Skew hook formula for $d$-complete posets via equivariant $K$-theory

Hiroshi Naruse & Soichi Okada

Abstract. Peterson and Proctor obtained a formula which expresses the multivariate generating function for $P$-partitions on a $d$-complete poset $P$ as a product in terms of hooks in $P$. In this paper, we give a skew generalization of Peterson–Proctor’s hook formula, i.e. a formula for the generating function of $(P \setminus F)$-partitions for a $d$-complete poset $P$ and an order filter $F$ of $P$, by using the notion of excited diagrams. Our proof uses the Billey-type formula and the Chevalley-type formula in the equivariant $K$-theory of Kac–Moody partial flag varieties. This generalization provides an alternate proof of Peterson–Proctor’s hook formula. As the equivariant cohomology version, we derive a skew generalization of a combinatorial reformulation of Nakada’s colored hook formula for roots.

1. Introduction

One of the most elegant formulas in combinatorics is the Frame–Robinson–Thrall hook formula [3, Theorem 1] for the number of standard tableaux. Given a partition $\lambda$ of $n$, a standard tableaux of shape $\lambda$ is a filling of the cells of the Young diagram $D(\lambda)$ of $\lambda$ with numbers $1, 2, \ldots, n$ such that each number appears once and the entries of each row and each column are increasing. The Frame–Robinson–Thrall hook formula asserts that the number $f^\lambda$ of standard tableaux of shape $\lambda$ is given by

$$f^\lambda = \frac{n!}{\prod_{v \in D(\lambda)} h_{D(\lambda)}(v)},$$

where $h_{D(\lambda)}(v)$ denotes the hook length of the cell $v$ in $D(\lambda)$. Similar formulas hold for the number of shifted standard tableaux ([14, 5.1.4, Exercise 21], see also [33, § 40] and [59, Theorem 1]) and the number of increasing labeling of rooted trees ([14, 5.1.4, Exercise 20]). These tableaux and labelings can be regarded as linear extensions of certain posets.

Stanley [35] introduced the notion of $P$-partitions for a poset $P$, and found a relationship between the univariate generating function and the number of linear extensions of $P$. Given a poset $P$, a $P$-partition is an order-reversing map $\sigma$ from $P$ to $\mathbb{N}$, the set of nonnegative integers. We denote by $A(P)$ the set of all $P$-partitions. For a $P$-partition $\sigma$, we write $|\sigma| = \sum_{v \in P} \sigma(x)$. Then Stanley [35] Corollaries 5.3
and 5.4] proved that, for a poset $P$ with $n$ elements, there exists a polynomial $W_P(q)$ satisfying
\begin{equation}
\sum_{\sigma \in A(P)} q^{\sigma} = \frac{W_P(q)}{prod_{i=1}^n (1 - q^i)},
\end{equation}
and that $W_P(1)$ is equal to the number of linear extensions of $P$. Also in [34, Proposition 18.3] he proved that, if $P$ is the Young diagram $D(\lambda)$ of a partition $\lambda$, viewed as a poset, the generating function of $D(\lambda)$-partitions (also called reverse plane partitions of shape $\lambda$) is given by
\begin{equation}
\sum_{\sigma \in A(D(\lambda))} q^{\sigma} = \frac{1}{prod_{v \in D(\lambda)} (1 - q^{h_{D(\lambda)}(v)})}.
\end{equation}
Combining (2) and (3) and taking the limit $q \to 1$, we obtain the Frame–Robinson–Thrall hook formula (1). Gansner [4, Theorem 5.1] gave a multivariate generalization of (3).

Proctor [29, 30] introduced a wide class of posets, called $d$-complete posets, enjoying “hook-length property”, as a generalization of Young diagrams, shifted Young diagrams and rooted trees. $d$-Complete posets are defined by certain local structural conditions (see Section 2 for a precise definition). Peterson and Proctor obtained the following theorem, which is a far-reaching generalization of the hook formulas (1) and (3).

**Theorem 1.1.** (Peterson–Proctor, see [31]) Let $P$ be a $d$-complete poset. The multivariate generating function of $P$-partitions is given by
\begin{equation}
\sum_{\sigma \in A(P)} z^{\sigma} = \frac{1}{prod_{v \in P} (1 - z[H_P(v)])}.
\end{equation}
(Refer to Section 2 for undefined notations.)

However the original proof of this theorem is not yet published, though an outline of their proof is given in [31]. Different proofs are sketched by Ishikawa–Tagawa [9, 10] and Nakada [23, 24]. Our skew generalization (Theorem 1.2 below) provides an alternate proof of Theorem 1.1. In the univariate case, a full proof is given by Kim–Yoo [12].

Another direction of generalizing the Frame–Robinson–Thrall hook formula (1) is to consider skew shapes. For partitions $\lambda \supset \mu$, a standard tableau of skew shape $\lambda/\mu$ is a filling of the cells of the skew Young diagram $D(\lambda/\mu) = D(\lambda) \setminus D(\mu)$ satisfying the same conditions as standard tableaux of straight shape. However one cannot expect a nice product formula for the number $f^{\lambda/\mu}$ of standard tableaux of skew shape $\lambda/\mu$ in general. Naruse [26] presented and sketched a proof of a subtraction-free formula for $f^{\lambda/\mu}$:
\begin{equation}
f^{\lambda/\mu} = n! \sum_{D \in D(\lambda) \setminus D(\mu)} \frac{1}{prod_{v \in D(\lambda) \setminus D} h_\lambda(v)},
\end{equation}
where $n = |\lambda/\mu|$, and $D$ runs over all excited diagrams of $D(\mu)$ in $D(\lambda)$. Morales–Pak–Panova [22] gave a $q$-analogue of Naruse’s skew hook formula for the univariate generating functions for $P$-partitions on $P = D(\lambda/\mu)$.

The main result of this paper is the following skew generalization of Peterson–Proctor’s hook formula (Theorem 1.1). Recall that a subset $F$ of a poset $P$ is called an order filter of $P$ if $x < y$ in $P$ and $x \in F$ imply $y \in F$. In particular the empty set $F = \emptyset$ is an order filter of $P$.
Theorem 1.2. Let $P$ be a $d$-complete poset and $F$ an order filter of $P$. Then the multivariate generating function of $(P \setminus F)$-partitions, where $P \setminus F$ is viewed as an induced subposet of $P$, is given by

$$
\sum_{\sigma \in \mathcal{A}(P \setminus F)} z^\sigma = \sum_{D \in \mathcal{E}(F)} \prod_{v \in \mathcal{B}(D)} z[H_P(v)]
\prod_{v \in P \setminus D} (1 - z[H_P(v)]),
$$

where $D$ runs over all excited diagrams of $F$ in $P$. (See Sections 2 and 3 for undefined notations.)

Taking an appropriate limit, we see that the number of linear extensions of $P \setminus F$ is given by

$$n! \sum_{D \in \mathcal{E}(F)} \prod_{v \in P \setminus D} h_P(v),
$$

where $n = \#(P \setminus F)$ and $h_P(v)$ is the hook length of $v$ in $P$. (See Corollary 5.6(b).)

If $F = \emptyset$, then our main theorem (Theorem 1.2) gives Peterson–Proctor’s hook formula (Theorem 1.1). If $P = D(\lambda)$ and $F = D(\mu)$ are the Young diagrams of partitions $\lambda \supset \mu$, then (6) reduces to Morales–Pak–Panova’s $q$-hook formula [22, Corollary 6.17] after specializing $z_i = q$ for all $i \in I$, and (7) is nothing but Naruse’s skew hook formula [3].

Our proof of Theorem 1.2 uses the equivariant $K$-theory of Kac–Moody partial flag varieties. In fact, the notion of excited diagrams and excited peaks for ordinary and shifted Young diagrams has its origin in the equivariant Schubert calculus (see [7], [8]; see also [5], [13], [15], [16]). Theorem 1.2 is obtained by proving that the both sides of (6) equal to the same ratio of the localized equivariant Schubert classes. (See Theorems 5.2 and 5.3.) A key role is played by the Billey-type formula due to Lam–Schilling–Shimozono [18] and the Chevalley-type formula due to Lenart–Shimozono [20] (see also [19]).

This paper is organized as follows. In Section 2, we review a definition and basic properties of $d$-complete posets. In Section 3, we introduce the notion of excited diagrams for $d$-complete posets, which is the key ingredient of the formulation of our main theorem, and study their properties. In Section 4, we recall some properties of the equivariant $K$-theory and translate the Billey-type formula and the Chevalley-type formula in terms of combinatorics of $d$-complete posets. We will give a proof of our main theorem (Theorem 1.2) and derive some corollaries in Section 5.

2. $d$-Complete posets

In this section we review a definition and some properties of $d$-complete posets and explain their connections to Weyl groups. See [29], [30], [31] and [38] for details. We use the terminology for posets (partially ordered sets) from [36, Chapter 3].

2.1. Combinatorics of $d$-complete posets. For an integer $k \geq 3$, we denote by $d_k(1)$ the poset consisting of $2k - 2$ elements $u_1, \ldots, u_{k-2}, x, y, v_{k-2}, \ldots, v_1$ with covering relations

$$
u_1 \gg u_2 \gg \cdots \gg u_{k-2},
$$

$$
u_{k-2} \gg x \gg v_{k-2},
$$

$$
v_{k-2} \gg \cdots \gg v_2 \gg v_1.
$$

Note that $x$ and $y$ are incomparable. The poset $d_k(1)$ is called the double-tailed diamond. The Hasse diagram of $d_k(1)$ is shown in Figure 1.
Let $P$ be a poset. An interval $[v, u] = \{ x \in P : v \leq x \leq u \}$ is called a $d_k$-interval if it is isomorphic to $d_k(1)$. Then $v$ and $u$ are called the bottom and top of $[v, u]$ respectively, and the two incomparable elements of $[v, u]$ are called the sides.

A subset $I$ of $P$ is called convex if $x < y < z$ in $P$ and $x, z \in I$ imply $y \in I$. A convex subset $I$ is called a $d_k$-convex set if it is isomorphic to the poset obtained by removing the top element from $d_k(1)$.

Definition 2.1. (See [32], [27]) A poset $P$ is $d$-complete if it satisfies the following three conditions for every $k \geq 3$:

(D1) If $I$ is a $d_k$-convex set, then there exists an element $u$ such that $u$ covers the maximal elements of $I$ and $I \cup \{u\}$ is a $d_k$-interval.

(D2) If $I = [v, u]$ is a $d_k$-interval and the top $u$ covers $u'$ in $P$, then $u' \in I$.

(D3) There are no $d_k$-convex sets which differ only in the minimal elements.

It is clear that rooted trees, viewed as posets with their roots being the maximum elements, are $d$-complete posets.

Example 2.2. For a partition $\lambda$, let $D(\lambda)$ be the Young diagram of $\lambda$ given by

$$D(\lambda) = \{(i, j) \in \mathbb{Z}^2 : i \geq 1, 1 \leq j \leq \lambda_i\}.$$ 

For a strict partition $\mu$, let $S(\mu)$ be the shifted Young diagram of $\mu$ given by

$$S(\mu) = \{(i, j) \in \mathbb{Z}^2 : i \geq 1, 1 \leq j \leq \mu_i + i - 1\}.$$ 

We endow $\mathbb{Z}^2$ with a poset structure by defining

$$ (i, j) \geq (i', j') \text{ if } i \leq i' \text{ and } j \leq j'.$$

Then we regard the Young diagram $D(\lambda)$ and the shifted Young diagram $S(\mu)$ as induced subposets of $\mathbb{Z}^2$. The resulting posets are called a shape and a shifted shape respectively. It can be shown that shapes and shifted shapes are $d$-complete posets. Figure 2 illustrates the Hasse diagrams of $D(5, 4, 2, 1)$ and $S(5, 4, 2, 1)$.

Example 2.3. Let $P$ be a subset of $\mathbb{Z}^2$ given by

$$P = \left\{ (1, 1), (1, 2), (1, 3), (1, 4), (1, 5), (2, 3), (2, 4), (2, 5), (3, 4), (3, 5), (3, 6), (4, 4), (4, 5), (4, 6), (4, 7), (4, 8) \right\}.$$ 

If we regard $P$ as an induced subposet of $\mathbb{Z}^2$ with ordering given by $\leq$, then $P$ is a $d$-complete poset, called a swivel. See Figure 3 for the Hasse diagram of $P$. 

Figure 1. Double-tailed diamond $d_k(1)$
A poset $P$ is called connected if its Hasse diagram is a connected graph. It is easy
to see that, if $P$ is a $d$-complete poset, then each connected component of $P$ is $d$-
complete. (For our purpose to prove Theorem 1.2, there is no harm in assuming that
a $d$-complete poset is connected.)

**Proposition 2.4.** ([29, §3]) Let $P$ be a $d$-complete poset. If $P$ is connected, then $P$
has a unique maximal element.

Let $P$ be a finite poset. The top forest $\Gamma$ of $P$ is a full subgraph of the Hasse
diagram of $P$, whose vertex set consists of all elements $x \in P$ such that every $y \geq x$
is covered by at most one other element. Note that two elements $x$ and $y \in \Gamma$ are
connected by an edge in $\Gamma$ if and only if $x$ covers $y$ or $y$ covers $x$. Then $\Gamma$ becomes a
forest as a graph (i.e. a disjoint union of trees). If $P$ is a connected $d$-complete poset,
then $\Gamma$ is a tree called the top tree of $P$. We can regard the top forest $\Gamma$ as a Dynkin
diagram of a Kac–Moody group. For example, the top trees of Figure 2 (a) and (b)
are of type $A_8$ and $D_6$ respectively. If $P$ is the swivel in Figure 3 the top tree is the
Dynkin diagram of type $E_6$. (See also Subsections 2.2 and 4.3.)

Remark 2.12 below will indicate how to combine the results of [30] and [38] to
obtain the following statement.

**Proposition 2.5.** ([30, Proposition 8.6], [38, Proposition 3.1]) Let $P$ be a $d$-complete
poset and $\Gamma$ its top forest. Let $I$ be a set of colors whose cardinality is the same as

---

**Figure 2.** Shape and shifted shape

(a) $D(5, 4, 2, 1)$

(b) $S(5, 4, 2, 1)$

**Figure 3.** Swivel
Γ. Then a bijective labeling $c : Γ \to I$ can be uniquely extended to a map $c : P \to I$ satisfying the following three conditions:

(C1) If $x$ and $y$ are incomparable, then $c(x) \neq c(y)$.
(C2) If an interval $[v, u]$ is a chain, then the colors $c(x)$ ($x \in [v, u]$) are distinct.
(C3) If $[v, u]$ is a $d_k$-interval then $c(v) = c(u)$.

Moreover this map $c$ satisfies

(C4) If $x$ covers $y$, then the nodes labeled by $c(x)$ and $c(y)$ are adjacent in $Γ$.
(C5) If $c(x) = c(y)$ or the nodes labeled by $c(x)$ and $c(y)$ are adjacent in $Γ$, then $x$ and $y$ are comparable.

Such a map $c : P \to I$ is called a $d$-complete coloring.

Let $P$ be a $d$-complete poset and $c : P \to I$ a $d$-complete coloring. Let $z = (z_i)_{i \in I}$ be indeterminates. Given an order filter $F$ of $P$, we regard $P \setminus F$ as an induced subposet. For a $(P \setminus F)$-partition $σ = A(\lambda)$, we put

$$z^σ = \prod_{v \in P \setminus F} z_{σ(v)}.$$

We are interested in the multivariate generating function

$$\sum_{σ \in A(P \setminus F)} z^σ$$

of $(P \setminus F)$-partitions. For a subset $D$ of $P$, we write

$$z_D = \prod_{v \in D} z_{c(v)}.$$ 

Instead of giving a definition of hooks $H_P(u) \subseteq P$ for a general $d$-complete poset $P$, we define associated monomials $z[H_P(u)]$ directly by induction as follows:

**Definition 2.6.** Let $P$ be a $d$-complete poset with $d$-complete coloring $c : P \to I$.

(i) If $u$ is not the top of any $d_k$-interval, then we define

$$z[H_P(u)] = \prod_{w \leq u} z_{c(w)}.$$

(ii) If $u$ is the top of a $d_k$-interval $[v, u]$, then we define

$$z[H_P(u)] = \frac{z[H_P(x)] \cdot z[H_P(y)]}{z[H_P(v)]},$$

where $x$ and $y$ are the sides of $[v, u]$.

**Example 2.7.** Let $P = D(λ)$ be the shape corresponding to a partition $λ$. Then the top tree $Γ$ of $D(λ)$ is given by

$$Γ = \{(i, j) : 1 \leq j \leq λ_1\} \cup \{(i, 1) : 1 \leq i \leq λ_1'\},$$

where $λ_1'$ is the number of cells in the first column of the Young diagram $D(λ)$. A $d$-complete coloring $c : D(λ) \to I = \{-(λ_1' - 1), \ldots, -1, 0, 1, \ldots, λ_1 - 1\}$ is given by

$$c(i, j) = j - i.$$ 

The classical definition of the hook $H_{D(λ)}(i, j) \subseteq D(λ)$ at $u = (i, j)$ in $D(λ)$ is as follows:

$$H_{D(λ)}(i, j) = \{(i, j)\} \cup \{(i, l) \in D(λ) : l > j\} \cup \{(k, j) \in D(λ) : k > i\}.$$
Then the hook monomial $z[H_{D(\lambda)}(i, j)]$ in Definition 2.6 and the hook $H_{D(\lambda)}(i, j)$ are related as

$$z[H_{D(\lambda)}(i, j)] = \prod_{(p, q) \in D(\lambda)} z_{c(p, q)}.$$  

**Example 2.8.** Let $P = S(\mu)$ be the shifted shape corresponding to a strict partition $\mu$ of length $\geq 2$. Then the top tree $\Gamma$ of $S(\mu)$ is given by

$$\Gamma = \{(1, j) : 1 \leq j \leq \mu_1\} \cup \{(2, 2)\},$$

and a $d$-complete coloring $c : S(\mu) \to I = \{0, 0', 1, 2, \ldots, \mu_1 - 1\}$ is given by

$$c(i, j) = \begin{cases} j - i & \text{if } i < j, \\ 0 & \text{if } i = j \text{ and } i \text{ is odd}, \\ 0' & \text{if } i = j \text{ and } i \text{ is even}. \end{cases}$$

The (shifted) hook $H_{S(\mu)}(i, j)$ of $u = (i, j)$ in $S(\mu)$ is the subset of $S(\mu)$ defined by

$$H_{S(\mu)}(i, j) = \{(i, j)\} \cup \{(i, l) \in S(\mu) : l > j\} \cup \{(k, j) \in S(\mu) : k > j\} \cup \{(j + 1, l) \in S(\mu) : l > j\}.$$

For example, if $\mu = (5, 4, 2, 1)$ and $(i, j) = (1, 2)$, then the corresponding hook is given by

$$H_{S(5,4,2,1)}(1, 2) = \{(1, 2), (1, 3), (1, 4), (1, 5), (2, 2), (3, 3), (3, 4)\},$$

and the hook monomial is $z[H_{S(5,4,2,1)}(1, 2)] = z_{0'}z_0z_2^2z_3z_4$.

2.2. $d$-Complete Posets and Weyl Groups. Let $P$ be a connected $d$-complete poset with top tree $\Gamma$. We regard $\Gamma$ as a (simply-laced) Dynkin diagram with node set $I$ and the $d$-complete coloring as a map $c : P \to I$. Let $A = (a_{ij})_{i,j \in I}$ be the generalized Cartan matrix of $\Gamma$ given by

$$a_{ij} = \begin{cases} 2 & \text{if } i = j, \\ -1 & \text{if } i \neq j \text{ and } i \text{ and } j \text{ are adjacent in } \Gamma, \\ 0 & \text{otherwise}. \end{cases}$$

We fix the following data associated to $A$:

- a free $\mathbb{Z}$-module $\Lambda$ of finite rank at least $\# \Gamma$, called the weight lattice,
- a linearly independent subset $\Pi = \{a_i : i \in I\}$ of $\Lambda$, called the simple roots,
- a subset $\Pi^\vee = \{a_i^\vee : i \in I\}$ of the dual lattice $\Lambda^* = \text{Hom}_{\mathbb{Z}}(\Lambda, \mathbb{Z})$, called the simple coroots,
- a subset $\{\lambda_i : i \in I\}$ of $\Lambda$, called the fundamental weights, such that

$$\langle a_i^\vee, a_j \rangle = a_{ij}, \quad \langle a_i^\vee, \lambda_j \rangle = \delta_{ij},$$

where $\langle \ , \ \rangle : \Lambda^* \times \Lambda \to \mathbb{Z}$ is the canonical pairing. Let $W$ be the corresponding (Kac–Moody) Weyl group generated by the simple reflections $\{s_i : i \in I\}$, where $s_i$ acts on $\Lambda$ and $\Lambda^*$ by the rule

$$s_i(\lambda) = \lambda - \langle \alpha_i^\vee, \lambda \rangle\alpha_i \quad (\lambda \in \Lambda), \quad s_i(\lambda^\vee) = \lambda^\vee - \langle \lambda^\vee, a_i \rangle a_i^\vee \quad (\lambda^\vee \in \Lambda^*).$$

Then $W$ is a Coxeter group, and we have the length function $l$ and the Bruhat order $\prec$ on $W$. The set of real roots $\Phi$ and the set of real coroots $\Phi^\vee$ are defined by $\Phi = W\Pi$ and $\Phi^\vee = W\Pi^\vee$ respectively. The set of simple roots $\Pi$ (resp. the set of simple coroots $\Pi^\vee$) determines the decomposition of $\Phi$ (resp. $\Phi^\vee$) into the positive system $\Phi_+$ (resp. $\Phi^\vee_+$) and the negative system $\Phi_-$ (resp. $\Phi^\vee_-$). We introduce the standard partial ordering on $\Phi_+$ (resp. $\Phi^\vee_+$) by setting $\alpha \succ \beta$ if $\alpha - \beta$ is a sum of simple roots $\{a_i : i \in I\}$ (resp. $\alpha^\vee \succ \beta^\vee$ if $\alpha^\vee - \beta^\vee$ is a sum of simple coroots $\{a_i^\vee : i \in I\}$).
For $p \in P$, we put
\[ \alpha(p) = \alpha_{c(p)}, \quad \alpha^\vee(p) = \alpha_{c(p)}^\vee, \quad s(p) = s_{c(p)}. \]
Let $\alpha_P$ and $\lambda_P$ be the simple root and the fundamental weight corresponding to the color $i_P$ of the maximum element of $P$.

Take a linear extension and label the elements of $P$ with $p_1, \ldots, p_N$ ($N = \#P$) so that $p_i < p_j$ in $P$ implies $i < j$. Then we construct an element $w_P \in W$ by putting
\[ w_P = s(p_1)s(p_2) \cdots s(p_N). \]

A Weyl group element $w \in W$ is called $\lambda$-minuscule if there exists a reduced expression $w = s_{i_1} \cdots s_{i_l}$ such that
\[ (\alpha_{i_k}, s_{i_{k+1}} \cdots s_{i_l} \lambda) = 1 \quad (1 \leq k \leq l), \]
or equivalently
\[ s_{i_k} \cdots s_{i_l} \lambda = \lambda - \alpha_{i_k} - \cdots - \alpha_{i_l}. \]

A element $w \in W$ is called fully commutative if any reduced expression of $w$ can be obtained from any other by using only the Coxeter relations of the form $st = ts$.

**Proposition 2.9.** (See [30] and [38] Proposition 2.1) Let $P$ be a connected $d$-complete poset. Then the Weyl group element $w_P \in W$ is $\lambda_P$-minuscule and hence fully commutative.

If $p = p_k \in P$, then we define
\[ \beta(p_k) = s(p_1) \cdots s(p_{k-1}) \alpha(p_k), \]
\[ \gamma(p_k) = s(p_N) \cdots s(p_{k+1}) \alpha(p_k), \]
\[ \gamma^\vee(p_k) = s(p_N) \cdots s(p_{k+1}) \alpha^\vee(p_k). \]

It follows from Proposition 2.9 that, for each $p \in P$, the roots $\beta(p)$, $\gamma(p)$ and the coroot $\gamma^\vee(p)$ are independent of the choices of linear extensions. For a Weyl group element $w \in W$, we put
\[ \Phi(w) = \Phi_+ \cap w\Phi_-, \quad \Phi^\vee(w) = \Phi_+^\vee \cap w\Phi_-. \]
Then it is well-known (see [3] §5.6]) that
\[ \Phi(w_P) = \{ \beta(p) : p \in P \}, \quad \Phi^\vee(w_P^{-1}) = \{ \gamma^\vee(p) : p \in P \}. \]
Moreover we have

**Proposition 2.10.** Let $P$ be a connected $d$-complete poset. Then we have
(a) (See [38] Proposition 3.1 and Theorem 5.5) The poset $P$ is isomorphic to the order dual of $\Phi^\vee(w_P^{-1})$ with the standard coroot ordering on $\Phi^\vee_+$.
(b) (See [31] Lemma IV) Under the identification $z_i = e^{\alpha_i}$ ($i \in I$), we have
\[ z[H_P(p)] = e^{\beta(p)} \quad (p \in P). \]
(c) (See [38] Proposition 5.1) We have
\[ \langle \gamma^\vee(p), \lambda_P \rangle = 1 \quad (p \in P). \]

Let $W_{\lambda_P}$ be the stabilizer of $\lambda_P$ in $W$. Then $W_{\lambda_P}$ is the maximal parabolic subgroup corresponding to $I \setminus \{i_P\}$. Let $W^{\lambda_P}$ be the set of minimum length coset representatives of $W/W_{\lambda_P}$. For a subset $D = \{p_{i_1}, \ldots, p_{i_r}\}$ ($i_1 < \cdots < i_r$) of $P$, we define
\[ w_D = s(p_{i_1}) \cdots s(p_{i_r}). \]
Since $w_P$ is fully commutative (Proposition 2.9), we see that $w_D$ is independent of the choices of linear extensions of $P$. 
PROPOSITION 2.11. Let $P$ be a connected $d$-complete poset. Then we have

(a) (See [31] Proposition 1) The map $F \mapsto w_F$ gives a poset isomorphism from the set of all order filters of $P$ ordered by inclusion to the Bruhat interval $[e, w_P]$ in $W^\lambda$.

(b) (See [38] Remark 2.7 (b)) If $F$ is an order filter of $P$, then $w_F$ is $\lambda_P$-minuscule, and

$$w_F \lambda_P = \lambda_P - \sum_{p \in F} \alpha(p).$$

REMARK 2.12. Let $A = (a_{ij})_{i,j \in I}$ be a symmetricizable generalized Cartan matrix, and $\Gamma$ the corresponding Dynkin diagram with node set $I$. Let $W$ be the associated Kac–Moody Weyl group generated by $\{s_i : i \in I\}$. Given a (not necessarily reduced) expression $s_{i_1} s_{i_2} \ldots s_{i_N}$ of an element $w \in W$ in simple reflections, we can define a poset $H$, called the heap, as follows (see [37]). The poset $H$ consists of the ground set $\{1, 2, \ldots, N\}$ and the partial ordering $\leq$ obtained by taking the transitive closure of the relations given by

$$a \preceq b \text{ if } a < b \text{ and either } s_{i_a} s_{i_b} \neq s_{i_b} s_{i_a} \text{ or } i_a = i_b.$$ 

The heap $H$ has a natural labeling (coloring) $c : H \to I$ given by $c(a) = i_a$. If $w \in W$ is fully commutative, then the heap defined by a reduced expression of $w$ is independent of the choices of reduced expressions. In this case we denote the resulting heap by $H(w)$.

If $a_{ij} = a_{ji} \in \{0, -1\}$ for any pair of vertices $i, j \in I$ ($i \neq j$), then we say that $A, W$ and $H(w)$ are simply-laced; otherwise they are multiply-laced. For a dominant weight $\lambda$ and a $\Lambda$-minuscule element $w$ in the simply-laced Weyl group $W$, Proctor [38] proved that the interval $[e, w]$ of $W^\lambda$ with respect to the Bruhat order is a distributive lattice, and that the order dual of the induced subposet consisting of all join-irreducible elements of $[e, w]$ is a $d$-complete poset colored by $I$. Stembridge [38] extends Proctor’s result to any symmetricizable Kac–Moody Weyl group in the setting of heaps. The results of [30] and [38] may be combined by using [37] Theorem 3.2 (c) to produce Proposition 2.11 above. Henceforth the simply-laced case will be referred to with the “$d$-complete poset” terminology and the general case will be referred to with the “heap” terminology. Every $d$-complete poset $P$ is isomorphic to the simply-laced heap $H(w_P)$.

In general, if $w \in W$ is dominant minuscule, i.e. $\lambda$-minuscule for some dominant weight $\lambda$, the corresponding heap $H(w)$ is isomorphic (as an unlabeled poset) to a $d$-complete poset. See [38] Sections 3 and 4.

The propositions in this section hold literally for heaps $H(w)$ of dominant minuscule elements, except for Proposition 2.5 and Proposition 2.10 (b). The latter half of Proposition 2.5 holds for heaps, i.e. the labeling $c : H(w) \to I$ satisfies (C4) and (C5). And we adopt Proposition 2.10 (b) as a definition of the hook monomial for $H(w)$. Below is an example of a non-simply-laced heap.

EXAMPLE 2.13. (Non-simply-laced heap) Let $\mu = (\mu_1, \ldots, \mu_l)$ be a strict partition of length $l$. Then the shifted shape $S(\mu)$ can be regarded as the heap associated to a dominant minuscule element of the Weyl group of type $B$, which is not simply-laced. Put $m = \mu_1$ and let $W$ be the Weyl group generated by $s_0, s_1, \ldots, s_{m-1}$ subject to the relations

$$s_i^2 = 1 \quad (i = 0, 1, \ldots, m-1),$$
$$s_0 s_1 s_0 s_1 = s_1 s_0 s_1 s_0,$$
$$s_i s_{i+1} s_i = s_{i+1} s_i s_{i+1} \quad (i = 1, 2, \ldots, m-2),$$
$$s_i s_j = s_j s_i \quad (|i-j| \geq 2).$$

Algebraic Combinatorics, draft (June 28, 2019)
Then we define an element $w_\mu \in W$ by putting
\[ w_\mu = (s_{\mu_1-1} \cdots s_1 s_0) \cdots (s_{\mu_k-1} \cdots s_1 s_0)(s_{\mu_1-1} \cdots s_1 s_0). \]
Then it can be shown that $w_\mu$ is $\lambda_0$-minuscule, where $\lambda_0$ is the fundamental weight corresponding to $s_0$, and that the map
\[ S(\mu) \ni (i,j) \mapsto \mu + \cdots + \mu_i - j + i \in H(w_\mu) \]
gives a poset isomorphism. We identify the ground set of $H(w_\mu)$ with $S(\mu)$ via the isomorphism \([10]\). Then the natural labeling $c' : S(\mu) \to \{0, 1, \ldots, m - 1\}$ of $H(w_\mu)$ is given by $c'(i,j) = j - i$, which is different from the $d$-complete coloring of $S(\mu)$ given in Example \([2, 8]\). And the \textquotedblleft hook\textquotedblright $H'_{S(\mu)}(v)$ (see \([24, \text{Definition 4.8}]\)) is defined by
\[
H'_{S(\mu)}(i,j) = \{(i,j)\} \cup \{(i,l) : l > j\} \cup \{(k,j) : S(\mu) : k > i\}
\]
\[
\cup \begin{cases}
\{(i,i)\} \cup \{(j,l) : S(\mu) : l \geq j\} & \text{if } i < j \text{ and } (j,j) \in S(\mu), \\
\emptyset & \text{otherwise},
\end{cases}
\]
which is also different from the shifted hook given in Example \([2, 8]\) (See also Example \([5, 9]\)).

3. Excited diagrams

In this section we introduce the notion of excited and $K$-theoretical excited diagrams in a $d$-complete poset and study their properties.

3.1. Excited diagrams. First we generalize the notion of excited diagrams for Young diagram and shifted Young diagram, which were introduced by Ikeda–Naruse \([17]\) and Kreiman \([15, 16]\) independently, to a general $d$-complete posets. And we give a generalization of backward movable positions or excited peaks introduced in \([8, 13]\) and \([22]\).

Let $P$ be a $d$-complete poset with top forest $\Gamma$ and $d$-complete coloring $c : P \to I$. For a subset $D \subset P$ and a color $i \in I$, we put
\[ D_i = \{x \in D : c(x) = i\}. \]
For $i \in I$, let $N_i$ be the subset of $P$ consisting of element $x \in P$ whose color $c(x)$ is adjacent to $i$ in the Dynkin diagram $\Gamma$. Note that, if $[v,u]$ is a $d_k$-interval, then $[v,u] \cap N_{c(u)}$ consists of elements $x \in [v,u]$ such that $x$ is covered by $u$ or covers $v$.

**Definition 3.1.** Let $P$ be a $d$-complete poset and let $F$ be an order filter of $P$.

(a) Let $D$ be a subset of $P$ and $u \in D$. We say that $u$ is $D$-active if there exists an element $v \in (P \searrow D)_c(u)$ such that $v < u$, $[v,u]$ is a $d_k$-interval and $[v,u] \cap D \cap N_{c(u)} = \emptyset$.

(b) Let $D$ be a subset of $P$ and $u \in D$. If $u$ is $D$-active, then we define $\alpha_u(D)$ to be the subset of $P$ obtained from $D$ by replacing $u \in D$ by the bottom element $v$ of the $d_k$-interval $[v,u]$. We call this replacement an (ordinary) elementary excitation.

(c) An excited diagram of $F$ in $P$ is a subset of $P$ obtained from $F$ after a sequence of elementary excitations on active elements. Let $E_F(P)$ be the set of all excited diagrams of $F$ in $P$.

(d) To an excited diagram $D \in E_F(P)$ we associate a subset $B(D) \subset P$ as follows: If $D = F$, then $B(F) = \emptyset$. If $D$ is an excited diagram with an active element $u$, then we define
\[
B(\alpha_u(D)) = (B(D) \searrow ([v,u] \cap N_{c(u)})) \cup \{u\},
\]
where \([v, u]\) is the \(d_k\)-interval with top element \(u\). We call \(B(D)\) the set of excited peaks of \(D\). (We will show that \(B(D)\) is a well-defined subset of \(P \setminus D\) in Proposition 3.7.)

In general, if two elements \(u \in D\) and \(v \notin D\) with \(v < u\) have the same color \(i = c(v) = c(u)\) and satisfy \([v, u] \cap D \cap N_i = \emptyset\), then \(D \setminus \{u\} \cup \{v\}\) is obtained from \(D\) by a sequence of elementary excitations.

If \(P\) is a shape or a shifted shape, our definition above coincides with the definitions of elementary excitations in [7], [8], or ladder moves in [15], [16], and backward movable positions in [8], [13] or excited peaks in [22] (only for a shape).

Example 3.2. If \(P = D(5, 4, 2, 1)\) is the shape corresponding to a partition \((5, 4, 2, 1)\) and \(F = D(3, 1)\), then there are 7 excited diagrams in \(\mathcal{E}_P(F)\) shown in Figure 4. In Figure 4 (and Figures 5) the shaded cells form an excited diagram and a cell with \(\times\) is an excited peak. And the arrow \(D \rightarrow D'\) means that \(D'\) is obtained from \(D\) by an elementary excitation.

Example 3.3. If \(P\) is the swivel given in Example 2.3 and \(F\) is the order filter consisting of three elements, then there are 8 excited diagrams in \(\mathcal{E}_P(F)\) shown in Figure 5.

Let \(P\) be a connected \(d\)-complete poset and \(W\) the Weyl group corresponding to the top tree \(\Gamma\) viewed as a Dynkin diagram. Fix a linear extension of \(P\), i.e. a labeling of the elements of \(P\) with \(p_1, \ldots, p_N\) so that \(p_i < p_j\) in \(P\) implies \(i < j\). Then we can associate to a subset \(D\) of \(P\) a well-defined element \(w_D \in W\) as in (9). The following proposition gives a characterization of excited diagrams.

Proposition 3.4. Let \(P\) be a connected \(d\)-complete poset and let \(F\) be an order filter of \(P\). Then a subset \(D \subset P\) is an excited diagram of \(F\) in \(P\) if and only if \(#D = #F\) and \(w_D = w_F\).

To prove this proposition, we prepare two lemmas.

Lemma 3.5. Let \(D\) be a subset of \(P\) and \(u\) and \(v\) elements of \(P\) such that \(v < u\) and \(c(u) = c(v) = i\). Suppose \(v = p_k\) and \(u = p_l\). If \([v, u] \cap D \cap N_i = \emptyset\), then we have \(s(p_j)s(p_l) = s(p_l)s(p_j)\) for any \(p_j \in D\) with \(k < j < l\).

Proof. follows from Property (C5) in Proposition 2.5.

Lemma 3.6. (See [5, Section 3]) Let \(v \in W\) be a fully commutative element and \(v = s_{i_1} \cdots s_{i_r} = s_{j_1} \cdots s_{j_r}\) be its reduced expressions. Then we have
Figure 5. Excited diagrams in a swivel

(a) Let $i$, $j$ be adjacent nodes in the Dynkin diagram. Then the subsequence of $(i_1, \ldots, i_r)$ consisting of $i$ and $j$ is identical with the subsequence of $(j_1, \ldots, j_r)$ consisting of $i$ and $j$.

(b) Let $i$ be a node in the Dynkin diagram. Then the number of occurrence of $i$ in $(i_1, \ldots, i_r)$ is equal to the number of occurrence of $i$ in $(j_1, \ldots, j_r)$.

We use these lemmas to prove the characterization of excited diagrams.

Proof of Proposition 3.4 We follow the same idea used in the proof of [5, Proposition 4.8]. We denote by $R_P(F)$ the set of all subsets $D \subset P$ satisfying $\#D = \#F$ and $w_D = w_F$.

First we prove that $E_P(F) \subset R_P(F)$. Since $F \in R_P(F)$, it is enough to show that, if $D' \in E_P(F)$ is obtained from $D \in E_P(F)$ by an elementary excitation, then $w_{D'} = w_D$.

Let $u, v \in P$ be elements such that $[v, u]$ is a $d_k$-interval, $[v, u] \cap D \cap N_{c(u)} = \emptyset$ and $D' = \alpha_u(D) = D \setminus \{u\} \cup \{v\}$. If $v = p_k$, $u = p_l$ and $\{j : k < j < l, p_j \in D\} =$
\{j_1, \ldots, j_m\} \ (j_1 < \cdots < j_m), \text{ then we have}\\
\quad w_D = \cdots s(p_{j_1}) \cdots s(p_{j_m}) s(p_t) \cdots, \quad w_{D'} = \cdots s(p_k) s(p_{j_1}) \cdots s(p_{j_m}) \cdots.\\
\end{align*}\\

Then by using Lemma 3.5, we have \(w_{D'} = w_D\).

Next we prove that \(\mathcal{R}_P(F) \subseteq \mathcal{E}_P(F)\). Since \(F\) is an order filter, we can take a linear extension of \(P\) such that \(F = \{p_{n+1}, \ldots, p_N\}\), where \(n = \#(P \setminus F)\). We define the energy \(e(D)\) of any subset \(D \subseteq P\) with \(\#D = \#F\) by putting\\
\[
\quad e(D) = \sum_{p_k \in F} k - \sum_{p_k \in D} k.\\
\]

Then, by the assumption on our linear extension, we see that \(e(D) \geq 0\) and that \(e(D) = 0\) if and only if \(D = F\).

We proceed by induction on \(e(D)\) to prove \(D \in \mathcal{R}_P(F)\) implies \(D \in \mathcal{E}_P(F)\). Let \(D \in \mathcal{R}_P(F)\). If \(e(D) = 0\), then we have \(D = F \in \mathcal{E}_P(F)\).

Suppose that \(e(D) > 0\). Then there exists an element \(u \in F\) such that \(u \notin D\). Let \(u\) be the last element, i.e. \(u = p_l\) with \(l\) largest, satisfying \(u \in F\) and \(u \notin D\). Since \(w_D = w_F\) and \(w_F\) is fully commutative, it follows from Lemma 3.5 (b) that there exists an element \(v \in D\) with the same color \(i\) as \(u\). Let \(v = p_k\) (\(1 \leq k < l\)) be the last element satisfying \(v \in D\) and \(c(v) = c(u) = i\). Then, by the choice of \(k\) and \(l\), we see that the reduced expressions of \(w_F\) and \(w_D\) are of the form \(w_F = \cdots s_i s_j \cdots s_l\) (\(s_i\) corresponds to \(u\)) and \(w_D = \cdots s_i s_j \cdots s_k s_{h_1} \cdots s_{h_r}\) (\(s_i\) corresponds to \(v\)) with no \(i\) appearing in the segment \((j_1, \ldots, j_m)\). If \(z \in [v, u] \cap D \cap N_i\), then \(j = c(z)\) appears in the segment \((j_1, \ldots, j_m)\) and this contradicts to the assertion of Lemma 3.6 (a). Hence we have \([v, u] \cap D \cap N_i = \emptyset\). If we put \(D' = D \setminus \{v\} \cup \{u\}\), then \(e(D') = w_F\) by Lemma 3.5 and \(e(D') < e(D)\). Then by the induction hypothesis we have \(D' \in \mathcal{E}_P(F)\). Since \(D\) is obtained from \(D'\) by a sequence of elementary excitations, we obtain \(D \in \mathcal{E}_P(F)\). \hfill \square

Next we give a non-recursive description of the set of excited peaks \(B(D)\), which implies that \(B(D)\) is well-defined, i.e. it is independent of the choices of elementary excitations to reach \(D\) from \(F\).

**Proposition 3.7.** Let \(D \in \mathcal{E}_P(F)\) be an excited diagram.

(a) The following are equivalent for \(x \in P\):

(i) \(x \in B(D)\).

(ii) There exists an element \(y \in D_{c(x)}\) such that \(y < x\) and \([y, x] \cap D \cap N_{c(x)} = \emptyset\).

(b) We have \(D \cap B(D) = \emptyset\).

In the proof of this proposition, we utilize the following lemma, which will be used also in the sequel of this section.

**Lemma 3.8.** Let \(x, y, z, u\) and \(v\) be elements of \(P\) such that \(c(x) = c(y) = c(z) = i\), \(c(u) = c(v) = j\), \(z < y < x\) and \(v < u\). Let \(D\) be a subset of \(P\). Then we have

(a) If \([z, y] \cap D \cap N_i = \emptyset\) and \([y, x] \cap D \cap N_i = \emptyset\), then we have \([z, x] \cap D \cap N_i = \emptyset\).

(b) Suppose \(u \in D\) and \(v \notin D\). If \([y, x] \cap D \cap N_i = \emptyset\) and \(x \notin [v, u] \cap N_{j}\), then we have \([y, x] \cap (D \cup \{v\}) \cap N_i = \emptyset\).

(c) Suppose \(u \in D\) and \(v \notin D\). If \([y, x] \cap (D \setminus \{u\}) \cap N_i = \emptyset\) and \(y \notin [v, u] \cap N_j\), then we have \([y, x] \cap D \cap N_i = \emptyset\).

(d) Suppose that \(u \notin D\) and \(v \in D\). If \([y, x] \cap D \cap N_i = \emptyset\) and \(y \notin [v, u] \cap N_j\), then we have \([y, x] \cap (D \cup \{u\}) \cap N_i = \emptyset\).

**Proof.** (a) By using Property (C5) in Proposition 2.3(e), we have \([z, x] \cap N_i = ([z, y] \cap N_i) \cup ([y, x] \cap N_i)\)
(b) Assume to the contrary that \([y, x] \cap (D \cup \{v\}) \cap N_i \neq \emptyset\). Since \([y, x] \cap D \cap N_i = \emptyset\), we have \(v \in [y, x] \cap N_i\). Thus \(s = c(u) = c(v)\) is adjacent to \(i = c(x)\) in \(\Gamma\). Since \(u \in D\) and \([y, x] \cap D \cap N_i = \emptyset\), we have \(u \notin [y, x] \cap N_i\). Hence, by using Property (C5) in Proposition 2.5, we see that \(y < v < x < u\) and \(x \in [v, u] \cap N_j\), which contradicts to the assumption.

(c) By an argument similar to (b), we can show that, if \([y, x] \cap D \cap N_i \neq \emptyset\), then \(v < y < u < x\), which contradicts to \(y \notin [v, u] \cap N_j\).

(d) By an argument similar to (b), we can show that, if \([y, x] \cap (D \cup \{u\}) \cap N_i \neq \emptyset\), then \(v < y < u < x\), which contradicts to \(y \notin [v, u] \cap N_j\). □

**Proof of Proposition 3.7** We denote by \(B'(D)\) the subset of \(P\) consisting of elements \(x \in P\) satisfying the condition (ii) in (a), and prove \(B(D) = B'(D)\) and \(D \cap B'(D) = \emptyset\). We proceed by induction on the number of elementary excitations to reach \(D\) from \(F\).

We begin with considering the case where \(D = F\). Let \(x\) and \(y\) be elements of \(F\) with the same color \(i\) satisfying \(y < x\). Then it follows from Properties (C4) and (C5) in Proposition 2.5 that an element \(z\) covered by \(x\) or covers \(y\) belongs to \([y, x] \cap F \cap N_i\). Hence we have \(B'(F) = \emptyset = B(F)\) and \(F \cap B'(F) = \emptyset\).

We prove that \(B(\alpha_u(D)) = B'(\alpha_u(D))\) and \(\alpha_u(D) \cap B'(\alpha_u(D)) = \emptyset\) for \(D \in \mathcal{P}(F)\) and a \(D\)-active element \(u \in D\). Let \(v\) be the element such that \(v < u\), \(c(v) = c(u)\), \([v, u] \cap D \cap N_i = \emptyset\), \([v, u]\) is a \(d_u\)-interval and \(\alpha_u(D) = D \setminus \{u\} \cup \{v\}\). Recall that, by definition, \(B(\alpha_u(D)) = (B(D) \setminus ([v, u] \cap N_i)) \cup \{u\}\).

First we show \(B(\alpha_u(D)) \subset B'(\alpha_u(D))\). Since \(v \in \alpha_u(D)\) and \([v, u] \cap D \cap N_i = \emptyset\), we have \(u \in B'(\alpha_u(D))\). Let \(x \in B(D)\) such that \(x \notin [v, u] \cap N_i\). Since \(B(D) = B'(D)\) by the induction hypothesis, there exists \(y \in D_{c(x)}\) such that \(y < x\) and \([y, x] \cap D \cap N_i = \emptyset\). Then, by using Lemma 3.3(b), we have \([y, x] \cap \alpha_u(D) \cap N_i = \emptyset\), hence \(x \in B'(\alpha_u(D))\).

Next, in order to show \(B'(\alpha_u(D)) \subset B(\alpha_u(D))\), we take an element \(x \in B'(\alpha_u(D))\), such that \(x \neq u\) and prove \(x \in B(D) \setminus ([v, u] \cap N_i)\). Then there exists \(y \in \alpha_u(D)_{c(x)}\) such that \(y < x\) and \([y, x] \cap \alpha_u(D) \cap N_i = \emptyset\). If \(y = v\), then \(\alpha_u(D) \cap N_i = D \setminus \{x\}\), hence \([v, u] \cap D \cap N_i \subset [v, x] \cap \alpha_u(D) \cap N_i = \emptyset\). Since \(u \in D\), we have \(x \in B'(D) = B(D)\) and \(x \notin N_i\). We consider the case where \(y \neq v\). In this case, \(y \in D\), \(y \notin [v, u] \cap N_i\) and it follows from Lemma 3.3(c) that \([y, x] \cap D \cap N_i = \emptyset\), so \(x \in B'(D) = B(D)\). Also we have \(x \notin [v, u] \cap N_i\). In fact, if \(x \in [v, u] \cap N_i\), then \(c(x) = c(x)\) is adjacent to \(c(u)\) and it follows from \(y \in D\) and \([v, u] \cap D \cap N_i = \emptyset\) that \(y \notin [v, u] \cap N_i\). Hence, by using Property (C5) in Proposition 2.5, we have \(y < v < x < u\) and this contradicts to the case where \(x \in B(D) \setminus ([v, u] \cap N_i)\).

Finally we show that \(\alpha_u(D) \cap B'(\alpha_u(D)) = \emptyset\). Let \(x\) and \(y\) be elements of \(\alpha_u(D)\) with the same color \(i\) satisfying \(y < x\). Since \(\alpha_u(D) = D \setminus \{u\} \cup \{v\}\), it is enough to show \([y, x] \cap \alpha_u(D) \cap N_i \neq \emptyset\) for the following three cases:

Case 1. \(x, y \in D\). Case 2. \(y = v\). Case 3. \(x = v\).

In Case 1, assume that \([y, x] \cap \alpha_u(D) \cap N_i = \emptyset\). If \([y, x] \cap D \cap N_i = \emptyset\), then we have \(x \in B(D)\) and this contradicts to the induction hypothesis \(D \cap B(D) = \emptyset\). Hence \([y, x] \cap D \cap N_i \neq \emptyset\) and this implies \(u \in [y, x] \cap N_i\), i.e. \(y < u < x\) and \(c(u) = c(v)\) is adjacent to \(i\) in \(\Gamma\). Since \(u \in \alpha_u(D)\), we have \(u \notin [y, x] \cap N_i\). Therefore, by using Property (C5) in Proposition 2.5, we see that \(v < y < u < x\), which contradicts to the \(D\)-activity of \(u\). In Case 2, we have \(v < u < x\) because \([v, u] \subset D\) is an \(d_u\)-interval and there is no element \(w \in [v, u] \setminus \{u\}\), \(w \neq v, u\) and \(c(w) = c(v) = c(u)\) by Property (C2) in Proposition 2.5. Since \([u, x] \cap D \cap N_i \neq \emptyset\) by the induction hypothesis, we have \([v, x] \cap \alpha_u(D) \cap N_i \neq \emptyset\). In Case 3, we have \([v, u] \cap D \cap N_i = \emptyset\) (\(u\) is \(D\)-active)
and \([y, u] \cap D \cap N_i \neq \emptyset\) (the induction hypothesis). Hence by using Lemma 3.8 (a) we obtain \([y, v] \cap \alpha_u(D) \cap N_i \neq \emptyset\). Therefore we see that any element satisfying the condition (ii) in (a) for \(\alpha_u(D)\) does not belong to \(\alpha_u(D)\), and \(\alpha_u(D) \cap B'(\alpha_u(D)) = \emptyset\). This completes the proof. \(\square\)

3.2. \(K\)-theoretical excited diagrams. We define \(K\)-theoretical excited diagrams and study their properties. For shapes and shifted shapes, these diagrams were introduced in [5].

**Definition 3.9.** Let \(P\) be a \(d\)-complete poset and let \(F\) be an order filter of \(P\).

(a) Let \(D\) be a subset of \(P\) and \(u \in D\). If \(u\) is \(D\)-active and \([v, u]\) is a \(d_k\)-interval, then we define \(\alpha^*_u(D)\) to be the subset of \(P\) obtained by adding \(v\) to \(D\). We call this operation a \(K\)-theoretical elementary excitation.

(b) A \(K\)-theoretical excited diagram of \(F\) in \(P\) is a subset of \(P\) obtained from \(F\) after a sequence of ordinary and \(K\)-theoretical elementary excitations on active elements. Let \(E^*_P(F)\) be the set of all \(K\)-theoretical excited diagrams of \(F\) in \(P\).

**Example 3.10.** If \(P = S(5, 4, 2, 1)\) is the shifted shape corresponding to a strict partition \((5, 4, 2, 1)\) and \(F = S(3, 1)\), then there are 11 \(K\)-theoretical excited diagrams in \(E^*_P(F)\) shown in Figure 6, and five of them are ordinary excited diagrams in \(E_P(F)\). In Figure 6, the shaded cells form a \(K\)-theoretical exited diagram, and the arrow \(D \rightarrow D'\) (resp. \(D \Rightarrow D'\)) indicates that \(D'\) is obtained from \(D\) by an ordinary (resp. \(K\)-theoretical) elementary excitation.

**Figure 6.** \(K\)-theoretical excited diagrams of \(S(3, 1)\) in \(S(5, 4, 2, 1)\)
For a fixed linear extension of $P$ and a subset $D = \{p_{i_1}, \ldots, p_{i_r}\}$ $(i_1 < \cdots < i_r)$ of $P$, we define an element $w^*_D \in W$ by putting
\[ w^*_D = s(p_{i_1}) * s(p_{i_2}) * \cdots * s(p_{i_r}), \]
where $*: W \times W \to W$ is the associative product, called the Demazure product, defined by
\[ s_i * w = \begin{cases} s_i w & \text{if } l(s_i w) = l(w) + 1, \\ w & \text{if } l(s_i w) = l(w) - 1. \end{cases} \]
For the fundamental properties of the Demazure product (also called the Hecke product), we refer to \cite[Section 3]{2}. Since $w^*_D$ is fully commutative (Proposition \ref{prop:fully-commutative}), the element $w^*_D$ is independent of the choices of linear extensions of $P$.

The following proposition is a key to rephrase the Billey-type formula for equivariant $K$-theory in terms of combinatorics of $d$-complete posets (see Proposition \ref{prop:billey}).

**Proposition 3.11.** Let $P$ be a connected $d$-complete poset and $F$ an order filter of $P$. Then a subset $D \subset P$ is a $K$-theoretical excited diagram of $F$ in $P$ if and only if $w^*_D = w_F$.

We follow the same idea as the proof of \cite[Proposition 4.8]{5}.

**Lemma 3.12.** (\cite[Lemma 3.1 and Proposition 3.4]{5}) Let $v \in W$ and $v = s_{i_1} * \cdots * s_{i_r}$ with $i_1, \ldots, i_r \in I$.
\begin{enumerate}[(a)]  \item There is an increasing sequence $1 \leq k_1 < k_2 < \cdots < k_l \leq r$ such that $v = s_{i_{k_1}} s_{i_{k_2}} \cdots s_{i_{k_l}}$ is a reduced expression of $v$. In particular, we have $l(v) \leq r$.  \item If $l(v) = r$, then $v = s_{i_1} * \cdots * s_{i_r}$.  \item If $v$ is fully commutative and $l(v) < r$, then there exist $a < b$ such that $s_{i_a} * s_{i_b}$ commutes with $s_{i_r}$ for every $a < c < b$. \end{enumerate}

**Proof of Proposition 3.11.** We denote by $R^*_P(F)$ the set of all subsets $D \subset P$ satisfying $w^*_D = w_F$.

First we prove $E^*_P(F) \subset R^*_P(F)$. Since $F \in R^*_P(F)$, it is enough to show that, if $D' \in E^*_P(F)$ is obtained from $D \in E^*_P(F)$ by an ordinary or $K$-theoretical elementary excitation, then $w^*_{D'} = w^*_D$. Let $u$ be a $D$-active element and $[v, u]$ be the $d_k$-interval with top element $u$. Let $v = p_k$, $u = p_l$ and $\{ j : k < j < l, p_j \in D \} = \{ j_1, \ldots, j_m \}$ $(j_1 < \cdots < j_m)$. If $D' = \alpha_u(D) = D \cup \{ v \} \cup \{ v \}$, then we have
\[ w^*_D = \cdots * s(p_{j_1}) * \cdots * s(p_{j_m}) * s(p_l) * \cdots, \]
\[ w^*_{D'} = \cdots * s(p_k) * s(p_{j_1}) * \cdots * s(p_{j_m}) * s(p_l) * \cdots. \]
If $D' = \alpha_u^*(D) = D \cup \{ v \}$, then we have
\[ w^*_D = \cdots * s(p_{j_1}) * \cdots * s(p_{j_m}) * s(p_l) * \cdots, \]
\[ w^*_{D'} = \cdots * s(p_k) * s(p_{j_1}) * \cdots * s(p_{j_m}) * s(p_l) * \cdots. \]
Since $u$ is $D$-active, it follows from Lemma \ref{lem:excitation} and $s(p_k) * s(p_l) = s(p_l) * s(p_k) = s(p_l)$ that $w^*_{D'} = w^*_D$ in both cases.

Next we prove $R^*_P(F) \subset E^*_P(F)$. We proceed by induction on $\#D$ to prove $D \in R^*_P(F)$ implies $D \in E^*_P(F)$. Since $w^*_D = w_F$, we have $\#D \geq l(w_F) = \#F$ by Lemma \ref{lem:fully-commutative} (a). If $\#D = \#F$, then $w^*_D = w_D$ by Lemma \ref{lem:fully-commutative} (b), thus we have $D \in E^*_P(F) \subset E^*_P(F)$ by Proposition \ref{prop:fully-commutative}. If $\#D > \#F$, then it follows from Lemma \ref{lem:fully-commutative} (c) that there exist $u, v \in \mathbb{E}$ with $v < u$ such that $c(u) = c(v)$ and $s(u) = s(v)$ commutes with $s(w)$ for every element $w$ between $u$ and $v$ in the expression of $w^*_D$. If we put $D' = D \setminus \{ v \}$, then we see that $w^*_D = w^*_{D'}$. Hence by the induction hypothesis
we have $D' \in \mathcal{E}_p^*(F)$. Since $D$ is obtained from $D'$ by a sequence of ordinary and $K$-theoretical elementary excitations, we obtain $D \in \mathcal{E}_p^*(F)$. □

The following proposition plays a crucial role in the proof of our main theorem (see the proof of Theorem 3.3).

**Proposition 3.13.** Let $P$ be a connected $d$-complete poset and $F$ an order filter of $P$. Then we have

$$
\mathcal{E}_p^*(F) = \bigcup_{D \in \mathcal{E}_p^*(F)} \{ D \cup S : S \subset B(D) \}.
$$

In order to prove this proposition, we prepare several lemmas.

**Lemma 3.14.** Let $x$ and $y$ be elements of $P$ such that $y < x$ and $c(x) = c(y) = i$, and let $D \in \mathcal{E}_p^*(F)$ be an excited diagram. If $[y, x] \cap D \cap N_i = \emptyset$ and $y \in D$, then we have $[y, x] \cap D \cap N_i = \emptyset$.

**Proof.** Assume to the contrary that $[y, x] \cap D \cap N_i \neq \emptyset$ and take an element $z \in [y, x] \cap D \cap N_i$. By Proposition 3.7 (a), there exists $w \in D_{c(z)}$ such that $w < z$ and $[w, z] \cap D \cap N_{c(z)} = \emptyset$. Then $c(w) = c(z)$ is adjacent to $i = c(y)$ in $\Gamma$ and $w \in D \cap N_{c(z)}$. Since $[y, x] \cap D \cap N_{c(z)} = \emptyset$, we have $w \notin [y, x]$. Hence by using Property (C5) in Proposition 2.5 we see that $w < y < z < x$, which contracts to $[w, z] \cap D \cap N_{c(z)} = \emptyset$. □

For $E \in \mathcal{E}_p^*(F)$, we define a subset $S(E)$ of $E$ by putting

$$
S(E) = \left\{ x \in E : \text{there exists } y \in E_{c(x)} \text{ such that } y < x \text{ and } [y, x] \cap E \cap N_{c(x)} = \emptyset \right\}.
$$

It follows from Property (C4) in Proposition 2.5 that $S(F) = \emptyset$ for an order filter $F$ of $P$.

**Lemma 3.15.** Let $E \in \mathcal{E}_p^*(F)$ and $u \in E$ an $E$-active element. Then we have

$$
S(\alpha_u(E)) = \begin{cases} 
S(E) \setminus \{u\} \cup \{v\} & \text{if } u \in S(E), \\
S(E) & \text{if } u \notin S(E),
\end{cases}
$$

$$
S(\alpha_u^*(E)) = \begin{cases} 
S(E) \cup \{v\} & \text{if } u \in S(E), \\
S(E) \cup \{u\} & \text{if } u \notin S(E),
\end{cases}
$$

where $[v, u]$ is the $d_k$-interval with top element $u$. In particular, we have

$$
\#S(\alpha_u(E)) = \#S(E), \quad \#S(\alpha_u^*(E)) = \#S(E) + 1,
$$

and $S(E) = \emptyset$ if and only if $E \in \mathcal{E}_p^*(F)$.

**Proof.** Since $\alpha_u(E) = E \setminus \{u\} \cup \{v\}$, the equality (13) follows from the following three claims:

(i) $S(\alpha_u(E)) \setminus \{v\} \subset S(E)$.
(ii) $u \in S(E)$ if and only if $v \in S(\alpha_u(E))$.
(iii) $S(\alpha_u(E)) \subset S(\alpha_u^*(E))$.

To prove (i), we take $x \in S(\alpha_u(E))$ such that $x \neq v$. Then, by the definition (12), there exists $y \in (\alpha_u(E))_{c(x)}$ such that $y < x$ and $[y, x] \cap \alpha_u(E) \cap N_{c(x)} = \emptyset$. If $y = v$, then $[u, x] \cap E \cap N_{c(z)} \subset [v, x] \cap E \cap N_{c(z)} = \emptyset$, hence $x \in S(E)$. We consider the case where $y \neq v$. In this case, $y \notin E$ and it follows from $[v, u] \cap E \cap N_{c(u)} = \emptyset$ that $y \notin [v, u] \cap N_{c(u)}$. Now we can use Lemma 3.3 (c) to obtain $[y, x] \cap E \cap N_{c(x)} = \emptyset$, hence $x \in S(E)$.
Next we prove (ii). If $v \in S(\alpha_u(E))$, then there exists $w \in \alpha_u(E)_{c(v)}$ such that $w < v$ and $[w, v] \cap \alpha_u(E) \cap N_{c(v)} = \emptyset$. Then by Lemma 3.15 (a) we have $[w, u] \cap E \cap N_{c(u)} = \emptyset$, hence $u \in S(E)$. Conversely, if $u \in S(E)$, then there exists $z \in E_{c(u)}$ such that $z < u$ and $[z, u] \cap E \cap N_{c(u)} = \emptyset$. Then we have $[z, v] \cap \alpha_u(E) \cap N_{c(v)} \subset [z, u] \cap \alpha_u(E) \cap N_{c(u)} = \emptyset$, hence $v \in S(\alpha_u(E))$.

To prove (iii), we take $x \in S(E)$. By the definition \[\text{12}], there exists $y \in E_{c(x)}$ such that $y < x$ and $[y, x] \cap E \cap N_{c(x)} = \emptyset$. Then we have $y = u$ or $y \in \alpha_u(E)$. If $y = u$, then $[u, x] \cap E \cap N_{c(x)} = \emptyset$ and $[v, u] \cap \alpha_u(E) \cap N_{c(u)} = \emptyset$ by the $E$-activity of $u$. Hence by using Lemma 3.15 (a) we have $[v, x] \cap \alpha_u(E) \cap N_{c(u)} = \emptyset$ and $x \in S(\alpha_u(E))$. We consider the case where $y \in \alpha_u(E)$. Since $[v, u] \cap E \cap N_{c(u)} = \emptyset$ and $x \in E$, we have $x \notin [v, u] \cap N_{c(u)}$.

Hence by using Lemma 3.15 (b) we see $[y, x] \cap \alpha_u(E) \cap N_{c(x)} = \emptyset$ and $x \in S(\alpha_u(E))$.

Since $\alpha_u^*(E) = E \cup \{v\}$ and $u \in S(\alpha_u^*(E))$, the equality (12) follows from the following three claims:

(iv) $S(\alpha_u^*(E)) = \{u, v\} \subset S(E)$.
(v) $v \in S(E)$ if and only if $v \in S(\alpha_u^*(E))$.
(vi) $S(E) \subset S(\alpha_u^*(E))$.

To prove (iv), we take $x \in S(\alpha_u^*(E))$ such that $x \neq u, v$. Then there exists $y \in (\alpha_u^*(E))_{c(x)}$ such that $y < x$ and $[y, x] \cap \alpha_u^*(E) \cap N_{c(x)} = \emptyset$. If $y = v$, then $[u, x] \cap E \cap N_{c(x)} \subset [v, x] \cap E \cap N_{c(x)} = \emptyset$, hence $x \in S(E)$. If $y \neq v$, then $[y, x] \cap E \cap N_{c(x)} \subset [y, x] \cap \alpha_u^*(E) \cap N_{c(x)} = \emptyset$, hence $x \in S(E)$.

Next we prove (v). If $v \in S(\alpha_u^*(E))$, then there exists $w \in (\alpha_u^*(E))_{c(v)}$ such that $w < v$ and $[w, v] \cap \alpha_u^*(E) \cap N_{c(v)} = \emptyset$. Then by using Lemma 3.15 (a) we have $[w, u] \cap E \cap N_{c(u)} = \emptyset$, hence $u \in S(E)$. Conversely, if $u \in S(E)$, then there exists $z \in E_{c(u)}$ such that $z < u$ and $[z, u] \cap E \cap N_{c(u)} = \emptyset$. Then we have $[z, v] \cap \alpha_u^*(E) \cap N_{c(v)} \subset [z, u] \cap \alpha_u^*(E) \cap N_{c(u)} = \emptyset$, hence $v \in S(\alpha_u^*(E))$.

To prove (vi), we take $x \in S(E)$. Then there exists $y \in E_{c(x)}$ such that $y < x$ and $[y, x] \cap E \cap N_{c(x)} = \emptyset$. Since $E \subseteq (\alpha_u^*(E))_{c(v)}$, we have $x \notin [v, u] \cap N_{c(u)} \subseteq (\alpha_u^*(E))_{c(v)}$. Hence by Lemma 3.15 (b) we see $[y, x] \cap \alpha_u^*(E) \cap N_{c(x)} = \emptyset$ and $x \in S(\alpha_u^*(E))$.

**Lemma 3.16.** If $D \in E_P(F)$ and $S \subset B(D)$, then we have $D \cup S \subset E_P(F)$ and $S = S(D \cup S)$. In particular, if $E \in E_P(F)$ is expressed as $E = D \cup S = D' \cup S'$ with $D, D' \in E_P(F)$ and $S \subset B(D), S' \subset B(D')$, then we have $D = D'$ and $S = S'$.

**Proof.** First we proceed by induction on $\#S$ to prove $D \cup S \in E_P(F)$. If $S = \emptyset$, then we have $D \in E_P(F) \subset E_P(F)$. If $S \neq \emptyset$, we take an element $x \in S$ and put $S' = S \setminus \{x\}$. By the induction hypothesis and Proposition 3.11 we have $D \cup S' \subset E_P(F)$ and $w_{D \cup S'} = w_F$. Using Proposition 3.7 (a), we see that there exists $y \in \tilde{D}_{c(x)}$ such that $y < x$ and $[y, x] \cap D \cap N_{c(x)} = \emptyset$. Then it follows from Lemma 3.14 that $[y, x] \cap (D \cup S) \cap N_{c(x)} = \emptyset$. If $y = p_k$, $x = p_l$ and $\{j : k < j < l, p_j \in D \cup S\} = \{j_1, \ldots, j_m\}$ with $j_1 < \cdots < j_m$, then we have

$$w_{D \cup S} = \cdots s(p_k) s(p_{j_1}) \cdots s(p_{j_m}) s(p_l) \cdots,$$

$$w_{D \cup S'} = \cdots s(p_k) s(p_{j_1}) \cdots s(p_{j_m}) \cdots .$$

By using Lemma 3.5 and $s(p_k) s(p_{j_1}) = s(p_k) s(p_{j_1}) = s(p_k)$, we obtain $w_{D \cup S} = w_{D \cup S'} = w_F$. Hence by Proposition 3.11 we have $D \cup S \in E_P(F)$.

Next we put $E = D \cup S$ and prove that $S = S(E)$. In order to show the inclusion $S \subset S(E)$, we take $x \in S \subset B(D)$. Then by Proposition 3.7 (a), there exists $y \in \tilde{D}_{c(x)}$ such that $[y, x] \cap D \cap N_{c(x)} = \emptyset$. Hence by using Lemma 3.14 we see that $[y, x] \cap E \cap N_{c(x)} = \emptyset$ and $x \in S(E)$. In order to show the reverse inclusion $S(E) \subset S$, we take $x \in S(E)$ and prove $x \in B(D)$. By the definition \[\text{12}], there exists $y \in E_{c(x)}$.
such that $y < x$ and $[y, x] \cap E \cap N_{c(x)} = \emptyset$. Since $D \subset E$, we have $[y, x] \cap D \cap N_{c(x)} = \emptyset$. If $y \in D$, then by Proposition 5.17 (a) we have $x \in B(D)$. If $y \in S$, then there exists $z \in D \cap S$ such that $z < y$ and $[z, y] \cap D \cap N_{c(y)} = \emptyset$. Then by using Lemma 5.3 (a) we have $[z, x] \cap D \cap N_{c(x)} = \emptyset$ and $x \in B(D)$.

Lemma 3.17. Let $E \in \mathcal{E}_p^r(F)$ and $z \in S(E)$. If we put $E' = E \smallsetminus \{z\}$, then we have

(a) $E' \in \mathcal{E}_p^r(F)$.
(b) $S(E') = S(E) \smallsetminus \{z\}$.

Proof. By the definition (12), there exists $w \in E_{c(z)}$ such that $w < z$ and $[w, z] \cap E \cap N_{c(z)} = \emptyset$.

(a) If $w = p_k$, $z = p_l$ and $\{j : k < j < l, \; p_j \in E\} = \{j_1, \ldots, j_m\}$ ($j_1 < \cdots < j_m$), then we have

$$w_E^* = \cdots \cdot s(p_{j_m}) \cdots \cdot s(p_j) \cdots s(p_{j_1}) \cdot s(p_l) \cdots s(p_k),$$

$$w_{E'}^* = \cdots \cdot s(p_{j_m}) \cdots \cdot s(p_j) \cdots s(p_{j_1}) \cdot s(p_k).$$

By using Lemma 3.5 and $s(p_k) \cdot s(p_l) = s(p_k)$, we obtain $w_E^* = w_{E'}^*$.

(b) First we prove that $S(E') \subset S(E)$. Let $x \in S(E')$. Then there exists $y \in (E')_c(z)$ such that $y < x$ and $[y, x] \cap E \cap N_{c(z)} = \emptyset$. Since $y \in E$ and $[w, z] \cap E \cap N_{c(z)} = \emptyset$, we have $y \notin [w, z] \cap N_{c(z)}$. Hence by using Lemma 5.8 (d) we have $[y, x] \cap E \cap N_{c(x)} = \emptyset$ and $x \in S(E)$.

Next we prove that $S(E) \smallsetminus \{z\} \subset S(E')$. We take an element $x \in S(E)$ such that $x \neq z$. Then there exists $y \in E_{c(z)}$ such that $y < x$ and $[y, x] \cap E \cap N_{c(x)} = \emptyset$. If $y \neq z$, then $y \in E'$ and $[y, x] \cap E' \cap N_{c(z)} = \emptyset$, hence $x \in S(E')$. We consider the case where $y = z$. In this case $[z, x] \cap E' \cap N_{c(z)} = \emptyset$. Since $[w, z] \cap E' \cap N_{c(z)} = \emptyset$, it follows from Lemma 5.8 (a) that $[w, x] \cap E' \cap N_{c(z)} = \emptyset$ and $x \in S(E')$.

Now we are in position to give a proof of Proposition 5.13.

Proof of Proposition 5.13. By using Lemma 5.16, it is enough to show that any $E \in \mathcal{E}_p^r(F)$ can be written as $E = D \cup S$ with $D \in \mathcal{E}_p^r(F)$ and $S \subset B(D)$. Given $E \in \mathcal{E}_p^r(F)$, we put $D = E \smallsetminus S(E)$ and prove that $D \in \mathcal{E}_p^r(F)$ and $S(E) \subset B(D)$. We proceed by induction on $\# S(E)$. If $S(E) = \emptyset$, then $E \in \mathcal{E}_p^r(F)$ by Lemma 5.13. We consider the case where $S(E) \neq \emptyset$. Then we take $z \in S(E)$ and put $E' = E \smallsetminus \{z\}$. Since $S(E') = S(E) \smallsetminus \{z\}$ by Lemma 5.17 (b), we see that $D = E \smallsetminus S(E) = E' \smallsetminus S(E')$. By the induction hypothesis, $D \in \mathcal{E}_p^r(F)$ and $S(E') \subset B(D)$. It remains to show that $z \in B(D)$. By the definition (12), there exists $w \in E_{c(z)}$ such that $w < z$ and $[w, z] \cap E \cap N_{c(z)} = \emptyset$. Let $w$ be the minimal such element. If $w \notin D$, i.e., $w \in S(E)$, then by definition there exists $w' \in E_{c(w)}$ such that $[w', w] \cap E \cap N_{c(w)} = \emptyset$. Then it follows from Lemma 5.3 (a) that $[w', z] \cap E \cap N_{c(z)} = \emptyset$, which contradicts to the minimality of $w$. Therefore we have $w \in D$ and $z \in B(D)$.

Remark 3.18. We can define the notion of $D$-active elements and ordinary and $K$-theoretical elementary excitations for a general dominant minuscule heap $H(w)$ just by replacing $d_k$-intervals with intervals $[v, u]$ such that $c(u) = c(v)$ and $[v, u] \cap H(w)_{c(u)} = \{u, v\}$. Then the arguments in this section work as well for $H(w)$. In particular, Propositions 5.11 and 5.13 holds for $H(w)$.

Example 3.19. Let $\mu$ be a strict partition and regard the shifted shape $S(\mu)$ as a heap for the Weyl group of type $B$ (see Example 2.13). Then the notion of active elements, (ordinary and $K$-theoretical) elementary excitations and excited peaks are modified as follows. Let $D$ be a subset of $S(\mu)$. 

Algebraic Combinatorics, draft (June 28, 2019) 19
(a) An element \( u = (i, j) \in D \) is \( D \)-active if either
\[ i < j \text{ and } (i, j + 1), (i + 1, j), (i + 1, j + 1) \in S(\mu) \setminus D, \]
or
\[ i = j \text{ and } (i, i + 1), (i + 1, i + 1) \in S(\mu) \setminus D. \]

(b) If \( u = (i, j) \in D \) is \( D \)-active, then we define an ordinary and \( K \)-theoretical elementary excitation by putting
\[ \alpha_u(D) = D \setminus \{(i, j)\} \cup \{(i + 1, j + 1)\}, \]
\[ \alpha_u^*(D) = D \cup \{(i + 1, j + 1)\}, \]
respectively.

(c) If \( u = (i, j) \in D \) is \( D \)-active, then we define
\[ B(\alpha_u(D)) = \begin{cases} B(D) \setminus \{(i, j + 1), (i + 1, j)\} \cup \{(i, j)\} & \text{if } i < j, \\ B(D) \setminus \{(i, j + 1)\} \cup \{(i, j)\} & \text{if } i = j. \end{cases} \]

This notion of excited diagrams is the same as Ikeda–Naruse’s excited diagrams of type \( F \) introduced in [7].

For example, if \( P = S(5, 4, 2, 1) \) and \( F = S(3, 1) \), then there are 10 excited diagrams of \( F \) in \( P \) as a heap for the type \( B \) Weyl group. See Figure 7.

![Figure 7. Excited diagrams in \( S(5, 4, 2, 1) \) viewed as a type \( B \) heap](image)

4. EQUIVARIANT \( K \)-THEORY OF KAC–MOODY PARTIAL FLAG VARIETIES

In this section we review the basic properties of the equivariant \( K \)-theory of thick flag varieties following [18, Section 3], and rephrase the Billey-type formula and the Chevalley-type formula in terms of combinatorics of \( d \)-complete posets.

**4.1. EQUIVARIANT \( K \)-THEORY AND LOCALIZATION.** Let \( A = (a_{ij})_{i,j \in I} \) be a symmetric generalized Cartan matrix, and \( \Gamma \) the corresponding Dynkin diagram with node set \( I \). Then the associated Kac–Moody group \( G \) over \( \mathbb{C} \) is constructed from the following data: the weight lattice (\( \mathbb{Z} \)-module) \( \Lambda \), the simple roots \( \Pi = \{ \alpha_i : i \in I \} \), the simple coroots \( \Pi^\vee = \{ \alpha^\vee_i : i \in I \} \), and the fundamental weights \( \{ \lambda_i : i \in I \} \) (see the beginning of Subsection 2.2).
In what follows, we fix a subset $J$ of $I$. Let $B$ be a Borel subgroup corresponding to the positive system $\Phi_+$ and $T \subset B$ a maximal torus. Let $P_-$ be the opposite parabolic subgroup corresponding to the subset $J$, which contains the opposite Borel subgroup $B_-$ such that $B \cap B_- = T$. Then we can introduce the Kashiwara thick partial flag variety $\mathcal{X} = G/P_-$. (We refer the readers to [11] for a construction of $\mathcal{X}$.)

Let $W_J$ be the parabolic subgroup of $W$ corresponding to $J$ and $W^J$ be the set of minimum length coset representatives of $W/W_J$. For each element $v \in W^J$, we put $\mathcal{X}_v^\circ = BvP_-/P_-$ and $\mathcal{X}_v = \mathcal{X}_v^\circ$, the Zariski closure of $\mathcal{X}_v^\circ$, which are called the Schubert cell and the Schubert variety respectively. Then $\mathcal{X}_v$ has codimension $l(v)$ in $\mathcal{X}$ and

$$\mathcal{X}_v = \bigcup_{w \in W^J, w \geq v} \mathcal{X}_w^\circ.$$ 

Let $K_T(\mathcal{X})$ be the $T$-equivariant $K$-theory of $\mathcal{X}$. Then $K_T(\mathcal{X})$ has a commutative associative $K_T(\text{pt})$-algebra structure. Here the $T$-equivariant $K$-theory $K_T(\text{pt})$ of a point is isomorphic to the group algebra $\mathbb{Z}[\Lambda]$ with basis $\{e^\lambda : \lambda \in \Lambda\}$, and to the representation ring $R(T)$ of $T$. For each $v \in W^J$, let $[O_v]$ be the class of the structure sheaf $O_v$ of $\mathcal{X}_v$ in $K_T(\mathcal{X})$ and call it the equivariant Schubert class. Then we have

$$K_T(\mathcal{X}) \cong \prod_{v \in W^J} K_T(\text{pt})[O_v].$$

Any elements of $K_T(\mathcal{X})$ is a (possibly infinite) $K_T(\text{pt})$-linear combination of the equivariant Schubert classes.

Each $w \in W^J$ gives a $T$-fixed point $e_w = wP_-/P_- \in \mathcal{X}$. Then the inclusion map $i_w : \{e_w\} \to \mathcal{X}$ induces the pull-back ring homomorphism, called the localization map at $w$,

$$i_w^* : K_T(\mathcal{X}) \to K_T(e_w) \cong \mathbb{Z}[\Lambda].$$

If $L^\lambda$ is the line bundle on $\mathcal{X}$ corresponding to a weight $\lambda \in \Lambda$, then the image of the class $[L^\lambda]$ under the localization map is given by $i_w^*([L^\lambda]) = e^{w\lambda}$. For two elements $v, w \in W^J$, we denote by $\xi^v|_w$ the image of the $T$-equivariant Schubert class $\xi^v = [O_v] \in K_T(\mathcal{X})$ under the localization map $i_w^*$:

$$\xi^v|_w = i_w^*([O_v]).$$

Then the Billey-type formula for the equivariant $K$-theory can be stated as follows:

**Proposition 4.1.** ([13 Proposition 2.10]) Let $v, w \in W^J$, and fix a reduced expression $w = s_{i_1}s_{i_2} \cdots s_{i_N}$ of $w$. Then we have

$$\xi^v|_w = \sum_{(k_1, \ldots, k_r)} (-1)^{r-l(v)} \prod_{a=1}^{r} \left(1 - e^{\beta(k_a)}\right),$$

where the summation is taken over all sequences $(k_1, \ldots, k_r)$ such that $1 \leq k_1 < k_2 < \cdots < k_r \leq N$ and $s_{i_{k_1}} \cdots s_{i_{k_r}} = v$ (with respect to the Demazure product), and $\beta(k)$ is given by $\beta(k) = s_{i_1} \cdots s_{i_{k-1}}(\alpha_{i_k})$ for $1 \leq k \leq N$.

By using Lemma 3.12 (a), we can deduce the following corollary from Proposition 4.1.

**Corollary 4.2.**

(a) For $w \in W^J$, we have

$$\xi^w|_w = \prod_{k=1}^{N} \left(1 - e^{\beta(k)}\right).$$

In particular, $\xi^w|_w \neq 0$.

(b) Let $v, w \in W^J$. If $\xi^v|_w \neq 0$, then we have $v \leq w$ in the Bruhat order.
4.2. Equivariant $K$-theoretical Littlewood–Richardson coefficients. We consider the structure constants for the multiplication in $K_T(X)$ with respect to the equivariant Schubert classes. For $u, v, w \in W^J$, we denote by $c^w_{u,v} \in K_T(pt)$ the structure constant determined by

$$[O_u][O_v] = \sum_{w \in W^J} c^w_{u,v}[O_w].$$

**Lemma 4.3.** If $c^w_{u,v} \neq 0$, then $u \leq w$ and $v \leq w$.

**Proof.** We use the induction on $l(w)$ to prove that, if $u \nleq w$ or $v \nleq w$, then $c^w_{u,v} = 0$. Assume that $u \nleq w$ or $v \nleq w$. By apply the localization map $\iota^*_w$ to $[O_u][O_v] = \sum_{x \in W^J} c^x_{u,v}[O_x]$ and then by using Corollary 4.2 (b), we have

$$(\xi^u|w) \cdot (\xi^v|w) = \sum_{x \leq w} c^x_{u,v}\xi^x|w.$$ If there exists an element $x \in W^J$ satisfying $x < w$ and $c^x_{u,v} \neq 0$, then we have $u \leq x$ and $v \leq x$ by the induction hypothesis, and hence $u \leq w$ and $v \leq w$, which contradicts to the assumption. Hence, by using Corollary 4.2 (b) and the assumption, we have

$$0 = c^w_{u,v} \xi^w|w.$$Since $\xi^w|w \neq 0$ (Corollary 4.2 (a)), we obtain $c^w_{u,v} = 0$. □

**Proposition 4.4.** For $v, w \in W^J$, we have

$$(17) c^w_{v,w} = \xi^v|w.$$ **Proof.** By apply the localization map $\iota^*_w$ to $[O_v][O_w] = \sum_{x \in W^J} c^x_{v,w}[O_x]$ and then by using Corollary 4.2 (b), we have

$$(\xi^v|w) \cdot (\xi^w|w) = \sum_{x \leq w} c^x_{v,w}\xi^x|w.$$ By Lemma 4.3 we see that $c^x_{v,w} = 0$ unless $w \leq x$. By Corollary 4.2 (b), we see that $\xi^x|w = 0$ unless $x \leq w$. Hence we have

$$(\xi^v|w) \cdot (\xi^w|w) = c^w_{v,w}\xi^w|w.$$Since $\xi^w|w \neq 0$ (Corollary 4.2 (a)), we obtain the desired equality. □

The following lemma gives a recurrence of the equivariant $K$-theoretical Littlewood–Richardson coefficients $c^w_{u,v}$. We use the same idea as [21 Corollary 6.5] and [28 Proposition 3.1].

**Lemma 4.5.** Let $u, v, w \in W^J$ and $s \in W^J$ a simple reflection. If $c^w_{s,u} \neq c^w_{s,v}$, then we have

$$c^w_{u,v} = \frac{1}{c^w_{s,u} - c^w_{s,v}} \left( \sum_{u \leq x < w} c^x_{u,s}c^w_{x,v} - \sum_{w \leq y < u} c^w_{y,s}c^w_{u,v} \right).$$

In particular, we have

$$(18) c^w_{u,v} = \frac{1}{c^w_{s,u} - c^w_{s,v}} \sum_{u \leq x < w} c^x_{u,s}c^w_{x,v}.$$
Note that the following two conditions:

\begin{align*}
\sum_{u \leq x \leq w} c_{s,u}^w e_{x,u}^w &= \sum_{u \leq x \leq w} c_{s,u}^w e_{w,x}^w = e_{s,w}^w c_{w,u}^w + \sum_{u \leq x \leq w} e_{s,u}^w c_{x,u}^w,
\end{align*}

from which we get the conclusion.

The Chevalley formula gives a combinatorial expression of \( c_{w,v}^v \) for a simple reflection \( s \). To state the Chevalley formula of \([20]\) we need several notations. For a dominant weight \( \lambda \in \Lambda \), we put

\[ \mathbb{H}_\lambda = \{ (\gamma', k) : \gamma' \in \Phi_+^\vee, \; k \in \mathbb{Z}, \; 0 \leq k < \langle \gamma', \lambda \rangle \}. \]

Fix a total order on \( I \) so that \( I = \{ i_1 < \cdots < i_r \} \), and define a map \( \iota : \mathbb{H}_\lambda \to \mathbb{Q}^{r+1} \)

\[ \iota(\gamma', k) = \frac{1}{\langle \gamma', \lambda \rangle} (k, c_1, \cdots, c_r). \]

where \( c_1, \ldots, c_r \) are the coefficients of the simple roots in \( \gamma' \) given by \( \gamma' = \sum_{j=1}^r c_j \alpha_j^\vee \). Then it is known that \( \iota \) is injective. We define a total ordering \(<\) on \( \mathbb{H}_\lambda \) by

\[ h < h' \iff \iota(h) <_{\text{lex}} \iota(h'), \]

where \(<_{\text{lex}}\) is the lexicographical ordering on \( \mathbb{Q}^{r+1} \). For \( h = (\gamma', k) \), we define affine transformations \( r_h \) and \( \tilde{r}_h \) on \( \Lambda \) by

\[ r_h(\mu) = \mu - \langle \gamma', \mu \rangle \gamma, \]

\[ \tilde{r}_h(\mu) = r_h(\mu) + (\langle \gamma', \lambda \rangle - k) \gamma. \]

Note that \( r_h = s_\gamma \). Now we can state the Chevalley formula for the equivariant \( K \)-theory of the partial flag variety \( X \).

**Proposition 4.6.** \([20] \text{ Theorem } 4.8 \text{ (4.12) and (4.13)}\), \text{ see also } [19] \text{ Corollary } 7.1\]

Let \( s \) be a simple reflection such that \( s \in W^J \) and \( v, w \in W^J \). If \( s = s_i \) and \( \lambda = \lambda_i \) is the corresponding fundamental weight, then we have

\[ c_{w,v}^w = \begin{cases} 
1 - e^{\lambda - v \lambda} & \text{if } w = v, \\
\sum_{(h_1, \ldots, h_r)} (-1)^{r-1} e^{\lambda - v \tilde{r}_{h_1} - \cdots - \tilde{r}_{h_r} \lambda} & \text{if } w > v, \\
0 & \text{otherwise},
\end{cases} \tag{19}
\]

where the summation is taken over all sequences \((h_1, \ldots, h_r)\) of length \( r \geq 1 \) satisfying the following two conditions:

\begin{enumerate}
\item[(H1)] \( h_1 > h_2 > \cdots > h_r \) in \( \mathbb{H}_\lambda \),
\item[(H2)] \( v < vr_{h_1} < vr_{h_1} r_{h_2} < \cdots < vr_{h_1} \cdots r_{h_r} = w \) is a saturated chain in \( W^J \).
\end{enumerate}

4.3. \text{Connection to } d\text{-complete posets.} \text{ In this subsection we rephrase the Billey-type formula and the Chevalley-type formula in terms of combinatorics of } d\text{-complete posets.}

Let \( P \) be a connected \( d\)-complete poset with top tree \( \Gamma \). We regard \( \Gamma \) as a simply-laced Dynkin diagram with node set \( I \). Let \( \alpha_P \) and \( \lambda_P \) be the simple root and the fundamental weight corresponding to the color \( i_P \) of the maximum element of \( P \). We apply the results of Subsections 4.1 and 4.2 to the Kashiwara thick partial flag variety \( X = \mathcal{G}/\mathcal{P}_- \), where \( \mathcal{P}_- \) is the maximal parabolic subgroup corresponding to \( J = I \setminus \{ i_P \} \). In this case, the parabolic subgroup \( W_J \) coincides with the stabilizer.
Proof of Proposition 2.10 (c), we see that

\[ \text{Proposition 2.5, and thus} \]

Then we have

\[ (20) \quad \xi_{wF}^{|wF|} = \sum_{E \in E_0^+(F)} (-1)^{#E - #F} \prod_{p \in E} (1 - z[H_P(p)]) , \]

under the identification \( z_i = e^{\alpha_i} \) (\( i \in I \)).

Proof. Follows from Proposition 4.11 by using Proposition 11(b) and Proposition 4.11.

Also the following explicit expression is obtained from the Chevalley-type formula.

Proposition 4.8. Let \( P \) be a connected \( d \)-complete poset and \( F \) an order filter of \( P \). Then we have

\[ (21) \quad c_{wF}^{wF} = \begin{cases} 1 - z[F] & \text{if } F' = F, \\ (-1)^{(F' \setminus F) - 1} z[F] & \text{if } F' \supseteq F \text{ and } F' \not\subseteq F \text{ is an antichain,} \\ 0 & \text{otherwise,} \end{cases} \]

under the identification \( z_i = e^{\alpha_i} \) (\( i \in I \)).

First we consider the case \( r = 1 \) in Proposition 4.6.

Lemma 4.9. Let \( F' \) be an order filter of \( P \) and \( h = (\gamma') \in \mathbb{H}_{\lambda_P} \). If \( w_{F' \cup h} \in W_{\lambda_P} \) and \( w_F < w_{F' \cup h} \leq w_F \), then there exists \( p \in P \) such that \( F' = F \cup \{ p \} \) is an order filter of \( P \), \( w_{F' \cup h} = w_F' \) and \( \gamma' = \gamma(p) \). In this case \( k = 0 \) and \( \tilde{r}_h \lambda_P = \lambda_P \).

Proof. Since the interval \([e, w_F^r]_\lambda\) in \( W_{\lambda_P} \) is isomorphic to the poset of order filters of \( P \) (Proposition 2.11(a)), there exists a unique order filter \( F' \) of \( P \) such that \( F' \supseteq F \), \( \#F' = \#F + 1 \) and \( w_{F'} = w_{F' \cup h} \). Hence we have \( p \in P \) such that \( F' = F \cup \{ p \} \) and \( w_{F'} = s(p)w_F \). We take a linear extension of \( P \) such that \( F = \{ p_{n+1}, \ldots, p_N \} \) with \( N = \#P \) and \( n = \#(P - F) \). If \( p = p_n \), then \( p \) is incomparable with \( p_{n+1}, \ldots, p_n \), hence \( s(p_n) \) is commutative with \( s(p_{n+1}), \ldots, s(p_n) \) by Property (C5) in Proposition 2.3 and thus \( s(p_i)\alpha^\vee(p_m) = \alpha^\vee(p_m) \) for \( m + 1 \leq i \leq n \). Hence we have

\[ \gamma' = w_{F'}^{-1} \alpha^\vee(p_m) = \cdots = s(p_{n+1})s(p_n) = s(p_{n+1})s(p_n) \cdots s(p_m) \alpha(p_m) = \gamma(p_n) . \]

By Proposition 2.11(c), we see that \( k = 0 \) and \( \tilde{r}_h \lambda_P = \lambda_P \). □

Now we deduce Proposition 4.8 from the Chevalley-type formula.

Proof of Proposition 4.8. It follows from Proposition 2.11(b) and Proposition 4.6 that

\[ c_{s,wF}^{s,wF} = 1 - z[F] . \]

Suppose that there exists a sequence \( (h_1, \ldots, h_r) \) of elements in \( \mathbb{H}_{\lambda_P} \) satisfying Conditions (H1) and (H2) in Proposition 4.9. Then by Lemma 4.9 we have a sequence \( (q_1, \ldots, q_r) \) of elements of \( P \) such that \( F_i = F \cup \{ q_1, \ldots, q_i \} \) is an order filter of \( P \),
Theorem 5.2. \( \xi(e^{(q_i)_{i=1}}) \) have
which contradicts to Condition (H1). Moreover it follows from Proposition 2.11 (b) the equivariant \( \bigcup P \) of \( q \) where
\( D \) runs over all excited diagrams of \( F \) in \( P \).

Conversely, suppose that \( F' \supset F \) and \( F' \prec F \) is an antichain. For \( q \in F' \prec F \), we put \( h(q) = (\gamma(q), 0) \in H_{\lambda_P} \). Since \( F' \prec F \) is an antichain, we can label the elements of \( F' \prec F \) so that \( h(q_1) > \cdots > h(q_r) \). Then \( (h(q_1), \cdots , h(q_r)) \) is the unique sequence satisfying Conditions (H1) and (H2) in Proposition 4.6.

5. PROOF AND COROLLARIES OF MAIN THEOREM

In this section, we give a proof of the main theorem (Theorem 1.2 in Introduction) and derive several consequences.

5.1. PROOF OF THE MAIN THEOREM. Recall the main theorem of this paper:

THEOREM 5.1. Let \( P \) be a \( d \)-complete poset and \( F \) an order filter. Then the multivariate generating function of \( (P \setminus F) \)-partitions, where \( P \setminus F \) is viewed as an induced subposet of \( P \), is given by

\[
\sum_{\sigma \in A(P \setminus F)} z^\sigma = \sum_{D \in \mathcal{E}(P \setminus F)} \prod_{p \in P \setminus D} z[H_P(v)]
\]

where \( D \) runs over all excited diagrams of \( F \) in \( P \).

Since the both sides of (22) factor into the product over the connected components of \( P \), the assertion of this theorem follows easily from the case where \( P \) is a connected \( d \)-complete poset. Hence Theorem 5.1 is a direct consequence of the following two theorems, which describe the ratio \( \xi_{wp} / \xi_{wp} \) of the localizations of elements in the equivariant \( K \)-theory \( K_T(X) \) in two ways.

THEOREM 5.2. For a connected \( d \)-complete poset \( P \) and an order filter \( F \) of \( P \), we have

\[
\frac{\xi_{wp} / \xi_{wp}}{\xi_{wp}} = \sum_{\sigma \in A(P \setminus F)} z^\sigma,
\]

under the identification \( z_i = e^\alpha_1 \) (\( i \in I \)).

THEOREM 5.3. For a connected \( d \)-complete poset \( P \) and an order filter \( F \) of \( P \), we have

\[
\frac{\xi_{wp} / \xi_{wp}}{\xi_{wp}} = \sum_{D \in \mathcal{E}(P \setminus F)} \prod_{p \in P \setminus D} z[H_P(p)]
\]

under the identification \( z_i = e^\alpha_1 \) (\( i \in I \)).

First we prove Theorem 5.2 by using the Chevalley-type formula (Proposition 4.8).

Proof of Theorem 5.2. For an order filter \( F \) of \( P \), we put

\[
Z_{P/F}(z) = \frac{\xi_{wp} / \xi_{wp}}{\xi_{wp} / \xi_{wp}}, \quad G_{P/F}(z) = \sum_{\sigma \in A(P \setminus F)} z^\sigma.
\]
It is clear that \( Z_{P/F}(z) = G_{P/F}(z) = 1 \). Hence it is enough to show that \( Z_{P/F}(z) \) and \( G_{P/F}(z) \) satisfy the same recurrences:

\[
Z_{P/F}(z) = \frac{1}{1 - z[P \setminus F]} \sum_{F'} (-1)^{|F' \setminus F| - 1} Z_{P/F'}(z),
\]

\[
G_{P/F}(z) = \frac{1}{1 - z[P \setminus F]} \sum_{F'} (-1)^{|F' \setminus F| - 1} G_{P/F'}(z),
\]

where \( F' \) runs over all order filters such that \( F \not\subseteq F' \subset P \) and \( F' \setminus F \) is an antichain.

First we prove (25). Under the isomorphism of posets given in Proposition 2.11 (a), the interval \( (w_F, w_P] = \{ z \in W^P : w_F < z \leq w_P \} \) corresponds to \( \{ F' : F' \setminus F \) is an order filter of \( P \) and \( F \not\subseteq F' \subset P \} \). Then by using the recurrence (18) and Proposition 4.8 we see that

\[
\xi_{w_F}|_{w_P} = \frac{1}{1 - z[P]} \frac{1}{1 - z[F]} \sum_{F'} (-1)^{|F' \setminus F| - 1} z[F] \xi_{w_{F'}}|_{w_P},
\]

\[
= \frac{1}{1 - z[P \setminus F]} \sum_{F'} (-1)^{|F' \setminus F| - 1} \xi_{w_{F'}}|_{w_P}.
\]

Next we prove (26). Let \( M \) be the set of maximal elements of \( P \setminus F \). Then we have

\[
\sum_{F'} (-1)^{|F' \setminus F| - 1} G_{P/F'}(z) = \sum_{I \subset M, I \neq \emptyset} (-1)^{|I| - 1} G_{P/(F \cup I)}(z).
\]

For \( I \subset M \), we put

\[
\mathcal{A}(P \setminus F)_I = \{ \sigma \in \mathcal{A}(P \setminus F) : \sigma(x) = 0 \text{ for all } x \in I \}.
\]

Then we have

\[
G_{P/(F \cup I)}(z) = \sum_{\sigma \in \mathcal{A}(P \setminus F)_I} z^\sigma.
\]

By the Inclusion-Exclusion Principle, we have

\[
\sum_{F'} (-1)^{|F' \setminus F| - 1} G_{P/F'}(z) = \sum_{\sigma \in \mathcal{A}'(P \setminus F)} z^\sigma,
\]

where we put

\[
\mathcal{A}'(P \setminus F) = \{ \sigma \in \mathcal{A}(P \setminus F) : \sigma(x) = 0 \text{ for some } x \in M \}.
\]

Given \( \sigma \in \mathcal{A}(P \setminus F) \), let \( m = \min \{ \sigma(x) : x \in P \setminus F \} \) and define \( \sigma' \in \mathcal{A}(P \setminus F) \) by \( \sigma'(x) = \sigma(x) - m \) \( x \in P \setminus F \). Then the map \( \sigma \mapsto (m, \sigma') \) gives a bijection from \( \mathcal{A}(P \setminus F) \) to \( \mathbb{N} \times \mathcal{A}'(P \setminus F) \), and

\[
z^\sigma = z[|P \setminus F]|^m \cdot z^{\sigma'}.
\]

Hence we have

\[
\sum_{\sigma \in \mathcal{A}(P \setminus F)} z^\sigma = \frac{1}{1 - z[|P \setminus F|]} \sum_{\sigma \in \mathcal{A}'(P \setminus F)} z^\sigma.
\]

This completes the proof. \( \square \)

Next we derive Theorem 5.3 from the Billey-type formula (Proposition 4.7).

**Proof of Theorem 5.3** By Proposition 4.7, we have

\[
\xi_{w_F}|_{w_P} = \sum_{E \in \mathcal{E}_F(P)} (-1)^{#E - #P} \prod_{p \in E} \left( 1 - z[H_P(p)] \right).
\]
By using Proposition 5.3.3 we see that
\[
\xi_{wp}|_w = \sum_{D \in \mathcal{E}(F)} \prod_{p \in D} (1 - z[H_P(p)]) \sum_{S \subseteq \mathcal{B}(D)} (-1)^{|S|} \prod_{p \in S} (1 - z[H_P(p)])
\]
\[
= \sum_{D \in \mathcal{E}(F)} \prod_{p \in D} (1 - z[H_P(p)]) \prod_{p \in B(D)} z[H_P(p)].
\]
By dividing the both sides by \(\xi_{wp}|_w = \prod_{p \in P} (1 - z[H_P(p)])\), we obtain the desired identity \[\square\]

5.2. Corollaries of the Main Theorem. First we derive the equivariant cohomology version of Theorem 5.1. In addition to translating Nakada’s colored hook corollaries of the Main Theorem.

Corollary 5.4. Let \(P\) be a \(d\)-complete poset with \(d\)-complete coloring \(c : P \rightarrow I\) and \(F\) an order filter of \(P\). Let \(a = (a_p)_{p \in I}\) be indeterminates. We put \(a(p) = a_{c(p)}(p \in P)\) and define a linear polynomial \(a(H_P(u))\) as follows:

(i) If \(u\) is not the top of any \(d_k\)-interval, then we define
\[
a(H_P(u)) = \sum_{w \leq u} a_{c(w)}.
\]

(ii) If \(u\) is the top of a \(d_k\)-interval \([v, u]\), then we define
\[
a(H_P(u)) = a(H_P(x)) + a(H_P(y)) - a(H_P(v)),
\]
where \(x\) and \(y\) are the sides of \([v, u]\).

Then we have
\[
\sum_{(q_1, \ldots, q_n)} \frac{1}{a(q_1)(a(q_1) + a(q_2)) \cdot \cdots \cdot (a(q_1) + \cdots + a(q_n))}
\]
\[
= \sum_{D \in \mathcal{E}(F)} \prod_{v \in P \setminus D} \frac{1}{a(H_P(v))},
\]
where \(n = \#(P \setminus F)\) and the summation is taken over all linear extensions of \(P \setminus F\), i.e. all labelings of the elements of \(P \setminus F\) with \(q_1, \ldots, q_n\) so that \(q_i < q_j\) in \(P \setminus F\) implies \(i < j\).

Proof. Any \((P \setminus F)\)-partition \(\sigma \in \mathcal{A}(P \setminus F)\) is determined by a nonnegative integer \(r \leq n\), an increasing sequence \(i_1 < \cdots < i_r\) of positive integers and an increasing sequence \(F \subset F_0 \subset F_1 \subset \cdots \subset F_r = P\) of order filters of \(P\), by the condition
\[
\sigma(x) = \begin{cases} 
0 & \text{if } x \in F_0 \setminus F, \\
i_k & \text{if } x \in F_k \setminus F_{k-1} \text{ and } 1 \leq k \leq r.
\end{cases}
\]
Hence we have
\[
\sum_{\sigma \in \mathcal{A}(P \setminus F)} z^\sigma
\]
\[
= \sum_{F \subset F_0 \subset F_1 \subset \cdots \subset F_r = P} \sum_{0 < i_1 < \cdots < i_r} z[F_1 \setminus F_0]^{i_1} z[F_2 \setminus F_1]^{i_2} \cdots z[P \setminus F_{r-1}]^{i_r}
\]
\[
= \sum_{F \subset F_0 \subset F_1 \subset \cdots \subset F_r = P} \frac{z[P \setminus F_0]}{1 - z[P \setminus F_0]} \cdot \frac{z[P \setminus F_1]}{1 - z[P \setminus F_1]} \cdots \frac{z[P \setminus F_{r-1}]}{1 - z[P \setminus F_{r-1}]}.
\]
Now by using Theorem 5.1 we have
\[ \sum_{F \subseteq F_0 \subseteq F_1 \subseteq \cdots \subseteq F_n = P} \frac{z[P \setminus F_0]}{1 - z[P \setminus F_0]} \cdots \frac{z[P \setminus F_{n-1}]}{1 - z[P \setminus F_{n-1}]} = \sum_{D \in \mathcal{E}_P(F) \setminus F} \prod_{v \in P \setminus D} \frac{z[H_P(v)]}{1 - z[H_P(v)]}, \]
By substituting \( z_i = t^{a_i} \) (\( i \in I \)) and multiplying the both sides by \((1-t)^n\), and then by taking the limit \( t \to 1 \), we obtain
\[ \sum_{F=F_0 \subseteq F_1 \subseteq \cdots \subseteq F_n = P} \frac{1}{a(P \setminus F_0)a(P \setminus F_1) \cdots a(P \setminus F_{n-1})} = \sum_{D \in \mathcal{E}_P(F) \setminus F} \frac{1}{a(H_P(v))}, \]
where the summation on the left hand side is taken over all increasing sequences \( F = F_0 \subseteq F_1 \subseteq \cdots \subseteq F_n = P \) of order filters of length \( n \), and \( a(D) = \sum_{a \in (p)} a_{\in (p)} \) for a subset \( D \subset P \). Such increasing sequences of order filters are in one-to-one correspondence with linear extensions \((q_1, \cdots, q_n)\) of \( P \setminus F \) by the relation
\[ F_k = F \cup \{q_n, \cdots, q_{n-k+1}\} \quad (0 \leq k \leq n). \]
Hence we obtain the desired result. \( \square \)

**Remark 5.5.** Corollary 5.4 can be proved by using the Billey formula [1, Theorem 4] and the Chevalley formula [17, Theorem 11.1.7 and Corollary 11.3.17] for the equivariant cohomology along the same line as Theorem 5.1.

By specializing \( z_i = q \) for all \( i \in I \) in [22], and \( a_i = 1 \) for all \( i \in I \) in [27], we obtain

**Corollary 5.6.** Let \( P \) be a d-complete poset and \( F \) an order filter of \( P \). We define the hook length \( h_P(u) \) at \( u \in P \) as follows:

(i) If \( u \) is not the top of any \( d_k \)-interval, then we define \( h_P(u) = \# \{ w \in P : w \leq u \} \).

(ii) If \( u \) is the top of a \( d_k \)-interval \([v, u]\), then we define \( h_P(u) = h_P(x) + h_P(y) - h_P(v) \), where \( x \) and \( y \) are the sides of \([v, u]\).

Then we have

(a) The univariate generating function of \((P \setminus F)\)-partitions is given by
\[ \sum_{\sigma \in \mathcal{A}(P \setminus F)} q^{\sigma} = \sum_{D \in \mathcal{E}(F) \setminus P} \prod_{v \in P \setminus D} \frac{q^{h_P(v)}}{1 - q^{h_P(v)}}. \]

(b) The number of linear extensions of \( P \setminus F \) is given by
\[ n! \sum_{D \in \mathcal{E}(F) \setminus P} \prod_{v \in P \setminus D} \frac{1}{h_P(v)}, \]
where \( n = \#(P \setminus F) \).

If \( P = D(\lambda) \) and \( F = D(\mu) \) are shapes corresponding to partitions \( \lambda \supset \mu \), Equations (28) and (29) reduce to Morales–Pak–Panova’s \( q \)-hook formula [22, Corollary 6.17] and Naruse’s hook formula [26] respectively. The trace generating function of reversion...
plane partitions of skew shape [22]. Corollary 6.20] is obtained from Theorem 5.1 by specializing

\[ z_i = \begin{cases} 
    tq & \text{if } i \text{ is the color of the maximum element of } D(\lambda), \\
    q & \text{otherwise.}
\end{cases} \]

**Remark 5.7.** Theorem 5.1 and its corollaries hold for heaps \( H(w) \) associated to dominant minuscule elements \( w \) in any symmetrizable Kac–Moody Weyl groups, after suitable modifications are made. See Remarks 2.12 and 3.18.

### 5.3. Example.

**Example 5.8.** Let \( P = S(3, 2, 1) \supset F = S(2) \) be the shifted shapes corresponding to strict partitions \( (3, 2, 1) \) and \( (2) \). If we regard \( P \) as a \( d \)-complete coloring \( c: P \to \{0, 0', 1, 2\} \) given in Example 2.8, then the hook monomials in \( z = (z_0, z_0', z_1, z_2) \) are given by

\[
  z[H_P(1, 1)] = z_0 z_0' z_1^2 z_2, \quad z[H_P(1, 2)] = z_0 z_0' z_1 z_2, \quad z[H_P(1, 3)] = z_0 z_1 z_2, \\
  z[H_P(2, 2)] = z_0 z_0' z_1, \quad z[H_P(2, 3)] = z_0 z_1, \quad z[H_P(3, 3)] = z_0.
\]

Since we have

\[
  \mathcal{E}_P(F) = \{ \begin{array}{c} \begin{array}{ccc} \times & \times & \times \\ \times & \times & \times \\ \times & \times & \times \\ \times & \times & \times \\ \times & \times & \times \\ \times & \times & \times \\ \end{array} \end{array}, \begin{array}{c} \begin{array}{ccc} \times & \times & \times \\ \times & \times & \times \\ \times & \times & \times \\ \times & \times & \times \\ \times & \times & \times \\ \times & \times & \times \\ \end{array} \end{array} \},
\]

we apply Theorem 5.1 to obtain

\[
(30) \quad \sum_{\pi \in \mathcal{A}(P \setminus F)} z^{\pi} = \frac{1}{(1 - z_0 z_1 z_2)(1 - z_0 z_0' z_1)(1 - z_0 z_1)(1 - z_0)} + \frac{z_0 z_0' z_1 z_2}{(1 - z_0 z_0' z_1 z_2)(1 - z_0 z_1 z_2)(1 - z_0 z_0' z_1)(1 - z_0)} = \frac{1 - z_0'^2 z_1^2 z_2^2}{(1 - z_0 z_0' z_1 z_2)(1 - z_0 z_1 z_2)(1 - z_0 z_0' z_1)(1 - z_0 z_1)(1 - z_0)}.
\]

where

\[
  z^{\pi} = z_0^\pi(1, 1) + z_0'(2, 2) + z_1^\pi(1, 2) + z_2^\pi(2, 3) + z_0^\pi(1, 3).
\]

**Example 5.9.** Let \( P = S(3, 2, 1) \supset F = S(2) \) be the same as in Example 5.8. If we regard \( P \) as the heap \( H(w_{(3, 2, 1)}) \) for the Weyl group of type \( B_3 \) (see Example 2.13), then the hook monomials in \( \pi = (z_0, z_1, z_2) \) are given by

\[
  \pi[H_P'(1, 1)] = z_0 z_1 z_2, \quad \pi[H_P'(1, 2)] = z_0^2 z_1 z_2, \quad \pi[H_P'(1, 3)] = z_0^2 z_1 z_2, \\
  \pi[H_P'(2, 2)] = z_0 z_1, \quad \pi[H_P'(2, 3)] = z_0^2 z_1, \quad \pi[H_P'(3, 3)] = z_0.
\]

Since we have

\[
  \mathcal{E}_P(F) = \{ \begin{array}{c} \begin{array}{ccc} \times & \times & \times \\ \times & \times & \times \\ \times & \times & \times \\ \times & \times & \times \\ \times & \times & \times \\ \times & \times & \times \\ \end{array} \end{array}, \begin{array}{c} \begin{array}{ccc} \times & \times & \times \\ \times & \times & \times \\ \times & \times & \times \\ \times & \times & \times \\ \times & \times & \times \\ \times & \times & \times \\ \end{array} \end{array} \},
\]

**Algebraic Combinatorics**, draft (June 28, 2019)
we apply a heap version of Theorem 5.1 to obtain

\begin{equation}
\sum_{\pi \in \mathcal{A}(P \setminus F)} \xi = \frac{1}{(1-z_0^2 z_1 z_2)(1-z_0 z_1)(1-z_0^2 z_1)(1-z_0)}
\end{equation}

\begin{equation}
+ \frac{2}{z_0^1 z_1^2 z_2}
\end{equation}

\begin{equation}
+ \frac{1}{z_0 z_1 z_2}
\end{equation}

\begin{equation}
+ \frac{1}{z_0 z_1 z_2}
\end{equation}

\begin{equation}
\frac{1}{1-\frac{z_0^3 z_1^2 z_2}{z_0 z_1 z_2}}
\end{equation}

where

\begin{equation}
\xi = \pi \in [1] + \pi (2.2) + \pi (3.3) + \pi (1.2) + \pi (2.3) + \pi (1.3)
\end{equation}

Note that Equation (31) is obtained from (30) by putting \( z_0 = z_0 \).
