurkar [CN98], Micciancio [Mic01], Khot [Kho05], and Haviv and Regev [HR12] simplified the reduction and showed hardness of the approximate version of SVP_p . We now know that SVP_p is NP-hard to approximate to within any constant factor and hard to approximate to within approximation factors as large as $n^{c/\log \log n}$ for some constant $c > 0$ under reasonable complexity-theoretic assumptions.²

However, such hardness proofs tell us very little about the *quantitative* or *fine-grained* complexity of SVP_p . E.g., does the fastest possible algorithm for SVP_2 still run in time at least, say, $2^{n/5}$, or is there an algorithm that runs in time $2^{n/20}$ or even $2^{\sqrt{n}}$? The above hardness results cannot distinguish between these cases, but we certainly need to be confident in our answers to such questions if we plan to base the security of widespread cryptosystems on these answers. Indeed, most proposed instantiations of lattice-based cryptosystems (i.e., proposed cryptosystems that specify a key size) can essentially be broken by solving SVP_2 with, say, $n \ll 600$ or SVP_p for any p with $n \ll 1500$. So, if we discovered an algorithm running in time, say, $2^{n/20}$ -time for SVP_2 or $2^{n/50}$ or $2^{n/\log^2 n}$ for SVP_p , then these schemes would be broken in practice. And, given the large number of recent algorithmic advances, one might (reasonably?) worry that such algorithms will be found. We would therefore very much like to rule out this possibility!

To rule out such algorithms, we typically rely on a fine-grained complexity-theoretic hypothesis—such as the Strong Exponential Time Hypothesis (SETH, see Section 2.3) or the Exponential Time Hypothesis (ETH). To that end, Bennett, Golovnev, and Stephens-Davidowitz recently showed quantitative hardness results for the Closest Vector Problem in ℓ_p norms (CVP_p) [BGS17], which is a close relative of SVP_p that is known to be at least as hard (so that this was a necessary first step towards proving similar results for SVP_p). In particular, assuming SETH, [BGS17] showed that there is no $2^{(1-\varepsilon)n}$ -time algorithm for CVP_p or SVP_∞ for any $\varepsilon > 0$ and “almost all” $1 \leq p \leq \infty$ (not including $p = 2$). Under ETH, [BGS17] showed that there is no $2^{o(n)}$ -time algorithm for CVP_p for any $1 \leq p \leq \infty$. We prove similar results for SVP_p for $p > 2$ (and a conditional result for $1 \leq p \leq 2$ that holds if there exists a family of lattices satisfying certain geometric conditions).

1.1 Our results

We now present our results, which are also summarized in Table 1.

¹Unlike all other algorithms mentioned here, this $2^{n/2+o(n)}$ -time algorithm does not actually find a short vector; it only outputs a length. In the exact case, these two problems are known to be equivalent under an efficient rank-preserving reduction [MG02], but this is not known to be true in the approximate case.

²All of these reductions for finite p are randomized, as are ours. An unconditional deterministic reduction would be a major breakthrough. See [Mic01, Mic12] for more discussion and even a conditional deterministic reduction that relies on a certain number-theoretic assumption.

	Upper Bound	Lower Bounds			Notes
		SETH	Gap-ETH	Gap-ETH + Kissing Number	
$p_0 < p < \infty$	$2^{O(n)}$	$2^{n/C_p}$	$2^{\Omega(n)}$	$2^{\Omega(n)}$	See Fig. 1. $p_0 \approx 2.1397$
$2 < p \leq p_0$	$2^{O(n)}$	–	$2^{\Omega(n)}$	$2^{\Omega(n)}$	
$p = 2$	2^n ($2^{0.3n}$)	–	–	$2^{\Omega(n)}$	
$1 \leq p < 2$	$2^{O(n)}$	–	–	$2^{\Omega(n)}$	
$p = \infty$	$2^{O(n)}$	2^n	$2^{\Omega(n)}$	$2^{\Omega(n)}$	[BGS17]

Table 1: Summary of known fine-grained upper and lower bounds for SVP_p for various p under various assumptions, with new results in blue. Lower bounds in **bold** also apply for some constant approximation factor strictly greater than one. The one upper bound in parentheses is due to a heuristic algorithm. The SETH-based lower bound only applies for “almost all” $p > p_0$, in the sense of Theorem 4.3. We have suppressed low-order terms for simplicity.

SETH-hardness. Our first main result essentially gives an explicit constant $C_p > 1$ for each $p > p_0 \approx 2.1397$ such that, under (randomized) SETH, there is no algorithm for SVP_p that runs in time better than $2^{n/C_p}$. The constants p_0 and C_p do not have a closed form, but they are easily computable to high precision in practice. (E.g., $p_0 = 2.13972134795007\dots$, $C_3 = 3.01717780317660\dots$, and $C_5 = 1.3018669052709\dots$) We plot C_p over a wide range of p in Figure 1. Notice that C_p is unbounded as p approaches p_0 , but it is a relatively small constant for, say, $p \gtrsim 3$.

We present this result informally here, as the actual statement is rather technical. In particular, because we use the theorem from [BGS17] that only applies to “almost all” p , our result also has this property. See Theorem 4.3 for the formal statement.

Figure 1: The value C_p for different values of $p > p_0$. In particular, up to the minor technical issues in Theorem 4.3, there is no $2^{n/C_p}$ -time algorithm for SVP_p unless SETH is false. The plot on the left shows C_p over a wide range of p , while the plot on the right shows the behavior when p is close to its minimal value $p_0 \approx 2.13972$.

Theorem 1.1 (Informal). *For “almost all” $p > p_0 \approx 2.1397$ (including all odd integers $p \geq 3$), there is no $2^{n/C_p}$ -time algorithm for SVP_p unless (randomized) SETH is false, where $C_p > 1$ is as in Figure 1. Furthermore, $C_p \rightarrow 1$ as $p \rightarrow \infty$.*

To prove this theorem, we give a (randomized) reduction from the CVP_p instances created by the reduction of [BGS17] to SVP_p that only increases the rank of the lattice by a constant factor. As we describe in Section 1.3, our reduction is surprisingly simple. In particular, the key step in Khot’s reduction [Kho05] uses a certain “gadget” consisting of a lattice \mathcal{L}^\dagger , vector \mathbf{t}^\dagger , and distance $r^\dagger > 0$ to convert a provably hard CVP_p instance into an SVP_p instance. Our reduction is similar to Khot’s reduction with the simple gadget given by $\mathcal{L}^\dagger := \mathbb{Z}^{n^\dagger}$, $\mathbf{t}^\dagger := (1/2, \dots, 1/2) \in \mathbb{R}^{n^\dagger}$, and $r^\dagger := n^{1/p}/2$.

We note in passing that we actually do not need the full strength of SETH. We can instead rely on the analogous assumption for Max- k -SAT, which is potentially weaker. (We inherit this property directly from [BGS17]. See Section 4.)

Gap-ETH-hardness. Our second main result is the Gap-ETH-hardness of SVP_p for all $p > 2$.³ In fact, we prove this even for the problem of approximating SVP_p up to some fixed constant $\gamma_p > 1$ depending only on p (and the approximation factor implicit in the Gap-ETH assumption). See Corollary 5.5.

Theorem 1.2 (Informal). *For any $p > 2$, there is no $2^{o(n)}$ -time algorithm for SVP_p unless (randomized) Gap-ETH is false. Furthermore, for each such p there is a constant $\gamma_p > 1$ such that the same result holds even for γ_p -approximate SVP_p .*

Our reduction is again quite simple (though the proof of correctness is not). We follow Khot’s reduction from approximate Exact Set Cover, and we again use the integer lattice as our gadget (with a different target).⁴

We note in passing that for this result (as well as Theorem 1.3 and Corollary 1.4), we actually rule out even $2^{o(d)}$ -time algorithms. However, we focus on the rank n instead of the dimension d for simplicity.

Towards $p = 2$. We are unable to extend either Theorem 1.1 or Theorem 1.2 to the important case when $p = 2$. Indeed, we cannot use the integer lattice as a gadget in the Euclidean norm. However, we do show that the existence of a certain type of lattice that is believed to exist would be sufficient to show (possibly non-uniform) Gap-ETH-hardness of SVP_2 . In particular, it would suffice to show the existence of any family of lattices with exponentially large kissing number. See Theorem 5.9 for the precise statement, which requires the existence of a structure that might be easier to construct (and see, e.g., [Alo97, CS98] for discussion of the lattice kissing number).

Theorem 1.3 (Informal). *There is no $2^{o(n)}$ -time algorithm for SVP_2 unless either (1) (non-uniform) Gap-ETH is false; or (2) the lattice kissing number is $2^{o(n)}$. Furthermore, there exists a constant $\gamma > 1$ such that the same result holds even for γ -approximate SVP_2 .*

In fact, Regev and Rosen show that ℓ_2 is in some sense the “easiest norm” [RR06]. (See Theorem 2.3.) In particular, to show that SVP_p is Gap-ETH-hard for all $1 \leq p \leq 2$, it suffices to show it for $p = 2$. From this, we derive the following. (See Corollary 5.10 for the formal statement.)

³Gap-ETH is the assumption that there is no $2^{o(n)}$ -time algorithm that distinguishes a satisfiable 3-SAT formula from one in which at most a constant fraction of the clauses are simultaneously satisfiable. See Section 2.3.

⁴We note that Khot claimed in Section 8 of [Kho05] that he had discovered a linear reduction from γ' -approximate CVP_p to $2^{1-3/p}$ -approximate SVP_p for $p \geq 4$ and some unspecified constant γ' . However, it is not clear whether γ' is a small enough constant to yield an alternate proof of Theorem 1.2 for $p \geq 4$. In particular, one would need to show Gap-ETH-hardness of γ' -approximate CVP_p .

Corollary 1.4 (Informal). *There is no $2^{o(n)}$ -time algorithm for SVP_p for any $1 \leq p \leq 2$ unless either (1) (non-uniform) Gap-ETH is false; or (2) the lattice kissing number is $2^{o(n)}$ (in the ℓ_2 norm). Furthermore, for each $1 \leq p \leq 2$, there exists a constant $\gamma_p > 1$ such that the same result holds even for γ_p -approximate SVP_p .*

1.2 Khot's reduction

Before we describe our own contribution, it will be useful to review Khot's elegant reduction from CVP_p to SVP_p [Kho05]. We do our best throughout this description to hide technicalities in an effort to focus on the high-level simplicity of Khot's reduction.⁵ (Since the hardness of SVP_p went unproven for many years, this simplicity is truly remarkable.)

First, some basic definitions and notation. For a lattice $\mathcal{L} \subset \mathbb{R}^d$ and $1 \leq p \leq \infty$, we write

$$\lambda_1^{(p)}(\mathcal{L}) := \min_{\mathbf{y} \in \mathcal{L} \setminus \{\mathbf{0}\}} \|\mathbf{y}\|_p$$

for the length of the shortest non-zero vector in \mathcal{L} in the ℓ_p norm. For a target vector $\mathbf{t} \in \mathbb{R}^d$, we write

$$\text{dist}_p(\mathbf{t}, \mathcal{L}) := \min_{\mathbf{y} \in \mathcal{L}} \|\mathbf{y} - \mathbf{t}\|_p$$

for the distance between \mathbf{t} and \mathcal{L} . For any radius $r > 0$, we write

$$N_p(\mathcal{L}, r, \mathbf{t}) := |\{\mathbf{y} \in \mathcal{L} : \|\mathbf{y} - \mathbf{t}\|_p \leq r\}|$$

for the number of lattice vectors within distance r of \mathbf{t} .

Recall that CVP_p is the problem that takes as input a lattice $\mathcal{L} \subset \mathbb{R}^d$, target vector $\mathbf{t} \in \mathbb{R}^d$, and distance $r > 0$ and asks us to distinguish the YES case when $\text{dist}_p(\mathbf{t}, \mathcal{L}) \leq r$ from the NO case when $\text{dist}_p(\mathbf{t}, \mathcal{L}) > r$. When talking about a particular CVP_p instance, we naturally call a lattice vector $\mathbf{y} \in \mathcal{L}$ with $\|\mathbf{y} - \mathbf{t}\|_p \leq r$ a *close vector*, and we notice that the number of close vectors is $N_p(\mathcal{L}, r, \mathbf{t})$.

The naive reduction and sparsification. The “naive reduction” from CVP_p to SVP_p simply takes a CVP_p instance consisting of a lattice $\mathcal{L} \subset \mathbb{R}^d$ with basis $\mathbf{B} \in \mathbb{R}^{d \times n}$, target $\mathbf{t} \in \mathbb{R}^d$, and distance $r > 0$ and constructs the SVP_p instance given by the basis of a lattice \mathcal{L}' of the form

$$\mathbf{B}' := \begin{pmatrix} \mathbf{B} & -\mathbf{t} \\ 0 & s \end{pmatrix},$$

where $s > 0$ is some parameter depending on the CVP_p instance. Notice that, if $\mathbf{y} \in \mathcal{L}$ is a close vector (i.e., $\|\mathbf{y} - \mathbf{t}\| \leq r$), then $\|(\mathbf{y} - \mathbf{t}, s)\|_p^p \leq r^p + s^p$. Therefore, in the YES case when there exists a vector close to \mathbf{t} , we will have $\lambda_1^{(p)}(\mathcal{L}') \leq r' := (r^p + s^p)^{1/p}$.

However, in the NO case there might still be non-zero vectors $\mathbf{y}' \in \mathcal{L}' \setminus \{\mathbf{0}\}$ whose length is less than r' . These vectors must be of the form $\mathbf{y}' = (\mathbf{y} - z\mathbf{t}, zs)$ for some integer $z \neq 1$. Let us for now only consider the case $z = 0$, in which case these vectors are in one-to-one correspondence with the non-zero vectors in \mathcal{L} of length less than r' . We naturally call these *short vectors*.

⁵Khot's primary motivation for his reduction was to prove hardness of approximating SVP_p to within any constant factor, by showing a reduction that is well-behaved under a certain tensor product. We are not interested in taking tensor products (since they produce lattices of superlinear rank), so we ignore this issue entirely.

Khot showed that a (randomized) reduction exists if we just assume that the number of close vectors in any YES case is significantly larger than the number of short vectors in any NO case. In particular, Khot showed that we can randomly “sparsify” the lattice \mathcal{L}' to obtain a sublattice \mathcal{L}'' such that each of the short non-zero vectors in \mathcal{L}' stays in \mathcal{L}'' with probability $1/q$ where $q \geq 2$ is some parameter that we can choose. So, if we take q to be significantly smaller than the number of close vectors in the YES case but significantly larger than the number of short vectors in the NO case, we can show that the resulting lattice will have $\lambda_1^{(p)}(\mathcal{L}) \leq r'$ in the YES case but $\lambda_1^{(p)}(\mathcal{L}) > r'$ in the NO case with high probability.

Unfortunately, the CVP_p instances produced by most hardness reductions typically have $2^{\Omega(n)}$ short vectors, and they might only have one close vector in the YES case. So, if we want this reduction to work, we will need some way to increase this ratio by an exponential factor.

Adding the gadget. To increase the ratio of close vectors to short vectors, Khot uses a certain gadget that is itself a CVP_p instance $(\mathcal{L}^\dagger, \mathbf{t}^\dagger, r^\dagger)$, where $\mathcal{L}^\dagger \subset \mathbb{R}^{d^\dagger}$ is a lattice with basis \mathbf{B}^\dagger , $\mathbf{t}^\dagger \in \mathbb{R}^{d^\dagger}$ is a target vector, and $r^\dagger > 0$ is some distance. He then takes the direct sum of the two instances. I.e., Khot considers the lattice

$$\widehat{\mathcal{L}} := \mathcal{L} \oplus \mathcal{L}^\dagger = \{(\mathbf{y}, \mathbf{y}^\dagger) : \mathbf{y} \in \mathcal{L}, \mathbf{y}^\dagger \in \mathcal{L}^\dagger\} \subset \mathbb{R}^{d+d^\dagger}$$

with basis

$$\widehat{\mathbf{B}} := \begin{pmatrix} \mathbf{B} & \mathbf{0} \\ \mathbf{0} & \mathbf{B}^\dagger \end{pmatrix},$$

the target $\widehat{\mathbf{t}} := (\mathbf{t}, \mathbf{t}^\dagger) \in \mathbb{R}^{d+d^\dagger}$, and the distance $\widehat{r} := (r^p + (r^\dagger)^p)^{1/p}$. We wish to apply the sparsification-based reduction described above to this new lattice. So, we proceed to make some observations about \mathcal{L}^\dagger to deduce some properties that it must have in order to make this reduction sufficient to derive our hardness results.

First, we simply notice that the rank of $\widehat{\mathcal{L}} = \mathcal{L} \oplus \mathcal{L}^\dagger$ is the sum of the ranks of \mathcal{L} and \mathcal{L}^\dagger . To prove the kind of fine-grained hardness results that we are after, we are only willing to increase the rank by a constant factor, so *the rank of \mathcal{L}^\dagger must be at most $O(n)$* . (Of course, prior work did not have this restriction.)

Next, we notice that any $\widehat{\mathbf{y}} = (\mathbf{y}, \mathbf{y}^\dagger) \in \widehat{\mathcal{L}}$ with $\|\mathbf{y} - \mathbf{t}\|_p \leq r$ and $\|\mathbf{y}^\dagger - \mathbf{t}^\dagger\|_p \leq r^\dagger$ satisfies $\|\widehat{\mathbf{y}} - \widehat{\mathbf{t}}\|_p \leq \widehat{r}$. We call these *good vectors*, and we notice that there are at least $N_p(\mathcal{L}^\dagger, r^\dagger, \mathbf{t}^\dagger)$ good vectors in the YES case.

Now, we worry about short vectors in $\widehat{\mathcal{L}}$ in the NO case, i.e., non-zero $\widehat{\mathbf{y}} = (\mathbf{y}, \mathbf{y}^\dagger)$ with $\|\widehat{\mathbf{y}}\|_p \leq \widehat{r}$. Clearly, $\widehat{\mathbf{y}}$ will be short if $\|\mathbf{y}\|_p \leq r$ and $\|\mathbf{y}^\dagger\|_p \leq r^\dagger$. Therefore, the number of short vectors is at least

$$N_p(\mathcal{L}, r, \mathbf{0}) \cdot N_p(\mathcal{L}^\dagger, r^\dagger, \mathbf{0}) \geq 2^{\Omega(n)} \cdot N_p(\mathcal{L}^\dagger, r^\dagger, \mathbf{0}) \geq 2^{\Omega(n^\dagger)} \cdot N_p(\mathcal{L}^\dagger, r^\dagger, \mathbf{0}),$$

where we have used the fact that $n^\dagger = O(n)$ and the fact that the input CVP_p instances that interest us have $2^{\Omega(n)}$ short vectors. (This is not true in general, but it is true of most CVP_p instances resulting from hardness proofs.) Since the number of good vectors in the YES case is potentially only $N_p(\mathcal{L}^\dagger, r^\dagger, \mathbf{t}^\dagger)$, *our gadget lattice must satisfy*

$$N_p(\mathcal{L}^\dagger, r^\dagger, \mathbf{t}^\dagger) \geq 2^{\Omega(n^\dagger)} \cdot N_p(\mathcal{L}^\dagger, r^\dagger, \mathbf{0}). \quad (1)$$

Though this in itself is not sufficient to make our reduction work, it is the most important feature that a gadget lattice must have. Indeed, we show in Corollary 5.3 that a slightly stronger condition

is sufficient to prove Gap-ETH hardness. (This property and various variants are sometimes called *local density*, and they play a key role in many hardness proofs for SVP_p .)

However, short vectors are no longer our only concern. We also have to worry about close vectors that are not good vectors, i.e., vectors $\widehat{\mathbf{y}} = (\mathbf{y}, \mathbf{y}^\dagger)$ in the NO case such that $\|\widehat{\mathbf{y}} - \widehat{\mathbf{t}}\|_p \leq \widehat{r}$ but $\|\mathbf{y} - \mathbf{t}\|_p > r$. We call such vectors *impostors*. Impostors certainly can exist in general, but our sparsification procedure will work on them just like any other vector. So, as long as our gadget lattice is chosen such that the number of impostors in the NO case is significantly lower than the number of good vectors in the YES case, they will not trouble us.

1.3 Our techniques

We learned in the previous section that, in order to make our reduction work, it is necessary (though not always sufficient) that our gadget $(\mathcal{L}^\dagger, \mathbf{t}^\dagger, r^\dagger)$ has exponentially more close vectors than short vectors. I.e., we need to find a family of gadgets that satisfies Eq. (1). Furthermore, we must somehow ensure that the the number of impostors in the NO case is exponentially lower than the number of good vectors in the YES case.

The integer lattice, Θ_p , and SETH-hardness. To prove Theorem 1.1, we take $\mathcal{L}^\dagger := \mathbb{Z}^{n^\dagger}$, $\mathbf{t}^\dagger := (1/2, \dots, 1/2) \in \mathbb{R}^{n^\dagger}$, and $r^\dagger := \text{dist}_p(\mathbf{t}^\dagger, \mathbb{Z}^{n^\dagger}) = (n^\dagger)^{1/p}/2$. Notice that, by taking $r^\dagger = \text{dist}_p(\mathbf{t}^\dagger, \mathcal{L}^\dagger)$, we ensure that there simply are no impostors in the NO instance (i.e., when $\|\mathbf{y} - \mathbf{t}\|_p > r$, we can never have $\|(\mathbf{y}, \mathbf{y}^\dagger) - (\mathbf{t}, \mathbf{t}^\dagger)\|_p^p \leq r^p + (r^\dagger)^p$).⁶

To prove that our reduction works, we wish to show that the ratio

$$\frac{N_p(\mathbb{Z}^{n^\dagger}, r^\dagger, \mathbf{t}^\dagger)}{N_p(\mathbb{Z}^{n^\dagger}, r^\dagger, \mathbf{0})}$$

is (exponentially) large. Of course, the numerator is easy to calculate. It is $|\{0, 1\}^{n^\dagger}| = 2^{n^\dagger}$. So, we wish to prove that

$$N_p(\mathbb{Z}^{n^\dagger}, r^\dagger, \mathbf{0}) \ll 2^{n^\dagger}. \quad (2)$$

Unfortunately, Eq. (2) does not hold for all ℓ_p norms. For example, for $p = 2$, consider the points in $\{-1, 0, 1\}^{n^\dagger}$ with $n^\dagger/4$ non-zero coordinates, which have ℓ_2 norm r^\dagger . There are

$$2^{n^\dagger/4} \cdot \binom{n^\dagger}{n^\dagger/4} \approx 2^{n^\dagger/4} \cdot 4^{n^\dagger/4} \cdot (4/3)^{3n^\dagger/4} \approx 2.0867^{n^\dagger}$$

such points. (In fact, this is a reasonable estimate for the exact value of $N_2(\mathbb{Z}^{n^\dagger}, r^\dagger, \mathbf{0})$, which is $C^{n^\dagger + O(\sqrt{n^\dagger})}$ for $C = 2.0891\dots$, as we show in Section 6.) However, $N_p(\mathbb{Z}^{n^\dagger}, (n^\dagger)^{1/p}/2, \mathbf{t}^\dagger)$ is decreasing in p . So, one might hope that Eq. (2) holds for slightly larger p .

To prove this, we wish to find a good upper bound on the number of integer points in a centered ℓ_p ball, $N_p(\mathbb{Z}^{n^\dagger}, r^\dagger, \mathbf{0})$. A very nice way to do this uses the function

$$\Theta_p(\tau) := \sum_{z \in \mathbb{Z}} \exp(-\tau|z|^p)$$

⁶We note that any gadget that allows us to use $r^\dagger = \text{dist}_p(\mathbf{t}^\dagger, \mathcal{L}^\dagger)$ must satisfy quite rigid requirements. We need exponentially many vectors that are all *exact* closest vectors, and we still must satisfy Eq. (1).

for $\tau > 0$ [MO90, EOR91].⁷ Notice that

$$\Theta_p(\tau)^{n^\dagger} = \sum_{z_1, z_2, \dots, z_n \in \mathbb{Z}} \exp(-\tau(|z_1|^p + \dots + |z_n|^p)) = \sum_{z \in \mathbb{Z}^{n^\dagger}} \exp(-\tau \|z\|_p^p).$$

In particular,

$$\Theta_p(\tau)^{n^\dagger} \geq \sum_{\substack{z \in \mathbb{Z}^{n^\dagger} \\ \|z\|_p \leq r^\dagger}} \exp(-\tau \|z\|_p^p) \geq \exp(-\tau (r^\dagger)^p) \cdot N_p(\mathbb{Z}^{n^\dagger}, r^\dagger, \mathbf{0}).$$

Rearranging and taking the infimum over τ , we see that

$$N_p(\mathbb{Z}^{n^\dagger}, r^\dagger, \mathbf{0}) \leq \inf_{\tau > 0} \exp(\tau (r^\dagger)^p) \Theta_p(\tau)^{n^\dagger}. \quad (3)$$

We can relatively easily compute this value numerically and see that it is less than 2^{n^\dagger} for $p > p_0 \approx 2.1397$. (Indeed, we will see below that there is a nearly matching lower bound in a more general context. So, Eq. (3) is quite tight.)

To prove Theorem 1.1, we can plug this very simple gadget into Khot's reduction described in Section 1.2 to reduce the SETH-hard instances of CVP_p from [BGS17] to SVP_p . To make the constant C_p as tight as we can, we exploit the structure of these SETH-hard CVP_p instances. In particular, we observe that these instances themselves actually look quite a bit like our gadget, in that they are in some sense "small perturbations" of the integer lattice with the all one-halves point as the target. (See Section 4. This is in fact quite common for the CVP_p instances resulting from hardness proofs.) This allows us to analyze the direct sum resulting from Khot's reduction very accurately in this case.

More Θ_p for $p > 2$, and Gap-ETH hardness. To extend our hardness results to all $p > 2$, we need to construct a gadget with exponentially more close vectors than short vectors for such p . We again choose our gadget lattice as \mathbb{Z}^{n^\dagger} , but we now take $\mathbf{t}^\dagger = (t, t, \dots, t) \in \mathbb{R}^{n^\dagger}$ for some $t \in (0, 1/2]$, and we take $r^\dagger = C(n^\dagger)^{1/p}$ for some constant $C > 0$.

Our previous gadget was quite convenient in that it was very easy to count the number of close vectors, but for arbitrary t and r^\dagger , it is no longer clear how to do this. Fortunately, Θ_p can be used for this purpose. In particular, we define

$$\Theta_p(\tau; t) := \sum_{z \in \mathbb{Z}} \exp(-\tau |z - t|^p).$$

By the same argument as before, we see that

$$N_p(\mathbb{Z}^{n^\dagger}, r^\dagger, \mathbf{t}^\dagger) \leq \inf_{\tau > 0} \exp(\tau (r^\dagger)^p) \Theta_p(\tau; t)^{n^\dagger} = \left(\inf_{\tau > 0} \exp(\tau C^p) \Theta_p(\tau; t) \right)^{n^\dagger}.$$

But, we need a *lower bound* on $N_p(\mathbb{Z}^{n^\dagger}, r^\dagger, \mathbf{t}^\dagger)$. To that end, we show that the above is actually quite tight. In particular,

$$N_p(\mathbb{Z}^{n^\dagger}, r^\dagger, \mathbf{t}^\dagger) = \left(\inf_{\tau > 0} \exp(\tau C^p) \Theta_p(\tau; t) \right)^{n^\dagger} \cdot 2^{-O(\sqrt{n^\dagger})}. \quad (4)$$

⁷One can think of this as a variant of Jacobi's Theta function. In particular, with $p = 2$, this is Jacobi's Theta function with a slightly different parametrization. Computer scientists might be more familiar with the closely related function $\rho_s(\mathbb{Z}) := \Theta_2(\pi/s^2)$.

I.e., Θ_p tells us the number of integer points in an ℓ_p ball up to lower-order terms. (Eq. (4) was already proven for $p = 2$ by Mazo and Odlyzko [MO90] and for all p by Elkies, Odlyzko, and Rush [EOR91]. See Section 6 for the proof.)

It follows that there exists a \mathbf{t}^\dagger and r^\dagger with exponentially more close integer vectors than short integer vectors in the ℓ_p norm if and only if there exists a $\tau > 0$ and $t \in (0, 1/2]$ such that $\Theta_p(\tau; t) > \Theta_p(\tau; 0)$. Furthermore, this holds if and only if $p > 2$. See Section 6 for the proof.

So, to prove Theorem 1.2, we start with the observation that approximating the Exact Set Cover problem is Gap-ETH-hard for some constant approximation factor $\eta < 1$. We then plug our gadget into Khot’s reduction from constant-factor-approximate Exact Set Cover to SVP_p . (This reduction uses CVP_p as an intermediate problem.) The above discussion explains why Eq. (1) is satisfied. And, like Khot, we exploit the approximation factor η to show that the number of impostors in a NO instance is much smaller than the number of good vectors in a YES instance.

Building gadgets in ℓ_2 from lattices with high kissing number. While we are not able to construct a gadget that satisfies Eq. (1) in the ℓ_2 norm, we show the existence of such a gadget under the reasonable assumption that for any n^\dagger , there exists a lattice \mathcal{L}^\dagger of rank n^\dagger with exponentially many non-zero vectors of minimal ℓ_2 norm. I.e., we show that such a gadget exists if there is a family of lattices with exponentially large kissing number. (We actually show that something potentially weaker suffices. See Theorem 5.9.)

To prove this, we show how to choose a \mathbf{t}^\dagger and $r^\dagger < \lambda_1(\mathcal{L}^\dagger)$ such that $N_p(\mathcal{L}^\dagger, r^\dagger, \mathbf{t}^\dagger) \geq 2^{\Omega(n^\dagger)}$. Indeed, we show that if we choose the vector \mathbf{t}^\dagger uniformly at random from vectors of an appropriate length, then the expected number of lattice vectors within distance r^\dagger from \mathbf{t}^\dagger is exponential in n^\dagger . And, we again exploit the fact that there is a constant-factor gap between the YES and the NO instances to show that the number of impostors in the NO instances is exponentially smaller than the number of good vectors in the YES instances.

1.4 Direction for future work

Our dream result would be an explicit 2^{Cn} -time lower bound on approximate SVP_2 for the approximation factors most relevant to cryptography (e.g., $\text{poly}(n)$) for some not-too-small explicit constant $C > 0$, under a reasonable complexity-theoretic assumption. This seems very far out of reach. There are even complexity-theoretic barriers towards achieving this result, since SVP with these approximation factors cannot be NP-hard unless the polynomial-time hierarchy collapses [AR05, Pei08]. So, any proof of something this strong would presumably have to use a non-standard reduction (e.g., a non-deterministic reduction). Nevertheless, we can still dream of such a result and take more modest steps to at least get results closer to this dream.

One obvious such step would be to extend our hardness results to the $p = 2$ case, i.e., to show that there is no $2^{o(n)}$ -time algorithm for SVP_2 under reasonable purely complexity-theoretic assumptions (as opposed to our geometric assumption). We provide one potential route towards proving this in Theorem 1.3 (or its more general version in Theorem 5.9), but this would require resolving an older open problem in the geometry of numbers. Perhaps a different approach will prove to be more fruitful?

Alternatively, one could try to improve the approximation factor given by Theorem 1.2. The currently known hardness of approximation proofs for SVP_p with large approximation factor (e.g., a large constant or superconstant) work by “boosting” the approximation factor via repeatedly taking the tensor product [Kho05, HR12]. I.e., given a family of lattices $\mathcal{L} \subset \mathbb{R}^d$ for which we know

that SVP_p is hard to approximate to within some small constant factor $\gamma > 1$, we argue that it is hard to approximate SVP_p to within a factor of γ^k on the tensor product $\mathcal{L}^{\otimes k}$ for some $k \geq 2$. Unfortunately, even a single tensor product increases the rank of the lattice quadratically. So, we cannot afford to use this technique to prove reasonable fine-grained hardness of approximation results. We therefore need a new technique.

Yet another direction would be to try to improve the constant C_p in Theorem 1.1. Perhaps the simple gadget that we use is not the best possible.

Finally, in a completely different direction, we note that Theorem 1.1 provides some additional incentive to study algorithms for SVP_p for $p \neq 2$ to improve the hidden (very large) constant in the $2^{O(n)}$ running time of existing algorithms. In particular, it would be interesting to see how close we can get to the lower bound given by Theorem 1.1.

Acknowledgments

The authors thank Huck Bennett, Vishwas Bhargav, Noam Elkies, Sasha Golovnev, Pasin Manurangsi, Priyanka Mukhopadhyay, and Oded Regev for helpful discussions. In particular, we thank Noam Elkies for pointing us to [EOR91] and Oded Regev for observing that the gadgets that we need are related to lattices with high kissing number.

2 Preliminaries

We denote column vectors $\mathbf{x} \in \mathbb{R}^d$ by bold lower-case letters. Matrices $\mathbf{B} \in \mathbb{R}^{d \times n}$ are denoted by bold upper-case letters, and we often think of a matrix as a list of column vectors. For $\mathbf{x} \in \mathbb{R}^{d_1}$, $\mathbf{y} \in \mathbb{R}^{d_2}$, we abuse notation a bit and write $(\mathbf{x}, \mathbf{y}) \in \mathbb{R}^{d_1+d_2}$ when we should technically write $(\mathbf{x}^T, \mathbf{y}^T)^T$. For $x \in \mathbb{R}$, we write

$$\exp(x) := e^x = 1 + x + x^2/2 + x^3/6 + \dots .$$

Logarithms are base e .

Throughout this paper, we consider computational problems over \mathbb{R}^d . Formally, we should specify a method of representing arbitrary real numbers, and our running times should depend in some way on the bit length of these representations and the cost of doing arithmetic in this representation. For convenience, we ignore these issues (in particular assuming that basic arithmetic operations always have unit cost), and we simply note that all of our reductions remain efficient when instantiated with any reasonable representation of \mathbb{R} . When we say that something is efficiently computable as a function of a dimension d , rank n , or cardinalities m , we mean that it is computable in time $\text{poly}(d)$, $\text{poly}(n)$, or $\text{poly}(m)$, respectively (as opposed to polynomial in the logarithm of these numbers).

2.1 Lattice problems

Definition 2.1. For any $1 \leq p \leq \infty$ and any $\gamma \geq 1$, the γ -approximate Shortest Vector Problem in the ℓ_p norm ($\text{SVP}_{p,\gamma}$) is the promise problem defined as follows. The input is a (basis for a) lattice $\mathcal{L} \subset \mathbb{R}^d$ and a length $r > 0$. It is a YES instance if $\lambda_1^{(p)}(\mathcal{L}) \leq r$ and a NO instance if $\lambda_1^{(p)}(\mathcal{L}) > \gamma r$.

Definition 2.2. For any $1 \leq p \leq \infty$ and any $\gamma \geq 1$, the γ -approximate Closest Vector Problem in the ℓ_p norm ($\text{CVP}_{p,\gamma}$) is the promise problem defined as follows. The input is a (basis for a) lattice

$\mathcal{L} \subset \mathbb{R}^d$, a target $\mathbf{t} \in \mathbb{R}^d$, and a distance $r > 0$. It is a YES instance if $\text{dist}_p(\mathbf{t}, \mathcal{L}) \leq r$ and a NO instance if $\text{dist}_p(\mathbf{t}, \mathcal{L}) > \gamma r$.

When $\gamma = 1$, we simply write SVP_p and CVP_p . We will need the following (simplified version of a) celebrated result, due to Figiel, Lindenstrauss, and Milman [FLM76].

Theorem 2.3 ([FLM76]). *For any $\varepsilon \in (0, 1)$, $1 \leq p \leq 2$, and any positive integers n and m with $m \geq n/\varepsilon^2$, there exists a linear map $f : \mathbb{R}^n \rightarrow \mathbb{R}^m$ such that for any $\mathbf{x} \in \mathbb{R}^n$,*

$$(1 - \varepsilon)\|\mathbf{x}\|_2 \leq \|f(\mathbf{x})\|_p \leq (1 + \varepsilon)\|\mathbf{x}\|_2 .$$

Regev and Rosen showed how theorems like this can be applied to obtain reductions between lattice problems in different norms [RR06]. Here, we only need the following immediate consequence of the above theorem. (The non-uniform reduction can be converted into an efficient randomized reduction and a similar result holds for $p > 2$, but we do not need this for our use case.)

Corollary 2.4. *For any constants $\gamma_1 > \gamma_2 > 1$ and $1 \leq p \leq 2$, there is an efficient rank-preserving non-uniform reduction from SVP_{2, γ_1} in dimension d to SVP_{p, γ_2} in dimension $O(d)$.*

2.2 Sparsification

A lattice vector $\mathbf{y} \in \mathcal{L}$ is *non-primitive* if $\mathbf{y} = k\mathbf{x}$ for some scalar $k > 1$ and lattice vector $\mathbf{x} \in \mathcal{L}$. Otherwise, \mathbf{y} is *primitive*. (Notice that $\mathbf{0}$ is non-primitive.) For a radius $r > 0$, we write

$$\xi_p(\mathcal{L}, r) := |\{\mathbf{y} \in \mathcal{L} : \mathbf{y} \text{ is primitive and } \|\mathbf{y}\|_p \leq r\}|/2$$

for the number of primitive lattice vectors of length at most r in the ℓ_p norm (counting $\pm\mathbf{y}$ only once). We will use the following generalization of a sparsification theorem from [Ste16] to all ℓ_p norms.

Theorem 2.5 ([Ste16, Proposition 4.2]). *There is an efficient algorithm that takes as input (a basis for) a lattice $\mathcal{L} \subset \mathbb{R}^d$ of rank n and a prime $q \geq 101$ and outputs a sublattice $\mathcal{L}' \subseteq \mathcal{L}$ of rank n such that for any radius $r < q \cdot \lambda_1^{(p)}(\mathcal{L})$ and any $1 \leq p \leq \infty$,*

$$\frac{N}{q} - \frac{N^2}{q^2} \leq \Pr[\lambda_1^{(p)}(\mathcal{L}') \leq r] \leq \frac{N}{q} ,$$

as long as $N \leq q/(20 \log q)$, where $N := \xi_p(\mathcal{L}, r)$ is the number of primitive lattice vectors of length r in the ℓ_p norm (up to the sign). Furthermore, if $r \geq q\lambda_1^{(p)}(\mathcal{L})$, then $\lambda_1^{(p)}(\mathcal{L}') \leq r$ always.

We note in passing that the algorithm works by taking a random linear equation $\langle \mathbf{z}, \mathbf{a} \rangle \equiv 0 \pmod{q}$ for uniformly random $\mathbf{z} \in \mathbb{Z}_q^n$ and setting \mathcal{L}' to be the set of lattice vectors whose coordinates in some arbitrary fixed basis satisfy this linear equation. (This idea was originally introduced by Khot.)

2.3 Fine-grained assumptions

Recall that, for integer $k \geq 2$, a k -SAT formula is the conjunction of clauses, where each clause is the disjunction of k literals. I.e., k -SAT formulas have the form $\bigwedge_{i=1}^m \bigvee_{j=1}^k b_{i,j}$, where $b_{i,j} = x_k$ or $b_{i,j} = \neg x_k$ for some boolean variable x_k .

Definition 2.6. For any $k \geq 2$, the decision problem k -SAT is defined as follows. The input is a k -SAT formula. It is a YES instance if there exists an assignment to the variables that makes the formula evaluate to true and a NO instance otherwise.

Definition 2.7. For any $k \geq 2$, the decision problem Max- k -SAT is defined as follows. The input is a k -SAT formula and an integer $S \geq 1$. It is a YES instance if there exists an assignment to the variables such that at least S of the clauses evaluate to true and a NO instance otherwise.

Notice that k -SAT is a special case of Max- k -SAT.

Impagliazzo and Paturi introduced the following celebrated and well-studied hypothesis concerning the fine-grained complexity of k -SAT [IP99].

Definition 2.8 (SETH). The (randomized) Strong Exponential Time Hypothesis ((randomized) SETH) asserts that, for every constant $\varepsilon > 0$, there exists a constant $k \geq 3$ such that there is no $2^{(1-\varepsilon)n}$ -time (randomized) algorithm for k -SAT formulas with n variables.

Definition 2.9. For $\eta \in (0, 1)$ and $k \geq 2$, the promise problem Gap- k -SAT $_\eta$ is defined as follows. The input is a k -SAT formula with m clauses. It is a YES instance if the formula is satisfiable, and it is a NO instance if the maximal number of simultaneously satisfiable clauses is strictly less than ηm .

Dinur [Din16] and Manurangsi and Raghavendra [MR16] recently introduced the following natural assumption, called Gap-ETH. We also consider a non-uniform variant.

Definition 2.10 (Gap-ETH). The (randomized) Gap-Exponential Time Hypothesis ((randomized) Gap-ETH) asserts that there exists a constant $\eta \in (0, 1)$ such that there is no (randomized) $2^{o(n)}$ -time algorithm for Gap-3-SAT $_\eta$ over n variables.

Non-uniform Gap-ETH asserts that there is no circuit family of size $2^{o(n)}$ for Gap-3-SAT $_\eta$ over n variables.

Definition 2.11. For $\eta \in (0, 1)$, $k \geq 2$, and $C \geq 2$, the promise problem Gap- k -SAT $_\eta^{\leq C}$ is defined as follows. The input is a k -SAT formula such that each variable appears in at most C clauses. It is a YES instance if the formula is satisfiable, and it is a NO instance if the maximal number of simultaneously satisfiable clauses is at most ηm .

We will need the following result due to Manurangsi and Raghavendra [MR16].

Theorem 2.12 ([MR16]). Unless Gap-ETH is false, there exist constants $\eta \in (0, 1)$ and $C \geq 2$ such that there is no $2^{o(n)}$ -time algorithm for Gap-3-SAT $_\eta^{\leq C}$.

Definition 2.13. For $\eta \in (0, 1)$, the promise problem ExactSetCover $_\eta$ is defined as follows. The input consists of sets $S_1, \dots, S_m \subseteq U$ with $|U| = k$ and a positive integer “size bound” $d \leq m$. It is a YES instance if there exist disjoint sets $S_{i_1}, \dots, S_{i_\ell}$ such that $\bigcup_j S_{i_j} = U$ for some $\ell \leq \eta d$. It is a NO instance if for every collection of (not necessarily disjoint) sets S_{i_1}, \dots, S_{i_d} , $\bigcup_j S_{i_j} \neq U$.

The following reduction is due to [Man17].

Theorem 2.14. For any constant $C' > 0$, and $\eta' \in (0, 1)$, there is a polynomial-time Karp reduction from Gap-3-SAT $_\eta^{\leq C'}$ on n variables to ExactSetCover $_\eta$ with $d := n/\eta$ and $m, k \in [n, Cn]$ for some constants $C > 1$ and $\eta \in (0, 1)$ depending only on C' and η' .

Proof. The reduction takes as input a set of clauses $\mathcal{C}_1, \mathcal{C}_2, \dots, \mathcal{C}_t$, over a set of variables x_1, \dots, x_n where each variable is in at most C' clauses. We assume without loss of generality that each variable or its negation is in at least one clause, and so $n/3 \leq t \leq C'n$.

Define U to be the set $\{\mathcal{C}_1, \dots, \mathcal{C}_t, x_1, \dots, x_n\}$. For each literal $b = x_i$ or $b = \neg x_i$ and for each set S of clauses containing b_i , we create a set $S \cup \{x_i\}$ in our instance. I.e. a literal that is contained in exactly r clauses will be contained in exactly 2^r sets. The reduction outputs YES if there exists an exact set cover of size at most n , and no, otherwise.

It is easy to see that the reduction is efficient and that $n \leq k \leq (C' + 1)n$ and $n \leq m \leq 2^{C'+1}n$. We now argue correctness.

Suppose the $\text{Gap-3-SAT}_{\eta'}^{\leq C'}$ instance is a YES instance, i.e. the formula is satisfiable. Then there exists a satisfying assignment obtained by setting $b_1 = b_2 = \dots = b_n = 1$, where each b_i is either x_i or $\neg x_i$. Thus, for all $i = 1, 2, \dots, n$, let S_i be the set of clauses containing b_i but not containing any of b_1, \dots, b_{i-1} . Clearly, each of these sets is disjoint, and $\cup_i S_i = \{\mathcal{C}_1, \dots, \mathcal{C}_t\}$, since b_1, \dots, b_n is a satisfying assignment. Thus, the sets $S_i \cup \{x_i\}$ form an exact set cover of U of size n .

Suppose, on the other hand, that the $\text{Gap-3-SAT}_{\eta'}^{\leq C'}$ instance is a NO instance, i.e. any assignment satisfies at most $\eta't$ clauses. Let S_1, \dots, S_ℓ be a set cover of U , where the sets are not necessarily disjoint. We wish to show that $\ell \geq d = n/\eta$ for some constant $\eta \in (0, 1)$.

Let $S(b)$ be the set of all clauses containing a literal b . Without loss of generality, we can assume that each set S_i equals either $S(x_j) \cup \{x_j\}$ or $S(\neg x_j) \cup \{x_j\}$ for some j . The total number of variables for which $S(x_i) \cup \{x_i\}$ and $S(\neg x_i) \cup \{x_i\}$ are both in the set cover is at most $\ell - n$. Thus, the total number of clauses covered by S_1, \dots, S_ℓ is at most $\eta't + C'(\ell - n)$, so we must have $\eta't + C'(\ell - n) \geq t$. This implies that

$$\ell \geq \frac{t}{C'}(1 - \eta') + n \geq \left(1 + \frac{1 - \eta'}{3C'}\right) \cdot n,$$

as needed. □

3 A reduction from a variant of CVP to SVP

As we discussed in Section 1.2, the “naive reduction” from $\text{CVP}_{p,\gamma'}$ to $\text{SVP}_{p,\gamma}$ simply takes a CVP instance consisting of a basis $\mathbf{B} \in \mathbb{R}^{d \times n}$ for a lattice $\mathcal{L} \subset \mathbb{R}^d$, target $\mathbf{t} \in \mathbb{R}^d$, and distance $r > 0$, and constructs the SVP instance given by the basis for \mathcal{L}' of the form

$$\mathbf{B}' := \begin{pmatrix} \mathbf{B} & -\mathbf{t} \\ 0 & s \end{pmatrix}$$

and length $r' := (r^p + s^p)^{1/p}$, where $s > 0$. Notice that, if the input is a YES instance (i.e., $\text{dist}_p(\mathbf{t}, \mathcal{L}) \leq r$), then $\lambda_1^{(p)}(\mathcal{L}') \leq r'$.

If the input instance is a NO instance (i.e., if $\text{dist}_p(\mathbf{t}, \mathcal{L}) > \gamma'r$), then we call a non-zero vector $\mathbf{y}' = (\mathbf{y} - z\mathbf{t}, zs) \in \mathcal{L}'$ *annoying* if $\|\mathbf{y}'\|_p \leq \gamma r'$. As Khot showed, we can sparsify (as in Theorem 2.5), to make this naive reduction work as long as there are significantly fewer annoying vectors than close vectors. We therefore define a rather unnatural quantity below that exactly counts the number of annoying vectors in a NO instance.

For $1 \leq p < \infty$, and $\gamma \geq 1$, a lattice $\mathcal{L} \subset \mathbb{R}^d$, target $\mathbf{t} \in \mathbb{R}^n$, and distances $r, s > 0$, we define

$$A_{r,s,\gamma}^{(p)}(\mathbf{t}, \mathcal{L}) := \sum_{z=0}^{\gamma(r^p/s^p+1)^{1/p}} N_p(\mathcal{L}, (\gamma^p r^p - (z^p - \gamma^p)s^p)^{1/p}, z\mathbf{t}) - 1.$$

Notice that $A_{r,s,\gamma}^{(p)}$ does in fact count the number of annoying vectors resulting from the above reduction (up to sign). In particular, the summand $N_p(\mathcal{L}, (\gamma^p r^p - (z^p - \gamma^p) s^p)^{1/p}, z\mathbf{t})$ is the number of vectors $\mathbf{y}' = (\mathbf{y} - z\mathbf{t}, zs) \in \mathcal{L}$ of length at most $\gamma r'$ for some fixed z .

We now define the class of CVP_p instances on which this sparsification-based reduction works.

Definition 3.1. For $1 \leq p < \infty$, $A = A(n) \geq 0$ (the number of annoying vectors), $G = G(n) \geq 1$ (the number of “good” or close vectors), and $\gamma = \gamma(n) \geq 1$ (the approximation factor), the promise problem $(A, G)\text{-CVP}_{p,\gamma}$ is defined as follows. The input is a (basis for a) lattice $\mathcal{L} \subset \mathbb{R}^d$, target $\mathbf{t} \in \mathbb{R}^d$, and distances $r, s > 0$. It is a YES instance if $N_p(\mathcal{L}, r, \mathbf{t}) \geq G$. It is a NO instance if $A_{r,s,\gamma}^{(p)}(\mathbf{t}, \mathcal{L}) \leq \alpha$.

Notice that the YES and NO instances of $(A, G)\text{-CVP}_{p,\gamma}$ are disjoint when $A < G$, since $A_{r,s,\gamma}^{(p)}(\mathbf{t}, \mathcal{L}) \geq N_p(\mathcal{L}, r, \mathbf{t})$.⁸ We drop the subscript γ from $A_{r,s,\gamma}^{(p)}(\mathbf{t}, \mathcal{L})$, $(A, G)\text{-CVP}_{p,\gamma}$ and $\text{SVP}_{p,\gamma}$ if $\gamma = 1$.

Having defined $(A, G)\text{-CVP}_{p,\gamma}$ specifically so that we can reduce it to $\text{SVP}_{p,\gamma}$, we now present the reduction from $(A, G)\text{-CVP}_{p,\gamma}$ to $\text{SVP}_{p,\gamma}$. It essentially follows from the definition of $A_{r,s,\gamma}^{(p)}$ together with Theorem 2.5.

Theorem 3.2. For $1 \leq p < \infty$ and efficiently computable $A = A(n) \geq 1$, $G = G(n) \geq 1000A(n)$, and $\gamma = \gamma(n) \geq 1$, there is a (randomized) reduction from $(A, G)\text{-CVP}_{p,\gamma}$ on a lattice with rank n in d dimensions to $\text{SVP}_{p,\gamma}$ on a lattice with rank $n + 1$ in $d + 1$ dimensions that runs in time $\text{poly}(d, \log A, \log G)$.

Proof. On input a basis \mathbf{B} for a lattice $\mathcal{L} \subset \mathbb{R}^n$, a target vector $\mathbf{t} \in \mathbb{R}^n$, and distances $r, s > 0$, the reduction does the following. Let \mathcal{L}' be the lattice generated by

$$\mathbf{B}' := \begin{pmatrix} \mathbf{B} & -\mathbf{t} \\ 0 & s \end{pmatrix},$$

as above. Let $M := 10\sqrt{AG}$. The reduction does the following $\ell := \lceil 100d \log M \rceil$ times. It finds a prime q with $10M \log M \leq q \leq 20M \log M$ and calls the procedure from Theorem 2.5, receiving as output some new lattice \mathcal{L}'' . It then calls its SVP oracle with input \mathcal{L}'' and $r' := (r^p + s^p)^{1/p}$. Finally, it outputs YES if and only if the SVP oracle returned YES more than $\delta \ell$ times, where

$$\delta := \frac{M}{20q} - \frac{M^2}{200q^2} \geq \frac{1}{100 \log M}.$$

The running time is clear, as is the fact that the reduction increases both the dimension and rank by exactly one.

If the input instance is a YES instance, then the number of vectors in \mathcal{L}' of the form $(\mathbf{v} - \mathbf{t}, s)$, where $\mathbf{v} \in \mathcal{L}$, is $N_p(\mathcal{L}, r, \mathbf{t}) \geq G$. These are primitive vectors in \mathcal{L}' and have length at most r' (and there is no pair $\pm \mathbf{y}$ in this collection of vectors). I.e., there are at least $M/10$ primitive lattice vectors in \mathcal{L}' of length at most r' , and it follows from Theorem 2.5 that

$$\Pr[\lambda_1^{(p)}(\mathcal{L}'') \leq r'] \geq 2\delta.$$

⁸We find it convenient to define the problem even for $A \geq G$ because it will not always be clear which of the two values is larger. Our results will always be vacuous when $A \geq G$. E.g., Theorem 3.2 requires $G \gg A$.

Then, by the Chernoff-Hoeffding bound, the oracle will output YES except with probability $\exp(-\Omega(d))$, as needed.

If the input instance is a NO instance, then notice the number of primitive vectors in \mathcal{L}' of length at most $\gamma r'$ is at most $A_{r,s,\gamma}^{(p)}(\mathbf{t}, \mathcal{L}) \leq A$ (up to sign). Furthermore, the total number of vectors of length at most $\gamma r'$ (including non-primitive vectors) is at most $2A_{r,s,\gamma}^{(p)}(\mathbf{t}, \mathcal{L}) + 1 \leq 2A + 1$. In particular, this implies that $\lambda_1^{(p)}(\mathcal{L}') > \gamma r' / (A + 1) > \gamma r' / q$.⁹ So, we may apply Theorem 2.5, and we have that

$$\Pr[\lambda_1^{(p)}(\mathcal{L}'') \leq \gamma r'] \leq \frac{A}{q} \leq \frac{\delta}{2}.$$

The result again follows by the Chernoff-Hoeffding bound. \square

4 SETH-hardness of this variant of CVP (and therefore SVP)

We now show that (A, G) -CVP $_p$ is SETH-hard. We first observe that the SETH-hard CVP $_p$ instances from [BGS17] “have a copy of \mathbb{Z}^n embedded in them.” This fact will allow us to compute $A_{r,s}^{(p)}$ quite accurately.

Theorem 4.1 ([BGS17]). *For any constant $k \geq 2$, the following holds for all but finitely many values of $p \geq 1$. There is a Karp reduction from Max- k -SAT on n variables to CVP $_p$ on a rank n lattice $\mathcal{L} \subset \mathbb{R}^d$ such that the resulting CVP $_p$ instance $(\mathbf{B}, \mathbf{t}, r)$ has the form*

$$\mathbf{B} = \begin{pmatrix} \Phi \\ I_n \end{pmatrix},$$

for some matrix $\Phi \in \mathbb{R}^{(d-n) \times n}$;

$$\mathbf{t} = \begin{pmatrix} t_1 \\ \vdots \\ t_{d-n} \\ 1/2 \\ \vdots \\ 1/2 \end{pmatrix},$$

for some scalars $t_i \in \mathbb{R}$; and $r = (n + 1)^{1/p} / 2$. Moreover, when $k = 2$, this holds for all $p \geq 1$, and for any $k \geq 2$, this holds for all odd integers $p \geq 1$.

We note the following easy corollary, which we can think of as either an application of Khot’s gadget reduction (as described in Section 1.2) or simply as a “padded” variant of Theorem 4.1.

Corollary 4.2. *For any constant integer $k \geq 2$, the following holds for all but finitely many values of $p \geq 1$. For any efficiently computable integer $n^\dagger = n^\dagger(n) \leq \text{poly}(n)$, there is a Karp reduction from Max- k -SAT on n variables to (A, G) -CVP $_p$ on a rank $n + n^\dagger(n)$ lattice with*

$$A := \sqrt{n + n^\dagger} \cdot N_p(\mathbb{Z}^{n+n^\dagger}, (r^p + 1)^{1/p}, \mathbf{0}) \quad \text{and} \quad G := 2^{n^\dagger},$$

⁹Suppose that $\lambda_1^{(p)}(\mathcal{L}') \leq \gamma r' / (A + 1)$, and let $\mathbf{v} \in \mathcal{L} \setminus \{\mathbf{0}\}$ with $\|\mathbf{v}\|_p \leq \gamma r' / (A + 1)$. Then, for every $z \in \{-A - 1, -A, \dots, A, A + 1\}$, $z\mathbf{v}$ is a distinct lattice vector with $\|z\mathbf{v}\|_p \leq \gamma r'$, which contradicts the fact that there are at most $2A + 1$ such vectors.

where $r := (n + n^\dagger + 1)^{1/p}/2$ and $\widehat{\mathbf{t}} := (1/2, \dots, 1/2) \in \mathbb{R}^{n+n^\dagger}$. Moreover, when $k = 2$, this holds for all $p \geq 1$, and for any $k \geq 2$, this holds for all odd integers $p \geq 1$.

Proof. It suffices to show how to convert the CVP_p instance from Theorem 4.1 into a (A, G) - CVP_p instance. To do this, we simply append the matrix I_{n^\dagger} to the basis and $\mathbf{t}^\dagger := (1/2, \dots, 1/2) \in \mathbb{R}^{n^\dagger}$ to the target. I.e., we construct,

$$\mathbf{B} := \begin{pmatrix} \Phi & 0 \\ I_n & 0 \\ 0 & I_{n^\dagger} \end{pmatrix},$$

where $\Phi \in \mathbb{R}^{(d-n-n^\dagger) \times n}$ is as in Theorem 4.1, and

$$\mathbf{t} := \begin{pmatrix} t_1 \\ \vdots \\ t_{d-n-n^\dagger} \\ 1/2 \\ \vdots \\ 1/2 \end{pmatrix} \in \mathbb{R}^d,$$

where $t_i \in \mathbb{R}$ are as in Theorem 4.1. We simply take $s = 1$.

Let $\mathcal{L} := \mathcal{L}(\mathbf{B}) \subset \mathbb{R}^d$. Let $\mathcal{L}' \subset \mathbb{R}^{d-n^\dagger}$ be the lattice generated by the basis without the additional identity matrix, and let $\mathbf{t}' \in \mathbb{R}^{d-n^\dagger}$ be the target without the additional coordinates. Notice that vectors in \mathcal{L} have the form $\mathbf{y} := (\mathbf{y}', \mathbf{z})$, where $\mathbf{y}' \in \mathcal{L}'$ and $\mathbf{z} \in \mathbb{Z}^{n^\dagger}$. In particular,

$$\|\mathbf{y} - \mathbf{t}\|_p^p = \|\mathbf{y}' - \mathbf{t}'\|_p^p + \|\mathbf{z} - \mathbf{t}^\dagger\|_p^p \geq \|\mathbf{y}' - \mathbf{t}'\|_p^p + n^\dagger/2^p.$$

So, if the input Max- k -SAT instance is a YES instance, then $\text{dist}_p(\mathbf{t}', \mathcal{L}') \leq (n+1)^{1/p}/2$, and so there are at least 2^{n^\dagger} distinct vectors in $\mathbf{y} \in \mathcal{L}$ such that $\|\mathbf{y} - \mathbf{t}\|_p \leq r$. (In particular, all vectors of the form $(\mathbf{y}', \mathbf{z})$ with $\mathbf{z} \in \{0, 1\}^{n^\dagger}$ and $\|\mathbf{y}' - \mathbf{t}'\|_p \leq (n+1)^{1/p}/2$ have this property.) Thus, the resulting (A, G) - CVP_p instance is a YES instance.

On the other hand, if the input Max- k -SAT instance is a NO instance, then we have that $\text{dist}_p(\mathbf{t}', \mathcal{L}') > (n+1)^{1/p}/2$. I.e., $N_p(\mathcal{L}, r, \mathbf{t}) = 0$. Therefore,

$$\begin{aligned} A_{r,1}^{(p)}(\mathbf{t}, \mathcal{L}) &= \sum_{z=0}^{(r^p+1)^{1/p}} N_p(\mathcal{L}, (r^p - z^p + 1)^{1/p}, z\mathbf{t}) - 1 \\ &\leq N_p(\mathbb{Z}^{n+n^\dagger}, (r^p + 1)^{1/p}, \mathbf{0}) - 1 + N_p(\mathcal{L}, r, \mathbf{t}) + \sum_{z=2}^{(r^p+1)^{1/p}} N_p(\mathbb{Z}^{n+n^\dagger}, (r^p - z^p + 1)^{1/p}, z\widehat{\mathbf{t}}) \\ &\leq r \cdot N_p(\mathbb{Z}^{n+n^\dagger}, (r^p + 1)^{1/p}, \mathbf{0}), \end{aligned}$$

where we have used the fact that $N_p(\mathbb{Z}^{n+n^\dagger}, (r^p - z^p + 1)^{1/p}, z\widehat{\mathbf{t}}) = 0$ for odd $z \geq 3$ and

$$N_p(\mathbb{Z}^{n+n^\dagger}, (r^p - z^p + 1)^{1/p}, z\widehat{\mathbf{t}}) = N_p(\mathbb{Z}^{n+n^\dagger}, (r^p - z^p + 1)^{1/p}, \mathbf{0}) \leq N_p(\mathbb{Z}^{n+n^\dagger}, (r^p + 1)^{1/p}, \mathbf{0})$$

for even z . Thus, the resulting (A, G) - CVP_p instance is a NO instance. \square

In the next section, we show that $A \ll G$ if and only if $p > p_0 \approx 2.13972$.

4.1 Finishing the proof

It remains to bound the number of integer points in an ℓ_p ball centered at the origin. As in Section 1.3, for $1 \leq p < \infty$ and $\tau > 0$, we define

$$\Theta_p(\tau) := \sum_{z \in \mathbb{Z}} \exp(-\tau|z|^p).$$

Notice that we can write $\Theta_p(\tau)^n$ as a summation over \mathbb{Z}^n ,

$$\Theta_p(\tau)^n = \sum_{z \in \mathbb{Z}^n} \exp(-\tau\|z\|_p^p).$$

In particular, for any radius $r > 0$ and $\tau > 0$, we have

$$\Theta_p(\tau)^n \geq \sum_{\substack{z \in \mathbb{Z}^n \\ \|z\|_p \leq r}} \exp(-\tau\|z\|_p^p) \geq \exp(-\tau r^p) N_p(\mathbb{Z}^n, r, \mathbf{0}).$$

Rearranging and taking the minimum over all $\tau > 0$, we see that

$$N_p(\mathbb{Z}^n, r, \mathbf{0}) \leq \min_{\tau > 0} \exp(\tau r^p) \Theta_p(\tau)^n. \quad (5)$$

(It is easy to see that the minimum is in fact achieved.) In Section 6, we will show that this upper bound is actually quite tight (even in the more general settings of shifted balls here). Here, we use this bound to prove the following theorem.

Theorem 4.3. *For any constant integer $k \geq 2$, the following holds for all but finitely many constants $p > p_0$. There is an efficient randomized reduction from Max- k -SAT on n variables to SVP $_p$ on a lattice of rank $\lceil C_p n + \log^2 n \rceil$, where*

$$C_p := \frac{1}{1 - \log_2 W_p} \quad \text{and} \quad W_p := \min_{\tau > 0} \exp(\tau/2^p) \Theta_p(\tau).$$

Here, $p_0 \approx 2.13972$ is the unique solution to the equation $W_{p_0} = 2$. Moreover, when $k = 2$, this holds for all $p > p_0$, and for any $k \geq 2$, this holds for all odd integers $p \geq 3$.

In particular, for every $\varepsilon > 0$, for all but finitely many $p > p_0$ (including all odd integers $p \geq 3$) there is no $2^{n/(C_n + \varepsilon)}$ -time algorithm for CVP $_p$ unless SETH is false.

Proof. Let $n^\dagger := \lceil C_p n + \log^2 n \rceil - n - 1$. Then, by Corollary 4.2 together with Theorem 3.2, it suffices to show that

$$N_p(\mathbb{Z}^{n+n^\dagger}, \hat{r}, \mathbf{0}) \leq 2^{n^\dagger - 10} / \sqrt{n + n^\dagger}$$

for sufficiently large n , where $\hat{r} := (n + n^\dagger + 2^{p+1})^{1/p}/2$.

Let $\tau_p > 0$ such that $W_p := \exp(\tau_p/2^p) \Theta_p(\tau_p)$. (One can check that τ_p exists, e.g., by differentiating $\exp(\tau/2^p) \Theta_p(\tau)$ with respect to τ .) By Eq. (5), we have

$$N_p(\mathbb{Z}^{n+n^\dagger}, \hat{r}, \mathbf{0}) \leq \exp(\tau_p \hat{r}^p) \Theta_p(\tau_p)^{n+n^\dagger} \leq \exp(2\tau_p) \cdot W_p^{n+n^\dagger} \leq \exp(2\tau_p + 1) \cdot 2^{n^\dagger - \log^2 n} \cdot W_p^{\log^2 n}.$$

The result follows by noting that $W_p < 2$ so that for sufficiently large n , $(2/W_p)^{\log^2 n} \geq \exp(2\tau_p + 20) \sqrt{n + n^\dagger}$. \square

Finally, we compute a simple bound on C_p . In particular, this implies the claim that $C_p \rightarrow 1$ as $p \rightarrow \infty$.

Claim 4.4. *For any $p \geq 3$, we have*

$$C_p < \frac{1}{1 - 2^{-p}(p + \log_2(3e))} .$$

Proof. We have

$$W_p := \min_{\tau > 0} \exp(\tau/2^p) \Theta_p(\tau) = \min_{x > 1} x^{2^{-p}} \cdot (1 + 2x^{-1} + 2x^{-2^p} + 2x^{-4^p} + \dots) .$$

Fix $x := 3 \cdot 2^p$. Then, we have

$$W_p \leq x^{2^{-p}} \cdot (1 + 2x^{-1} + 2x^{-2^p} + 2x^{-4^p} + \dots) < x^{2^{-p}} \cdot (1 + 3x^{-1}) = x^{2^{-p}} \cdot (1 + 2^{-p}) .$$

Therefore,

$$\log_2 W_p < 2^{-p} \log_2 x + \log_2(1 + 2^{-p}) < 2^{-p}(p + \log_2(3e)) ,$$

so that

$$C_p = \frac{1}{1 - \log_2 W_p} < \frac{1}{1 - 2^{-p}(p + \log_2(3e))} ,$$

as needed. □

5 Gap-ETH-hardness via a gadget

The following theorem shows how to use a certain gadget lattice $\mathcal{L}^\dagger \subset \mathbb{R}^{d^\dagger}$ and target $\mathbf{t}^\dagger \in \mathbb{R}^{d^\dagger}$ with certain properties to reduce $\text{ExactSetCover}_\eta$ to $(A, G)\text{-CVP}_p$. In particular, the ratio of the number of “close points” in \mathcal{L}^\dagger to \mathbf{t}^\dagger compared to the number of “short points” in \mathcal{L}^\dagger should be larger than the total number of short points in \mathbb{Z}^m . (For $p > 2$, we construct such a gadget in Section 6 that will be sufficient to prove the Gap-ETH-hardness of SVP_p . For $1 \leq p \leq 2$, we do not know of such a gadget, but in Section 5.2, we will show that one exists under plausible conjectures.)

For $1 \leq p \leq \infty$, a lattice $\mathcal{L} \subset \mathbb{R}^n$, and radius $r > 0$, we define the maximal density at radius r of \mathcal{L} as

$$D_p(\mathcal{L}, r) := \max_{\mathbf{t} \in \mathbb{R}^n} N_p(\mathcal{L}, r, \mathbf{t}) .$$

We observe the trivial fact that $D_p(\mathcal{L}, r)$ is non-decreasing in r .

Theorem 5.1. *For any $p \geq 1$, constant $\eta \in (0, 1)$ and $\gamma \geq 1$, there is a Karp reduction from $\text{ExactSetCover}_\eta$ on m sets with size bound d to $(A, G)\text{-CVP}_{p, \gamma}$ on a lattice of rank $m + n^\dagger$ that requires as auxiliary input a gadget consisting of a lattice $\mathcal{L}^\dagger \subset \mathbb{R}^{d^\dagger}$ of rank n^\dagger , target $\mathbf{t}^\dagger \in \mathbb{R}^{d^\dagger}$, and distances $r \geq d^{1/p}$ and $s > 0$ for any*

$$A \geq N_p(\mathbb{Z}^m, r^*, \mathbf{0}) \cdot (N_p(\mathcal{L}^\dagger, r^*, \mathbf{0}) + (r^*/s) \cdot D_p(\mathcal{L}^\dagger, ((r^*)^p - d)^{1/p})) ,$$

and $G \leq N_p(\mathcal{L}^\dagger, (r^p - \eta d)^{1/p}, \mathbf{t}^\dagger)$, where $r^* := \gamma(r^p + s^p)^{1/p}$.

Proof. The reduction takes as input $S_1, \dots, S_m \subseteq U = \{u_1, \dots, u_k\}$ with $\bigcup S_i = U$, size bound $d \leq m$, a lattice $\mathcal{L}^\dagger \subset \mathbb{R}^{d^\dagger}$ with basis \mathbf{B}^\dagger , target $\mathbf{t}^\dagger \in \mathbb{R}^{d^\dagger}$, and distances $r, s > 0$ and behaves as follows. We first define the intermediate CVP instance consisting of the lattice $\widehat{\mathcal{L}} := \mathcal{L}(\widehat{\mathbf{B}}) \subset \mathbb{R}^{m+k}$ and target $\widehat{\mathbf{t}} \in \mathbb{R}^{m+k}$ given by

$$\widehat{\mathbf{B}} := (\widehat{\mathbf{b}}_1, \dots, \widehat{\mathbf{b}}_m) = \begin{array}{c} \begin{array}{c} u_1 \\ \vdots \\ u_i \\ \vdots \\ u_k \end{array} \begin{array}{|c|} \hline \begin{array}{c} S_1 \cdots S_j \quad \cdots \quad S_m \\ \vdots \\ \vdots \\ \cdots \quad r^* \quad \text{if } u_i \in S_j \\ \vdots \\ 0 \quad \text{otherwise} \end{array} \\ \hline \begin{array}{c} 1 \\ \quad \ddots \\ \quad \quad \ddots \\ \quad \quad \quad \ddots \\ \quad \quad \quad \quad 1 \end{array} \end{array} \end{array} \quad \begin{array}{|c|} \hline \begin{array}{c} r^* \\ r^* \\ \vdots \\ \vdots \\ \vdots \\ r^* \end{array} \\ \hline \end{array} = \widehat{\mathbf{t}} \quad .$$

The reduction then constructs the (A, G) -CVP instance consisting of a lattice $\mathcal{L} := \mathcal{L}(\mathbf{B}) \subset \mathbb{R}^{m+k+d^\dagger}$, $\mathbf{t} \in \mathbb{R}^{m+k+d^\dagger}$, and the distances r, s , where

$$\mathbf{B} := \begin{pmatrix} \widehat{\mathbf{B}} & \mathbf{0} \\ \mathbf{0} & \mathbf{B}^\dagger \end{pmatrix},$$

and

$$\mathbf{t} := \begin{pmatrix} \widehat{\mathbf{t}} \\ \mathbf{t}^\dagger \end{pmatrix}.$$

The reduction then outputs YES if the (A, G) -CVP $_p$ oracle on input $(\mathbf{B}, \mathbf{t}, r, s)$ outputs YES, and NO, otherwise.

Suppose the input is a YES instance, and let i_1, \dots, i_j with $j \leq \eta d$ such that the S_{i_ℓ} are disjoint with $\bigcup S_{i_\ell} = U$. Let $\widehat{\mathbf{v}} := \widehat{\mathbf{b}}_{i_1} + \dots + \widehat{\mathbf{b}}_{i_j}$ be the corresponding vector in $\widehat{\mathcal{L}}$. Notice that $\|\widehat{\mathbf{v}} - \widehat{\mathbf{t}}\|_p^p = j \leq \eta d$. Therefore, for any $\mathbf{v}^\dagger \in \mathcal{L}^\dagger$ with $\|\mathbf{v}^\dagger\|_p^p \leq r^p - \eta d$, the vector $\mathbf{v} := (\widehat{\mathbf{v}}, \mathbf{v}^\dagger)$ is in \mathcal{L} with $\|\mathbf{v}\|_p \leq r$. So,

$$N_p(\mathcal{L}, r, \mathbf{t}) \geq N_p(\mathcal{L}^\dagger, (r^p - \eta d)^{1/p}, \mathbf{t}^\dagger) \geq G,$$

as needed.

Now, suppose the input is a NO instance. Then, we wish to show that

$$\sum_{\ell=0}^{\gamma(r^p/s^p+1)^{1/p}} N_p(\mathcal{L}, (\ell^p - \gamma^p)s^p)^{1/p}, \ell \cdot \mathbf{t} \leq A.$$

We first bound the $\ell = 0$ term as

$$N_p(\mathcal{L}, r^*) \leq N_p(\mathbb{Z}^m \oplus \mathcal{L}^\dagger, r^*, \mathbf{0}) \leq N_p(\mathbb{Z}^m, r^*, \mathbf{0}) \cdot N_p(\mathcal{L}^\dagger, r^*, \mathbf{0}).$$

Turning to the $\ell \geq 1$ terms, let $\mathbf{v} = (\widehat{\mathbf{v}} - \ell \cdot \widehat{\mathbf{t}}, \mathbf{v}^\dagger - \ell \cdot \mathbf{t}^\dagger) \in \mathcal{L}$ with $\ell \geq 1$, and suppose that $\|\mathbf{v} - \ell \cdot \mathbf{t}\|_p^p \leq \gamma^p r^p - (\ell^p - \gamma^p) s^p$. Let $\widehat{\mathbf{v}} = \sum_{i=1}^m z_i \widehat{\mathbf{b}}_i$. First, notice that $\|(z_1, \dots, z_m)\|_p^p \leq \gamma^p r^p - (\ell^p - \gamma^p) s^p \leq (r^*)^p$ because of the ‘‘identity matrix gadget’’ at the bottom of $\widehat{\mathbf{B}}$. Furthermore, if there are at most d non-zero z_i 's, z_{i_1}, \dots, z_{i_j} , then since the input is a NO instance, there must be an element $u \in U$ not contained in $S_{i_1} \cup \dots \cup S_{i_j}$. Thus, the u th coordinate of $\widehat{\mathbf{v}} - \ell \cdot \widehat{\mathbf{t}}$ is at least r^* , and we cannot possibly have $\|\mathbf{v}\|_p^p \leq \gamma^p r^p - (\ell^p - \gamma^p) s^p$.

So, it must be the case that there are at least d non-zero z_i . In particular, $\|(z_1, \dots, z_m)\|_p^p \geq d$, so we must have $\|\mathbf{v}^\dagger - \ell \cdot \mathbf{t}^\dagger\|_p^p \leq \gamma^p r^p - d - (\ell^p - \gamma^p) s^p < (r^*)^p - d$. Therefore,

$$\begin{aligned} N_p(\mathcal{L}, (\gamma^p r^p - (\ell^p - \gamma^p) s^p)^{1/p}, \ell \cdot \mathbf{t}) &\leq N_p(\mathbb{Z}^m, r^*, \mathbf{0}) \cdot N_p(\mathcal{L}^\dagger, ((r^*)^p - d)^{1/p}, \ell \cdot \widehat{\mathbf{t}}) \\ &\leq N_p(\mathbb{Z}^m, r^*, \mathbf{0}) \cdot D_p(\mathcal{L}^\dagger, ((r^*)^p - d)^{1/p}). \end{aligned}$$

The result follows by noting that the total contribution of the terms with $\ell \geq 1$ is at most r^*/s times this quantity (since there are at most r^*/s such terms). \square

Our goal is now to construct a useful gadget $\mathcal{L}^\dagger, \mathbf{t}^\dagger, r^\dagger$ for Theorem 5.1. In particular we wish to find a gadget with $\text{rank}(\mathcal{L}^\dagger) = O(n)$ and $G \gg A$. In the following rather technical lemma, we show that such a gadget exists if there exists any lattice with ‘‘an exponential gap between the number of close vectors and the number of short vectors.’’

Lemma 5.2. *Suppose that for some constants $p \geq 1$, $\varepsilon \in (0, 1/2)$, and $\beta > 1$, the following holds. For every sufficiently large integer n , there exists a lattice $\mathcal{L}_n \subset \mathbb{R}^{d_n}$ with $\text{rank}(\mathcal{L}_n) = n$ and $d_n \leq \text{poly}(n)$, target $\mathbf{t}_n \in \mathbb{R}^{d_n}$, and radius $r_n > 0$ such that*

$$N_p(\mathcal{L}_n, (1 - \varepsilon)^{1/p} \cdot r_n, \mathbf{t}_n) \geq \beta^n \cdot N_p(\mathcal{L}_n, r_n, \mathbf{0}). \quad (6)$$

Then, for any constants $C \geq 1$ and $\eta \in (2\varepsilon^2, 1)$, there exist constants $\gamma > 1$, $C^\dagger > 0$ such that the following holds.

1. *For any sufficiently large integers m and d satisfying $m/C \leq d \leq Cd$, there exist distances $r, s > 0$ and $\mathbf{t}^\dagger \in \mathbb{R}^{d_{n^\dagger}}$ for $n^\dagger := \lceil C^\dagger m \rceil$ such that*

$$N_p(\mathbb{Z}^m, r^*, \mathbf{0}) \cdot (N_p(\mathcal{L}^\dagger, r^*, \mathbf{0}) + (r^*/s) \cdot D_p(\mathcal{L}^\dagger, ((r^*)^p - d)^{1/p})) < 2^{-m} \cdot N_p(\mathcal{L}^\dagger, (r^p - \eta d)^{1/p}, \mathbf{t}^\dagger), \quad (7)$$

where $r^ := \gamma(r^p + s^p)^{1/p}$ and $\mathcal{L}^\dagger := \alpha \mathcal{L}_{n^\dagger}$ for some $\alpha > 0$.*

2. *If we also have*

$$N_p(\mathcal{L}_n, (1 - \varepsilon)^{1/p} r_n, \mathbf{t}_n) \geq \beta^n \cdot D_p(\mathcal{L}_n, (1 - \varepsilon/\sqrt{\eta})^{1/p} r_n), \quad (8)$$

then we can take $r = (1 - \varepsilon/2)^{1/p} \alpha r_{n^\dagger}$, $\mathbf{t}^\dagger = \alpha \mathbf{t}_{n^\dagger}$, $s = 1$, and $\alpha = (2\eta d / (\varepsilon r_{n^\dagger}^p))^{1/p}$.

Proof. We prove Item 2 first. We take $\mathcal{L}^\dagger = \alpha \mathcal{L}_{n^\dagger}$, $r = (1 - \varepsilon/2)^{1/p} \alpha r_{n^\dagger}$, $\mathbf{t}^\dagger = \alpha \mathbf{t}_{n^\dagger}$, $s = 1$, and $\alpha = (2\eta d / (\varepsilon r_{n^\dagger}^p))^{1/p}$, as above. Notice that $r^p = 2(1 - \varepsilon/2)\eta d / \varepsilon$. We choose

$$\gamma^p = 1 + \min\{1/100, (1/\sqrt{\eta} - 1)^2/2\} \cdot \varepsilon > 1.$$

We assume without loss of generality that $\eta d \geq 10$, and $\varepsilon d(1 - \sqrt{\eta})^2 \geq 2\gamma^p$

Notice that $r^* = O(m^{1/p})$. Thus, there is some constant \tilde{C} such that

$$N_p(\mathbb{Z}^m, r^*, \mathbf{0}) \leq \tilde{C}^m .$$

(This follows, e.g., from Eq. (3).) Furthermore, notice that

$$(r^*)^p = \gamma^p(r^p + 1) \leq ((1 - \varepsilon/2)\alpha^p r_{n^\dagger}^p + 1) \cdot (1 + \varepsilon/100) \leq \alpha^p r_{n^\dagger}^p ,$$

where the last inequality uses the assumption that $\varepsilon\alpha^p r_{n^\dagger}^p/2 = \eta d \geq 10$. Therefore, by Eq. (6),

$$N_p(\mathcal{L}^\dagger, r^*, \mathbf{0}) \leq \beta^{-C^\dagger m} N_p(\mathcal{L}_{n^\dagger}, (1 - \varepsilon)^{1/p} \cdot r_{n^\dagger}, \mathbf{t}_{n^\dagger}) = \beta^{-C^\dagger m} N_p(\mathcal{L}^\dagger, (r^p - \eta d)^{1/p}, \mathbf{t}^\dagger) ,$$

where the last equality uses the fact that $\alpha^p(1 - \varepsilon)r_{n^\dagger}^p = r^p \cdot (1 - \varepsilon)/(1 - \varepsilon/2) = r^p - \eta d$. Finally, we note that

$$\begin{aligned} (r^*)^p - d &\leq 2\eta d \cdot \frac{(1 - \varepsilon/2) \cdot (1 + (1/\sqrt{\eta} - 1)^2 \cdot \varepsilon/2)}{\varepsilon} - d + \gamma^p \\ &= 2\eta d \cdot \frac{(1 - \varepsilon/\sqrt{\eta})}{\varepsilon} - \frac{\varepsilon d}{2} \cdot (1 - \sqrt{\eta})^2 + \gamma^p \\ &\leq 2\eta d \cdot \frac{(1 - \varepsilon/\sqrt{\eta})}{\varepsilon} \\ &= (1 - \varepsilon/\sqrt{\eta}) \cdot \alpha^p r_{n^\dagger}^p . \end{aligned}$$

Therefore, applying Eq. (8), we have

$$D_p(\mathcal{L}^\dagger, ((r^*)^p - d)^{1/p}) \leq D_p(\mathcal{L}_{n^\dagger}, (1 - \varepsilon/\sqrt{\eta})^{1/p} r_{n^\dagger}) \leq \beta^{-C^\dagger m} N_p(\mathcal{L}_{n^\dagger}, (1 - \varepsilon)r_{n^\dagger}, \mathbf{t}_{n^\dagger}) .$$

Putting everything together, we see that it suffices to take $C^\dagger > 0$ to be a large enough constant so that $\tilde{C}^m \beta^{-C^\dagger m} < 2^{-m}/(1 + r^*/s)$.

We now move to proving Item 1. By Item 2, it suffices to find some new family of targets $\mathbf{t}'_1, \mathbf{t}'_2, \dots$, and radii r'_1, r'_2, \dots , satisfying Eqs. (6) and (8), perhaps for some new constants $\varepsilon' \in (0, 1)$ and $\beta' > 1$. We would of course like to simply take $\mathbf{t}'_n = \mathbf{t}_n$ and $r'_n = r_n$, but we have to worry about the possibility that $D_p(\mathcal{L}_n, (1 - \varepsilon/\sqrt{\eta})r_n)$ is not much smaller than $N_p(\mathcal{L}_n, (1 - \varepsilon)^{1/p}r_n, \mathbf{t}_n)$. Intuitively, this can only happen if either (1) $D_p(\mathcal{L}_n, (1 - \varepsilon)^{1/p}r_n) \gg N_p(\mathcal{L}_n, (1 - \varepsilon)^{1/p}r_n, \mathbf{t}_n)$, in which case we should clearly replace \mathbf{t}_n with \mathbf{t}'_n such that $N_p(\mathcal{L}_n, (1 - \varepsilon)^{1/p}r_n, \mathbf{t}'_n) = D_p(\mathcal{L}_n, (1 - \varepsilon)^{1/p}r_n)$; or (2) $D_p(\mathcal{L}_n, (1 - \varepsilon)^{1/p}r'_n) \approx D_p(\mathcal{L}_n, (1 - \varepsilon)^{1/p}r_n)$, for some $r'_n < r_n$, in which case we should clearly replace r_n with r'_n . So, intuitively, as long as \mathbf{t}_n and r_n are “reasonable,” we should be done.

To make this rigorous, let $N_n := N_p(\mathcal{L}_n, r_n, \mathbf{0})$, $\varepsilon_0 := \varepsilon$, and $r_n^{(-1)} = r_n$. For $i = 1, \dots, \ell + 1$, let $\varepsilon_i := \varepsilon_{i-1}/\sqrt{\eta}$ and $r_n^{(i)} := (1 - \varepsilon_{i-1}) \cdot r_n^{(i-1)}$. Here, ℓ is the largest integer such that $r_n^{(\ell)} > r_n/2$. In particular, ℓ is a constant. Let $N_n^{(i)} := D_p(\mathcal{L}_n, r_n^{(i)})$. It follows that $N_n^{(\ell+1)} \leq N_n$, since if there were $N_n + 1$ distinct lattice vectors $\mathbf{v}_1, \dots, \mathbf{v}_{N_n+1}$ at distance $r_n/2$ from any vector \mathbf{t} then, by triangle inequality, there would necessary be $N_n + 1$ distinct lattice vectors $\mathbf{v}_i - \mathbf{v}_1$ for $i = 1, \dots, N_n + 1$ of length at most r_n , contradicting the definition of N_n .

By Eq. (6), we have $N_n^{(0)} \geq \beta^{n^\dagger} \cdot N_n$. Thus, there exists an $i \in \{0, \dots, \ell\}$ such that

$$\frac{N_n^{(i)}}{N_n^{(i+1)}} \geq (\beta')^n ,$$

and

$$\frac{N_n^{(i)}}{N_n} \geq (\beta')^n,$$

where $\beta' := \beta^{1/(\ell+1)} > 1$. Fix such an i . Then, taking $\varepsilon' := \varepsilon_{i-1}$, $r'_n := r_n^{(i-1)}$, and \mathbf{t}'_n to be any vector satisfying $N_p(\mathcal{L}, r_n^{(i)}, \mathbf{t}'_n) = D_p(\mathcal{L}, r_n^{(i)})$ gives the result. \square

Putting everything together, we get the following conditional result.

Corollary 5.3. *Suppose that for some constants $p \geq 1$, $\varepsilon \in (0, 1/2)$, and $\beta > 1$, the following holds. For every sufficiently large integer n , there exists a lattice $\mathcal{L}_n \subset \mathbb{R}^{d_n}$ with $\text{rank}(\mathcal{L}_n) = n$ and $d_n \leq \text{poly}(n)$, target $\mathbf{t}_n \in \mathbb{R}^{d_n}$, and radius $r_n > 0$ such that*

$$N_p(\mathcal{L}_n, (1 - \varepsilon)^{1/p} \cdot r_n, \mathbf{t}_n) \geq \beta^n \cdot N_p(\mathcal{L}_n, r_n, \mathbf{0}). \quad (9)$$

Then for any constant $C \geq 1$ and $\eta \in (0, 1)$, there is a constant $\gamma > 1$, such that there is an efficient (non-uniform) reduction from $\text{Gap-3-SAT}_{\frac{1}{\eta}}^{\leq C}$ on n variables to $\text{SVP}_{p, \gamma}$ on a lattice of rank $O(n)$ and dimension $O(n) + d_{O(n)}$, for some constant $\gamma > 1$.

Furthermore, if \mathcal{L}_n , \mathbf{t}_n , and r_n are computable in time $\text{poly}(n)$ and for any constant $\delta \in (\varepsilon, 1)$, there exists a $\beta' > 1$ such that

$$N_p(\mathcal{L}_n, (1 - \varepsilon)^{1/p} r_n, \mathbf{t}_n) \geq (\beta')^n \cdot D_p(\mathcal{L}_n, (1 - \varepsilon/\delta)^{1/p} r_n), \quad (10)$$

then we may replace the non-uniform reduction with a randomized reduction.

Proof. By Theorem 2.14, it suffices to show a reduction from $\text{ExactSetCover}_{\eta'}$ with $d = n/\eta'$ and $m \in [n, C'n]$ for some constants $C' \geq 1$ and $\eta' \in (0, 1)$. By Theorem 3.2, it suffices to reduce this to $(A, G)\text{-CVP}_{p, \gamma}$ on a rank $O(n)$ lattice with $A \leq 2^{-m}G$. By Theorem 5.1, such a reduction exists, but it requires a gadget a lattice of rank $O(n)$ satisfying Eq. (7) as auxiliary input.

By Item 1 of Lemma 5.2, such a gadget exists for sufficiently large n if Eq. (9) holds. Therefore, we get a non-uniform reduction that uses this gadget as advice.

To prove the ‘‘furthermore,’’ it suffices to show that the additional assumptions are sufficient to make this gadget efficiently computable. Indeed, by Item 2 of Lemma 5.2, if Eq. (10) holds with $\delta = 1/\sqrt{\eta'}$, then we may take the gadget to be a scaling of \mathcal{L}_{n^\dagger} , \mathbf{t}_{n^\dagger} , and r_{n^\dagger} for an appropriate choice of $n^\dagger = O(n)$. The scaling and n^\dagger are clearly efficiently computable. So, if both Eqs. (9) and (10) hold and the family is efficiently computable, then the advice is indeed efficiently computable, as needed. \square

5.1 Gap-ETH Hardness of SVP_p for $p > 2$

In order to prove Gap-ETH hardness of SVP_p , we will need the following lemma. The proof can be found in Section 6.

Lemma 5.4. *For any constants $p > 2$ and $\delta \in (0, 1)$, there exist (efficiently computable) constants $\beta > 1$, $t \in (0, 1/2]$, $C_r > 0$, and $\varepsilon \in (0, \delta)$, such that for any positive integer n ,*

$$N_p(\mathbb{Z}^n, (1 - \varepsilon)^{1/p} \cdot r, \mathbf{t}) \geq \beta^n \cdot N_p(\mathcal{L}, r, \mathbf{0}),$$

where $r := C_r n^{1/p}$ and $\mathbf{t} = (t, t, \dots, t) \in \mathbb{R}^n$, and

$$N_p(\mathbb{Z}^n, (1 - \varepsilon)^{1/p} r, \mathbf{t}) \geq \beta^n \cdot D_p(\mathbb{Z}^n, (1 - \varepsilon/\delta)^{1/p} r).$$

Corollary 5.5. *For any constants $p > 2$ and $C' \geq 1$, there exists a constant $\gamma > 1$ such that there is an efficient (randomized) reduction from $\text{Gap-3-SAT}_{\eta'}^{\leq C'}$ on n variables to $\text{SVP}_{p,\gamma}$ on a lattice of rank and dimension $O(n)$*

In particular, for some constant $\gamma > 1$, there is no $2^{o(n)}$ -time algorithm for $\text{SVP}_{p,\gamma}$ unless (randomized) Gap-ETH is false.

Proof. Simply combine Corollary 5.3 with Lemma 5.4, with $\mathcal{L}_n := \mathbb{Z}^n$, $r_n := C_r n^{1/p}$, and $\mathbf{t}_n := (t, t, \dots, t) \in \mathbb{R}^n$. \square

5.2 Gap-ETH-hardness of SVP_2 under a certain assumption

We now show that, at least in the special case of the ℓ_2 norm, we can simplify Corollary 5.3 a bit further to get a relatively clean conditional hardness result. (See Theorem 5.9 below.) We focus on the ℓ_2 norm because (1) we obtain the simplest statement in this case; and (2) hardness in the ℓ_2 norm implies hardness in other norms. But, we mention in passing that qualitatively similar results hold for all ℓ_p norms.

Lemma 5.6. *For any integer $n \geq 100$, let $\mathbf{u} \in \mathbb{R}^n$ be a fixed vector, and let $\mathbf{t} \in \mathbb{R}^n$ be a uniformly random unit vector in the ℓ_2 norm. Then for any $0 < \theta_1 < \theta_2 < \pi$, the probability that the angle between \mathbf{u} and \mathbf{t} is between θ_1 and θ_2 is at least*

$$\int_{\theta_1}^{\theta_2} \sin^{n-2} \theta \, d\theta .$$

Proof. The probability density function of the angle θ is proportional to $\sin^{n-2} \theta$ [CFJ13]. So, it suffices to show that the constant of proportionality is at least one. I.e., it suffices to show that the integral of this from 0 to π is at most one. Indeed,

$$\begin{aligned} \int_0^\pi \sin^{n-2} \theta \, d\theta &= 2 \int_0^{\pi/2} \sin^{n-2} \theta \, d\theta \\ &= 2 \int_0^{2\pi/5} \sin^{n-2} \theta \, d\theta + 2 \int_{2\pi/5}^{\pi/2} \sin^{n-2} \theta \, d\theta \\ &\leq 2 \sin^{98}(2\pi/5) + 2(\pi/2 - 2\pi/5) \\ &\leq 1 . \end{aligned}$$

The result follows. \square

Corollary 5.7. *For any $\varepsilon, \delta \in (0, 1/100)$ with $\varepsilon \leq \sqrt{\delta}/10$ and vector $\mathbf{v} \in \mathbb{R}^n$ with $n \geq 100$ and $1 \leq \|\mathbf{v}\|_2^2 \leq 1 + \delta$, we have*

$$\Pr[\|\mathbf{v} - \mathbf{t}\|_2^2 \leq 1 - \varepsilon] \geq \frac{\varepsilon}{2\sqrt{\delta}(1 + \delta)} \cdot \left(\frac{1 - 2\varepsilon - \varepsilon^2/\delta}{1 + \delta} \right)^{n/2} ,$$

where $\mathbf{t} \in \mathbb{R}^n$ is a vector of ℓ_2 norm $\sqrt{\delta}$ chosen uniformly at random.

Proof. Let θ be the angle between \mathbf{v} and \mathbf{t} . We have

$$\begin{aligned}
\Pr[\|\mathbf{v} - \mathbf{t}\|^2 \leq 1 - \varepsilon] &= \Pr[\|\mathbf{v}\|_2^2 + \|\mathbf{t}\|_2^2 - 2\|\mathbf{v}\|_2\|\mathbf{t}\|_2 \cos \theta \leq 1 - \varepsilon] \\
&\geq \Pr\left[\cos \theta \geq \frac{1 + \delta + \delta - 1 + \varepsilon}{2\sqrt{\delta(1 + \delta)}}\right] \\
&\geq \Pr\left[\cos \theta \geq (2\delta + \varepsilon)/(2\sqrt{\delta(1 + \delta)})\right] \\
&\geq \int_{\arccos\left(\frac{\delta + \varepsilon}{\sqrt{\delta(1 + \delta)}}\right)}^{\arccos\left(\frac{2\delta + \varepsilon}{2\sqrt{\delta(1 + \delta)}}\right)} \sin^{n-2} \theta \, d\theta \\
&\geq \left(\arccos\left(\frac{\delta + \varepsilon}{\sqrt{\delta(1 + \delta)}}\right) - \arccos\left(\frac{2\delta + \varepsilon}{2\sqrt{\delta(1 + \delta)}}\right)\right) \cdot \left(\frac{1 - 2\varepsilon - \varepsilon^2/\delta}{1 + \delta}\right)^{n/2} \\
&\geq \frac{\varepsilon}{2\sqrt{\delta(1 + \delta)}} \cdot \left(\frac{1 - 2\varepsilon - \varepsilon^2/\delta}{1 + \delta}\right)^{n/2},
\end{aligned}$$

where the first inequality uses the fact that $x - a/x$ is an increasing function of x if $a > 0$, the second-to-last inequality uses the fact that $\sin(\arccos(x)) = \sqrt{1 - x^2}$, and the last inequality uses the fact that $\frac{\partial}{\partial x} \arccos(x) = -(1 - x^2)^{-1/2} \leq -1$. \square

Corollary 5.8. *For any lattice $\mathcal{L} \subset \mathbb{R}^n$ with $n \geq 100$, $\varepsilon, \delta \in (0, 1/100)$ with $\varepsilon \leq \sqrt{\delta}/10$, radius $r > 0$, and target $\mathbf{t} \in \mathbb{R}^n$, there exists a vector $\mathbf{t}' \in \mathbb{R}^n$ such that*

$$N_2(\mathcal{L}, \sqrt{1 - \varepsilon} \cdot r, \mathbf{t}') \geq \frac{\varepsilon}{2\sqrt{\delta(1 + \delta)}} \cdot \left(\frac{1 - 2\varepsilon - \varepsilon^2/\delta}{1 + \delta}\right)^{n/2} \cdot N_2(\mathcal{L}, \sqrt{1 + \delta} \cdot r, \mathbf{t}).$$

Proof. Take $\mathbf{t}' \in \mathbb{R}^n$ to be a uniformly random vector that is at ℓ_2 distance $\sqrt{\delta} \cdot r$ away from \mathbf{t} as in Corollary 5.7. Then, by the corollary, the expectation of $N_2(\mathcal{L}, \sqrt{1 - \varepsilon} \cdot r, \mathbf{t}')$ is at least the right-hand side of the above inequality, and the result follows. \square

We now show that a family of lattices with “surprisingly many” points in a ball is enough to instantiate Corollary 5.3. In more detail, notice that we expect $N_2(\mathcal{L}, r, \mathbf{t})$ to “typically” be proportional r^n , and in particular, we expect $N_2(\mathcal{L}, r', \mathbf{t}) \lesssim (r'/r)^n \cdot N_2(\mathcal{L}, r, \mathbf{0})$ for $r' > r$. We show that, in order to instantiate Corollary 5.3, it suffices to find a family of lattices, radii, and targets such $N_2(\mathcal{L}, r', \mathbf{t}) \geq \beta^n \cdot (r'/r)^n \cdot N_2(\mathcal{L}, r, \mathbf{0})$ for some constant $\beta > 1$ and $r' \leq O(r)$. For example, by taking $r = \lambda_1^{(2)}(\mathcal{L}) - \varepsilon$, $r' = \lambda_1^{(2)}(\mathcal{L})$, and $\mathbf{t} = \mathbf{0}$, we see that it would suffice to find a family of lattices with exponentially many non-zero vectors of minimal length in the ℓ_2 norm—i.e., a family with exponentially large kissing number.

Theorem 5.9. *Suppose that for some constants $\beta, \alpha > 1$, the following holds. For every sufficiently large integer n , there exists a lattice $\mathcal{L}_n \subset \mathbb{R}^n$, radii $0 < r_n \leq r'_n \leq \alpha r_n$, and a target $\mathbf{t}_n \in \mathbb{R}^n$ such that*

$$N_2(\mathcal{L}_n, r'_n, \mathbf{t}_n) \geq \beta^n \cdot (r'_n/r_n)^n \cdot N_2(\mathcal{L}_n, r_n, \mathbf{0}). \quad (11)$$

Then for any constant $C \geq 1$ and $\eta \in (0, 1)$, there is an efficient (non-uniform) reduction from $\text{Gap-3-SAT}_{\eta}^{\leq C}$ on n variables to $\text{SVP}_{2,\gamma}$ on a lattice of rank and dimension $O(n)$, for some constant $\gamma > 1$.

In particular, if such a family of lattices and radii exists, then for some constant $\gamma > 1$, there is no $2^{o(n)}$ -time algorithm for $\text{SVP}_{2,\gamma}$ unless (non-uniform) Gap-ETH is false.

Proof. We first prove the theorem under the assumption that $r'_n/r_n < 1 + 1/400$. We may assume without loss of generality that $r'_n/r_n > \beta^{1/2}$. (Otherwise, we may replace r'_n with $r_n \cdot \beta^{1/2}$ and β with $\beta^{1/2}$. Then, clearly $r'_n/r_n > \beta^{1/2}$ and Eq. (11) still holds.)

Let $s_n := r_n \cdot \sqrt{1 - \varepsilon'}/\sqrt{1 - \varepsilon}$ for some small constants $0 < \varepsilon' < \varepsilon < 1/100$ to be chosen later. By Corollary 5.3, it suffices to find a $\mathbf{t}'_n \in \mathbb{R}^n$ such that

$$N_2(\mathcal{L}_n, \sqrt{1 - \varepsilon'} \cdot r_n, \mathbf{t}'_n) = N_2(\mathcal{L}_n, \sqrt{1 - \varepsilon} \cdot s_n, \mathbf{t}'_n) \geq (\beta')^n \cdot N_2(\mathcal{L}_n, r_n, \mathbf{0}), \quad (12)$$

for some constant $\beta' > 1$ and sufficiently large n . Let $\delta := (r'_n/s_n)^2 - 1 \in (\beta^{1/2} - 1, 1/100)$. By Corollary 5.8, as long as $\varepsilon < \sqrt{\beta^{1/2} - 1}/10$, we see that there exists a $\mathbf{t}'_n \in \mathbb{R}^n$ with

$$\begin{aligned} N_2(\mathcal{L}_n, \sqrt{1 - \varepsilon} \cdot s_n, \mathbf{t}'_n) &\geq \frac{\varepsilon}{2\sqrt{\delta(1 + \delta)}} \cdot \left(\frac{1 - 2\varepsilon - \varepsilon^2/\delta}{1 + \delta} \right)^{n/2} \cdot N_2(\mathcal{L}_n, \sqrt{1 + \delta} \cdot s_n, \mathbf{t}'_n) \\ &= \frac{\varepsilon}{2\sqrt{\delta(1 + \delta)}} \cdot \left(\frac{1 - 2\varepsilon - \varepsilon^2/\delta}{1 + \delta} \right)^{n/2} \cdot N_2(\mathcal{L}_n, r'_n, \mathbf{t}'_n) \\ &\geq \frac{\varepsilon}{2\sqrt{\delta(1 + \delta)}} \cdot \left(\frac{1 - 2\varepsilon - \varepsilon^2/\delta}{1 + \delta} \right)^{n/2} \cdot (r'_n/r_n)^n \cdot \beta^n \cdot N_2(\mathcal{L}_n, r_n, \mathbf{0}) \\ &> \frac{\varepsilon}{2\sqrt{\delta(1 + \delta)}} \cdot (1 - 2\varepsilon - \varepsilon^2/\delta)^{n/2} \cdot \beta^n \cdot N_2(\mathcal{L}_n, r_n, \mathbf{0}). \end{aligned}$$

The result follows by taking ε and β' to be a small enough constant that $(1 - 2\varepsilon - \varepsilon^2/\delta)^{1/2} \cdot \beta > \beta' > 1$.

Now, suppose $r'_n/r_n \geq 1 + 1/400$. We claim that there exists some $0 < s_n \leq s'_n < (1 + 1/400) \cdot s_n$ such that

$$D_2(\mathcal{L}_n, s'_n) \geq (\beta')^n \cdot (s'_n/s_n)^n \cdot N_2(\mathcal{L}_n, s_n, \mathbf{0}) \quad (13)$$

for some constant $\beta' > 1$ depending only on β and α . Clearly, this suffices to prove the result.

To that end, for $i = 0, \dots, \ell := \lceil 2000 \log(r'_n/r_n) \rceil$, let $s_n^{(i)} := (r'_n/r_n)^{i/\ell} \cdot r_n$, $D_n^{(i)} := D_2(\mathcal{L}_n, s_n^{(i)})$, and $N_n^{(i)} := N_2(\mathcal{L}_n, s_n^{(i)}, \mathbf{0})$. We take to be the constant $\beta' := \beta^{1/\lceil 2000\beta \log \alpha \rceil} \leq \beta^{1/\ell}$. We claim that it suffices to find an index i such that $D_n^{(i+1)}/N_n^{(i)} \geq (r'_n/r_n)^{n/\ell} \beta^{n/\ell}$. Indeed, if such an index exists, then we can take $s'_n := s_n^{(i+1)}$ and $s_n := s_n^{(i)}$. Clearly, $s'_n/s_n = (r'_n/r_n)^{1/\ell} \leq 1 + 1/400$, and Eq. (13) is indeed satisfied.

It remains to find such an index i . By assumption, we have $D_n^{(\ell)}/N_n^{(0)} \geq (r'_n/r_n)^n \cdot \beta^n$, and by definition, we have $D_n^{(i)} \geq N_n^{(i)}$. If there exists an index i such that $D_n^{(i+1)}/D_n^{(i)} \geq (r'_n/r_n)^{n/\ell} \beta^{n/\ell}$, then we are done, since $N_n^{(i)} \leq D_n^{(i)}$. Otherwise, we have

$$D_n^{(1)} \geq (r'_n/r_n)^{-(\ell-1)n/\ell} \cdot \beta^{-(\ell-1)n/\ell} D_n^{(\ell)} \geq (r'_n/r_n)^{n/\ell} \cdot \beta^{n/\ell} N_n^{(0)},$$

as needed. □

Corollary 5.10. *Suppose that for some constants $\beta, \alpha > 1$, the following holds. For every sufficiently large integer n , there exists a lattice $\mathcal{L}_n \subset \mathbb{R}^n$, radii $0 < r_n \leq r'_n \leq \alpha r_n$, and a target $\mathbf{t}_n \in \mathbb{R}^n$ such that*

$$N_2(\mathcal{L}_n, r'_n, \mathbf{t}_n) \geq \beta^n \cdot (r'_n/r_n)^n \cdot N_2(\mathcal{L}_n, r_n, \mathbf{0}).$$

Then for any constants $C \geq 1$, $\eta \in (0, 1)$, and $p \in [1, 2]$, there is an efficient (non-uniform) reduction from $\text{Gap-3-SAT}_{\eta}^{\leq C}$ on n variables to $\text{SVP}_{p, \gamma}$ on a lattice of rank and dimension $O(n)$, for some constant $\gamma > 1$.

In particular, if such a family of lattices and radii exists, then for each constant $p \in [1, 2]$ there exists a constant $\gamma_p > 1$, such that there is no $2^{o(n)}$ -time algorithm for SVP_{p, γ_p} unless (non-uniform) Gap-ETH is false.

Proof. Combine Theorem 5.9 with Corollary 2.4. □

6 On the number of integer points in an ℓ_p ball

In this section, we prove Lemma 5.4 by studying the function $N_p(\mathbb{Z}^n, r, \mathbf{t})$. The results in this section were originally proven by Mazo and Odlyzko [MO90] for $p = 2$ and Elkies, Odlyzko, and Rush [EOR91] for arbitrary p . In particular, the main theorem of this section, Theorem 6.1, appeared in [MO90] for $p = 2$ and in [EOR91] for arbitrary p (and even in a more general setting), and (a variant of) Lemma 5.4 already appeared in [EOR91]. Our proof mostly follows that of Mazo and Odlyzko.

6.1 Approximation by Θ_p

We extend our definition of $\Theta_p(\tau)$ to “shifted sums” as follows. For $1 \leq p < \infty$, $\tau > 0$, and $t \in \mathbb{R}$, let

$$\Theta_p(\tau; t) := \sum_{z \in \mathbb{Z}} \exp(-\tau|z - t|^p).$$

We then further extend this definition to vectors $\mathbf{t} = (t_1, \dots, t_n) \in \mathbb{R}^n$ by

$$\Theta_p(\tau; \mathbf{t}) := \prod_{i=1}^n \Theta_p(\tau; t_i)$$

We will often assume without loss of generality that $t \in [0, 1/2]$ and $\mathbf{t} \in [0, 1/2]^n$.

We have

$$\Theta_p(\tau; \mathbf{t}) = \sum_{\mathbf{z} \in \mathbb{Z}^n} \exp(-\tau \|\mathbf{z} - \mathbf{t}\|_p^p).$$

It follows that for any radius $r > 0$ and any $\tau > 0$,

$$N_p(\mathbb{Z}^n, r, \mathbf{t}) \leq \exp(\tau r^p) \Theta_p(\tau; \mathbf{t}). \tag{14}$$

We wish to show that this inequality is quite tight if τ satisfies $\mu_p(\tau; \mathbf{t}) = r^p$, where

$$\mu_p(\tau; \mathbf{t}) := \sum_{i=1}^n \mathbb{E}_{X \sim D_p(\tau; t_i)} [|X|^p],$$

and $D_p(\tau; t)$ is the probability distribution over $\mathbb{Z} - t$ that assigns to each $x \in \mathbb{Z} - t$ probability $\exp(-\tau|x|^p)/\Theta_p(\tau; t)$.¹⁰ Indeed, the main theorem that we prove in this section is the following (which, again, was originally proven in [MO90, EOR91]).

¹⁰It is easy to see that there exists a τ satisfying $\mu_p(\tau; \mathbf{t}) = r^p$ if and only if there is a lattice point inside the open ℓ_p ball of radius r around \mathbf{t} . So, we do not lose much by assuming that $r^p = \mu_p(\tau; \mathbf{t})$ for some $\tau > 0$.

Theorem 6.1. For any constants $p \geq 1$ and $\tau > 0$, there is another constant $C^* > 0$ such that

$$\exp(\tau\mu_p(\tau; \mathbf{t}) - C^*\sqrt{n}) \cdot \Theta_p(\tau; \mathbf{t}) \leq N_p(\mathbb{Z}^n, \mu_p(\tau; \mathbf{t})^{1/p}, \mathbf{t}) \leq \exp(\tau\mu_p(\tau; \mathbf{t})) \cdot \Theta_p(\tau; \mathbf{t}),$$

for any $\mathbf{t} \in \mathbb{R}^n$ and any positive integer n .

Lemma 6.2. For any $1 \leq p < \infty$, $\tau > 0$, and $t \in \mathbb{R}$,

$$\frac{\partial}{\partial \tau} \log \Theta_p(\tau; t) = -\mu_p(\tau; t) < 0,$$

and

$$\frac{\partial^2}{\partial \tau^2} \log \Theta_p(\tau; t) = \mathbb{E}_{X \sim D_p(\tau; t)} [|X|^{2p}] - \mu_p(\tau; t)^2 > 0.$$

Proof. We have

$$\begin{aligned} \frac{\partial}{\partial \tau} \log \Theta_p(\tau; t) &= \frac{1}{\Theta(\tau; t)} \cdot \sum_{z \in \mathbb{Z}} \frac{\partial}{\partial \tau} \exp(-\tau|z - t|^p) \\ &= -\frac{1}{\Theta(\tau; t)} \cdot \sum_{z \in \mathbb{Z}} |z - t|^p \exp(-\tau|z - t|^p) \\ &= -\mu_p(\tau; t). \end{aligned}$$

The second derivative follows from a similar computation. \square

To use $\Theta_p(\tau; \mathbf{t})$ to get a lower bound on $N_p(\mathbb{Z}^n, r, \mathbf{t})$, we wish to “isolate” the contribution of vectors of length roughly r to the sum $\Theta_p(\tau; \mathbf{t})$. To do so, we define for $\delta > 0$ the (rather unnatural) function

$$H_p(\tau, \delta; \mathbf{t}) := \Theta_p(\tau + \delta; \mathbf{t}) - \exp(-\delta\mu_p(\tau; \mathbf{t}))\Theta_p(\tau; \mathbf{t}) - \exp(\delta\mu_p(\tau + 2\delta; \mathbf{t}))\Theta_p(\tau + 2\delta; \mathbf{t}).$$

The following lemma shows why we are interested in H_p .

Lemma 6.3. For any $1 \leq p < \infty$, $\tau > 0$, $\delta > 0$, and $\mathbf{t} \in [0, 1/2]^n$,

$$N_p(\mathbb{Z}^n, \mu_p(\tau; \mathbf{t})^{1/p}, \mathbf{t}) \geq \exp(\tau\mu_p(\tau + 2\delta; \mathbf{t}))H_p(\tau, \delta; \mathbf{t}).$$

Proof. We can write

$$H_p(\tau, \delta; \mathbf{t}) = \sum_{z \in \mathbb{Z}^n} \exp(-(\tau + \delta)\|z - \mathbf{t}\|_p^p) \cdot (1 - f_1(z) - f_2(z)),$$

where $f_1(z) := \exp(\delta(\|z - \mathbf{t}\|_p^p - \mu_p(\tau; \mathbf{t})))$, and $f_2(z) := \exp(\delta(\mu_p(\tau + 2\delta; \mathbf{t}) - \|z - \mathbf{t}\|_p^p))$. In particular, the summand is negative if $\|z - \mathbf{t}\|_p^p \geq \mu_p(\tau; \mathbf{t})$ or $\|z - \mathbf{t}\|_p^p \leq \mu_p(\tau + 2\delta; \mathbf{t})$. Therefore, there are at most $N_p(\mathbb{Z}^n, \mu_p(\tau; \mathbf{t})^{1/p}, \mathbf{t})$ positive summands, and each has magnitude at most

$$\exp(-(\tau + \delta)\mu_p(\tau + 2\delta; \mathbf{t})) \leq \exp(-\tau\mu_p(\tau + 2\delta; \mathbf{t})).$$

The result follows. \square

Proof of Theorem 6.1. We may assume without loss of generality that $\mathbf{t} \in [0, 1/2]^n$. Let $\delta > 0$ with $\delta = O(1)$ to be chosen later. By taking the Taylor expansion of $\log \Theta_p(\tau; \mathbf{t})$ around τ , we see by Lemma 6.2 that

$$\log \Theta_p(\tau; \mathbf{t}) - \log \Theta_p(\tau + \delta; \mathbf{t}) \leq \delta \mu_p(\tau; \mathbf{t}) - \frac{\delta^2}{2} \inf_{\tau \leq \tau' \leq \tau + \delta} \sum_{i=1}^n V(\tau'; t_i),$$

where

$$V(\tau'; t_i) := \mathbb{E}_{X \sim D_p(\tau'; t_i)} [|X|^{2p}] - \mu_p(\tau'; t_i)^2.$$

Notice that $V(\tau'; t_i)$ is a continuous positive function. Therefore, it has a positive lower bound on the compact set $\tau \leq \tau' \leq \tau + 2\delta$ and $0 \leq t_i \leq 1/2$. (We have deliberately taken the upper limit on τ' to be $\tau + 2\delta$ rather than just $\tau + \delta$.) Let $C_{\min} > 0$ be such a bound. We therefore have

$$\log \Theta_p(\tau; \mathbf{t}) - \log \Theta_p(\tau + \delta; \mathbf{t}) \leq \delta \mu_p(\tau; \mathbf{t}) - C_{\min} n \delta^2 / 2.$$

By an essentially identical argument, we have,

$$\log \Theta_p(\tau + 2\delta; \mathbf{t}) - \log \Theta_p(\tau + \delta; \mathbf{t}) \leq -\delta \mu_p(\tau + 2\delta; \mathbf{t}) - C_{\min} n \delta^2 / 2.$$

It follows that

$$H_p(\tau, \delta; \mathbf{t}) \geq \Theta_p(\tau + \delta; \mathbf{t}) \cdot (1 - 2 \exp(-C_{\min} n \delta^2 / 2)).$$

Plugging this in to Lemma 6.3, we see that

$$N_p(\mathbb{Z}^n, \mu_p(\tau; \mathbf{t})^{1/p}, \mathbf{t}) \geq \exp(\tau \mu_p(\tau + 2\delta; \mathbf{t})) \Theta_p(\tau + \delta; \mathbf{t}) \cdot (1 - 2 \exp(-C_{\min} n \delta^2 / 2)).$$

By a similar argument, we see that there is some constant $C_{\max} > 0$ such that $\mu_p(\tau; t_i) - \mu_p(\tau + 2\delta; t_i) \leq C_{\max} \delta$ and $\log \Theta_p(\tau; t_i) - \log \Theta_p(\tau + \delta; t_i) \leq C_{\max} \delta$. Therefore,

$$N_p(\mathbb{Z}^n, \mu_p(\tau; \mathbf{t})^{1/p}, \mathbf{t}) \geq \exp(\tau \mu_p(\tau; \mathbf{t})) \Theta_p(\tau; \mathbf{t}) \cdot \exp(-C_{\max} \delta n (\tau + 1)) (1 - 2 \exp(-C_{\min} n \delta^2 / 2)).$$

The result follows by taking $\delta = C^\dagger / \sqrt{n}$ for a sufficiently large constant $C^\dagger > 0$. \square

6.2 Dense shifted balls and the proof of Lemma 5.4

We now wish to show that for $p > 2$, there exist shifts $\mathbf{t} \in \mathbb{R}^n$ such that $N_p(\mathbb{Z}^n, r, \mathbf{t})$ is exponentially larger than $N_p(\mathbb{Z}^n, r, \mathbf{0})$. (Again, this result is not original to us, as it was already proven in [EOR91].) By Theorem 6.1, it suffices to show that there exists $\tau > 0$ and $t \in (0, 1/2]$ such that $\Theta_p(\tau; t) > \Theta_p(\tau; 0)$.

Lemma 6.4. *For any $p > 2$ and $\tau \geq 1 - 1/p$, there exists a $t \in (0, 1/2]$ such that*

$$\Theta_p(\tau; t) > \Theta_p(\tau; 0).$$

Proof. We have $\frac{\partial}{\partial t} \Theta_p(\tau; t)|_{t=0} = 0$, and

$$\frac{\partial^2}{\partial t^2} \Theta_p(\tau; t)|_{t=0} = p\tau \sum_{z \in \mathbb{Z}} \exp(-\tau |z|^p) |z|^{p-2} (p\tau |z|^p - (p-1)). \quad (15)$$

(Here, we have used the fact that $\exp(-\tau |t|^p)$ is twice differentiable at $t = 0$ for $p > 2$, with first and second derivative both zero. Notice that this is false for $p \leq 2$.) For $\tau \geq 1 - 1/p$, all of the summands are non-negative, so that 0 is a local minimum of the function $t \mapsto \Theta_p(\tau; t)$. Therefore, for sufficiently small $t > 0$, $\Theta_p(\tau; t) > \Theta_p(\tau; 0)$, as needed. \square

Proof of Lemma 5.4. Choose $t \in [0, 1/2]$ to maximize $\Theta_p(1; t)$. (Since $\Theta_p(1; t)$ is a continuous function and $[0, 1/2]$ is a compact set, such a maximizer is guaranteed to exist.) By Lemma 6.4, we must have $\Theta_p(1; t) > \Theta_p(1; 0)$, and in particular $t > 0$. Let $\varepsilon \in (0, \delta)$ be a constant to be chosen later. Let $C_r := \mu_p(1; t)^{1/p} / (1 - \varepsilon)^{1/p}$.

Let $\varepsilon \in (0, \delta)$ be a constant to be chosen later, and let $r := C_r n^{1/p}$ and $\mathbf{t} := (t, t, \dots, t) \in \mathbb{R}^n$. Notice that $(1 - \varepsilon)r^p = \mu_p(1; \mathbf{t})$. By Theorem 6.1, we have

$$N_p(\mathbb{Z}^n, (1 - \varepsilon)^{1/p} \cdot r, \mathbf{t}) \geq \exp(-C^* \sqrt{n}) \cdot \exp((1 - \varepsilon)r^p) \cdot \Theta_p(1; t)^n \quad (16)$$

for some constant $C^* > 0$.

We have

$$N_p(\mathbb{Z}^n, r, \mathbf{0}) \leq \exp(r^p) \Theta_p(1; 0)^n.$$

Let $\alpha := \Theta_p(1; t) / \Theta_p(1; 0) > 1$. Then, combining the above with Eq. (16), we see that

$$\frac{N_p(\mathbb{Z}^n, (1 - \varepsilon)^{1/p} r, \mathbf{t})}{N_p(\mathbb{Z}^n, r, \mathbf{0})} \geq \alpha^n \cdot \exp(-\varepsilon C_r^p n).$$

We therefore take $\varepsilon \in (0, \delta)$ to be any constant small enough to make $\alpha \exp(-\varepsilon C_r^p) > 1$.

Now, for any $\mathbf{t}' = (t'_1, \dots, t'_n) \in \mathbb{R}^n$, we may repeat the above argument to show that

$$\frac{N_p(\mathbb{Z}^n, (1 - \varepsilon)^{1/p} r, \mathbf{t})}{N_p(\mathbb{Z}^n, (1 - \varepsilon/\delta)r, \mathbf{t}')} \geq \exp(\varepsilon C_r^p n \cdot (1/\delta - 1)) \cdot \Theta_p(1; t)^n / \Theta_p(1; \mathbf{t}')$$

Recall that, by definition, $\Theta_p(1; \mathbf{t}') = \prod_i \Theta_p(1; t'_i) \leq \Theta_p(1; t)^n$, where the last inequality follows from our choice of t . Therefore,

$$\frac{N_p(\mathbb{Z}^n, (1 - \varepsilon)^{1/p} r, \mathbf{t})}{D_p(\mathbb{Z}^n, (1 - \varepsilon/\delta)r)} \geq \exp(\varepsilon C_r^p n \cdot (1/\delta - 1)).$$

The result follows by taking $\beta := \min\{\alpha \exp(-\varepsilon C_r^p), \exp(\varepsilon C_r^p (1/\delta - 1))\} > 1$. \square
