

Width of the Whitehead double of a nontrivial knot

Qilong Guo, Zhenkun Li

February 6, 2022

Abstract

In this paper, we prove that $w(K) = 4w(J)$, where $w(\cdot)$ is the width of a knot and K is the Whitehead double of a nontrivial knot J .

1 Introduction

Width is a knot invariant introduced in Gabai [1]. It has been studied intensively since then. Zupan in [4] conjectured that

$$w(K) \geq n^2 w(J),$$

where K is a satellite knot with companion J and wrapping number n . This conjecture is still open. The authors of this paper proved in [2] a weaker version of the conjecture with wrapping number being replaced by winding number. In this paper we prove a special case of K having wrapping number 2 and winding number 0, which is not covered by the discussion in [2].

Theorem. Suppose J is a nontrivial knot and K is a Whitehead double of J . Then we have

$$w(K) = 4 \cdot w(J).$$

The gap between wrapping number and winding number in the proof in author's previous paper [2] lies in lemma 4.4, which says that any properly embedded surface representing a generator of $H_2(V, \partial V)$ has the number of intersection points with the satellite knot K being no smaller than the

absolute value of the winding number of K . Here V is the tubular neighborhood of J containing K . This is in general not true for wrapping number but for the special case that K is a Whitehead double, we can somehow overcome this difficulty.

2 Width of a Whitehead double

In what follows, we will use capital letters K, J, L to denote the knot or link classes while use lower case letters k, j, l to denote particular knots or links within the corresponding classes.

Definition 2.1. Suppose $l_w = \hat{k} \cup \hat{j}$ is a Whitehead link in S^3 . Let $\hat{V} = S^3 \setminus \text{int}(N(\hat{j}))$ be the exterior of \hat{j} containing \hat{k} in its interior. Since \hat{j} is the unknot in S^3 , \hat{V} is a solid torus and $\hat{k} \in \text{int}(\hat{V})$ can be thought as in figure 1. Let $j \subset S^3$ be a non-trivial knot and let $V = N(j)$ be the closure of a tubular neighborhood of j in S^3 . Let $f : \hat{V} \rightarrow S^3$ be an embedding such that $f(\hat{V}) = V$, and let $k = f(\hat{k})$. Then k is called a *Whitehead double* of j and j is called its *companion*.

Figure 1: The pattern of a Whitehead double.

Lemma 2.2. *Suppose k, j, V are defined as in definition 2.1, then any meridian disk D of V would intersect k at least two times.*

Proof. See Rolfsen [3]. □

Remark 2.3. The above lemma actually means that the wrapping number of k is 2. On the other hand, $[k] = 0 \in H_1(V)$ so the winding number of k is 0.

Definition 2.4. Suppose $h' : \mathbb{R}^4 \rightarrow \mathbb{R}$ is the projection onto the forth coordinate, $S^3 \subset \mathbb{R}^4$ is the unit 3-sphere, and $h = h'|_{S^3}$. Fix any knot class K , let \mathcal{K} be the set of knots $k : S^1 \hookrightarrow S^3$ within the class K , so that k does not contain the critical points of $h = h'|_{S^3}$, the function $h \circ k : S^1 \rightarrow \mathbb{R}$ is Morse, and any two critical points have different critical values.

For any $k \in \mathcal{K}$, let $c_1 < \dots < c_n$ be all the critical values of $h \circ k$. Pick regular values r_1, \dots, r_{n-1} so that

$$c_1 < r_1 < c_2 < r_2 < \dots < c_{n-1} < r_{n-1} < c_n,$$

and define

$$w(k) = \sum_{i=1}^{n-1} |h^{-1}(r_i) \cap k|, \quad w(K) = \min_{k \in \mathcal{K}} w(k).$$

Here $|\cdot|$ means the number of intersection points. Then $w(K)$ is called the *width* of K .

As discussed in the introduction, the key lemma is the following.

Lemma 2.5. *(Key lemma.) Suppose S is a connected properly embedded planar surface inside V which represents a generator of $H_2(V, \partial V)$, then S intersects k at least 2 times.*

We will prove this lemma in next section while first use this lemma to prove our main result.

Theorem 2.6. *Suppose J is a nontrivial knot (class) and K is a Whitehead double of J , then we have*

$$w(K) = 4w(J).$$

Proof. It is easy to construct examples to show that

$$w(K) \leq 4w(J).$$

In order to prove the reversed inequality, we repeat the whole argument as in the authors' previous paper [2] except for applying the key lemma 2.5. We only sketch the proof as follows. For details, readers are referred to that paper.

First pick a knot $k \in \mathcal{K}$ so that $w(k) = w(K)$. There are corresponding companion knot j and its tubular neighborhood V so that $k \subset V$. Let $T = \partial V$. We can perturb V (while fixing k, j) so that V does not contain the critical points of $h = h'|_{S^3}$, $h|_T$ is Morse and all critical points of $h|_T$ have different critical values.

As in [2], there is a Reeb graph $\Gamma_R(V)$ associated to the pair $(V, h|_V)$. There is a natural way to embed $\Gamma_R(V)$ into V and there is a unique loop l in Γ_V so that

(1). We have that l represents a generator of $H_1(V)$.

(2). We have that $w(L) \geq w(J)$.

(3). We can isotope l into a new position l' with the following significance. If r is a regular level of $h \circ k$, and $m = |h^{-1}(r) \cap k|$, then there exists P_1, P_2, \dots, P_m as pair-wise disjoint connected components of $h^{-1}(r) \cap V$, so that for each j with $1 \leq j \leq m$, P_j intersects l' transversely at one point.

Now let r_1, \dots, r_{n-1} be all regular values picked as in definition 2.4. For each i with $1 \leq i \leq n - 1$, we pick connected components $P_{i,1}, \dots, P_{i,m_i}$ of $h^{-1}(r_i) \cap V$ as in (3). For each j with $1 \leq j \leq m_i$, we know that $P_{i,j}$ is contained in $h^{-1}(r_i) \cong S^2$ so it is a planar surface. From (1) and the fact that $P_{i,j}$ intersects l' transversely at one point, we know that $P_{i,j}$ represents a generator of $H_2(V, \partial V)$. Hence lemma 2.5 applies and

$$|P_{i,j} \cap k| \geq 2.$$

Now we can apply the identical combinatorial arguments as in the proof of lemma 4.6 in [2] to finish the proof here. \square

3 The proof of the key lemma

In order to prove the key lemma, we need some preparations first.

Definition 3.1. Suppose $M = B^3$ or S^3 is either a 3-ball or a 3-sphere. Suppose S is a properly embedded surface in M . This means when $M = B^3$, $\partial S \subset \partial M$ and when $M = S^3$, S is closed. Then we can define a map

$$C_{M,S} : (M \setminus S) \times (M \setminus S) \rightarrow \{\pm 1\}$$

as

$$C_{M,S}(x, y) = (-1)^{|\gamma \cap S|},$$

where $x, y \in M \setminus S$ are two points and γ is an arc connecting two points x and y that is transverse to S . The notation $|\cdot|$ means the number of intersection points.

The function $C_{M,S}(x, y)$ is independent of the choice of the arc γ . Suppose γ and γ' are two such arcs, then $\beta = \gamma \cup \gamma'$ is a closed curve. We know that

$$|\beta \cap S| \equiv 0 \pmod{2}$$

since $0 = [S, \partial S] \in H_2(M, \partial M) = 0$. Hence we conclude

$$|\gamma \cap S| \equiv |\gamma' \cap S| \pmod{2}.$$

From the definition, we know that $C_{M,S}(x, y) = -1$ would imply that x and y are not in the same component of $M \setminus S$.

Another good property of this function is the following equality: for any 3 points $x, y, z \in M \setminus S$, we have

$$C_{M,S}(x, y) \cdot C_{M,S}(y, z) = C_{M,S}(x, z). \quad (1)$$

Remark 3.2. This type of functions are called potentials in Gabai [1].

Lemma 3.3. *Suppose S is a connected, properly embedded planar surface inside a 3-ball B . Let B_1 and B_2 be the two components of $B \setminus S$. Then there is no Hopf link $l_h = l_1 \cup l_2$ inside B such that*

$$l_i \subset B_i \text{ for } i = 1, 2.$$

Proof. Assume, on the contrary, that there is a Hopf link $l_h = l_1 \cup l_2$ such that $l_i \subset B_i$.

Note $B \setminus S$ has two components. To show this, let $N(S)$ be a product neighborhood of S , and $B' = B \setminus \text{int}(N(S))$. We know that $\text{int}(B')$ and $B \setminus S$ are homotopic. From the connectedness of S and Mayer-Vietoris sequence

$$\begin{array}{ccccccccc}
 H_1(B) & \longrightarrow & H_0(\partial N(S)) & \longrightarrow & H_0(N(S)) \oplus H_0(B') & \longrightarrow & H_0(B) & \longrightarrow & 0 \\
 \parallel & & \parallel & & \parallel & & \parallel & & \\
 0 & \longrightarrow & \mathbb{Z} \oplus \mathbb{Z} & \longrightarrow & \mathbb{Z} \oplus H_0(B') & \longrightarrow & \mathbb{Z} & \longrightarrow & 0
 \end{array}$$

we know that $H_0(B') = \mathbb{Z} \oplus \mathbb{Z}$. Let $x_1 \in l_1$ and $x_2 \in l_2$ be two points, then from the hypothesis of the lemma, x_1 and x_2 lie in two different components of $B \setminus S$. Since there are only two components of $B \setminus S$, we know that

$$C_{B,S}(x_1, x_2) = -1,$$

and hence there exists a curve γ connecting x_1 with x_2 and having an odd number of intersections with S .

We can pick another 3-ball B'' and glue it to B along their common spherical boundary to get an S^3 . Inside this S^3 , $l_h = l_1 \cup l_2$ is still a Hopf link. Inside B'' , we can pick disks D_1, \dots, D_t so that

$$S^2 = S \cup D_1 \cup \dots, D_t \subset S^3$$

is a 2-sphere. Since $\gamma \subset B$, we know that $\gamma \cap S^2 = \gamma \cap S$ and conclude that

$$C_{S^3, S^2}(x_1, x_2) = -1,$$

so the two components of the Hopf link l_h lie in two different components of $S^3 \setminus S^2$, which is absurd since it is well-known that the Hopf link is non-separating. □

Now we are ready to prove the key lemma.

proof of lemma 2.5. Suppose k is a Whitehead double of j , V is the tubular neighborhood of j containing k and S is a connected, properly embedded planar surface in V , representing a generator of $H_2(V, \partial V)$. Assume that S and k have less than 2 intersections, then since $[k] = 0 \in H_1(V)$, we know that S and k must be disjoint.

It is straightforward to see that there is a meridian disk D of V , such that in $B = V \setminus \text{int}(N(D))$, D intersects S transversely, and that after

Figure 2: After cutting and re-gluing we will get a Hopf link l .

adding two small arcs to $(k - \text{int}(N(D)))$ near $\partial N(D)$, we will get a Hopf link l out of k . Here $N(D)$ is a neighborhood of D in V . See figure 2.

If $D \cap S = \emptyset$, then we can apply lemma 3.3 directly to conclude a contradiction. Note the two components of the Hopf link l are in two different components of $B \setminus S$. This argument for this is exactly the same as the following more general case (when $D \cap S \neq \emptyset$): in figure 3, we have $C_{B,S}(u, v) = -1$ for the same reason while $C_{B,S}(x, u) = C_{B,S}(y, v) = 0$ as there is no need for doing any surgeries.

If $D \cap S \neq \emptyset$, we can assume that

$$D \cap S = \beta_1 \cup \beta_2 \dots \cup \beta_m,$$

where β_1, \dots, β_n are intersection circles of the two surfaces and are in the order such that β_j bounds a disk $D_j \subset D$ disjoint from any β_i for $i < j$.

If all D_i are disjoint from k , then we can do a series surgeries on S with respect to D_n, D_{n-1}, \dots, D_1 one by one to get a surface S'' so that S'' is disjoint from D and k . We can pick some connected component of S'' , and it will also have such properties that we can apply the argument above to get a contradiction.

Now we are in the most complicated case where some D_i intersects k . Suppose j_0 is the greatest index such that $D_{j_0} \cap k \neq \emptyset$. We first claim that D_{j_0} cannot have a unique intersection point with k . Suppose the contrary, then a sequence of surgeries on S with respect to D_n, \dots, D_{j_0+1}

would generate a surface S' such that S' represent a generator of $H_2(V, \partial V)$, S' is disjoint from k and

$$D_{j_0} \cap S' = \partial D_{j_0} = \beta_{j_0}.$$

Suppose S'_0 is the component of S' containing β_{j_0} , then S'_0 is still a planar surface. A surgery on S'_0 with respect to D_{j_0} would result in two surfaces S'_1 and S'_2 , each of which contains one copy of D_{j_0} and hence has a unique intersection point with k . This is impossible since $[k] = 0 \in H_1(V)$.

Hence we conclude that D_{j_0} has two intersection points with k , which are all the intersection points of D with k . Now, as before, we can do a sequence of surgeries on S with respect to $D_n, \dots, D_{j_0+1}, D_{j_0}$ to get S' . When doing last surgery with respect to D_j , we shall modify k at the same time: cut k along D and glue two small arcs to the newly born boundary points near D to get a Hopf link l disjoint from S' and D . See figure 3. Now we can apply the remaining sequence of surgeries on S' , with respect to D_{j_0-1}, \dots, D_1 , to get a surface S'' which represents a generator of $H_2(V, \partial V)$ and is disjoint from D and l .

Figure 3: Surgery on S along D_n, \dots, D_{j_0-1} .

Now we can cut off a neighborhood $N(D)$ of D from V , which is disjoint from l and S'' , to get a 3-ball $B = V \setminus \text{int}(N(D))$. In order to see that the two components of l are in different components of $B \setminus S''$, we can pick points x, y on two arcs of l which do not belong to k , and pick two points u, v near the boundary $\partial N(D)$ but on different sides of D . See figure 4.

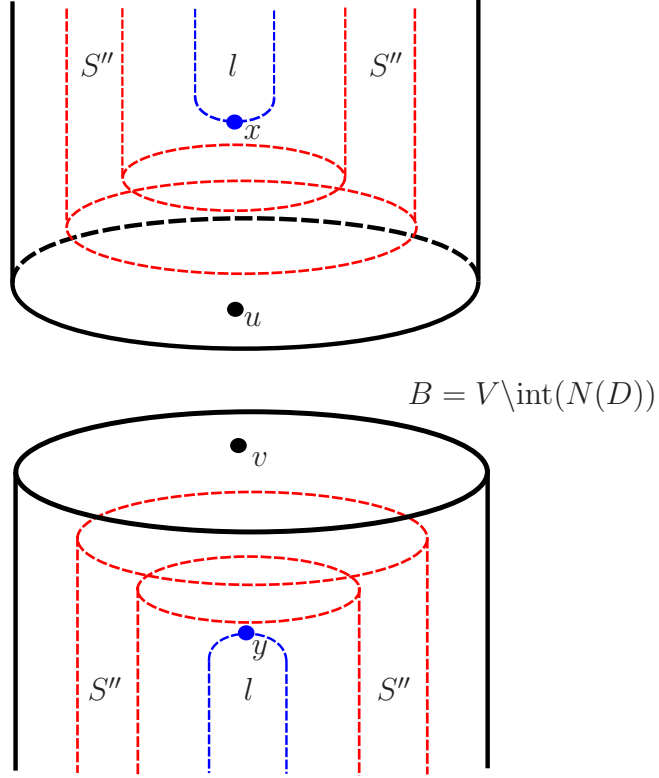

Figure 4: Surgery on S along D_n, \dots, D_{j_0-1} .

There is a symmetry between the two pairs (x, u) and (y, v) with respect to D so we have

$$C_{B, S''}(x, u) = C_{B, S''}(v, y),$$

where $C_{B, S''}$ is defined as in definition 3.1. Since S'' represents a generator of $H_2(V, \partial V)$, we have

$$C_{B, S''}(u, v) = -1.$$

Using equality (1), we have

$$C_{B, S''}(x, y) = C_{B, S''}(x, u) \cdot C_{B, S''}(u, v) \cdot C_{B, S''}(v, y) = -1.$$

Thus the two components of l are in different components of $B \setminus S''$. Pick a connected component S''_0 which separates the two components of l , we can apply lemma 3.3 to get a contradiction. \square
