Developing Takeuti-Yasumoto forcing

Satoru Kuroda

March 16, 2022

1 Introduction

In late 90’s two consecutive papers by G. Takeuti and Y. Yasumoto [6], [7] were published. These papers aimed at applying Boolean valued model constructions for bounded arithmetic and relating them to separation problems of complexity classes.

Prior to their work, forcing was used to construct models of bounded arithmetic in different contexts. The first application of forcing in bounded arithmetic was done by Paris and Wilkie, who proved that the theory $IE_1$ extended by a single predicate symbol $R$ does not prove that $R$ is not a bijection from $n+1$ to $n$. Their construction was later extended to $I\Delta_0$ by M. Ajtai and to Buss’ theory by S. Riis.

Besides these results, J. Krajíček [4] gave different type of forcing construction for models of bounded arithmetic $PV$ and $V^1$. Krajíček’s motivation for these results is to provide nonstandard models of weak theories which satisfies unproven separation of complexity classes.

Then Takeuti and Yasumoto tried to give a comprehensive theory for forcing in nonstandard models of bounded arithmetic. Their main motivation was to relate separations of complexity classes in the standard world to generic models constructed from nonstandard models.

Although forcing type arguments seems very useful in bounded arithmetic just like in other branches of mathematical logic, there are few connections between the above mentioned results.

In this paper, we rearrange Takeuti-Yasumoto type forcing argument in a frame work which is different from the one they adopted. Namely we rework on the construction of generic models in two sort language in Cook and Nguyen [2]. It seems that some of the proofs in [6] and [7] have flaws and we give a correct proofs of some of their results.
We will also show that Krajíček’s results can be obtained as Takeuti-Yasumoto forcing construction. Furthermore, we will consider the problem of violating or satisfying surjective weak pigeonhole principles for polynomial time functions in generic models. Actually, we show that under an assumption on propositional logic in the ground model, we can construct a generic model violating \(dWPHP(PV)\). On the other hand, we can construct generic models for \(dWPHP(PV)\) by extending the base Boolean algebra to allow random inputs.

Our results suggest that Takeuti-Yasumoto forcing works as a general framework for forcing constructions in bounded arithmetic.

2 Preliminaries

We will work on two-sort bounded arithmetic which was developed by Cook and Nguyen [2]. The language of two-sort bounded arithmetic comprises two sorts of variables; number variables \(x, y, z, \ldots\) and string variables \(X, Y, Z, \ldots\). The language \(L^2_A\) has a constant symbol 0, function symbols \(s(x), x + y, x \cdot y, |X|\) and a relation symbol \(x \leq y\) where \(|X|\) denotes the length of string \(X\). We use either expressions \(X(i)\) and \(i \in X\) to denote that the \(i\)th bit of \(X\) is 1.

A bounded number quantifier is of the form \(\forall x < t\) or \(\exists x < t\). A bounded string quantifier is of the form \(\forall X < t\) or \(\exists X < t\) whose intended meanings are

\[
\forall X(|X| < t \rightarrow \cdot \cdot \cdot) \text{ and } \exists X(|X| < t \land \cdot \cdot \cdot)
\]

respectively. \(\Sigma^B_0\) is the set of formulas which contains only bounded number quantifiers. \(\Sigma^B_1\) is the set of formulas which contains bounded number quantifiers, positive occurrences of bounded existential string quantifiers and negative occurrences of bounded existential string quantifiers.

In this paper we treat theories for PTIME and their extensions. In particular the following three theories for PTIME are considered.

\(VP\) is the \(L^2_A\) theory whose axioms are \(BASIC_2\) and a single axiom \(MCV\) given as

\[
MCV \equiv \forall a \forall C, E \exists Y \ \delta_{MCV}(a, C, E, Y)
\]

where

\[
\delta_{MCV}(a, C, E, Y) \equiv \\
\neg Y(0) \land Y(1) \land \forall x < a \ x \geq 2 \rightarrow \\
Y(x) \leftrightarrow [(C(x) \land \forall y < x (E(y, x) \rightarrow Y(y)) \lor (\neg C(x) \land \exists y < x (E(y, x) \land Y(y))))].
\]
The second theory $\text{PV}$ is defined over the language $\mathcal{L}_{\text{PV}}^2$ which extends $\mathcal{L}_A^2$ by function symbols for Cobham’s function algebra for PTIME. Then $\text{PV}$ consists of $\text{BASIC}_2$ and defining axioms for such functions.

A seemingly stronger theory $\text{V}^1$ is an $\mathcal{L}_A^2$-theory which comprises $\text{BASIC}_2$ together with

$$\Sigma_1^B\text{-COMP} : \exists Y < a \forall x < a (Y(x) \leftrightarrow \varphi(x)), \varphi(x) \in \Sigma_1^B.$$ 

It is known that all these theories corresponds to the class PTIME in the sense that

**Theorem 1 (Cook-Nguyen [2])** For $T = \text{VP}, \text{PV}$ or $\text{V}^1$, a function is $\Sigma_1^B$-definable in $T$ if and only if it is computable in PTIME.

We will work with the circuit models for PTIME. In the axiom MCV, monotone circuits are coded by pairs of the form $(G, E)$ of strings such that

$$\text{Circuit}_n(G, E) \leftrightarrow E \subseteq G \times G.$$ 

The following fact is folklore and will be used elsewhere in this paper.

**Proposition 1** Let $F(X)$ be a $\text{PV}$ function. Then $\text{PV}$ proves the following.

$$\forall n \exists(C_0, \ldots, C_{t-1}) \forall i < t(C_i(X) = 1 \leftrightarrow F(X)(i))$$

where $t$ is the bounding term for $F$.

Next we review basic notions of Boolean valued models in [6] in terms of the two-sort bounded arithmetic.

Let $(M_0, M)$ be a structure of some two-sort language of bounded arithmetic. Throughout the paper we will concentrate on nonstandard countable model $(M_0, M) \models \text{VP} + \neg \text{Exp}$.

**Example.** The original Takeuti-Yasumoto forcing starts with the ground model which is defined in the following manner. Let $M \models \text{Th}(\mathbb{N})$ be a countable nonstandard model and fix $n \in M \setminus \omega$. Define

$$M^* = \{x \in M : x \leq n\# \cdots \# n \text{ for some } k \in \omega\}$$

and

$$M_0 = \{|x| : x \in M^*\}.$$ 

We regard $(M_0, M^*)$ as a two-sort structure by identifying each element $x \in M^*$ with its binary representation. It is easy to see that $(M_0, M^*) \models \text{V}^\infty$. 

Let $n_0 = |n|$ and $\bar{p} = p_0, \ldots, p_{n_0-1}$ be the list of propositional variables coded by elements in $M_0$. We define $\mathbb{C}$ as a set of Boolean formulas over variables from $\bar{p}$ coded in $M^*$. The precise definition of $\mathbb{C}$ can be found in [6].

$\mathbb{C}$ can be regarded as a Boolean algebra with respect to either one of the following two partial orders:

\[
C \leq_A C' \iff \forall X (|X| = n \rightarrow \text{eval}(C, X) \leq \text{eval}(C', X)), \\
C \leq_{EF} C' \iff \exists P \text{Prf}_{EF}(C \rightarrow C', P).
\]

Note that these two partial orders are identical only if Extended Frege is super. In the following definitions, the partial order $\leq$ on $\mathbb{C}$ represents either $\leq_A$ or $\leq_{EF}$.

Define $\mathbb{B}_A = \mathbb{C}/\equiv_A$ and $\mathbb{B}_{EF} = \mathbb{C}/\equiv_{EF}$. We omit the subscript and denote either Boolean algebra by $\mathbb{B}$ when there is no fear of confusion.

A set $I \subseteq \mathbb{B}$ is an ideal if $0 \in I$, $1 \notin I$ it is closed under $\lor$ and lower closed with respect to the partial order. An ideal $I$ is $M_0$-complete if

\[
\forall n \in M_0 \forall X : a \rightarrow B \forall i < a \ X(i) \in I \Rightarrow \bigvee_{i<a} X(i) \in I.
\]

A set $F \subseteq \mathbb{B}$ is a filter if $0 \notin I$, $1 \in I$ it is closed under $\land$ and upper closed with respect to the partial order. A set $D \subseteq \mathbb{B}$ is dense over an $M_0$-complete ideal $I$ if for any $X \in \mathbb{B} \setminus I$ there is $X' \in \mathbb{B} \setminus I$ such that $X' \leq X$. $D$ is definable if there exists a formula $\varphi$ such that

\[
D = \{ X \in \mathbb{B} : M \models \varphi(X) \}.
\]

A filter $G \subseteq \mathbb{B}$ is $\mathcal{M}$-generic if $(D \setminus I) \cap G \neq \emptyset$ whenever $D$ is dense over $I$ and definable. Remark that an $\mathcal{M}$-generic $G$ is not definable in $(M_0, M)$. We define the generic model analogous to that in set theory. First define

\[
M^\mathbb{B} = \{ X \in M : X : a \rightarrow \mathbb{B} \text{ for some } a \in M_0 \}.
\]

For a $\mathcal{M}$-generic $G$ over an $M_0$-complete ideal $I$ and $X : a \rightarrow \mathbb{B}$ we define

\[
i_G(X) = \{ y < a : X(y) \in G \}.
\]

Finally we define

\[
M[G] = \{ i_G(X) : X \in \mathbb{B} \}.
\]

Since the length of any $i_G(X)$ is bounded by some element in $M_0$, we can regard the pair $(M_0, M[G])$ as a two-sort structure with a natural interpretation. First we will show that $(M_0, M[G])$ is a model of the base theory $V^0$. 
Definition 1 Let \( \varphi(\bar{x}, \bar{X}) \in \Sigma^B_0 \) and
\[
\| \varphi(\bar{x}, \bar{X}) \|_{\bar{m}, \bar{n}}(\bar{p}_0, \ldots, \bar{p}_{n-1})
\]
be its propositional translation where \( \bar{p}_i \) corresponds to the variable \( X_i \). For \( \bar{a} \in M_0 \) and \( \bar{A} \in M^B \) with \( A_i : b_i \to \mathbb{B} \), we define
\[
\llbracket \varphi(\bar{a}, \bar{A}) \rrbracket \| \varphi(\bar{x}, \bar{X}) \|_{\bar{a}, b}(X_0, \ldots, X_{n-1}).
\]

Theorem 2 (Forcing Theorem for \( \Sigma^B_0 \) formulas) Let \( \mathbb{B} \) be a Boolean algebra in \( M^* \) and suppose that it admits a \( \Sigma^B_0 \)-translation. Let \( \varphi(\bar{x}, \bar{X}) \) be a \( \Sigma^B_0 \) formula with parameters as indicated. Then for \( \bar{a} \in M_0 \) and \( \bar{A} \in M^B \)
\[
(M_0, M[G]) \models \varphi(\bar{a}, \bar{A}[\bar{X}]) \iff \llbracket \varphi \rrbracket \in G
\]
for a \( M \)-generic \( G \) over an \( M_0 \)-complete ideal \( I \)

Theorem 3 Let \( \mathbb{B} \) be a Boolean algebra in \( M^* \) and suppose that it admits a \( \Sigma^B_0 \)-translation. If \( G \subseteq \mathbb{B} \) is a \( M \)-generic over an \( M_0 \)-complete ideal \( I \subseteq \mathbb{B} \) then
\[
(M_0, M[G]) \models V^0.
\]

For the Boolean algebra \( \mathbb{B} \), we have a stronger forcing theorem, that is \( \Sigma^b_0 \) formula may contain \( PV \)-functions.

Theorem 4 (Cobham, Cook-Nguyen) A string function is in \( FP \) if and only if it is obtained by \( AC^0 \) functions by finitely many applications of composition and limited recursion.

Lemma 1 If \( F(\bar{x}, \bar{X}) \in \mathcal{L}^2_{PV} \) then there exists a term \( t(\bar{x}, \bar{y}) \) such that \( PV \) proves
\[
\forall x \forall X F(\bar{x}, \bar{X}) \leq t(\bar{x}, |\bar{X}|).
\]

Let \( \mathcal{L}^2_{PV} \) be the language which consists of function symbols for all \( FP \) functions. We denote the class of \( \Sigma^b_0 \) formulas in the language \( \mathcal{L}^2_{PV} \) by \( \Sigma^b_0(PV) \).

Definition 2 For \( \varphi(\bar{x}, \bar{X}) \in \Sigma^B_0(PV) \), \( \bar{x} \in M^*_0 \) and \( \bar{X} \in M^B \), we define \( \llbracket \varphi(\bar{x}, \bar{X}) \rrbracket \) inductively as follows:
- if \( \varphi(\bar{x}) \) is an atomic formula which contains only number terms then
\[
\llbracket \varphi(\bar{a}) \rrbracket = \begin{cases} 1 & \text{if } (M^*_0, M^*) \models \varphi(\bar{a}), \\ 0 & \text{otherwise}. \end{cases}
\]
• if $X : a \to \mathbb{B}$ then

$$[i \in X] = \begin{cases} X(i) & \text{if } i < a, \\ 0 & \text{otherwise.} \end{cases}$$

Let $F(\bar{x}, \bar{X}) \in \mathcal{L}_{P^V}^2$, $\bar{a} \in M_0^*$ and $\bar{A}, Z \in M^\mathbb{B}$. We define $[[F(\bar{a}, \bar{A}) = Z]]$ by induction along the construction of $F$.

• if $F(\bar{x}, \bar{X})$ is an $AC^0$ function and $t(\bar{x}, |\bar{X}|)$ be a term bounding the length of $F(\bar{x}, \bar{X})$ as in Lemma 7. Then we have $C_0, \ldots, C_{t(\bar{x}, |\bar{X}|)}$ such that each $C_i(\bar{x}, \bar{X})$ outputs the $i$-th bit of $F(\bar{x}, \bar{X})$. Let $\bar{a} \in M_0^*$ and $\bar{A} \in M^\mathbb{B}$. We define

$$[F(\bar{a}, \bar{A}) = Z] = \begin{cases} \bigwedge_{0 \leq i < t} (C_i(\bar{a}, \bar{A}) \leftrightarrow Z(i)) & \text{if } |Z| = t, \\ 0 & \text{otherwise.} \end{cases}$$

What axioms the generic model satisfies depends on the complexity of the Boolean algebra. Cook and Nguyen [2] gave a general method for constructing a minimal theory corresponding to a given subclasses of $P$. That is, for a variety of complexity classes $C \subseteq P$ we can give a single axiom $Ax_C$ which represents a concept for complete problems for $C$ such that $VC = V^0 + Ax_C$ captures $C$.

We expect that if the Boolean algebra represents such a computational concept then the generic model based on that algebra satisfies $Ax_C$ and for some complexity classes we actually have such correspondences. In this paper, we mainly treat Boolean algebras which consists of Boolean circuits. It is possible to construct Boolean algebras for subclasses of $P$ to form generic models for theories for such classes. We will pursue this problem in the forthcoming paper [5].

**Theorem 5** Let $G \subseteq \mathbb{B}$ be $M$-generic then $(M_0^*, M[G]) \models VP$.

(Proof). Recall that $VP = V^0 + MCV$ where

$$MCV \equiv \forall a \forall C, E \exists Y \delta_{MCV}(a, C, E, Y)$$

and

$$\delta_{MCV}(a, C, E, Y) \equiv \neg Y(0) \land Y(1) \land \forall x < a x \geq 2 \rightarrow Y(x) \leftrightarrow [(C(x) \land \forall y < x (E(y, x) \rightarrow Y(y)))$$

$$\lor (\neg C(x) \land \exists y < x (E(y, x) \land Y(y))).$$
Let $a \in M^*_0$, $C : a \rightarrow \mathbb{B}$ and $E : \langle a, a \rangle \rightarrow \mathbb{B}$. We define $Y : a \rightarrow \mathbb{B}$ by $Y(0) = 0$, $Y(1) = 1$ and for $x \geq 2$,

$$Y(x) = (C(x) \land \bigwedge_{y<x} (E(y, x) \rightarrow Y(y))) \lor (-C(x) \land \bigvee_{y<x} (E(y, x) \land Y(y))).$$

Then it is readily seen that for any $C : a \rightarrow \mathbb{B}$ and $E : \langle a, a \rangle \rightarrow \mathbb{B}$,

$$(M_0, M) \models \forall A \in 2^a \text{ eval}(A, [\delta_{MCV}(a, C, E, Y)]) = 1$$

which implies that $[\delta_{MCV}(a, C, E, Y)] \in G$.

### 3 Separation problems and generic models

Takeuti and Yasumoto relates the separation of complexity classes to properties of generic models. However, their proof seems to have flaws and so we represent it with a correct proof.

**Theorem 6 (Takeuti-Yasumoto)** Let $I \subseteq \mathbb{B}$ be a $M_0$-complete ideal and $G$ be a $M$-generic maximal filter over $I$. If $P = NP$ then $(M^*_0, M[G]) \models \Sigma^B_1$-COMP.

**(Proof).** Assume that $P = NP$. Then $(M^*_0, M^*) \models P = NP$ too. Let $\varphi(x, X, Z) \in \Sigma^B_1$, $t(a)$ be a term and $\psi(x, X) \equiv \exists Z < t(|X|) \varphi(x, X, Z)$. We will show that for any $a, b \in M^*_0$ and $X : b \rightarrow \mathbb{B}$,

$$(M^*_0, M^*) \models \exists Y < a \forall x < a \,(Y(x) \leftrightarrow \exists Z < t(b) \psi(x, i_G(X))).$$

Since $P = NP$, we can construct a PV function $F(x, X)$ such that

$$\exists Z < t(|X|) \varphi(x, X, Z) \rightarrow \varphi(x, X, F(x, X)) \land |F(x, X)| < t(|X|)$$

using binary search. Moreover, we can define $F(x, X)$ so that

$$\neg \exists Z < t(|X|) \varphi(x, X, Z) \leftrightarrow |F(x, X)| \geq t(|X|).$$

By the translation lemma for PV formulas, we have a sequence of circuits

$$C_{0,x}(X), \ldots, C_{t(|X|)-1,x}(X) \in \mathbb{B}$$

such that

$$\forall X \, |X| = a \rightarrow \forall i < t(a) \,(i \in F(x, X) \leftrightarrow C_{i,x}(X) = 1).$$
Define $Z : t(b) \to \mathbb{B}$ and $Y : a \to \mathbb{B}$ by

$$Z(i) = C_{i,x}(X)$$

and

$$Y(x) = \begin{cases} 
    \llbracket \varphi(x, X, Z) \rrbracket & \text{if } |F(x, X)| < t(|X|), \\
    0 & \text{otherwise.}
\end{cases}$$

Then we have

$$Y \in G \Rightarrow |F(x, X)| < t(b) \Rightarrow \llbracket \varphi(x, X, Z) \rrbracket \in G \Rightarrow (M_0^*, M[G]) \models \exists Z < t(b) \varphi(x, i_G(X), Z)$$

and

$$Y \notin G \Rightarrow |F(x, X)| \geq t(b) \Rightarrow \llbracket \varphi(x, X, Z) \rrbracket \notin G \Rightarrow \text{there is no } Z : t(b) \to \mathbb{B} \text{ such that } \llbracket \varphi(x, X, Z) \rrbracket \in G \Rightarrow (M_0^*, M[G]) \models \neg \exists Z < t(b) \varphi(x, i_G(X), Z)$$

4 Krajíček forcing and T-Y forcing

In this section, we show that Krajíček’s forcing construction can be done by means of Takeuti-Yasumoto forcing.

**Theorem 7** Let $(M_0, M) \models VP$ be countable and nonstandard. If $(M_0, M) \models NP \nsubseteq P/poly$ then there exists an $M_0$-complete ideal $I \subseteq \mathbb{B}$ such that $(M_0^*, M[G]) \models NP \nsubseteq co-NP$.

(Proof). Let $(M_0, M) \models VP$ be as above. Then there exists $n \in M_0 \setminus \omega$ such that $Sat_n(X)$ is not recognized by a circuit in $(M_0, M)$, that is

$$(M_0, M) \models \forall C \in Circuit_n \exists X (Sat_n(X) \not\leftrightarrow X \models C).$$

Let $\vec{p} = p_0, \ldots, p_{n-1}$ be a list of propositional variables in $(M_0, M)$. Let $\varphi(X, Z) \in \Sigma_0^B$ be such that $\psi(X) \equiv \exists Z < |X| \varphi(X, Z)$ denotes a NP complete predicate. Define

$$T = \{ \llbracket A \models X \rrbracket : A : n \to \mathbb{B} \} \cup \{ \llbracket \varphi(X, Z) \rrbracket : Z : n \to \mathbb{B} \}.$$ 

Then $T$ is consistent in $(M_0, M)$, that is, for any $T' \subseteq T$ with $|T'| \in M_0$, it is the case that

$$(M_0, M) \models \neg \exists P Prf_{EF}(\bigwedge T' \rightarrow, P).$$

Then the theorem follows from the following observation:
Lemma 2 If $T \subseteq B$ is a consistent set in $(M_0, M)$ then there exists an $M_0$ complete ideal $I$ such that $T \subseteq G$ whenever $G$ is an $M$-generic ultrafilter over $I$.

(Proof). Let $T$ be consistent in $(M_0, M)$. Let $T^*$ be the closure of $T$ under $\lor$. Note that $T^*$ is also consistent in $(M_0, M)$. Define $I \subseteq B$ by

$$I = \{ X \in B : \text{there exists } Z \in T^* \text{ such that } X < Z \}.$$ 

First we claim that $I$ is an $M_0$-complete ideal. By the definition of $I$, it is straightforward to see that $0 \in I$ and $1 \not\in I$. The upward closedness is also trivial.

Let $X_0, X_1 \in I$. Then there exist $Z_0, Z_1 \in T^*$ such that $X_i < Z_i$ for $i = 0, 1$. Since $T^*$ is closed under $\land$, we have

$$X_0 \lor X_1 < Z_0 \lor Z_1 \in T^*$$

as desired. Moreover, $M_0$-completeness is proven in a similar manner.

Finally we show that if $G$ is $M$-generic over $I$ then $T \subseteq G$. To see this, let $X \in T$ and define

$$D = \{ Z \in B : Z \leq X \}.$$ 

We will show that $D$ is dense over $I$. Let $Y \in B \setminus I$. Then there in no $Z \in T^*$ such that $Y < Z$. Define $Z := X \land Y$. Then $Z \in D$ and also by the definition of $I$, we have $Z \not\in I$.

Now if $G$ is $M$-generic over $I$ then there is $z \in G \cap D$. So we have $Z \leq X$ and $X \in G$ since $G$ is a filter. □

Krajíček gave another forcing construction.

Theorem 8 (Krajíček) If $(M_0^*, M^*) \models \neg \exists P \Prf_{EF}(\tau, P)$ for some propositional formula $\tau$. Then there exists a $\Pi^B_1$-elementary cofinal extension $(M_0^*, M')$ in which $\neg \tau$ is satisfiable.

Krajíček proved this using a forcing construction with the forcing notion. We will show that the generic model of Theorem 8 can be obtained by Takeuti-Yasumoto forcing.

Theorem 9 If $(M_0, M) \models V^1 + \neg \exists P \Prf_{EF}(\tau, P)$ for some propositional formula $\tau$. Then there exists a $M$-generic $G \subseteq B$ over some $M_0$-complete ideal such that $(M_0, M[G]) \models V^1$ and $\neg \tau$ is satisfiable.
Proof. We show that for any $\mathcal{G}$ which is generic in $\mathcal{P}$ there exists an $M_0$-complete ideal $I$ and an $\mathcal{M}$-generic $G$ over $I$ such that $G = \cup \mathcal{G}$. Then Krajíček’s theorem implies the claim.

Let $(M_0, M)$ be as above. By compactness, we construct an elementary extension $(M_0^*, M^*)$ such that there exists $c \in M_0^*$ so that

$$(M_0^*, M^*) \models a < c$$

for all $a \in M_0$. Construct the Boolean algebra $\mathbb{B} \subseteq M$. Let $S \subseteq \mathbb{B}$. An $EF(S)$-proof is a sequence $P = \langle P_0, \ldots, P_l \rangle$ such that each $P_j$ is either an axiom of EF, an member of $S$ or obtained from $P_{j_0}, \ldots, P_{j_k}$ for some $j_0, \ldots, j_k < i$. Note that we have a $\Sigma^B_0 \cup \{S\}$-formula

$$Prf_{EF}(S, P, C) \iff P \text{ is an } EF(S)-\text{proof of } C.$$

For $S \subseteq \mathbb{B}$, $C \in \mathbb{B}$ and $l \in M^*$ we say that $S$ $l$-entails $C$ if

$$(M_0^*, M^*) \models \exists P \Prf_{EF}(S, P, C) \land |P| \leq l$$

$S$ is $l$-consistent if it does not entail 0. Otherwise $S$ is $l$-inconsistent. Define

$$\mathcal{P} = \{S \subseteq \mathbb{B} : S \text{ is } \Delta^B_1 \text{ definable and } l\text{-consistent for some } l \in M_0^* \setminus M_0\}.$$

$\mathcal{P}$ is partially ordered by the reverse inclusion.

A set $\mathcal{D} \subseteq \mathcal{P}$ is dense in $\mathcal{P}$ if for any $S \in \mathcal{P}$ there exists $S' \in \mathcal{D}$ such that $S \subseteq S'$. $\mathcal{D}$ is definable if

$$\mathcal{D} = \{S \subseteq \mathbb{B} : (M_0^*, M^*) \models \eta(S)\}$$

for some formula $\eta(S)$ with a placeholder for an unary predicate $S$. A set $\mathcal{G} \subseteq \mathcal{P}$ is a generic if it is downward closed and for any dense and definable set $\mathcal{D} \subseteq \mathcal{P}$, $\mathcal{D} \cap \mathcal{G} \neq \emptyset$.

First we show that if $\mathcal{G} \subseteq \mathcal{P}$ is a generic and $G = \cup \mathcal{G}$ then $(M_0, M[G]) \models \mathbb{V}^1$. Notice that the following claim can be proved in almost the same manner as for Claim 7 of [4].

Claim 1. Let $S \in \mathcal{P}$ be $l$-consistent for some $l \in M_0^* \setminus M_0$, $\varphi(x, \bar{y}, \bar{X}, Z) \in \Sigma^B_0$, $t$ be an $\mathcal{L}^2_A$ term and $a \in M_0$. For any $\bar{b} \in M_0$ and $\bar{A} \in M^B$ at least one of the following sets is $l$-consistent:

(a) $S \cup \{-\llbracket \varphi(0, \bar{b}, \bar{A}, Z) \rrbracket : Z : t \rightarrow \mathbb{B}\}$,

(b) $S \cup \{\llbracket \varphi(a, \bar{b}, \bar{A}, Z_a) \rrbracket\}$ for some $Z_a : t \rightarrow \mathbb{B}$,
(c) \(S \cup \{[\varphi(a, \bar{b}, \bar{A}, Z_x)]\} \cup \{-[\varphi(x+1, \bar{b}, \bar{A}, Z_x)]: Z : t \to \mathbb{B}\}\) for some \(x < a\) and \(Z_x : t \to \mathbb{B}\).

Note that by Claim 1, at least one of the following conditions holds for \(G = \cup \mathcal{G}\);

(a) \([-[\varphi(0, \bar{b}, \bar{A}, Z)]]: Z: t \to \mathbb{B}\) \(\subseteq G\),

(b) \([\varphi(a, \bar{b}, \bar{A}, Z_a)]\) \(\subseteq G\) for some \(Z_a : t \to \mathbb{B}\),

(c) \([\varphi(a, \bar{b}, \bar{A}, Z_x)]\) \(\cup \{-[\varphi(x + 1, \bar{b}, \bar{A}, Z_x)]: Z : t \to \mathbb{B}\}\) \(\subseteq G\) for some \(x < a\) and \(Z_x : t \to \mathbb{B}\).

So by Forcing Theorem we have

\[(M_0, M[G]) \models IND_a(\psi(x, \bar{y}, i_G(A)))\]

where \(\psi(x, \bar{y}, \bar{X}) \equiv \exists z < t \varphi(x, \bar{y}, \bar{X}, Z)\).

Now it remains to show that

Claim 2. There exists an \(M_0\)-complete ideal such that if \(G\) is \(\mathcal{P}\)-generic then \(G = \cup \mathcal{P}\) is \(\mathcal{M}\)-generic over \(I\).

(Proof of Claim). Define

\[
I = \{C \in \mathbb{B} : \text{there exists } S \in \mathcal{P} \text{ such that } \{X\} \cup S \text{ is } l\text{-inconsistent for some } l \in M_0\}. 
\]

Then \(I\) is an \(M_0\)-complete ideal.

We will show that if \(G\) is \(\mathcal{P}\)-generic then \(G = \cup \mathcal{P}\) is \(\mathcal{M}\)-generic over \(I\).

To show this let \(D \subset \mathbb{B}\) be a definable and dense over \(I\). It suffices to show that \(G \cap (D \setminus I) \neq \emptyset\). Define

\[
\mathcal{D} = \{S \in \mathcal{P} : S \cap (D \setminus I) \neq \emptyset\}. 
\]

We claim that \(\mathcal{D}\) is dense in \(\mathcal{P}\). Let \(S \in \mathcal{P}\). If \(S \not\in \mathcal{D}\) then \(S \cap \mathcal{D} = \emptyset\). So there exists \(X \in S \setminus I\) such that \(X \in D\). We claim that \(S' = \{X\} \cup S \in \mathcal{D}\). Since \(S' \cap D \neq \emptyset\) is trivial, it suffices to show that \(S' \in \mathcal{P}\).

Since \(X \not\in I\), \(\{X\} \cup S\) is \(l\)-consistent for all \(S\) and \(l \in M_0\). So by overspill, there exists \(l \in M_0^{*} \setminus M_0\) such that \(\{X\} \cup S\) is \(l\)-consistent. Thus the proof terminates. \(\square\)
5 Generic models and the pigeonhole principle

In this section we consider the problem of whether the pigeonhole principle holds in T-Y generic extensions. Let \( F \) be an unary function symbol. The dual weak surjective pigeonhole principle for \( F \) is the following axiom:

\[
dWPHP(F)^m_n \equiv \exists Y : |Y| = m \forall X : |X| = n F(X) \neq Y.
\]

where \( n < m \). Jerabek [3] considered theories \( VP \) and \( V^1 \) extended by axioms \( dWPHP(F)^n_m \) for all PV functions \( F \). In particular., he gave a propositional proof system which corresponds to these theories.

**Definition 3** The propositional proof system \( WF \) extends \( CF \) in the following manner; an \( WF \)-proof is a sequence of circuits \( X_1, \ldots, X_k \) such that each \( X_i \) for \( 1 \leq i \leq k \) is either an axiom of \( CF \), obtained from \( X_{j_1}, \ldots, X_{j_l} \) for \( j_1, \ldots, j_l < i \) or a circuit of the form

\[
\bigvee_{i<m} (r_i \not\leftrightarrow C_i(D_{i,0}, \ldots, D_{i,n-1}))
\]

where \( n < m \), \( C_0, \ldots, C_{m-1}, D_0, \ldots, D_{n-1} \) are circuits and \( r_i \) are variables which may not occur in \( X_j \)s for \( j < i \) or \( C_i \) but may occur in \( D_{i,j} \)s.

Jerabek showed the following relations;

**Theorem 10 (Jerabek)** \( V^1 + dWPHP(PV) \) proves the reflection principle for \( WF \).

**Theorem 11 (Jerabek)** If \( V^1 + dWPHP(PV) \) proves \( \forall \vec{x} \forall \vec{X} \varphi(\vec{X}, \vec{X}) \) for \( \varphi(\vec{X}, \vec{X}) \) then the propositional translation of \( \varphi(\vec{X}, \vec{X}) \) have polynomial size \( WF \)-proofs.

Jerabek also considered a slightly weaker theory \( APC_1 \) which extends \( PV \) by \( dWPHP(PV) \) and and established connections between several probabilistic complexity classes. He also showed that \( APC_1 \) is strong enough to manage basic combinatorial arguments such as inclusion-exclusion principles and Chernoff’s bounds.

We consider the problem of whether we can construct a generic extension of models of \( V^1 + dWPHP(PV) \) in which \( dWPHP(PV) \) fails. It turns out that the answer is affirmative if we assume a condition about the complexity of propositional proofs.
Theorem 12 Let \((M_0, M) \models V^1 + dWPHP(PV)\) and suppose that

\[(M_0, M) \models \forall Y : |Y| = n \bigwedge_{i<m} (Y(i) \leftrightarrow C_i(D_0, \ldots, D_{n-1}))\]

is satisfiable.

for some \(m, n \in M_0\) with \(n < m\) and circuits \(C_0, \ldots, C_{m-1}, D_0, \ldots, D_{n-1} \in M\). Then there exists an \(M\)-generic \(G \subseteq \mathbb{B}_1 \subseteq M\) such that

\[(M_0, M[G]) \models V^1 + \neg dWPHP(F)^m_n\]

for some PV function \(F\).

(Proof). Let \((M_0, M)\) be as above and \(F\) be a PV function such that

\[(M_0, M) \models \forall X : |X| = n (|F(X)| = m \wedge \forall i < m (F(X)(i) \leftrightarrow C_i(X))).\]

We will show that there exists an \(M\)-generic \(G \subseteq \mathbb{B}_1 \subseteq M\) such that

\[(M_0, M[G]) \models \forall Y : |Y| = m \exists X : |X| = n (F(X) = Y).\]

To this end, it suffices to show that for any \(Y : m \to \mathbb{B}_1\) there exists \(X : n \to \mathbb{B}_1\) such that

\[\bigwedge_{i<m} (Y(i) \leftrightarrow C_i(X)) \in G.\]

First remark that there exist \(Z_0, \ldots, Z_{m-1} \in \mathbb{B}_1\) such that for all \(Y \in 2^m\),

\[\bigwedge_{i<m} (Y(i) \leftrightarrow C_i(D_0, \ldots, D_{n-1}))\]

evaluates to true on \((Z_0(Y), \ldots, Z_{m-1}(Y))\) in \((M_0, M)\).

For each \(Y : m \to \mathbb{B}_1\), we define \(X_Y : n \to \mathbb{B}_1\) as

\[X_Y(i) = D_i(Z_0(Y), \ldots, Z_{m-1}(Y))\]

and set

\[S = \left\{ \bigwedge_{i<m} (Y(i) \leftrightarrow C_i(X_Y)) : Y : m \to \mathbb{B}_1 \right\}.\]

We claim that \(S\) is consistent in \((M_0, M)\).

The idea for \(S\) is that it forms an embedding \(2^m \to 2^n\). Moreover, for the fact that any subset \(S'\) of \(S\) with \(|S'| \in M_0\) is consistent is guaranteed by the assumption.
Specifically, let \( S' \subseteq S \) be such that \( |S'| \in M_0 \). By assumption we have 

\[
(M_0, M) \models \forall Y : |Y| = m \land \bigwedge_{i < m} (Y(i) \leftrightarrow C_i(X_Y)) \text{ is true.}
\]

So for each \( Y : m \rightarrow \mathbb{B}_1 \), we have 

\[
(M_0, M) \models \bigwedge_{i < m} (Y(i) \leftrightarrow C_i(X_Y)) \text{ is a tautology.}
\]

Thus we also have 

\[
(M_0, M) \models \bigwedge S' \text{ is a tautology.}
\]

and so 

\[
(M_0, M) \models \bigwedge S' \rightarrow \text{ is not satisfiable.}
\]

Thus by the soundness of \( EF \) in \((M_0, M)\), we have the claim.

Now, recall that any consistent set can be extended to some \( \mathcal{M} \)-generic \( G \) so that we have 

\[
(M_0, M[G]) \models \neg dWPHP(F)_n^m.
\]

Next we consider the problem of constructing generic extensions for \( APC_1 \). In fact, we can expand the Boolean algebra so that it contains enough information to order that generic extensions satisfy weak pigeonhole principles for \( PV \) functions. The idea is to construct a Boolean algebra which consists of "randomized" circuits.

A randomized circuit with input variables \( \bar{p} = p_0, \ldots, p_{n-1} \) and random variables \( \bar{z} = z_0, \ldots, z_{m-1} \) is a Boolean circuit with variables \( \bar{a} \bar{r} \bar{p}, \bar{z} \). We denote randomized a circuit with random variables \( \bar{z} \) as \( R\bar{z}C(\bar{p}, \bar{z}) \) where \( C(\bar{p}, \bar{z}) \) is a Boolean circuit.

**Definition 4** \( \mathcal{R}C(\bar{p}) \) consists of circuits defined as follows:

1. a circuit \( C(\bar{p}) \) with variables \( \bar{p} \) is in \( \mathcal{R}C(\bar{p}) \).
2. a randomized circuit \( R\bar{z}C(\bar{p}, \bar{z}) \) is in \( \mathcal{R}C(\bar{p}) \).
3. if \( C(x_0, \ldots, x_l) \) is a circuit with inputs \( x_0, \ldots, x_l \) and 

\[
R\bar{z}C_0(\bar{p}, \bar{z}), \ldots, R\bar{z}C_l(\bar{p}, \bar{z})
\]

are randomized circuits in \( \mathcal{R}C(\bar{p}) \) then the circuit 

\[
C(R\bar{z}C_0(\bar{p}, \bar{z}), \ldots, R\bar{z}C_l(\bar{p}, \bar{z}))
\]

which is obtained by replacing each \( x_i \) in \( C \) by \( R\bar{z}C_i(\bar{p}, \bar{z}) \) is in \( \mathcal{R}C(\bar{p}) \).
Circuits in $\mathbb{RC}(\bar{p})$ may contain arbitrary number of random inputs. If $C \in \mathbb{RC}(\bar{p})$ contains more than one randomized subcircuits then we may assume that they contain the same set of random variables.

**Definition 5** For $C \in \mathbb{RC}(\bar{p})$ and $A \in 2^n$ we define $eval_R(A, C)$ as follows:

1. if $C$ is a Boolean circuit then
   
   $$eval_R(A, C) = eval(A, C).$$

2. Let $C = R\bar{z}C_0(\bar{p}, \bar{z}) \in \mathbb{RC}(\bar{p})$ We define
   
   $$\left| \{ Z \in 2^m : eval((A, Z), C_0(\bar{p}, \bar{z})) = 1 \} \right| \geq 0 \frac{3}{4} \cdot 2^m \Rightarrow eval_R(A, C) = 1$$
   
   $$\left| \{ Z \in 2^m : eval((A, Z), C_0(\bar{p}, \bar{z})) = 1 \} \right| \leq 0 \frac{1}{4} \cdot 2^m \Rightarrow eval_R(A, C) = 0$$

3. Let $C = C'(R\bar{z}C_0(\bar{p}, \bar{z}), \ldots, R\bar{z}C_l(\bar{p}, \bar{z}))$. We define
   
   $$eval_R(A, C) = eval(D, C(e_0, \ldots, e_l))$$
   
   where $D(i) = eval_R(A, R\bar{z}C_i(\bar{p}, \bar{z}))$ for $i \leq l$.

Note that we use approximate counting in the definition of the function $eval_r$ as the exact counting is not definable in the ground model. Also note that $eval_R(A, C)$ is $\Sigma^B_1$-definable in $APC_1$.

**Definition 6** For $C, C' \in \mathbb{RC}(\bar{p})$, we define

$$C \leq_R C' \iff \forall A \in 2^n (eval_R(A, C) \leq eval_R(A, C')).$$

and

$$C =_R C' \iff C \leq_R C' \land C' \leq_R C.$$

Define $\mathbb{B}_R = \mathbb{RC}(\bar{p})/\equiv_R$.

It is easy to see that $\mathbb{B}_R$ forms a Boolean algebra. So we may define generic extensions in the same manner as for $\mathbb{B}_A$. Moreover, forcing theorem for $\Sigma^B_0$ formulas holds for $\mathcal{M}$-generic $G \subseteq \mathbb{B}_R$.

We will show that $\mathbb{B}_R$ is a suitable Boolean algebra for $APC_1$.

**Theorem 13** If $(M_0, M) \models APC$ and $G \subseteq \mathbb{B}_R$ is an $\mathcal{M}$-generic over some $M_0$-complete ideal then

$$(M_0, M[G]) \models APC_1.$$
(Proof). Since $B_A \subseteq B_R$ it is straightforward to see that $(M_0, M[G]) \models PV$. So it suffices to show that $(M_0, M[G]) \models dWPHP(PV)$. Let $F(X)$ be a $PV$-function and $a \in M_0$ be such that $a \geq 2$. Without loss of generality we may assume that
\[
\forall X \in 2^a |F(X)| = 2^a.
\]
So there are circuits $C_0, \ldots, C_{2^a-1} \in M$ such that
\[
\forall X \in 2^a \forall i < 2^a (F(X)(i) \leftrightarrow C_i(X) = 1).
\]
Our goal is to show that $(M_0, M) \models \exists Y : 2^a \rightarrow B_R$ such that for all $X : a \rightarrow B_R$ it is the case that
\[
\bigvee_{i < 2^a} (Y(i) \leftrightarrow C_i(X)) \in G.
\]
We will prove the following claim which immediately implies the above assertion:

Claim. There exists $Y : 2^a \rightarrow B_R$ such that for all $X : a \rightarrow B_R$
\[
(M_0, M) \models \forall A \in 2^a eval(A, \bigvee_{i < 2^a} (Y(i) \leftrightarrow C_i(X))).
\]
(Proof of Claim). Let $\tilde{z} = z_0, \ldots, z_m$ be the list of random variables appearing in $X : a \rightarrow B_R$. Set $Y : 2^a \rightarrow B_R$ to be $Y(i) = y_i$ where $y_0, \ldots, y_{a-1}$ are flesh random variables which are distinct from $\tilde{z}$. Set
\[
P(A) = \{ (\tilde{b}, \tilde{c}) : \tilde{b} \in 2^{2a}, \tilde{c} \in 2^a, eval(\langle A, \tilde{b}, \tilde{c} \rangle, \bigvee_{i < 2^a} (y_i \not\leftrightarrow C_i(X))) = 1 \}.
\]
where $\tilde{b}$ and $\tilde{c}$ are assignments for $\tilde{y}$ and $\tilde{z}$ respectively. Then it suffices to show that $(M_0, M) \models P(A) \geq 3/4 \cdot 2^{2a + m}$.

Let $\tilde{x} = x_0, \ldots, x_{a-1}$ be flesh variables and
\[
P' = \{ (\tilde{b}, \tilde{c}) : \tilde{b} \in 2^{2a}, \tilde{c} \in 2^a, eval(\langle \tilde{b}, \tilde{c} \rangle, \bigvee_{i < 2^a} (y_i \not\leftrightarrow C_i(\tilde{x}))) = 1 \}.
\]
Then we have
\[
P' \simeq 0 2^{3a} - 2^a \times |range(\tilde{C})| \geq 0 2^{3a} - 2^a \cdot 2^a = 2^{3a} - 2^{2a}
\]
16
in \((M_0, M)\) where
\[
\text{range}(\mathcal{C}) = \{Y \in 2^{2^a} : \exists X \in 2^a (F(X) = Y)\}.
\]
Therefore
\[
P(A) \succeq_0 (2^{3^a} - 2^{2^a}) \times 2^m = 2^{2a+m}(2^a - 1) \geq 3/4 \cdot 2^{2a+m}
\]
for \(a \geq 2\) which proves the claim. \(\square\)

**Theorem 14** Let \((M_0, M) \models V^1 + dWPHP(PV)\). Then there exists an \(M\)-generic \(G \subseteq B_R\) such that \((M_0, M[G]) \models V^1 + dWPHP(PV)\).

(Proof). It is easy to see that the proof of Theorem 9 can be applied to show that there exists an \(M\)-generic \(G \subseteq B_R\) such that \((M_0, M[G]) \models V^1\). Then by Theorem 13 we have \((M_0, M[G]) \models dWPHP(PV)\). \(\square\)
