

# FRACTIONAL MAXIMAL OPERATOR IN ORLICZ SPACES

VÍT MUSIL

**ABSTRACT.** We study the fractional maximal operator acting between Orlicz spaces. We characterise whether the operator is bounded between two given Orlicz spaces. Also a necessary and sufficient conditions for the existence of an optimal target and domain spaces are established and the explicit formulas of corresponding optimal Young functions are presented.

## 1. INTRODUCTION

Let  $n \in \mathbb{N}$  and  $0 < \gamma < n$  be fixed. The fractional maximal operator  $M_\gamma$  is defined for any locally integrable function  $f$  in  $\mathbb{R}^n$  by

$$M_\gamma f(x) = \sup_{Q \ni x} |Q|^{\frac{n}{\gamma}-1} \int_Q |f(y)| dy, \quad x \in \mathbb{R}^n,$$

where the supremum is taken over all cubes  $Q$  containing  $x$  and having the sides parallel to the coordinate axes.

Our first aim is to analyse the boundedness of  $M_\gamma$  acting between Orlicz spaces. More specifically, given Orlicz spaces  $L^A(\mathbb{R}^n)$  and  $L^B(\mathbb{R}^n)$ , we want to decide whether

$$(1.1) \quad M_\gamma: L^A(\mathbb{R}^n) \rightarrow L^B(\mathbb{R}^n).$$

We show that (1.1) is equivalent to one-dimensional inequalities involving only the Young functions  $A$  and  $B$ . Resulting inequality is then much more easier to verify. Such a simplification is often called reduction principle. Similar reductions in Orlicz spaces have already appeared in the literature for various types of operators, let us mention for instance the reduction principle for the Hardy-Littlewood maximal operator [15], fractional integrals and Riesz potential [4], Sobolev and Poincaré inequalities [5], Sobolev embeddings [3, 9], Sobolev trace embeddings [6] or Korn type inequalities [7]. The reduction principle for fractional maximal operator under some restrictive assumptions can be found in [13]. Our general result is stated in Theorem 3.3.

*Key words and phrases.* Fractional maximal operator, Orlicz spaces, reduction theorem, optimality.

This research was partly supported by the grant P201-18-00580S of the Grant Agency of the Czech Republic, by the Charles University, project GAUK No. 33315 and by the grant 8X17028 of the Czech Ministry of Education.

The principal innovation of this paper however lays in the description of optimal Orlicz spaces in (1.1). More specifically, given  $L^A(\mathbb{R}^n)$ , we seek for the smallest Orlicz space  $L^B(\mathbb{R}^n)$  such that (1.1) holds. By “smallest” we mean that if (1.1) holds with  $L^B(\mathbb{R}^n)$  replaced with another Orlicz space  $L^{\hat{B}}(\mathbb{R}^n)$ , then  $L^B(\mathbb{R}^n) \rightarrow L^{\hat{B}}(\mathbb{R}^n)$ . Instead of smallest we also often say optimal.

Let us briefly look at the situation in the class of the Lebesgue spaces. It is well known that

$$M_\gamma: L^p(\mathbb{R}^n) \rightarrow \begin{cases} L^{\frac{np}{n-\gamma p}}(\mathbb{R}^n), & 1 < p < \frac{n}{\gamma}, \\ L^\infty(\mathbb{R}^n), & p = \frac{n}{\gamma}, \end{cases}$$

and this result is sharp within Lebesgue spaces. However, there is no Lebesgue space  $L^q(\mathbb{R}^n)$  for which

$$M_\gamma: L^1(\mathbb{R}^n) \rightarrow L^q(\mathbb{R}^n).$$

The situation in the class of Orlicz spaces is much more subtle and not many results are available in the literature. The authors of [12] characterised the boundedness of  $M_\gamma$  (they work with more general operator, in fact) on classical Lorentz spaces. In the cases when such spaces coincide with Orlicz spaces, we may recover the following result (see Section 2.2 for the definitions of the spaces involved).

$$(1.2) \quad M_\gamma: L^p(\log L)^\Delta(\mathbb{R}^n) \rightarrow \begin{cases} L^{\frac{n}{n-\gamma}}(\log L)^{\frac{n\Delta}{n-\gamma}-1}(\mathbb{R}^n), & p = 1, \alpha_0 < 0, \alpha_\infty > 0, \\ L^{\frac{np}{n-\gamma p}}(\log L)^{\frac{n\Delta}{n-\gamma p}}(\mathbb{R}^n), & 1 < p < \frac{n}{\gamma}, \\ \exp L^{-\frac{n}{\gamma\Delta}}(\mathbb{R}^n), & p = \frac{n}{\gamma}, \alpha_0 > 0, \alpha_\infty < 0, \end{cases}$$

however, it does not say anything about its sharpness. In Theorem 3.4, we give the complete characterization of the existence of the optimal Orlicz target and, in the affirmative case, we give its full description. It turns out that the spaces obtained in (1.2) are optimal in the cases when  $p > 1$ . If  $p = 1$ , then the target space  $L^{\frac{n}{n-\gamma}}(\log L)^{\frac{n\Delta}{n-\gamma}-1}(\mathbb{R}^n)$  is not the best possible Orlicz space and even more, the optimal Orlicz target does not exist in this case. This means that any Orlicz space  $L^B(\mathbb{R}^n)$  for which  $M_\gamma: L^p(\log L)^\Delta(\mathbb{R}^n) \rightarrow L^B(\mathbb{R}^n)$  may be replaced by essentially smaller space, whence there is an “open” set of all the eligible Orlicz spaces. The details on this particular case are discussed in Example 3.5.

One can also ask the converse problem, i.e. when the target space  $L^B(\mathbb{R}^n)$  is given and we seek for the largest possible  $L^A(\mathbb{R}^n)$  rendering (1.1) true. Analogously, by “largest” we mean that if (1.1) holds with  $L^A(\mathbb{R}^n)$  replaced by  $L^{\hat{A}}(\mathbb{R}^n)$ , then  $L^{\hat{A}}(\mathbb{R}^n) \rightarrow L^A(\mathbb{R}^n)$ . Again, we shorten this notion to the word “optimal” since no confusion with the above situation is likely to happen. The solution of this task is the subject of Theorem 3.7, where we give the complete description of optimal domains. If we return back to the example in (1.2), one gets that the Orlicz domain  $L^A(\log L)^\Delta(\mathbb{R}^n)$  is the optimal one in all three cases. See Example 3.8 for further details.

The paper is organized as follows. The main results are stated in Section 3 as well as examples of particular Orlicz spaces. In the Section 2 we collect necessary preliminary material and in Section 4 we prove the results.

## 2. BACKGROUND

We call  $A: [0, \infty) \rightarrow [0, \infty]$  a Young function if it is convex, left-continuous, and  $A(0) = 0$ . Any function of this kind satisfies, in particular,

$$(2.1) \quad kA(t) \leq A(kt) \quad \text{if } k \geq 1 \text{ and } t \geq 0.$$

Every Young function admits the representation

$$A(t) = \int_0^t a(s) \, ds \quad \text{for } t \geq 0,$$

where  $a: [0, \infty) \rightarrow [0, \infty]$  is nondecreasing and left-continuous function. It holds that

$$(2.2) \quad A(t) \leq ta(t) \leq A(2t) \quad \text{for } t \geq 0.$$

The Young conjugate  $\tilde{A}$  of  $A$  is given by

$$\tilde{A}(t) = \sup\{st - A(s) : s \geq 0\} \quad \text{for } t \geq 0.$$

The function  $\tilde{A}$  is a Young function as well, and its Young conjugate is again  $A$ . One has that

$$(2.3) \quad t \leq A^{-1}(t) \tilde{A}^{-1}(t) \leq 2t \quad \text{for } t \geq 0,$$

where  $A^{-1}$  denotes the generalized right-continuous inverse of  $A$ . A Young function  $A$  is said to dominate another Young function  $B$  if there exists a constant  $c > 0$  such that

$$B(t) \leq A(ct) \quad \text{for } t \geq 0.$$

The functions  $A$  and  $B$  are called equivalent if they dominate each other. A Young function  $A$  is said to essentially dominate another Young function  $B$  if

$$\sup_{0 < t < \infty} \frac{A(t)}{B(\lambda t)} = \infty \quad \text{for every } \lambda \geq 1.$$

**2.1. Boyd indices.** Given a Young function  $A$ , we define the function  $h_A: (0, \infty) \rightarrow [0, \infty)$  as

$$h_A(t) = \sup_{0 < s < \infty} \frac{A^{-1}(st)}{A^{-1}(s)} \quad \text{for } t > 0.$$

The lower and upper Boyd indices of  $A$  are then defined as

$$i_A = \sup_{1 < t < \infty} \frac{\log t}{\log h_A(t)} \quad \text{and} \quad I_A = \inf_{0 < t < 1} \frac{\log t}{\log h_A(t)},$$

respectively. One has that

$$1 \leq i_A \leq I_A \leq \infty.$$

It can also be shown that

$$(2.4) \quad i_A = \lim_{t \rightarrow \infty} \frac{\log t}{\log h_A(t)} \quad \text{and} \quad I_A = \lim_{t \rightarrow 0^+} \frac{\log t}{\log h_A(t)}.$$

Further details on Boyd indices can be found for instance in [2].

**2.2. Orlicz spaces.** Let  $n \in \mathbb{N}$ . Denote by  $\mathcal{M}(\mathbb{R}^n)$  the space of real-valued Lebesgue measurable functions in  $\mathbb{R}^n$ . Given a Young function  $A$ , the Orlicz space  $L^A(\mathbb{R}^n)$  is the collection of all functions  $f \in \mathcal{M}(\mathbb{R}^n)$  such that

$$\int_{\mathbb{R}^n} A\left(\frac{|f(x)|}{\lambda}\right) dx < \infty$$

for some  $\lambda > 0$ . The Orlicz space  $L^A(\mathbb{R}^n)$  is a Banach space endowed with the Luxemburg norm defined as

$$\|f\|_{L^A(\mathbb{R}^n)} = \inf \left\{ \lambda > 0 : \int_{\mathbb{R}^n} A\left(\frac{|f(x)|}{\lambda}\right) dx \leq 1 \right\}$$

for  $f \in \mathcal{M}(\mathbb{R}^n)$ . The choice  $A(t) = t^p$ , with  $1 \leq p < \infty$ , yields  $L^A(\mathbb{R}^n) = L^p(\mathbb{R}^n)$ , the customary Lebesgue space. When  $A(t) = 0$  for  $t \in [0, 1]$  and  $A(t) = \infty$  for  $t \in (1, \infty)$ , one has that  $L^A(\mathbb{R}^n) = L^\infty(\mathbb{R}^n)$ .

Orlicz space is an example of a so-called rearrangement-invariant space – see e.g. [1, Section 4, Chapter 2]. Hence, given any Young function  $A$ , one has that

$$\|f\|_{L^A(\mathbb{R}^n)} = \|f^*\|_{L^A(0, \infty)}$$

where  $f^*$  is the nonincreasing rearrangement of  $f$  given by

$$f^*(t) = \inf \{ \lambda > 0 : |\{x \in \mathbb{R}^n : |f(x)| > \lambda\}| \leq t \} \quad \text{for } t \geq 0.$$

The inclusion relations between Orlicz spaces can be characterized in terms of the notion of domination between Young functions. Let  $A$  and  $B$  be Young functions. Then

$$L^A(\mathbb{R}^n) \rightarrow L^B(\mathbb{R}^n) \text{ if and only if } A \text{ dominates } B$$

and the inclusion is strict if and only if  $A$  dominates  $B$  essentially.

The alternate notation  $A(L)(\mathbb{R}^n)$  for the Orlicz space  $L^A(\mathbb{R}^n)$  will be adopted when convenient. In particular, if  $A(t)$  is equivalent to  $t^p \ell(t)^{\alpha_0}$  near zero and to  $t^p \ell(t)^{\alpha_\infty}$  near infinity where  $\ell(t) = 1 + |\log t|$ ,  $t > 0$ , and either  $p > 1$  and  $\alpha_0, \alpha_\infty \in \mathbb{R}$  or  $p = 1$  and  $\alpha_0 \leq 0$  and  $\alpha_\infty \geq 0$ , then the Orlicz space  $L^A(\mathbb{R}^n)$  is the so called Zygmund space denoted by  $L^p(\log L)^\mathbb{A}(\mathbb{R}^n)$ , where  $\mathbb{A} = [\alpha_0, \alpha_\infty]$ . Observe that  $i_A = I_A = p$ . If

$$A(t) \text{ is equivalent to } \begin{cases} \exp(-t^{\beta_0}) & \text{near zero,} \\ \exp(t^{\beta_\infty}) & \text{near infinity,} \end{cases}$$

with  $\beta_0 < 0 < \beta_\infty$ , then Orlicz space  $L^A(\mathbb{R}^n)$  is the space of exponential type, denoted by  $\exp L^\mathbb{B}(\mathbb{R}^n)$  where  $\mathbb{B} = [\beta_0, \beta_\infty]$ . We have  $i_A = I_A = \infty$  in this case.

In some particular, rather rare, situations, we adopt the relation  $L \simeq R$  if  $L$  and  $R$  bound each other up to positive multiplicative constants independent of the quantities involved in  $L$  and  $R$ .

## 3. MAIN RESULTS

We start by introducing a crucial tool often named as a reduction principle. Such a principle translates the boundedness of the operator  $M_\gamma$  acting between Orlicz spaces in  $\mathbb{R}^n$  to a much simpler one-dimensional inequality containing only the Young functions and the parameters  $n$  and  $\gamma$ . That enables us to simplify our analysis and helps us to understand the behaviour of the operator and the spaces involved.

At first, we need to introduce several constructions of Young functions. Their importance will then be resembled in the following theorem. Let  $A$  be a given Young function. Assume that

$$(3.1) \quad \inf_{0 < t < 1} A(t) t^{-\frac{n}{\gamma}} > 0$$

and define  $A_{\frac{n}{\gamma}}$  by

$$(3.2) \quad A_{\frac{n}{\gamma}}(t) = \int_0^t \frac{G_{\frac{n}{\gamma}}^{-1}(s)}{s} ds \quad \text{for } t \geq 0,$$

where  $G_{\frac{n}{\gamma}}: [0, \infty) \rightarrow [0, \infty)$  is a nondecreasing function defined by

$$G_{\frac{n}{\gamma}}(t) = \sup_{0 < s \leq t} A^{-1}(s) s^{-\frac{\gamma}{n}} \quad \text{for } t \geq 0$$

and  $G_{\frac{n}{\gamma}}^{-1}$  represents its generalized right-continuous inverse.

**Remark 3.1.** Note that  $A_{\frac{n}{\gamma}}$  is a Young function. First of all, (3.1) ensures that  $G_{\frac{n}{\gamma}}$  is finite near zero and  $A_{\frac{n}{\gamma}}$  is well-defined. Next, observe that

$$\frac{G_{\frac{n}{\gamma}}(t)}{t} = t^{-\frac{\gamma}{n}} \sup_{0 < y < 1} \frac{A^{-1}(ty)}{ty} y^{1-\frac{\gamma}{n}}.$$

Since  $A(t)/t$  is nondecreasing,  $A^{-1}(s)/s$  is nonincreasing and thus  $G_{\frac{n}{\gamma}}(t)/t$  is decreasing and  $G_{\frac{n}{\gamma}}^{-1}(s)/s$  is increasing. Therefore  $A_{\frac{n}{\gamma}}$  is a Young function and moreover, by (2.2),  $A_{\frac{n}{\gamma}}$  is globally equivalent to  $G_{\frac{n}{\gamma}}^{-1}$ .

Let  $B$  be a given Young function. Assume that

$$(3.3) \quad \int_0^\infty \frac{B(s)}{s^{n/(n-\gamma)+1}} ds < \infty,$$

and define (with the little abuse of notation)

$$(3.4) \quad B_{\frac{n}{\gamma}}(t) = \int_0^t \frac{E_{\frac{n}{\gamma}}^{-1}(s)}{s} ds \quad \text{for } t \geq 0.$$

Here,  $E_{\frac{n}{\gamma}}: [0, \infty) \rightarrow [0, \infty)$  is given by

$$E_{\frac{n}{\gamma}}(t) = t^{\frac{\gamma}{n}} F_{\frac{n}{\gamma}}^{-1}(t) \quad \text{for } t \geq 0,$$

where  $F_{\frac{n}{\gamma}} : [0, \infty) \rightarrow [0, \infty)$  is defined by

$$(3.5) \quad F_{\frac{n}{\gamma}}(t) = t^{n/(n-\gamma)} \int_0^t \frac{B(s)}{s^{n/(n-\gamma)+1}} ds \quad \text{for } t \geq 0.$$

**Remark 3.2.** Observe that  $B_{\frac{n}{\gamma}}$  is well-defined Young function. The assumption (3.3) guarantees that  $F_{\frac{n}{\gamma}}$  is finite and increasing. Thus  $F_{\frac{n}{\gamma}}^{-1}$  is increasing and so is  $E_{\frac{n}{\gamma}}$ . Next, since  $F_{\frac{n}{\gamma}}(t)/t^{n/(n-\gamma)}$  is nondecreasing,  $F_{\frac{n}{\gamma}}^{-1}(t)/t^{1-\frac{\gamma}{n}}$  is nonincreasing, hence  $E_{\frac{n}{\gamma}}(t)/t$  is nonincreasing and  $E_{\frac{n}{\gamma}}^{-1}(s)/s$  is nondecreasing. Therefore,  $B_{\frac{n}{\gamma}}$  is convex. In addition, by (2.2),  $B_{\frac{n}{\gamma}}$  is equivalent to  $E_{\frac{n}{\gamma}}^{-1}$ .

Our first principal result then reads as follows.

**Theorem 3.3 [Reduction principle in Orlicz spaces].** *Let  $n \in \mathbb{N}$  and  $0 < \gamma < n$  and suppose that  $A$  and  $B$  are Young functions. The following assertions are equivalent:*

(i) *There exists a constant  $C_1 > 0$  such that*

$$\|M_{\gamma}f\|_{L^B(\mathbb{R}^n)} \leq C_1 \|f\|_{L^A(\mathbb{R}^n)}$$

*for every  $f \in L^A(\mathbb{R}^n)$ ;*

(ii) *There exists a constant  $C_2 > 0$  such that*

$$\int_{\mathbb{R}^n} B\left(\frac{M_{\gamma}f(x)}{C_2 \left(\int_{\mathbb{R}^n} A(|f(y)|) dy\right)^{\gamma/n}}\right) dx \leq \int_{\mathbb{R}^n} A(|f(x)|) dx$$

*for every  $f \in L^A(\mathbb{R}^n)$ ;*

(iii)  *$A$  satisfies (3.1) and there exists a constant  $C_3 > 0$  such that*

$$\int_0^t \frac{B(s)}{s^{n/(n-\gamma)+1}} ds \leq \frac{A_{\frac{n}{\gamma}}(C_3 t)}{t^{n/(n-\gamma)}} \quad \text{for } t > 0$$

*where  $A_{\frac{n}{\gamma}}$  is the Young function from (3.2);*

(iv)  *$B$  satisfies (3.3) and there exists a constant  $C_4 > 0$  such that*

$$B_{\frac{n}{\gamma}}(t) \leq A(C_4 t) \quad \text{for } t > 0$$

*where  $B_{\frac{n}{\gamma}}$  is the Young function from (3.4).*

Moreover, the constants  $C_1$ ,  $C_2$ ,  $C_3$  and  $C_4$  depend on each other and on  $n$  and  $\gamma$ .

We would like to point out the philosophy behind the criteria (iii) and (iv) in our reduction principle. They look completely different at a first glance and they rely on auxiliary Young functions  $A_{\frac{n}{\gamma}}$  or  $B_{\frac{n}{\gamma}}$  respectively. In situations when both  $A$  and  $B$  are given, there is no significantly better choice of a condition to check. However, imagine that we have one  $A$  and a bunch of candidates  $B$  to choose from. Then the condition (iii) comes handy as we compute  $A_{\frac{n}{\gamma}}$  once and we check the inequality against every choice of  $B$ . The condition (iv) is then welcome in the reciprocal case.

It is no surprise that the Young functions  $A_{\frac{n}{\gamma}}$  and  $B_{\frac{n}{\gamma}}$  play the major role in the problem of establishing the corresponding optimal Orlicz spaces. Let us begin with the targets.

**Theorem 3.4 [Optimal Orlicz target].** *Let  $n \in \mathbb{N}$  and  $0 < \gamma < n$ . Suppose that  $A$  is a Young function satisfying (3.1) and set  $A_{\frac{n}{\gamma}}$  as in (3.2). If*

$$(3.6) \quad i_{A_{\frac{n}{\gamma}}} > \frac{n}{n-\gamma},$$

then

$$(3.7) \quad M_{\gamma}: L^A(\mathbb{R}^n) \rightarrow L^{A_{\frac{n}{\gamma}}}(\mathbb{R}^n)$$

and  $L^{A_{\frac{n}{\gamma}}}(\mathbb{R}^n)$  is the smallest among all Orlicz spaces in (3.7).

Conversely, if (3.6) fails, then there is no optimal Orlicz space in (1.1) in a sense that any Orlicz space  $L^B(\mathbb{R}^n)$  for which (1.1) holds true can be replaced by a strictly smaller Orlicz space for which (1.1) is still valid.

In particular, if  $I_A < \frac{n}{\gamma}$ , then (3.6) is equivalent to  $i_A > 1$  and

$$(3.8) \quad A_{\frac{n}{\gamma}}^{-1}(t) \simeq A^{-1}(t) t^{-\frac{n}{\gamma}}, \quad t > 0.$$

In addition, if (3.1) is not satisfied, then there does not exist an Orlicz target space  $L^B(\mathbb{R}^n)$  for which (1.1) holds.

**Example 3.5.** Let  $1 \leq p_0, p_{\infty} \leq \infty$  and  $\alpha_0, \alpha_{\infty} \in \mathbb{R}$ . If  $p_0 = 1$  then let  $\alpha_0 \leq 0$  and if  $p_{\infty} = 1$  then let  $\alpha_{\infty} \geq 0$ . Suppose that

$$A(t) \text{ is equivalent to } \begin{cases} t^{p_0} \ell(t)^{\alpha_0} & \text{near zero,} \\ t^{p_{\infty}} \ell(t)^{\alpha_{\infty}} & \text{near infinity.} \end{cases}$$

Let us consider the nontrivial cases only, i.e. let us assume that (3.1) is satisfied. This implies that either  $1 \leq p_0 < \frac{n}{\gamma}$  or  $p_0 = \frac{n}{\gamma}$  and  $\alpha_0 \geq 0$ . Computations show that

$$A_{\frac{n}{\gamma}}(t) \text{ is equivalent to } \begin{cases} t^{\frac{np_0}{n-\gamma p_0}} \ell(t)^{\frac{n\alpha_0}{n-\gamma p_0}}, & 1 \leq p_0 < \frac{n}{\gamma}, \alpha_0 \in \mathbb{R} \text{ or} \\ & p_0 = 1, \alpha_0 \leq 0, \\ \exp(-t^{-\frac{n}{\gamma\alpha_0}}), & p_0 = \frac{n}{\gamma}, \alpha_0 > 0, \\ 0, & p_0 = \frac{n}{\gamma}, \alpha_0 = 0, \end{cases}$$

near zero and

$$A_{\frac{n}{\gamma}}(t) \text{ is equivalent to } \begin{cases} t^{\frac{np_{\infty}}{n-\gamma p_{\infty}}} \ell(t)^{\frac{n\alpha_{\infty}}{n-\gamma p_{\infty}}}, & 1 \leq p_{\infty} < \frac{n}{\gamma}, \alpha_{\infty} \in \mathbb{R} \text{ or} \\ & p_{\infty} = 1, \alpha_{\infty} \geq 0, \\ \exp(t^{-\frac{n}{\gamma\alpha_{\infty}}}), & \text{if } p_{\infty} = \frac{n}{\gamma}, \alpha_{\infty} < 0, \\ \infty, & p_{\infty} = \frac{n}{\gamma}, \alpha_{\infty} \geq 0 \text{ or} \\ & p_{\infty} > \frac{n}{\gamma}, \alpha_{\infty} \in \mathbb{R}, \end{cases}$$

near infinity. Moreover,

$$i_{A_{\frac{n}{\gamma}}} = \begin{cases} \min \left\{ \frac{np_0}{n-\gamma p_0}, \frac{np_{\infty}}{n-\gamma p_{\infty}} \right\}, & 1 \leq \min\{p_0, p_{\infty}\} < \frac{n}{\gamma}, \\ \infty, & p_0 = p_{\infty} = \frac{n}{\gamma}, \end{cases}$$

whence  $i_{A_{\frac{n}{\gamma}}} > \frac{n}{n-\gamma}$  if and only if both  $p_0 > 1$  and  $p_{\infty} > 1$ . Therefore, by Theorem 3.4,

$$M_{\gamma}: L^A(\mathbb{R}^n) \rightarrow L^{A_{\frac{n}{\gamma}}}(\mathbb{R}^n)$$

and the range spaces are optimal among all Orlicz spaces.

If  $p_0 = 1$  or  $p_{\infty} = 1$ , then every Young function  $B$  satisfying (1.1) can be essentially enlarged near zero or near infinity, respectively.

**Example 3.6.** Let  $1 \leq p_0, p_{\infty} \leq \infty$ . Suppose that

$$A(t) \text{ is equivalent to } \begin{cases} t^{p_0} e^{-\sqrt{\log 1/t}} & \text{near zero,} \\ t^{p_{\infty}} e^{\sqrt{\log t}} & \text{near infinity.} \end{cases}$$

In order to ensure (3.1), assume that  $1 \leq p_0 < \frac{n}{\gamma}$ . We have that  $A(t)t^{-\frac{n}{\gamma}}$  is decreasing near zero hence  $A^{-1}(s)s^{-\frac{\gamma}{n}}$  is increasing near zero. Thus the supremum in the definition of  $A_{\frac{n}{\gamma}}$  may be disregarded and  $A_{\frac{n}{\gamma}}$  obeys (3.8) near zero. Calculation shows that

$$A^{-1}(s) \simeq s^{\frac{1}{p_0}} e^{-p_0^{-\frac{3}{2}} \sqrt{\log 1/s}} \quad \text{near zero}$$

and then

$$A_{\frac{n}{\gamma}}(t) \text{ is equivalent to } t^{\frac{np_0}{n-\gamma p_0}} e^{-\left(\frac{n}{n-\gamma p_0}\right)^{\frac{3}{2}} \sqrt{\log 1/t}} \quad \text{near zero}$$

If  $p_{\infty} \geq \frac{n}{\gamma}$ , then  $A(t)t^{-\frac{n}{\gamma}}$  is increasing,  $A^{-1}(s)s^{-\frac{\gamma}{n}}$  is decreasing, hence  $G_{\frac{n}{\gamma}}$  is a constant function and  $A_{\frac{n}{\gamma}} = \infty$  near infinity. If  $1 \leq p_{\infty} < \frac{n}{\gamma}$ , then, similarly as before,  $A_{\frac{n}{\gamma}}$  satisfies (3.8) near infinity. To sum it up,

$$A_{\frac{n}{\gamma}}(t) \text{ is equivalent to } \begin{cases} t^{\frac{np_{\infty}}{n-\gamma p_{\infty}}} e^{\left(\frac{n}{n-\gamma p_{\infty}}\right)^{\frac{3}{2}} \sqrt{\log t}}, & 1 \leq p_{\infty} < \frac{n}{\gamma}, \\ \infty, & p_{\infty} \geq \frac{n}{\gamma}, \end{cases}$$

near infinity. In conclusion

$$i_{A_{\frac{n}{\gamma}}} = \begin{cases} \min \left\{ \frac{np_0}{n-\gamma p_0}, \frac{np_{\infty}}{n-\gamma p_{\infty}} \right\}, & 1 \leq p_{\infty} < \frac{n}{\gamma}, \\ \frac{np_0}{n-\gamma p_0}, & p_{\infty} \geq \frac{n}{\gamma}, \end{cases}$$

and  $i_{A_{\frac{n}{\gamma}}} > \frac{n}{n-\gamma}$  if and only if both  $p_0 > 1$  and  $p_{\infty} > 1$ , otherwise any Young function  $B$  satisfying (1.1) can be essentially enlarged near zero or near infinity, respectively.

**Theorem 3.7 [Optimal Orlicz domain].** *Let  $n \in \mathbb{N}$  and  $0 < \gamma < n$  and suppose that  $B$  is a Young function. If  $B$  satisfies (3.3), then  $B_{\frac{n}{\gamma}}$  is a Young function for which*

$$(3.9) \quad M_{\gamma}: L^{B_{\frac{n}{\gamma}}}(\mathbb{R}^n) \rightarrow L^B(\mathbb{R}^n)$$

and  $L^{\frac{B_{\frac{n}{\gamma}}}{\gamma}}(\mathbb{R}^n)$  is the largest possible Orlicz space satisfying (3.9).

In addition, if  $i_B > \frac{n}{n-\gamma}$ , then  $B$  satisfies (3.3) and  $B_{\frac{n}{\gamma}}$  obeys the simpler relation

$$(3.10) \quad B_{\frac{n}{\gamma}}^{-1}(t) \simeq t^{\frac{\gamma}{n}} B^{-1}(t), \quad t > 0.$$

Conversely, if (3.3) fails, then there is no Orlicz space  $L^A(\mathbb{R}^n)$  for which (1.1) holds.

**Example 3.8.** Let  $1 < q_0, q_{\infty} \leq \infty$  and  $\alpha_0, \alpha_{\infty} \in \mathbb{R}$ . Suppose that  $B$  is a Young function such that

$$B(t) \text{ is equivalent to } \begin{cases} t^{q_0} \ell(t)^{\alpha_0} & \text{near zero,} \\ t^{q_{\infty}} \ell(t)^{\alpha_{\infty}} & \text{near infinity.} \end{cases}$$

The condition (3.3) requires that either  $q_0 > n/(n-\gamma)$  or  $q_0 = n/(n-\gamma)$  and  $\alpha_0 < -1$ . One can compute that

$$B_{\frac{n}{\gamma}}(t) \text{ is equivalent to } \begin{cases} t^{\frac{nq_0}{n+\gamma q_0}} \ell(t)^{\frac{n\alpha_0}{n+\gamma q_0}}, & q_0 > \frac{n}{n-\gamma}, \\ t \ell(t)^{(1-\frac{\gamma}{n})(\alpha_0+1)}, & q_0 = \frac{n}{n-\gamma}, \alpha_0 < -1, \end{cases}$$

near zero and

$$B_{\frac{n}{\gamma}}(t) \text{ is equivalent to } \begin{cases} t^{\frac{nq_{\infty}}{n+\gamma q_{\infty}}} \ell(t)^{\frac{n\alpha_{\infty}}{n+\gamma q_{\infty}}}, & q_{\infty} > \frac{n}{n-\gamma}, \\ t \ell(t)^{(1-\frac{\gamma}{n})(\alpha_{\infty}+1)}, & q_{\infty} = \frac{n}{n-\gamma}, \alpha_{\infty} > -1, \\ t \ell(t)^{(1-\frac{\gamma}{n})}, & q_{\infty} = \frac{n}{n-\gamma}, \alpha_{\infty} = -1, \\ t, & q_{\infty} = \frac{n}{n-\gamma}, \alpha_{\infty} < -1 \text{ or} \\ & q_{\infty} < \frac{n}{\gamma}, \end{cases}$$

near infinity. By Theorem 3.7,

$$M_{\gamma}: L^{\frac{B_{\frac{n}{\gamma}}}{\gamma}}(\mathbb{R}^n) \rightarrow L^B(\mathbb{R}^n)$$

and  $L^{\frac{B_{\frac{n}{\gamma}}}{\gamma}}(\mathbb{R}^n)$  is the optimal Orlicz space.

**Example 3.9.** Let  $1 \leq q_0, q_{\infty} \leq \infty$ . We deal with the Young function  $B$  such that

$$B(t) \text{ is equivalent to } \begin{cases} t^{q_0} e^{-\sqrt{\log 1/t}} & \text{near zero,} \\ t^{q_{\infty}} e^{\sqrt{\log t}} & \text{near infinity.} \end{cases}$$

The condition (3.3) forces that  $q_0 \geq n/(n-\gamma)$ . If  $q_0 > n/(n-\gamma)$  then  $i_B > n/(n-\gamma)$  and  $B_{\frac{n}{\gamma}}$  satisfies the simplified relation (3.10) near zero. In the case when  $q_0 = n/(n-\gamma)$  then

$$F_{\frac{n}{\gamma}}(t) \simeq t^{\frac{n}{n-\gamma}} e^{-\sqrt{\log 1/t}} \sqrt{\log 1/t} \quad \text{near zero}$$

and

$$B_{\frac{n}{\gamma}}^{-1}(s) \simeq F_{\frac{n}{\gamma}}^{-1}(s) s^{\frac{\gamma}{n}} \simeq s e^{-(1-\frac{\gamma}{n})\frac{3}{2}\sqrt{\log 1/s}} (\log 1/s)^{-\frac{n-\gamma}{2n}} \quad \text{near zero.}$$

Calculating the inverses, we get that

$$B_{\frac{n}{\gamma}}(t) \text{ is equivalent to } \begin{cases} t^{\frac{nq_0}{n+\gamma q_0}} e^{-\left(\frac{n}{n+\gamma q_0}\right)^{\frac{3}{2}} \sqrt{\log 1/t}}, & q_0 > \frac{n}{n-\gamma}, \\ te^{-(1-\frac{n}{\gamma})^{\frac{3}{2}} \sqrt{\log 1/t}} (\log 1/t)^{\frac{2n}{n-\gamma}}, & q_0 = \frac{n}{n-\gamma}, \end{cases}$$

near zero.

Let us also sketch the calculations near infinity. If  $g_{\infty} < n/(n-\gamma)$ , then

$$\int_{-\infty}^{\infty} \frac{B(s)}{s^{n/(n-\gamma)+1}} ds < \infty$$

whence  $F_{\frac{n}{\gamma}}(t) \simeq t^{\frac{n}{n-\gamma}}$  and  $B_{\frac{n}{\gamma}}(t)$  is equivalent to  $t$  near infinity. If  $q_{\infty} > n/(n-\gamma)$  then  $B_{\frac{n}{\gamma}}$  obeys the relation (3.10) near infinity, and finally, when  $q_{\infty} = n/(n-\gamma)$ , then

$$F_{\frac{n}{\gamma}}(t) \simeq t^{\frac{n}{n-\gamma}} e^{\sqrt{\log t}} \sqrt{\log t} \quad \text{near zero.}$$

In conclusion, we have

$$B_{\frac{n}{\gamma}}(t) \text{ is equivalent to } \begin{cases} t^{\frac{nq_{\infty}}{n+\gamma q_{\infty}}} e^{\left(\frac{n}{n+\gamma q_{\infty}}\right)^{\frac{3}{2}} \sqrt{\log t}}, & q_{\infty} > \frac{n}{n-\gamma}, \\ te^{(1-\frac{n}{\gamma})^{\frac{3}{2}} \sqrt{\log t}} (\log t)^{\frac{2n}{n-\gamma}}, & q_{\infty} = \frac{n}{n-\gamma}, \\ t, & q_{\infty} < \frac{n}{n-\gamma}, \end{cases}$$

near infinity and by Theorem 3.7,

$$M_{\gamma}: L^{B_{\frac{n}{\gamma}}}(\mathbb{R}^n) \rightarrow L^B(\mathbb{R}^n),$$

in which  $L^{B_{\frac{n}{\gamma}}}(\mathbb{R}^n)$  is optimal within Orlicz spaces.

Concerning optimality, one may naturally ask the question if the relation ‘‘be optimal Orlicz space for someone’’ is symmetric. We will look closely what is meant by this now.

Let us start on the target side, so let us have some Young function  $B$  fixed. By Theorem 3.7, the optimal Orlicz domain always exists and is described by the Young function  $B_{\frac{n}{\gamma}}$ . At this stage we may set  $A = B_{\frac{n}{\gamma}}$  and try to use Theorem 3.4 to investigate the corresponding best possible Orlicz target.

We illustrate what is happening on a basic example. Assume that  $B(t) = t^q$  near infinity and  $q > \frac{n}{n-\gamma}$  (we will be ignoring the behaviour near zero for the sake of this paragraph, the careful reader may adapt the Young functions also near zero). Then  $B_{\frac{n}{\gamma}}(t)$  is equivalent to  $t^{\frac{nq}{n+\gamma q}}$  near infinity. Set  $A = B_{\frac{n}{\gamma}}$  and observe that  $A_{\frac{n}{\gamma}}(t)$  is equivalent to  $t^q$ , whence  $i_{A_{\frac{n}{\gamma}}}$   $= q > \frac{n}{n-\gamma}$ . Thus  $A_{\frac{n}{\gamma}}$  is equivalent to  $B$  and both domain  $L^A$  and range  $L^B$  are optimal Orlicz spaces.

Now, if  $B(t) = t^{\frac{n}{n-\gamma}}$  near infinity, then  $B_{\frac{n}{\gamma}}$  is equivalent to  $t \log(t)^{(1-\frac{n}{\gamma})}$  near infinity. Denoting  $A = B_{\frac{n}{\gamma}}$ ,  $A_{\frac{n}{\gamma}}(t)$  is equivalent to  $t^{n/(n-\gamma)} \log(t)$  which exceeds  $B(t)$ . However,  $i_{A_{\frac{n}{\gamma}}} = \frac{n}{n-\gamma}$  thus  $B$  is not the optimal Orlicz space to  $L^A$  and moreover, no such Orlicz space exists.

From this example we may guess that the borderline lays somewhere around the space  $L^{\frac{n}{n-\gamma}}$ . Indeed, the proper classification of this phenomenon relies on the Boyd index of  $B$  as the following theorem shows.

**Theorem 3.10 [Orlicz range reiteration].** *Let  $B$  be a Young function. Suppose that  $B$  obeys*

$$(3.11) \quad i_B > \frac{n}{n-\gamma}.$$

*Then the Young function  $B_{\frac{n}{\gamma}}$  from (3.4) satisfies (3.10) and*

$$(3.12) \quad M_\gamma: L^{B_{\frac{n}{\gamma}}}(\mathbb{R}^n) \rightarrow L^B(\mathbb{R}^n)$$

*where both domain and target spaces are optimal among all Orlicz spaces.*

*Conversely, if (3.11) fails, then  $L^{B_{\frac{n}{\gamma}}}(\mathbb{R}^n)$  is optimal Orlicz domain and no optimal Orlicz range exists in (3.12).*

In this iteration scheme, we may also assume that  $A$  is given and we try to make one step further and then one step back, or more precisely, we can compute  $A_{\frac{n}{\gamma}}$ , then set  $B = A_{\frac{n}{\gamma}}$  and then analyze the relation of  $B_{\frac{n}{\gamma}}$  and  $A$ . The main difference between this case and the previous one is that even the success after first step is not guaranteed any more. So one has to restrict his attention to the positive cases only. Let us look at similar trivial example.

Assume that  $A(t) = t^{p_0}$  near zero and  $A(t) = t^{p_\infty}$  near infinity, where  $1 < p_0 < \frac{n}{\gamma} < p_\infty < \infty$ . Calculations gives that  $A_{\frac{n}{\gamma}}(t)$  is equivalent to  $t^{\frac{np_0}{n-\gamma p_0}}$  and to  $\infty$  near infinity. Since  $i_{A_{\frac{n}{\gamma}}} > \frac{n}{n-\gamma}$ ,  $M_\gamma$  acts from  $L^A$  to  $L^{A_{\frac{n}{\gamma}}}$  and the range is optimal within Orlicz spaces. If we set  $B = A_{\frac{n}{\gamma}}$ , then  $B_{\frac{n}{\gamma}}(t)$  is equivalent to  $t^{p_0}$  near zero and to  $t^{\frac{n}{\gamma}}$  near infinity. We see that  $B_{\frac{n}{\gamma}}$  coincides with  $A$  near zero while there is a significant improvement near infinity.

To state the result in its full generality, we need to introduce a way how to define the improved Young function to  $A$ .

Let  $A$  be a Young function satisfying (3.1) and let  $A_{\text{sup}}$  be given by

$$(3.13) \quad A_{\text{sup}}(t) = \int_0^t \frac{G_{\text{sup}}^{-1}(s)}{s} ds, \quad t > 0.$$

where  $G_{\text{sup}}$  is defined by

$$G_{\text{sup}}(t) = t^{\frac{n}{\gamma}} \sup_{0 < s \leq t} A^{-1}(s) t^{-\frac{n}{\gamma}}, \quad t > 0.$$

Using similar arguments as in Remark 3.1, one can easily observe that  $G_{\text{sup}}$  is increasing and  $A_{\text{sup}}$  is well-defined Young function equivalent to  $G_{\text{sup}}^{-1}$ .

The spirit of this improvement lays in the observation that any domain  $A$  can be always replaced by  $A_{\text{sup}}$ . This is the essence of the next theorem.

**Theorem 3.11 [Orlicz domain reiteration].** *Let  $A$  and  $B$  be a Young functions. Suppose that  $A$  satisfies (3.1) and let  $A_{\text{sup}}$  be the Young function from (3.13). Then (1.1) holds if and only if*

$$(3.14) \quad M_\gamma : L^{A_{\text{sup}}}(\mathbb{R}^n) \rightarrow L^B(\mathbb{R}^n).$$

Moreover, if

$$(3.15) \quad i_{A_{\text{sup}}} > 1,$$

then

$$M_\gamma : L^{A_{\text{sup}}}(\mathbb{R}^n) \rightarrow L^{A_{\frac{n}{\gamma}}}(\mathbb{R}^n)$$

and both domain and target spaces are optimal in the class of Orlicz spaces.

Conversely, if (3.15) fails, then  $L^A(\mathbb{R}^n)$  can be replaced by  $L^{A_{\text{sup}}}(\mathbb{R}^n)$  and no optimal Orlicz target exists.

At the end of this section, we present special cases of the reduction principle for the spaces  $L^1$  and  $L^\infty$ .

**Corollary 3.12 [Endpoint embeddings].** *Let  $n \in \mathbb{N}$  and  $0 < \gamma < n$  and suppose that  $A$  and  $B$  are Young functions. Then the following statements hold true:*

(i)

$$M_\gamma : L^A(\mathbb{R}^n) \rightarrow L^\infty(\mathbb{R}^n)$$

if and only if there is a constant  $C > 0$  such that

$$A(t) \geq Ct^{\frac{n}{\gamma}} \quad \text{for } t > 0;$$

(ii)

$$M_\gamma : L^1(\mathbb{R}^n) \rightarrow L^B(\mathbb{R}^n)$$

if and only if

$$\int_0^\infty \frac{B(s)}{s^{n/(n-\gamma)+1}} ds < \infty.$$

#### 4. PROOFS

We start with an auxiliary reduction principle for fractional maximal operator. Note that the result remains valid also if we replace Orlicz spaces by any so-called rearrangement-invariant function spaces. For further details on this general setting we refer to [11].

**Proposition 4.1.** *Let  $n \in \mathbb{N}$ ,  $0 < \gamma < n$  and let  $A$  and  $B$  be Young functions. The following statements are equivalent:*

(i) *There is a constant  $C_1 > 0$  such that*

$$\|M_\gamma f\|_{L^B(\mathbb{R}^n)} \leq C_1 \|f\|_{L^A(\mathbb{R}^n)}, \quad f \in L^A(\mathbb{R}^n);$$

(ii) *There is a constant  $C_2 > 0$  such that*

$$\left\| t^{\frac{\gamma}{n}-1} \int_0^t g(s) ds \right\|_{L^B(0,\infty)} \leq C_2 \|g\|_{L^A(0,\infty)}, \quad g \in L^A(0,\infty).$$

Moreover, the constants  $C_1$  and  $C_2$  depend on each other, on  $n$  and  $\gamma$ .

**Proof.** Assume (ii). By [8, Theorem 1.1], there is a constant  $c_1 > 0$ , depending only on  $n$  and  $\gamma$ , such that

$$(M_\gamma f)^*(t) \leq c_1 \sup_{t \leq s < \infty} s^{\frac{\gamma}{n}} f^{**}(s) \quad \text{for } t > 0$$

and for every  $f \in L^1_{\text{loc}}(\mathbb{R}^n)$ . Here,  $f^{**}$  is the function defined by

$$f^{**}(t) = \frac{1}{t} \int_0^t f^*(s) \, ds \quad \text{for } t > 0.$$

Then

$$\|M_\gamma f\|_{L^B(\mathbb{R}^n)} = \|(M_\gamma f)^*\|_{L^B(0, \infty)} \leq c_1 \left\| \sup_{t \leq s < \infty} s^{\frac{\gamma}{n}} f^{**}(s) \right\|_{L^B(0, \infty)}.$$

The supremum may be dropped paying another constant  $c_2 = c_2(n, \gamma)$ , thanks to [14, Theorem 3.9]. Hence

$$\|M_\gamma f\|_{L^B(\mathbb{R}^n)} \leq c_1 c_2 \|t^{\frac{\gamma}{n}} f^{**}(t)\|_{L^B(0, \infty)} \leq c_1 c_2 C_2 \|f^*\|_{L^A(0, \infty)} = C_1 \|f\|_{L^A(\mathbb{R}^n)},$$

due to the assumption (ii) where we take  $g = f^*$ .

Conversely, suppose (i). Let  $\varphi: (0, \infty) \rightarrow [0, \infty)$  be a nonincreasing function. By [8, Theorem 1.1], there is a function  $f$  on  $\mathbb{R}^n$  such that  $f^* = \varphi$  and

$$(M_\gamma f)^*(t) \geq c_3 \sup_{t \leq s < \infty} s^{\frac{\gamma}{n}} f^{**}(s) \quad \text{for } t \in (0, \infty)$$

where  $c_3 = c_3(n, \gamma)$  is a positive constant independent of  $f$ . We have

$$\begin{aligned} C_1 \|\varphi\|_{L^A(0, \infty)} &= C_1 \|f\|_{L^A(\mathbb{R}^n)} \geq \|M_\gamma f\|_{L^B(\mathbb{R}^n)} = \|(M_\gamma f)^*\|_{L^B(0, \infty)} \\ &\geq c_3 \left\| \sup_{t \leq s < \infty} s^{\frac{\gamma}{n}} f^{**}(s) \right\|_{L^A(0, \infty)} \geq c_3 \left\| t^{\frac{\gamma}{n}-1} \int_0^t \varphi(s) \, ds \right\|_{L^A(0, \infty)}, \end{aligned}$$

hence (ii) holds for every nonincreasing function  $\varphi$  with  $C_2 = C_1/c_3$ . The inequality (ii) for any function then follows by Hardy's lemma.  $\square$

**Proof of Theorem 3.3.** We begin with the preliminary statement, equivalent to (i). Recall the Hardy operator  $H_{\frac{\gamma}{n}}$ , defined by

$$H_{\frac{\gamma}{n}} f(t) = \int_t^\infty f(s) s^{\frac{\gamma}{n}-1} \, ds, \quad t \in (0, \infty),$$

for  $f \in \mathcal{M}(0, \infty)$  and its dual,  $H'_{\frac{\gamma}{n}}$  say, given by

$$H'_{\frac{\gamma}{n}} g(t) = t^{\frac{\gamma}{n}-1} \int_0^t g(s) \, ds, \quad t \in (0, \infty),$$

for  $g \in \mathcal{M}(0, \infty)$ . By Proposition 4.1, (i) holds if and only if  $H'_{\frac{\gamma}{n}}$  is bounded from  $L^A(0, \infty)$  to  $L^B(0, \infty)$  with the operator norm comparable to  $C_1$ . Hence, by the duality, (i) is equivalent to the following statement.

(i') There exist a constant  $C'_1 > 0$  such that

$$\|H_{\frac{\gamma}{n}} f\|_{L^{\tilde{A}}(0,\infty)} \leq C'_1 \|f\|_{L^{\tilde{B}}(0,\infty)}.$$

Moreover the constants  $C_1$  and  $C'_1$  are comparable.

We now show (i')  $\Leftrightarrow$  (iii). By the combination of [9, Proposition 5.2 and Lemma 5.3], (i') holds true if and only if

$$(4.1) \quad \sup_{0 < t < 1} \tilde{A}(t) t^{\frac{n}{n-\gamma}} < \infty$$

and there is a constant  $C'_3 > 0$  such that the inequality

$$\int_0^t \frac{B(s)}{s^{n/(n-\gamma)+1}} ds \leq \frac{E(C'_3 t)}{t^{n/(n-\gamma)}}, \quad t > 0,$$

holds true, where  $E$  is a Young function satisfying

$$\tilde{E}^{-1}(t) \simeq t \inf_{0 < s \leq t} \tilde{A}^{-1}(s) s^{\frac{\gamma}{n}-1}, \quad t > 0.$$

Now, clearly (4.1) holds if and only if (3.1) holds and  $E$  is equivalent to  $A_{\frac{n}{\gamma}}$ , by passing to complementary Young functions using (2.3).

The equivalence of (i') and (iv) is a consequence of a different method of characterization of the boundedness of the Hardy operator  $H_{\frac{\gamma}{n}}$  in Orlicz spaces [3, Lemma 1] (see also [17, Section 9.3]). We moreover use the equivalent formulation of  $B_{\frac{n}{\gamma}}$  which might be derived from [3, (4.6) and (4.7)].

Let us establish (ii) from (i). Suppose that  $N > 0$  is given and set  $A_N = A/N$ , a scaled Young function. Then

$$(A_N)_{\frac{n}{\gamma}}(t) = \frac{1}{N} A_{\frac{n}{\gamma}}(tN^{-\frac{\gamma}{n}}), \quad t \geq 0,$$

where  $(A_N)_{\frac{n}{\gamma}}$  is a Young function associated to  $A_N$  as in (3.2). Define also  $B_N$  by

$$B_N(t) = \frac{1}{N} B(tN^{-\frac{\gamma}{n}}), \quad t \geq 0.$$

We claim that

$$(4.2) \quad \|M_{\gamma} f\|_{L^{B_N}(\mathbb{R}^n)} \leq C_2 \|f\|_{L^{A_N}(\mathbb{R}^n)}$$

for all  $f \in L^{A_N}(\mathbb{R}^n)$  with the constant  $C_2$  independent of  $N$ . Indeed, as one can readily check by the change of variables, (iii) holds with  $A$  and  $B$  replaced by  $A_N$  and  $B_N$  respectively with the same constant  $C_3$ . The claim follows by the already proven equivalence of (i) and (iii).

Now, let  $f \in L^A(\mathbb{R}^n)$ . If  $\int_{\mathbb{R}^n} A(|f|) = \infty$ , then there is nothing to prove. Otherwise, set  $N = \int_{\mathbb{R}^n} A(|f|)$ . It is  $\|f\|_{L^{A_N}(\mathbb{R}^n)} \leq 1$  and, by (4.2),  $\|f\|_{L^{B_N}(\mathbb{R}^n)} \leq C_2$ . Therefore

$$\int_{\mathbb{R}^n} B_N\left(\frac{M_{\gamma} f(x)}{C_2}\right) dx \leq 1$$

and (ii) follows by the definition of  $B_N$ .

The converse implication (ii)  $\Rightarrow$  (i) is trivial. □

**Proof of Corollary 3.12.** (i) Suppose that  $B(t) = 0$  on  $[0, 1]$  and  $B(t) = \infty$  for  $t > 1$ . Then  $L^B(\mathbb{R}^n) = L^\infty(\mathbb{R}^n)$ , (3.3) holds and, by (3.4),  $B_{\frac{n}{\gamma}}$  is equivalent to  $t^{\frac{n}{\gamma}}$  on  $[0, \infty)$ . By Theorem 3.3 (the equivalence of (i) and (iv)), we have (i).

(ii) Let us set  $A(t) = t$ ,  $t \geq 0$ , so  $L^A(\mathbb{R}^n) = L^1(\mathbb{R}^n)$ . Clearly,  $A$  satisfies (3.1) and, by (3.2),  $A_{\frac{n}{\gamma}}(t)$  is equivalent to  $t^{\frac{n}{n-\gamma}}$  on  $[0, \infty)$ . Thus (ii) follows by Theorem 3.3, the equivalence of (i) and (iii).  $\square$

**Lemma 4.2.** *Let  $B$  be a Young function satisfying (3.3) and let  $F_{\frac{n}{\gamma}}$  be defined as in (3.5). Then  $F_{\frac{n}{\gamma}}$  is a Young function and*

$$i_{F_{\frac{n}{\gamma}}} > \frac{n}{n-\gamma} \quad \text{if and only if} \quad i_B > \frac{n}{n-\gamma}.$$

Furthermore, if this is the case, then  $F_{\frac{n}{\gamma}}$  is equivalent to  $B$ .

**Proof.** Suppose that  $i_B > \frac{n}{n-\gamma}$ . Then, by [9, Proposition 4.1],  $B$  is equivalent to  $F_{\frac{n}{\gamma}}$  and therefore  $i_{F_{\frac{n}{\gamma}}} > \frac{n}{n-\gamma}$ .

Conversely, suppose that  $i_{F_{\frac{n}{\gamma}}} > \frac{n}{n-\gamma}$ . Then, thanks to [9, Proposition 4.1], there exist  $\sigma > 1$  and  $c > 1$  such that

$$(4.3) \quad F_{\frac{n}{\gamma}}(\sigma t) \geq c \sigma^{\frac{n}{n-\gamma}} F_{\frac{n}{\gamma}}(t), \quad t > 0.$$

Let us write  $c = 1 + \varepsilon$  for some  $\varepsilon > 0$ . Then (4.3) becomes

$$\int_0^t \frac{B(s)}{s^{n/(n-\gamma)+1}} ds \leq \frac{1}{\varepsilon} \int_t^{\sigma t} \frac{B(s)}{s^{n/(n-\gamma)+1}} ds \leq B(\sigma t) \frac{1}{\varepsilon} \int_t^{\sigma t} \frac{1}{s^{n/(n-\gamma)+1}} ds \leq \frac{B(kt)}{t^{n/(n-\gamma)}}$$

for every  $t > 0$  and for a suitable constant  $k$ . Another use of [9, Proposition 4.1] gives that  $i_B > \frac{n}{n-\gamma}$ .  $\square$

**Proof of Theorem 3.7.** Assume that  $B$  satisfies (3.3). Then  $B_{\frac{n}{\gamma}}$  is well-defined and (3.9) holds by Theorem 3.3. To observe the optimality, assume that  $L^A(\mathbb{R}^n)$  satisfies (1.1). Then, again due to Theorem 3.3,  $A$  dominates  $B_{\frac{n}{\gamma}}$ , whence  $L^A(\mathbb{R}^n) \rightarrow L^{B_{\frac{n}{\gamma}}}(\mathbb{R}^n)$  and  $L^{B_{\frac{n}{\gamma}}}(\mathbb{R}^n)$  is optimal.

If (3.3) is violated, then no Orlicz space  $L^A(\mathbb{R}^n)$  might satisfy (1.1) since otherwise it would contradict Theorem 3.3.

Furthermore, if  $i_B > \frac{n}{n-\gamma}$ , then Lemma 4.2 gives that  $F_{\frac{n}{\gamma}}$  is equivalent to  $B$  and the formula (3.10) is immediate.  $\square$

**Lemma 4.3.** *Let  $n \in \mathbb{N}$ ,  $0 < \gamma < n$  and let  $D$  be a Young function such that  $D(t)/t^{n/(n-\gamma)}$  is nondecreasing,*

$$(4.4) \quad \lim_{t \rightarrow 0} \frac{D(t)}{t^{n/(n-\gamma)}} = 0$$

and

$$(4.5) \quad \sup_{0 < t < 1} \frac{t^{n/(n-\gamma)}}{D(Kt)} \int_0^t \frac{D(s)}{s^{n/(n-\gamma)+1}} ds = \infty$$

for every  $K \geq 1$ . Suppose that  $B$  is a Young such that

$$(4.6) \quad \int_0^t \frac{B(s)}{s^{n/(n-\gamma)+1}} ds \leq \frac{D(Ct)}{t^{n/(n-\gamma)}}, \quad 0 < t < 1,$$

for some  $C \leq 1$ . Then there exists a Young function  $B_1$  essentially dominating  $B$  and satisfying

$$(4.7) \quad \int_0^t \frac{B_1(s)}{s^{n/(n-\gamma)+1}} ds \leq \frac{D(5Ct)}{t^{n/(n-\gamma)}}, \quad 0 < t < 1.$$

**Proof.** Let  $D$  and  $B$  be the Young functions from the statement. Fix  $t \in (0, 1)$  and define the set  $G_t$  by

$$G_t = \left\{ s \in (0, 1) : \frac{B(s)}{s} \leq \frac{D(t)}{t} \right\}.$$

We claim that  $B(s)/s$  is a nondecreasing mapping from  $(0, 1)$  onto some neighbourhood of zero, and hence the sets  $G_t$  are nonempty for every  $t \in (0, 1)$ . Indeed, if  $\lim_{s \rightarrow 0+} B(s)/s > 0$ , then  $B(s) \geq cs$  on  $(0, 1)$  for some  $c > 0$  and thus

$$\int_0^t \frac{B(s)}{s^{n/(n-\gamma)+1}} ds \geq c \int_0^t \frac{ds}{s^{n/(n-\gamma)}} = \infty$$

which contradicts (4.6).

Let us define  $\tau = \tau_t = \sup G_t$ . Observe that, by the continuity of Young functions,

$$(4.8) \quad \frac{B(\tau)}{\tau} = \frac{D(t)}{t}, \quad 0 < t < 1.$$

Also,

$$(4.9) \quad \limsup_{t \rightarrow \infty} \frac{B(\tau_t)}{\tau_t} \cdot \frac{t}{B(Kt)} = \infty$$

for every  $K \geq 1$ . Indeed, suppose that there is some  $K \geq 1$  for which (4.9) is violated. We then have some  $L > 0$  such that

$$\frac{B(Kt)}{t} \geq L \frac{B(\tau)}{\tau}, \quad 0 < t < 1,$$

which in connection with (4.8) gives  $B(Ks) \geq L D(s)$  on  $(0, 1)$ . Thus

$$\begin{aligned} \frac{D(CKt)}{t^{n/(n-\gamma)}} &\geq \int_0^{Kt} \frac{B(s)}{s^{n/(n-\gamma)+1}} ds = K^{\frac{n}{\gamma-n}} \int_0^t \frac{B(Ks)}{s^{n/(n-\gamma)+1}} ds \\ &\geq LK^{\frac{n}{\gamma-n}} \int_0^t \frac{D(s)}{s^{n/(n-\gamma)+1}} ds, \quad 0 < t < 1, \end{aligned}$$

which contradicts (4.5) and therefore (4.9) holds true.

Next, by (4.9), we can take a decreasing sequence  $t_k \in (0, 1)$ ,  $k \in \mathbb{N}$ , such that

$$(4.10) \quad \lim_{k \rightarrow \infty} \frac{B(\tau_k)}{\tau_k} \cdot \frac{t_k}{B(kt_k)} = \infty,$$

where we set  $\tau_k = \tau_{t_k}$ . Without loss of generality we may assume that  $2t_k < \tau_k$  for every  $k \in \mathbb{N}$ . For contradiction, suppose that there exists a subsequence  $\{k_j\}$  such that  $\tau_{k_j} \leq 2t_{k_j}$ . Then, since  $B(s)/s$  does not increase and thanks to (2.1),

$$\frac{B(\tau_{k_j})}{\tau_{k_j}} \cdot \frac{t_{k_j}}{B(k_j t_{k_j})} \leq \frac{B(2t_{k_j})}{2t_{k_j}} \cdot \frac{t_{k_j}}{B(k_j t_{k_j})} \leq \frac{B(2t_{k_j})}{B(2t_{k_j})} \cdot \frac{1}{k_j} = \frac{1}{k_j} \rightarrow 0 \quad \text{as } k \rightarrow \infty,$$

which is impossible due to (4.10). We may also require that  $t_{k+1}$  is chosen in a way that  $2t_{k+1} \leq \tau_{k+1} < t_k$ , which is ensured if  $\tau_t \rightarrow 0$  as  $t \rightarrow 0$ . To observe that, by (4.8), we need to have  $\lim_{t \rightarrow 0+} D(t)/t = 0$  which is however guaranteed by the stronger condition (4.4). Furthermore, from (4.4) take  $t_{k+1}$  small enough so that

$$(4.11) \quad \frac{D(t_{k+1})}{t_{k+1}^{n/(n-\gamma)}} \leq \frac{1}{2} \cdot \frac{D(t_k)}{t_k^{n/(n-\gamma)}}.$$

We now define a function  $B_1$  by the formula

$$B_1(t) = \begin{cases} B(t_k) + \frac{B(\tau_k) - B(t_k)}{\tau_k - t_k} (t - t_k), & t \in (t_k, \tau_k), k \in \mathbb{N}, \\ B(t), & \text{otherwise.} \end{cases}$$

Obviously,  $B_1$  is a well-defined Young function and  $B_1 \geq B$ . Moreover, for  $k \in \mathbb{N}$ ,  $2B(t_k) \leq B(\tau_k)$  by (2.1) and therefore

$$\frac{B_1(2t_k)}{B(kt_k)} = \frac{B(t_k) + \frac{B(\tau_k) - B(t_k)}{\tau_k - t_k} t_k}{B(kt_k)} \geq \frac{B(\tau_k) - B(t_k)}{B(kt_k)} \cdot \frac{t_k}{\tau_k} \geq \frac{1}{2} \cdot \frac{B(\tau_k)}{\tau_k} \cdot \frac{t_k}{B(kt_k)}$$

and the latter tends to infinity as  $k \rightarrow \infty$  by (4.10). Consequently

$$\limsup_{t \rightarrow 0+} \frac{B_1(t)}{B(\lambda t)} = \infty$$

for every  $\lambda \geq 1$  and  $B_1$  essentially dominates  $B$ . It remains to show that  $B_1$  fulfills (4.7). Let  $t \in (0, 1)$  be fixed and let  $j \in \mathbb{N}$  be such that  $t \in [t_j, t_{j+1})$ . Then we have (4.12)

$$\int_0^t \frac{B_1(s)}{s^{n/(n-\gamma)+1}} ds \leq \int_0^t \frac{B(s)}{s^{n/(n-\gamma)+1}} ds + \sum_{k=j}^{\infty} \frac{B(\tau_k) - B(t_k)}{\tau_k - t_k} \int_{t_k}^{\tau_k} \frac{s - t_k}{s^{n/(n-\gamma)+1}} ds.$$

By the assumption, the former integral is dominated by the right hand side of (4.6). Let us follow with estimates of the latter sum. Thanks to  $2t_k < \tau_k$  and (4.8),

$$(4.13) \quad \frac{B(\tau_k) - B(t_k)}{\tau_k - t_k} \leq \frac{2B(\tau_k)}{\tau_k} = \frac{2D(t_k)}{t_k}$$

and since  $n/(n-\gamma) > 1$ , we have

$$(4.14) \quad \int_{t_k}^{\tau_k} \frac{(s - t_k)}{s^{n/(n-\gamma)+1}} ds \leq \int_{t_k}^{\infty} \frac{1}{s^{n/(n-\gamma)}} ds \leq \frac{1}{t_k^{n/(n-\gamma)-1}}.$$

Combination of (4.12) and (4.13) with (4.14) then gives

$$(4.15) \quad \int_0^t \frac{B_1(s)}{s^{n/(n-\gamma)+1}} ds \leq \frac{D(Ct)}{t^{n/(n-\gamma)}} + 2 \sum_{k=j}^{\infty} \frac{D(t_k)}{t_k^{n/(n-\gamma)}}.$$

It follows from (4.11) that

$$\frac{D(t_k)}{t_k^{n/(n-\gamma)}} \leq 2^{k-j} \frac{D(t_j)}{t_j^{n/(n-\gamma)}} \leq 2^{k-j} \frac{D(t)}{t^{n/(n-\gamma)}}, \quad j \leq k < \infty,$$

whence

$$(4.16) \quad \sum_{k=j}^{\infty} \frac{D(t_k)}{t_k^{n/(n-\gamma)}} \leq \frac{D(t)}{t^{n/(n-\gamma)}} \sum_{j=k}^{\infty} 2^{k-j} \leq \frac{2D(t)}{t^{n/(n-\gamma)}}.$$

The inequality (4.7) thus follows by (4.15) and (4.16).  $\square$

**Lemma 4.4.** *Let  $B$  be a Young function satisfying*

$$(4.17) \quad \int_0^1 \frac{B(s)}{s^{n/(n-\gamma)+1}} ds < \infty.$$

*Then there is a Young function  $B_1$  such that  $B_1$  essentially dominates  $B$  and also*

$$(4.18) \quad \int_0^1 \frac{B_1(s)}{s^{n/(n-\gamma)+1}} ds < \infty.$$

**Proof.** Assume that  $B$  is given and fulfills (4.17). Let us define  $d_k = 1/\log(k+1)$ ,  $k \in \mathbb{N}$ , and let  $t_k$ ,  $k \in \mathbb{N}$ , satisfy  $t_k \leq t_{k-1}/k$  and

$$\int_0^{t_k} \frac{B(s)}{s^{n/(n-\gamma)+1}} ds \leq d_k \quad \text{for } k \in \mathbb{N}.$$

Then define  $D_1$  by

$$D_1(t) = \sum_{k=1}^{\infty} d_k t^{\frac{n}{n-\gamma}} \chi_{[t_{k+1}, t_k)}(t) + Ct^{\frac{n}{n-\gamma}} \chi_{[1, \infty)}(t), \quad t \geq 0,$$

where  $C$  is a constant which dominates the integral in (4.17), and set  $D$  by

$$D(t) = \int_0^{2t} \frac{D_1(s)}{s} ds, \quad t \geq 0.$$

Since  $D_1$  is nondecreasing,  $D$  is a Young function and  $D_1(t) \leq D(t)$ .

We shall show that  $B$  and  $D$  satisfy the assumptions of Lemma 4.3. Clearly  $D(t)/t^{n/(n-\gamma)}$  is nondecreasing and  $\lim_{t \rightarrow 0+} D(t)/t^{n/(n-\gamma)} = \lim_{k \rightarrow \infty} d_k = 0$ . Next, let  $t \in (0, 1)$  be arbitrary and let  $j \in \mathbb{N}$  be such that  $t \in [t_{j+1}, t_j)$ . Then

$$\begin{aligned} \int_0^t \frac{D(s)}{s^{n/(n-\gamma)+1}} ds &\geq \int_0^t \frac{D_1(s)}{s^{n/(n-\gamma)+1}} ds \geq \sum_{k=j+1}^{\infty} \int_{t_{k+1}}^{t_k} \frac{D_1(s)}{s^{n/(n-\gamma)+1}} ds \\ &\geq \sum_{k=j+1}^{\infty} d_k \int_{t_{k+1}}^{t_k} \frac{ds}{s} \geq \sum_{k=j+1}^{\infty} d_k \log(k+1) = \infty \end{aligned}$$

which gives (4.5) and also

$$\int_0^t \frac{B(s)}{s^{n/(n-\gamma)+1}} ds \leq \int_0^{t_j} \frac{B(s)}{s^{n/(n-\gamma)+1}} ds = d_j = \frac{D_1(t)}{t^{n/(n-\gamma)}} \leq \frac{D(t)}{t^{n/(n-\gamma)}}$$

which is (4.6). Lemma 4.3 gives us a Young function  $B_1$  essentially dominating  $B$  such that

$$\int_0^t \frac{B_1(s)}{s^{n/(n-\gamma)+1}} ds \leq \frac{D(5t)}{t^{n/(n-\gamma)}}, \quad 0 < t < 1.$$

Then we have (4.18) as a special case.  $\square$

**Proof of Theorem 3.4.** Let  $A$  be a Young function satisfying (3.1) and assume (3.6). By [9, Proposition 4.1], (3.6) is equivalent to the inequality

$$(4.19) \quad \int_0^t \frac{A_{\frac{n}{\gamma}}(s)}{s^{n/(n-\gamma)+1}} ds \leq \frac{A_{\frac{n}{\gamma}}(Ct)}{t^{n/(n-\gamma)}}, \quad t > 0,$$

for some constant  $C > 0$ . Theorem 3.3 then guarantees (3.7).

Let us prove the optimality. Suppose that  $L^B(\mathbb{R}^n)$  satisfies (1.1). Then, by Theorem 3.3, there is a constant  $C > 0$  such that

$$(4.20) \quad \int_0^t \frac{B(s)}{s^{n/(n-\gamma)+1}} ds \leq \frac{A_{\frac{n}{\gamma}}(Ct)}{t^{n/(n-\gamma)}}, \quad t > 0.$$

Thus,

$$\begin{aligned} A_{\frac{n}{\gamma}}(2Ct) &\geq t^{n/(n-\gamma)} \int_0^{2t} \frac{B(s)}{s^{n/(n-\gamma)+1}} ds \geq t^{n/(n-\gamma)} \int_t^{2t} \frac{B(s)}{s^{n/(n-\gamma)+1}} ds \\ &\geq B(t) t^{n/(n-\gamma)} \int_t^{2t} \frac{ds}{s^{n/(n-\gamma)+1}} \geq B(t) C_{n,\gamma} \end{aligned}$$

for all  $t > 0$  and hence  $A_{\frac{n}{\gamma}}$  dominates  $B$  which gives  $L^{A_{\frac{n}{\gamma}}}(\mathbb{R}^n) \rightarrow L^B(\mathbb{R}^n)$ .

Suppose that  $A$  satisfies (3.1) and (3.6) fails. Then, by [9, Proposition 4.1], the inequality (4.19) is violated for every  $C > 0$ . Note that in this case is  $L^{A_{\frac{n}{\gamma}}}(\mathbb{R}^n) \neq L^\infty(\mathbb{R}^n)$  and hence  $A_{\frac{n}{\gamma}}$  is finite-valued. The failure of (4.19) occurs under one of these two conditions, namely

$$(4.21) \quad \sup_{1 < t < \infty} \frac{t^{n/(n-\gamma)}}{A_{\frac{n}{\gamma}}(Ct)} \int_1^t \frac{A_{\frac{n}{\gamma}}(s)}{s^{n/(n-\gamma)+1}} ds = \infty \quad \text{for every } C > 0$$

or

$$(4.22) \quad \sup_{0 < t < 1} \frac{t^{n/(n-\gamma)}}{A_{\frac{n}{\gamma}}(Ct)} \int_0^t \frac{A_{\frac{n}{\gamma}}(s)}{s^{n/(n-\gamma)+1}} ds = \infty \quad \text{for every } C > 0.$$

Assume that  $B$  is a Young function such that (1.1) holds, i.e., by Theorem 3.3, the inequality (4.20) holds for some  $C > 0$ . In both cases, we will show that there is a Young function  $B_1$  such that  $L^{B_1}(\mathbb{R}^n) \subsetneq L^B(\mathbb{R}^n)$  and also

$$(4.23) \quad M_\gamma: L^A(\mathbb{R}^n) \rightarrow L^{B_1}(\mathbb{R}^n).$$

or equivalently, by Theorem 3.3,

$$(4.24) \quad \int_0^t \frac{B_1(s)}{s^{n/(n-\gamma)+1}} ds \leq \frac{A_\gamma^n(Ct)}{t^{n/(n-\gamma)}}, \quad t > 0,$$

where  $C$  is a possibly different constant. If (4.21) holds, we modify the Young function  $B$  only near infinity and, similarly, if (4.22) holds, we do that near zero.

Let us start with the “near infinity” case. First observe that  $A_\gamma^n(t)/t^{n/(n-\gamma)}$  is nondecreasing, by the same argument used in Remark 3.1. Thus  $A_\gamma^n(t)/t^{n/(n-\gamma)}$  is either bounded near infinity or

$$(4.25) \quad \lim_{t \rightarrow \infty} \frac{A_\gamma^n(t)}{t^{n/(n-\gamma)}} = \infty.$$

In the former case, (4.20) reads as

$$(4.26) \quad \int_0^t \frac{B(s)}{s^{n/(n-\gamma)+1}} ds \leq \frac{A_\gamma^n(Ct)}{t^{n/(n-\gamma)}}, \quad 0 < t < 1,$$

and

$$\int_1^\infty \frac{B(s)}{s^{n/(n-\gamma)+1}} ds < \infty.$$

By [10, Theorem 6.4 (ii)], there is a modification of  $B$  on  $(1, \infty)$ , say  $B_1$ , such that  $B_1$  essentially dominates  $B$  and also

$$\int_1^\infty \frac{B_1(s)}{s^{n/(n-\gamma)+1}} ds < \infty.$$

Let us moreover set  $B_1 = B$  on  $(0, 1)$ . Then (4.26) holds with  $B$  replaced by  $B_1$  and hence (4.24) and therefore (4.23).

Now, assume (4.21) and (4.25). The condition (4.20) now splits into (4.26) and

$$(4.27) \quad \int_1^t \frac{B(s)}{s^{n/(n-\gamma)+1}} ds \leq \frac{A_\gamma^n(Ct)}{t^{n/(n-\gamma)}}, \quad 1 < t < \infty.$$

By [16, Theorem 4.1], there exists a modified Young function  $B_1$  such that  $B_1$  is essentially larger than  $B$  and also satisfies (4.27) with  $B_1$  in place of  $B$ . If we keep  $B_1 = B$  on  $(0, 1)$ , then (4.26) remains valid for  $B_1$ . That gives us (4.24) also in this case.

Let us now work “near zero”. We again distinguish two cases, when  $A_\gamma^n(t)/t^{n/(n-\gamma)}$  is equivalent to a constant function on  $(0, 1)$  and when

$$(4.28) \quad \lim_{t \rightarrow 0} \frac{A_\gamma^n(t)}{t^{n/(n-\gamma)}} = 0.$$

In the constant case, (4.20) boils down to (4.27) and

$$\int_0^1 \frac{B(s)}{s^{n/(n-\gamma)+1}} ds < \infty.$$

Lemma 4.4 ensures that there is an essentially larger Young function than  $B$ ,  $B_1$  say, such that

$$\int_0^1 \frac{B_1(s)}{s^{n/(n-\gamma)+1}} ds < \infty.$$

Let  $B_1 = B$  on  $(1, \infty)$  and thus (4.27) holds for  $B$  replaced by  $B_1$ . Therefore (4.24) also in this case.

Finally assume (4.22) and (4.28). The inequality (4.20) splits into (4.26) and (4.27). On using Lemma 4.3, one gets a modified Young function  $B_1$  which essentially enlarges  $B$  on  $(0, 1)$  and still satisfies (4.26). Again, if we set  $B_1 = B$  on  $(0, \infty)$ , we obtain (4.24).

Let us prove the “in particular” statement. The condition  $I_A < \frac{n}{\gamma}$  holds if and only if  $i_{\tilde{A}} > \frac{n}{n-\gamma}$  is satisfied. Then, by [9, Lemma 4.2 (ii)],

$$\inf_{0 < s \leq t} \tilde{A}^{-1}(s) s^{\frac{2}{n}-1} \simeq \tilde{A}^{-1}(t) t^{\frac{2}{n}-1} \quad \text{for } t > 0$$

which, thanks to (2.3), rewrites as

$$\sup_{0 < s \leq t} A^{-1}(s) s^{-\frac{2}{n}} \simeq A^{-1}(t) t^{-\frac{2}{n}} \quad \text{for } t > 0.$$

Thus, (3.8) follows by the definition of  $A_{\frac{n}{\gamma}}$  and by Remark 3.1. Also, if  $i_{\tilde{A}} > \frac{n}{n-\gamma}$ , then  $i_{A_{\frac{n}{\gamma}}} > \frac{n}{\gamma}$  is equivalent to  $i_A > 1$  due to [9, Lemma 4.3] and the duality.

The necessity of the condition (3.1) for the existence of any Orlicz space  $L^B(\mathbb{R}^n)$  satisfying (1.1) follows by Theorem 3.3.  $\square$

**Proof of Theorem 3.10.** The boundedness of  $M_\gamma$  in (3.12) and the optimality of the domain space is a consequence of Theorem 3.7.

As for the range, set  $A = B_{\frac{n}{\gamma}}$  and let us compute  $A_{\frac{n}{\gamma}}$  by (3.2). We have

$$A_{\frac{n}{\gamma}}^{-1}(t) \simeq G_{\frac{n}{\gamma}}(t) = \sup_{0 < s \leq t} B_{\frac{n}{\gamma}}^{-1}(s) s^{-\frac{2}{n}} \simeq \sup_{0 < s \leq t} F_{\frac{n}{\gamma}}^{-1}(s) = F_{\frac{n}{\gamma}}^{-1}(t), \quad t > 0,$$

whence  $A_{\frac{n}{\gamma}}$  is equivalent to  $F_{\frac{n}{\gamma}}$ . Therefore  $i_{A_{\frac{n}{\gamma}}} > \frac{n}{n-\gamma}$  if and only if  $i_{F_{\frac{n}{\gamma}}} > n/(n-\gamma)$  which is due to Lemma 4.2 the same as  $i_B > \frac{n}{n-\gamma}$ . The optimality of the range in (3.12) is then driven by the condition (3.11) thanks to Theorem 3.4.  $\square$

**Proof of Theorem 3.11.** Let  $A$  be a Young function such that (3.1) holds true. Then  $A_{\text{sup}}$  satisfies (3.1) as well and the Young function  $(A_{\text{sup}})_{\frac{n}{\gamma}}$  associated to  $A_{\text{sup}}$  as in (3.2) satisfies

$$\begin{aligned} (A_{\text{sup}})_{\frac{n}{\gamma}}^{-1}(t) &\simeq \sup_{0 < s \leq t} s^{-\frac{n}{\gamma}} A_{\text{sup}}^{-1}(s) \\ &\simeq \sup_{0 < s \leq t} \sup_{0 < y \leq s} y^{-\frac{n}{\gamma}} A^{-1}(y) \\ &= \sup_{0 < y \leq t} y^{-\frac{n}{\gamma}} A^{-1}(y) \simeq A_{\frac{n}{\gamma}}^{-1}(t), \quad t > 0, \end{aligned}$$

in other words,  $(A_{\text{sup}})_{\frac{n}{\gamma}}$  is equivalent to  $A_{\frac{n}{\gamma}}$ . Therefore, by Theorem 3.3, criterion (iii), (1.1) holds if and only if (3.14). Also,

$$(A_{\text{sup}})_{\frac{n}{\gamma}}^{-1}(t) \simeq t^{-\frac{n}{\gamma}} A_{\text{sup}}^{-1}(t), \quad t > 0,$$

and thus

$$h_{(A_{\text{sup}})_{\frac{n}{\gamma}}}(t) = \sup_{s>0} \frac{(A_{\text{sup}})_{\frac{n}{\gamma}}^{-1}(st)}{(A_{\text{sup}})_{\frac{n}{\gamma}}^{-1}(s)} \simeq t^{-\frac{n}{\gamma}} \sup_{s>0} \frac{A_{\text{sup}}^{-1}(st)}{A_{\text{sup}}^{-1}(s)} = t^{-\frac{n}{\gamma}} h_{A_{\text{sup}}}(t), \quad t > 0.$$

Whence, by the definition of the lower Boyd index (2.4),

$$\frac{1}{i_{(A_{\text{sup}})_{\frac{n}{\gamma}}}} + \frac{\gamma}{n} = \frac{1}{i_{A_{\text{sup}}}}$$

and therefore  $i_{(A_{\text{sup}})_{\frac{n}{\gamma}}} > \frac{n}{n-\gamma}$  if and only if  $i_{A_{\text{sup}}} > 1$ . The claim now follows by Theorem 3.4.  $\square$
