

The Frobenius problem for homomorphic embeddings of languages into the integers

Michel Dekking

DIAM, Delft University of Technology, December 12, 2017

1 Introduction

The Frobenius problem is also known as the ‘coin problem’. Since the value of a coin can only be positive, we will consider exclusively embeddings into the natural numbers $\mathbb{N} = \{1, 2, 3, \dots\}$. Let \mathcal{L} be a language, i.e., a sub-semigroup of the free semigroup generated by a finite alphabet under the concatenation operation.

A homomorphism of \mathcal{L} into the natural numbers is a map $S : \mathcal{L} \rightarrow \mathbb{N}$ satisfying

$$S(vw) = S(v) + S(w), \quad \text{for all } v, w \in \mathcal{L}.$$

The two main questions to be asked about the image set $S(\mathcal{L})$ are

(Q1) Is the complement $\mathbb{N} \setminus S(\mathcal{L})$ finite or infinite?

(Q2) If the complement of $S(\mathcal{L})$ is finite, then what is the largest element in this set?

These two questions are known as the Frobenius problem in the special case that \mathcal{L} is the full language consisting of *all* words over a finite alphabet. In this case they have been posed as a problem (with solution) for an alphabet $\{a, b\}$ of cardinality 2 by James Joseph Sylvester in 1884 [14]: $\mathbb{N} \setminus S(\mathcal{L})$ is finite, and its largest element is

$$S(a)S(b) - S(a) - S(b).$$

In this paper we will also restrict ourselves to the two symbol case: alphabet $\{a, b\}$.

In Section 2 we prove that for the golden mean language (“no bb ”) the set $\mathbb{N} \setminus S(\mathcal{L})$ is finite, with largest element

$$S(a)^2 + S(a)S(b) - 3S(a) - S(b).$$

Our main interest is however not in sofic languages¹, but in languages with low complexity, where the complement of $S(\mathcal{L})$ can be infinite.

In Section 3 we analyse the case of Sturmian languages, and show that for the Fibonacci language a $0-\infty$ law holds: either the complement is empty or it has infinite cardinality.

In Section 4 we show that for any homomorphism S the image of the Thue-Morse language will consist of a union of 5 arithmetic sequences.

In Section 5 we consider two-dimensional embeddings, which behave quite differently.

¹Languages defined by the labelling of infinite paths of an automaton.

We usually suppose that $\gcd(S(a), S(b)) = 1$. First of all this is not a big loss since automatically the complement will have infinite cardinality in this case. Secondly, if r divides both $S_1(a)$ and $S_1(b)$ for some homomorphism S_1 , then

$$S_1(\mathcal{L}^n) = r^n S_2(\mathcal{L}^n), \quad \text{for } n = 1, 2, \dots, \text{ where } S_2(a) = \frac{S_1(a)}{r}, S_2(b) = \frac{S_1(b)}{r}.$$

Our work is related to the work on *abelian complexity*, see, e.g., [3], [12], [8]. See Lemma 3.1 for such a connection.

Our work is also related to the notion of *additive complexity*, see [13] and [2]. The *additive complexity* of an infinite word w over a finite set of integers (see [2]) is the function $n \rightarrow \phi^+(w, n)$ that counts the number of distinct sums obtained by summing n consecutive symbols of w . In general we write \mathcal{L}^n for the set of words of length n in a language \mathcal{L} . Let \mathcal{L}_w be the language of all words occurring in the infinite word w . Then the additive complexity is $\phi^+(w, n) = \text{Card}\{S(u) : u \in \mathcal{L}_w^n\}$, where S is the identity map on the alphabet of w .

We finally mention that homomorphisms S from a language to the natural numbers already occur in the 1972 paper [4, Section 6] in the context of the Fibonacci language, where they are called *weights*.

2 Homomorphic images of the golden-mean language

The golden mean language is the language \mathcal{L}_{GM} consisting of all words over $\{a, b\}$ in which bb does not occur as a subword. Now if S satisfies $S(a) = 1$ or $S(b) = 1$, then it is easily seen that $S(\mathcal{L}_{\text{GM}}) = \mathbb{N}$, so for these homomorphisms the golden mean and the full language both map to \mathbb{N} . One could say they both have Frobenius number 0. In general however, the Frobenius number will increase substantially. If we take S defined by

$$S(a) = 100, S(b) = 3,$$

then the Frobenius number of the full language under S is $300 - 100 - 3 = 197$, and the Frobenius number of $S(\mathcal{L}_{\text{GM}})$ is equal to 9997. For arbitrary homomorphisms the solution of the Frobenius problem for the golden mean language is given by the following, where we write $S_a := S(a)$, $S_b := S(b)$.

Theorem 2.1 *Let $S : \mathcal{L}_{\text{GM}} \rightarrow \mathbb{N}$ be a homomorphism. Suppose $\gcd(S_a, S_b) = 1$, and both $S_a > 1$ and $S_b > 1$. Then the Frobenius number of $S(\mathcal{L}_{\text{GM}})$ is equal to*

$$\max \mathbb{N} \setminus S(\mathcal{L}_{\text{GM}}) = S_a(S_a - 3) + S_b(S_a - 1).$$

Proof: Let an S_a -point be defined as a multiple nS_a , $n = 0, 1, \dots$, and an S_a -interval as the set of numbers between two consecutive S_a -points. We also consider S_b -chains, defined for $n \geq 0$ by

$$C(n) = \{nS_a + S_b, nS_a + 2S_b, \dots, nS_a + (n+1)S_b\}.$$

Note that the union of the S_a -points and the S_b -chains will give \mathcal{L}_{GM} . The key observation is that the S_b -chain $C(S_a - 2)$ has $S_a - 1$ elements, which are all different modulo S_a . This is a consequence of $\gcd(S_a, S_b) = 1$. It follows that the S_b -chains fill in more and more points of the S_a -intervals. The last point to be filled in is modulo S_a equal to $S_a - S_b$, produced by the last element of the chain $C(S_a - 2)$. This is the number

$$P := (S_a - 2)S_a + (S_a - 1)S_b.$$

But then the largest number in the complement of \mathcal{L}_{GM} is $P - S_a$, which is the number as claimed in the theorem. In this argument we used that if a point in an S_a -interval is filled in, then the corresponding points modulo S_a in all later intervals will also be filled in, simply because the later chains will be extensions of the earlier ones. \square

Figure 1: Example with $S(a) = 7, S(b) = 3$: row n shows the S_a -points in blue, and the S_b -chain $C(n - 1)$ in yellow and green, for $n = 1, \dots, 8$ (truncated at 56).

3 Sturmian languages

Sturmian words are infinite words over a two letter alphabet that have exactly $n + 1$ subwords for each $n = 1, 2, \dots$. We call the collection of these subwords a Sturmian language. There is a surprising characterization of Sturmian words: s is Sturmian if and only if s is irrational *mechanical*, which means that there exists an irrational number $\alpha \in (0, 1)$ and a number ρ such that $s = s_{\alpha, \rho}$, or $s = s'_{\alpha, \rho}$, where

$$s_{\alpha, \rho} = ([(n + 1) \alpha + \rho] - [n \alpha + \rho])_{n \geq 0}, \quad s'_{\alpha, \rho} = ([(n + 1) \alpha + \rho] - [n \alpha + \rho])_{n \geq 0}.$$

See, e.g., [10, Prop. 2.1.13]. Because of this representation, we will use the alphabet $\{0, 1\}$ instead of $\{a, b\}$ in this section.

Of special interest are the Sturmian words $s_\alpha := s_{\alpha, 0}$ and $s'_\alpha := s'_{\alpha, 0}$ of intercept 0. These have the property that they only differ in the first element:

$$s_\alpha = 0 c_\alpha, \quad s'_\alpha = 1 c_\alpha.$$

Here $c_\alpha := s_{\alpha, \alpha}$ is called the *characteristic word* of α . For $n \geq 0$ we have

$$c_\alpha(n) = s_{\alpha, \alpha}(n) = [(n + 1) \alpha + \alpha] - [n \alpha + \alpha] = [(n + 2) \alpha] - [(n + 1) \alpha].$$

The words s_α, s'_α and c_α generate the same language ([10, Prop.2.1.18]), which we denote \mathcal{L}_α . Recall that \mathcal{L}_α^n is the set of words of length n in \mathcal{L}_α .

Lemma 3.1 *Let \mathcal{L}_α be a Sturmian language, and let S be a homomorphism with $S(0) \neq S(1)$. Then $\text{Card } S(\mathcal{L}_\alpha^n) = 2$ for all $n \geq 1$.*

Proof: This follows directly from the fact ([10, Th.2.1.5]) that Sturmian words are *balanced*, i.e., any two words of the same length can at most differ 1 in their number of ones. \square

A sequence $([n\alpha])$, where $[.]$ denotes integer part, is called a *Beatty sequence* if $\alpha > 1$, and a *slow Beatty sequence* if $0 < \alpha < 1$ (terminology from [9]).

Theorem 3.1 *Let α be an irrational number from $(0, 1)$. Let \mathcal{L}_α be the Sturmian language generated by α , and let $(q_n)_{n \geq 0}$ be the slow Beatty sequence defined by*

$$q_n = [(n+1)\alpha].$$

Let $S : \mathcal{L}_\alpha \rightarrow \mathbb{N}$ be a homomorphism. Define $S_0 = S(0), S_1 = S(1)$. Then

$$S(\mathcal{L}_\alpha) = \{(S_1 - S_0)q_n + nS_0 + S_0 : n = 0, \dots\} \cup \{(S_1 - S_0)q_n + nS_0 + S_1 : n = 0, \dots\}.$$

Proof: If $S_0 = S_1$ then this is certainly true, so suppose $S_0 \neq S_1$ in the sequel. We denote $c_\alpha[i, j] := c_\alpha(i) \dots c_\alpha(j)$ for integers $0 \leq i < j$. Let $N_\ell(w)$ denote the number of occurrences of the letter ℓ in a word w for $\ell = 0, 1$. Then

$$N_1(c_\alpha[0, n-1]) = \sum_{k=0}^{n-1} c_\alpha(k) = [(n+1)\alpha] - [\alpha] = q_n, \quad N_0(c_\alpha[0, n-1]) = n - q_n.$$

Of course all words $c_\alpha[0, n-1]$ are in the Sturmian language \mathcal{L}_α , but \mathcal{L}_α also contains the words $0c_\alpha[0, n-1]$ and $1c_\alpha[0, n-1]$. It thus follows from Lemma 3.1 that $S(\mathcal{L}_\alpha)$ is given by the union of all images $S(0c_\alpha[0, n-1])$ and $S(1c_\alpha[0, n-1])$. Since

$$S(0c_\alpha[0, n-1]) = S_0 + (n - q_n)S_0 + q_nS_1 = (S_1 - S_0)q_n + nS_0 + S_0,$$

the result follows. \square

3.1 The Fibonacci language

Let $\Phi = (\sqrt{5} + 1)/2 = 1.61803\dots$ be the golden mean, and let $\alpha := 2 - \Phi$. We have

$$c_\alpha = ([(n+1)\alpha] - [n\alpha])_{n \geq 1} = 0, 1, 0, 0, 1, 0, 1, 0, 0, 1, 0, 0, 1, 0, 0, 1, 0, 1, 0, 0, \dots,$$

the infinite Fibonacci word. We write $\mathcal{L}_F := \mathcal{L}_\alpha$.

Theorem 3.2 *Let $S : \mathcal{L}_F \rightarrow \mathbb{N}$ be a homomorphism. Then*

$$S(\mathcal{L}_F) = ((S_0 - S_1)[n\Phi] + (2S_1 - S_0)n + S_0 - S_1)_{n \geq 1} \cup ((S_0 - S_1)[n\Phi] + (2S_1 - S_0)n)_{n \geq 1}.$$

Proof: This is a corollary to Theorem 3.1, using $[-x] = -[x] - 1$ for non-integer x :

$$\begin{aligned}
(S_1 - S_0)q_{n-1} + nS_0 &= (S_1 - S_0)[n\alpha] + nS_0 = (S_1 - S_0)[n(2 - \Phi)] + nS_0 \\
&= 2(S_1 - S_0)n + (S_1 - S_0)[-n\Phi] + nS_0 \\
&= (2S_1 - S_0)n + (S_1 - S_0)(-[n\Phi] - 1) \\
&= (S_0 - S_1)[n\Phi] + (2S_1 - S_0)n + S_0 - S_1.
\end{aligned}$$

□

Lemma 3.2 For $S(0) = 1, S(1) \leq 3$ or $S(0) = 2, S(1) = 1$ one has $S(\mathcal{L}_F) = \mathbb{N}$.

Proof: Take $(S_0, S_1) = (1, 1)$. Then obviously $S(\mathcal{L}_F) = \mathbb{N}$.

Take $(S_0, S_1) = (2, 1)$. Then $S(\mathcal{L}_F) = \mathbb{N}$, since by Theorem 3.2 $S(\mathcal{L}_F)$ is the union of $([n\Phi])$ and $([n\Phi] + 1)$, where the difference of two consecutive terms in $([n\Phi])$ is never more than 2.

Take $(S_0, S_1) = (1, 2)$. Then $S(\mathcal{L}_F) = \mathbb{N}$, since $S(\mathcal{L}_F)$ is the union of $([n(3 - \Phi)])$ and $([n(3 - \Phi)] + 1)$, where the difference of two consecutive terms in $([n(3 - \Phi)])$ is never more than 2.

Take $(S_0, S_1) = (1, 3)$. This case is more complicated. Let $u := (-2[n\Phi] + 5n - 2)_{n \geq 1}$, and $v := u + 2$. Then according to Theorem 3.2, the union of the sets determined by u and v is $S(\mathcal{L}_F)$. Let Δu be the difference sequence defined by $\Delta u_n = u_{n+1} - u_n$ for $n \geq 0$. It is easy to see that the difference sequences Δv and Δu are both equal to the Fibonacci sequence $1, 3, 1, 1, 3, 1, \dots$ on the alphabet $\{1, 3\}$ (cf. [1]). We claim that if two consecutive numbers $m, m + 1$ are missing in u , then these two do appear in v , implying that $S(\mathcal{L}_F) = \mathbb{N}$. Indeed the two missing numbers are characterized by $u_{n+1} - u_n = 3$ for some n , and the missing numbers are $m = u_n + 1$ and $u_n + 2$. The second number appears in v , simply because $v = u + 2$. The first number appears because $u_{n+1} - u_n = 3$ implies $u_n - u_{n-1} = 1$ (no 33 in the 1-3-Fibonacci sequence), and so $v_{n-1} = v_n - 1 = u_n + 1$. □

We define $\mathcal{E} := \{(1, 1), (1, 2), (1, 3), (2, 1)\}$.

Theorem 3.3 Let $S : \mathcal{L}_F \rightarrow \mathbb{N}$ be a homomorphism. Then $\mathbb{N} \setminus S(\mathcal{L}_F)$ has infinite cardinality, unless $(S(0), S(1)) \in \mathcal{E}$, in which case the complement is empty.

Proof: According to Lemma 3.2 the complement of $S(\mathcal{L}_F)$ is empty for $(S_0, S_1) \in \mathcal{E}$. The density of the set $S(\mathcal{L}_F)$ in the natural numbers exists, and equals

$$\delta := \frac{2}{(S_0 - S_1)\Phi + 2S_1 - S_0}.$$

The theorem will be proved if we show that $\delta < 1$ for (S_0, S_1) not in \mathcal{E} . First we note that the denominator of δ is positive:

$$(S_0 - S_1)(\Phi - 1) + S_1 > -S_1(\Phi - 1) + S_1 = S_1(2 - \Phi) > 0,$$

where we used that $1 < \Phi < 2$. We now have

$$\delta < 1 \Leftrightarrow (S_0 - S_1)\Phi + 2S_1 - S_0 > 2 \Leftrightarrow (S_0 - S_1)\Phi > S_0 - S_1 + 2 - S_1.$$

If $S_0 > S_1$, this is satisfied, since under this condition $(2 - S_1)/(S_0 - S_1) \leq 0$, unless $(S_0, S_1) = (2, 1) \in \mathcal{E}$. If $S_0 < S_1$, we have to see that $\Phi < 1 + (2 - S_1)/(S_0 - S_1)$. This holds for $S_0 \geq 2$, since then $(2 - S_1)/(S_0 - S_1) \geq 1$. If $S_0 = 1$, then this does not hold for $S_1 = 1, 2, 3$, i.e., for pairs from \mathcal{E} , but it will hold for all $S_1 \geq 4$. \square

For particular values of $S(0)$ and $S(1)$ the complement of the embedding of the language has a nice structure, as it can be expressed in the classical Beatty sequences $A(n) = [n\Phi]$ for $n \geq 1$, and $B(n) = [n\Phi^2]$ for $n \geq 1$. The sequences A and B are called the *lower Wythoff sequence* and *upper Wythoff sequence*; they are extremely well-studied.

Example 1. Let S be given by $S(0) = 3$ and $S(1) = 2$. In the following we use the notation $pX + qY + r = (pX(n) + qY(n) + r)_{n \geq 1}$ for real numbers p, q, r and functions $X, Y : \mathbb{N} \rightarrow \mathbb{N}$. Then

$$S(\mathcal{L}_F) = B(\mathbb{N}) \cup B+1(\mathbb{N}), \quad \mathbb{N} \setminus S(\mathcal{L}_F) = \{1, 4, 9, 12, \dots\} = 2A + \text{Id} + 1(\mathbb{N} \cup \{0\}).$$

The first statement follows directly from Theorem 3.2. The second statement follows in a number of steps from the fact that A and B form a Beatty pair: $A(\mathbb{N}) \cap B(\mathbb{N}) = \emptyset$, and $A(\mathbb{N}) \cup B(\mathbb{N}) = \mathbb{N}$. This implies that $A(A(\mathbb{N})) \cup A(B(\mathbb{N})) \cup B(\mathbb{N}) = \mathbb{N}$, where the three sets are disjoint. But $AA = B - 1$ (see, e.g., Formula (3.2) in [4]). Adding 1 to all three sequences it follows that

$$B(\mathbb{N}) \cup B + 1(\mathbb{N}) \cup AB + 1(\mathbb{N}) = \mathbb{N} \setminus \{1\}.$$

Moreover, according to [4, Formula (3.5)] one has $AB = A + B = 2A + \text{Id}$.

But then the three sequences $([n\Phi] + n)_{n \geq 1}$, $([n\Phi] + n + 1)_{n \geq 1}$, $(2[n\Phi] + n + 1)_{n \geq 0}$, form a complementary triple, i.e., as sets they are disjoint, and their union is \mathbb{N} .

A similar result holds for² $S(0) = 4$, $S(1) = 3$.

Example 2. Let S be given by $S(0) = 3$ and $S(1) = 1$, then by Theorem 3.2

$$S(\mathcal{L}_F) = 2A - \text{Id}(\mathbb{N}) \cup 2A - \text{Id} + 2(\mathbb{N}).$$

It is proved in [1] that

$$\mathbb{N} \setminus S(\mathcal{L}_F) = \{2, 9, 20, 27, 38, 49, \dots\} = 4A + 3\text{Id} + 2(\mathbb{N} \cup \{0\}),$$

and that the three sequences $(2[n\Phi] - n)_{n \geq 1}$, $(2[n\Phi] - n + 2)_{n \geq 1}$, $(4[n\Phi] + 3n + 2)_{n \geq 0}$, form a complementary triple.

4 The Thue-Morse language

Let θ given by $\theta(a) = ab$, $\theta(b) = ba$ be the Thue-Morse morphism. Let \mathcal{L}_{TM} be the language generated by this morphism.

Let $R_{r,s} = \{s, r + s, 2r + s, \dots\}$ be the set determined by the arithmetic sequence with terms $rn + s$ for $n = 0, 1, \dots$

Theorem 4.1 *Let $S : \mathcal{L}_{\text{TM}} \rightarrow \mathbb{N}$ be a homomorphism. Define $p = S(0)$, $q = S(1)$. Then*

$$S(\mathcal{L}_{\text{TM}}) = R_{p+q,0} \cup R_{p+q,p} \cup R_{p+q,q} \cup R_{p+q,2p} \cup R_{p+q,2q}.$$

²In these two cases $\mathbb{N} \setminus S(\mathcal{L}_F)$ is given by sequences A276885, respectively A276886 in OEIS ([11]). It is easily seen that the definitions of these sequences in OEIS are equivalent to the way in which we obtain them.

Proof: Let $\mathcal{L}_{\text{TM}}^n$ be the set of words of length n in the Thue-Morse language. Put $r = S(ab) = p + q$. It is clear (and for $p = 0, q = 1$ observed also in [12]) that since the Thue-Morse word is a non-periodic concatenation of ab and ba that for $n = 1, 2, \dots$

$$S(\mathcal{L}_{\text{TM}}^{2n}) = \{rn, rn + q - p, rn + p - q\}, \quad S(\mathcal{L}_{\text{TM}}^{2n-1}) = \{rn + p, rn + q\}.$$

This implies the statement of the theorem. \square

Theorem 4.2 *Let $S : \mathcal{L}_{\text{TM}} \rightarrow \mathbb{N}$ be a homomorphism. Then $\mathbb{N} \setminus S(\mathcal{L}_{\text{F}})$ has infinite cardinality if and only if $S(a) + S(b) \geq 6$. For $S(a) + S(b) < 6$, the complement is either empty or a singleton.*

Proof: This follows directly from Theorem 4.1. If $S(a) + S(b) \geq 6$, then the density of $\mathbb{N} \setminus S(\mathcal{L}_{\text{TM}})$, is at least $1/6$, so the set has infinite cardinality. The results for $S(a) + S(b) < 6$ follow also directly from the previous theorem. \square

Remark Let σ given by $\sigma(a) = ab, \sigma(b) = aa$ be the period-doubling or Toeplitz morphism. The difficulty—see [8, Lemma 6]—of determining the abelian complexity of the period-doubling morphism already indicates that solving the Frobenius problem for the period-doubling language will be much more involved than for the Thue-Morse language.

5 Two dimensional embeddings

Here we consider homomorphisms $S : \mathcal{L} \rightarrow \mathbb{N} \times \mathbb{N}$ and $S : \mathcal{L} \rightarrow \mathbb{Z} \times \mathbb{Z}$. The situation changes drastically for this ‘double-coin’ problem.

Proposition 5.1 *Let \mathcal{L} be a language on the alphabet $\{a, b\}$, and let $S : \mathcal{L} \rightarrow \mathbb{N} \times \mathbb{N}$ be a homomorphism. Then $\mathbb{N} \times \mathbb{N} \setminus S(\mathcal{L})$ has infinite cardinality for all pairs $\{S(a), S(b)\}$ which are not equal to the pair $\{(0, 1), (1, 0)\}$.*

Proof: It suffices to prove this for the full language $\mathcal{L}_{\text{full}}$. The image under S is an integer lattice, with a complement of infinite cardinality, unless $S(a)$ and $S(b)$ are the unit vectors. \square

We learn from this that the alphabet is ‘too small’, and that we should rather consider embeddings in $\mathbb{Z} \times \mathbb{Z}$ instead of $\mathbb{N} \times \mathbb{N}$. We focus again on low complexity languages, in particular on those generated by a primitive morphism φ on an alphabet A . Such a morphism has a language \mathcal{L}_φ associated to it, where each word $w \in \mathcal{L}_\varphi$ has a measure $\mu_\varphi(w)$. For a given homomorphism $S : \mathcal{L}_\varphi \rightarrow \mathbb{Z} \times \mathbb{Z}$ we call the average

$$\Delta_\varphi(S) := \sum_{a \in A} \mu_\varphi(a)S(a)$$

the *drift* of S .

Proposition 5.2 *Let \mathcal{L}_φ be a language generated by primitive morphism on an alphabet A , and let $S : \mathcal{L}_\varphi \rightarrow \mathbb{Z} \times \mathbb{Z}$ be a homomorphism. Then $\mathbb{Z} \times \mathbb{Z} \setminus S(\mathcal{L})$ has infinite cardinality if $\Delta_\varphi(S) \neq (0, 0)$.*

Proof: It is well-known that the measure μ_φ is strictly ergodic. Because of this, we have for words w from \mathcal{L}_φ , where $|w|$ denotes the length of w ,

$$\frac{1}{|w|}S(w) = \frac{1}{|w|} \sum_{a \in A} N_a(w)S(a) \rightarrow \sum_{a \in A} \mu_\varphi(a)S(a) = \Delta_\varphi(S) \text{ as } |w| \rightarrow \infty.$$

Thus for long words w the images $S(w)$ will be concentrated around the line in the direction of the drift of S , and so the complement of $S(\mathcal{L}_\varphi)$ will have infinite cardinality if the drift is not $(0, 0)$. \square

Can we say something about the Frobenius problem for homomorphic images of morphic languages of an embedding with drift $(0, 0)$? We shall give an infinite family of morphic languages \mathcal{L}_θ on an alphabet $A = \{a, b, c, d\}$ of four letters where for the homomorphism S^\oplus given by

$$S^\oplus(a) = (1, 0), S^\oplus(b) = (0, 1), S^\oplus(c) = (-1, 0), S^\oplus(d) = (0, -1)$$

the homomorphic embedding is the whole $\mathbb{Z} \times \mathbb{Z}$ —and thus the complement is empty. We shall make use of the paperfolding morphisms introduced in [6]. Let σ be the rotation morphism on the alphabet $\{a, b, c, d\}$ given by $\sigma(a) = b$, $\sigma(b) = c$, $\sigma(c) = d$, $\sigma(d) = a$, and let τ be the anti-morphism given by $\tau(w_1 \dots w_n) = w_n \dots w_1$. A morphism θ on $\{a, b, c, d\}$ is called a *paperfolding* morphism if

- 1) $\sigma\tau\theta = \theta$,
- 2) Letters from $\{a, c\}$ alternate³ with letters from $\{b, d\}$ in $\theta(a)$.

A paperfolding morphism is called *symmetric* if $\sigma\theta = \theta$. It is clear that this happens if and only if the word $\theta(a)$ is a palindrome.

Let G be a (semi-) group with operation $+$ and unit e . In general an infinite word $x = (x_n)$ over an alphabet A and a homomorphism $S : A^* \rightarrow G$ generate a *walk* $Z = (Z_n)_{n \geq 0}$ by (cf. [5])

$$Z_0 = e, \quad Z_{n+1} = Z_n + S(x_n) = S(x_0 \dots x_n), \text{ for } n \geq 0.$$

A paperfolding morphism θ with $\theta(a) = a\dots$ is called *perfect* if the four walks generated by the fixed point $x = \theta^\infty(a)$, and its three rotations over $\pi/2, \pi$ and $3\pi/2$ visit every integer point in the plane exactly twice (except the origin, which is visited 4 times).

In [6] it is—not explicitly—proved that for any odd integer N that is the sum of two squares there exists a perfect symmetric paperfolding morphism of length N . To make the proof explicit, one uses that according to the paragraph at the end of Section 7 in [6] there exists a symmetric plane-filling and self-avoiding string for each such N , and then one observes that the construction of such a string in the proof of [6, Theorem 4] always satisfies the perfectness criterion given in [6, Theorem 5].

The smallest length is $N = 5$, with morphism θ given by

$$\theta(a) = abcba, \theta(b) = bcdcb, \theta(c) = cdadc, \theta(d) = dabad.$$

³This corrects an omission in [6, Definition 1].

Figure 2: The four images of the words $\theta^4(a), \dots, \theta^4(d)$ under S^\oplus , where θ is the perfect symmetric 5-folding morphism. The origin is not covered, but it is the image of the word $abcd \in \mathcal{L}_\theta$.

Proposition 5.3 *Let \mathcal{L}_θ be the language generated by a perfect symmetric paperfolding morphism θ . Then $S^\oplus(\mathcal{L}_\theta) = \mathbb{Z} \times \mathbb{Z}$.*

Proof: This follows directly from Theorem 5 in [6], using the observation above. \square
