Stratification of Singular Hyperkähler Quotients

Maxence Mayrand

Abstract. Hyperkähler quotients by non-free actions are typically highly singular, but are remarkably still partitioned into smooth hyperkähler manifolds. We show that these partitions are topological stratifications, in a strong sense. We also endow the quotients with global Poisson structures which induce the hyperkähler structures on the strata. Finally, we give a local model which shows that these quotients are locally isomorphic to linear complex-symplectic reductions in the GIT sense. These results can be thought of as the hyperkähler analogues of Sjamaar–Lerman’s theorems for symplectic reduction. They are based on a local normal form for the underlying complex-Hamiltonian manifold, which may be of independent interest.

1. Introduction

1.1. Overview. Let $M$ be a hyperkähler manifold and $K$ a compact Lie group acting on $M$ by preserving the hyperkähler structure and with hyperkähler moment map $\mu : M \to \mathfrak{k}^* \otimes \mathbb{R}^3$. If $K$ acts freely, then the hyperkähler quotient

$$M // K := \mu^{-1}(0)/K$$

is a smooth manifold endowed with a canonical hyperkähler structure [21].

If the action is not necessarily free, the quotient $\mu^{-1}(0)/K$ is typically highly singular, but is remarkably still a union of smooth hyperkähler manifolds. This was first observed by Nakajima [34] for quiver varieties and, in general, by Dancer–Swann [5]. It is an adaptation of the work of Sjamaar–Lerman [39] on symplectic reductions by non-free actions, which yields to stratified symplectic spaces.

However, not all results of Sjamaar–Lerman have been adapted to the hyperkähler setting. Stratified symplectic spaces have much more structure than a union of symplectic manifolds: the symplectic manifolds “fit together nicely” in many ways, and there is a local model generalizing the Darboux theorem. The goal of this paper is to prove analogues of these results for hyperkähler quotients.

First, one of the main results of [39] is that the partition of a singular symplectic reduction into symplectic manifolds is a topological stratification in a strong sense (see Definition 2.4). We will show that the same holds for the partition of a singular hyperkähler quotient into hyperkähler manifolds.

Second, Sjamaar–Lerman [39] showed that a singular symplectic reduction has a certain Poisson structure which induces the symplectic structures on the strata. Similarly, we will endow each singular hyperkähler quotient with a global structure that induces the hyperkähler structures $(g_S, J_S, K_S)$ on the strata $S \subseteq M // K$.

During the preparation of this work, the author was supported by a Moussouris Scholarship from the University of Oxford, a PGS-D and a PDF scholarship from the Natural Sciences and Engineering Research Council of Canada (NSERC), and a postdoctoral scholarship from the Fonds de Recherche du Québec Nature et technologies (FRQNT).
More precisely, for each choice of frame of complex structures \((I,J,K)\) on \(M\), there is a complex-analytic structure \(O_1\) on \(M//K\) together with a holomorphic Poisson bracket \(\{\cdot,\cdot\} : O_1 \times O_1 \to O_1\) such that the inclusion \(S \hookrightarrow M//K\) of each stratum is holomorphic Poisson with respect to \(I_S\) and the complex-symplectic structure \(\omega_{J_S} + i\omega_{K_S}\) (where \(\omega_{J_S}, \omega_{J_S}, \omega_{K_S}\) are the Kähler forms of \(S\)). Moreover, \(M//K\) has the structure of a real stratified symplectic space (in the sense of [39]) compatible with the first Kähler forms \(\omega_{I_S}\). That is, there is a subalgebra \(C^\infty(M//K)\) of the algebra of continuous functions, together with a Poisson bracket, such that the inclusions \(S \hookrightarrow M//K\) are smooth and Poisson with respect to \(\omega_{I_S}\). These two global structures on the singular space \(M//K\) determine the Kähler forms \(\omega_{I_S}, \omega_{J_S}, \omega_{K_S}\) and hence the whole hyperkähler structures.

Third, we extend another important result of [39], which is that singular symplectic reductions are locally isomorphic to linear symplectic reductions, i.e. reductions of symplectic vector spaces by linear actions. This can be viewed as a generalization of the Darboux theorem. We show that, similarly, singular hyperkähler quotients are locally biholomorphic with respect to \(I_S\) to linear hyperkähler quotients, in a way that is compatible with the complex-symplectic structures \(\omega_{I_S} + i\omega_{K_S}\) on the strata. These isomorphisms are not necessarily compatible with the first Kähler forms \(\omega_{I_S}\), since there is no Darboux theorem for hyperkähler manifolds describing all three Kähler forms simultaneously.

To get these results, we prove a local normal form for the complex-Hamiltonian structure of \(M\), analogous to Guillemin–Sternberg’s local normal form for a real moment map [12]. This result may be of independent interest.

1.2. Statements of results. We now give precise statements of our results; the proofs will be in the body of the paper.

A hyperkähler manifold is a tuple \((M,g,1,J,K)\), where \(M\) is a smooth manifold, \(g\) is a Riemannian metric on \(M\), and \(1,J,K\) are three complex structures which are Kähler with respect to \(g\) and satisfy \(JK = -1\). The corresponding Kähler forms will be denoted \(\omega_I, \omega_J, \omega_K\). We say that a tri-Hamiltonian hyperkähler manifold is a triple \((M,K,\mu)\), where \(M\) is a hyperkähler manifold, \(K\) is a compact Lie group acting on \(M\) by preserving the hyperkähler structure, and \(\mu : M \to \mathfrak{k}^* \otimes \mathbb{R}^3\) is a hyperkähler moment map, where \(\mathfrak{k} = \text{Lie}(K)\).

We will also assume that the \(K\)-action extends to a holomorphic \(K_C\)-action with respect to any of the complex structures (where \(K_C\) is the complexification of \(K\)). In that case, we say that \((M,K,\mu)\) is integrable (or \(I\)-integrable if we need to specify the complex structure). This is a natural assumption in the context of Kähler or hyperkähler quotients and holds in most examples that one encounters (cf. Sjamaar [38], Heinzner–Loose [18], or Kaledin [23]). The terminology comes from the fact that it is equivalent to the completeness of the vector fields \(\mathfrak{x}^\#\), for \(x \in \mathfrak{k} = \text{Lie}(K)\). For example, it holds if \(M\) is a complex affine variety and the action is real algebraic (see e.g. [16, p. 226]).

Let \((M,K,\mu)\) be a tri-Hamiltonian hyperkähler manifold. Then, the quotient \(M//K := \mu^{-1}(0)/K\) has a natural orbit-type partition, whose pieces are the connected components of the subspaces \(\mu^{-1}(0)(H)/K\) for all subgroups \(H \subseteq K\), where \(\mu^{-1}(0)(H)\) is the set of points with stabilizer conjugate to \(H\) in \(K\). These pieces are, in fact, smooth hyperkähler manifolds:
Theorem 1.1 (Dancer–Swann [5]). Let \((M, K, \mu)\) be a tri-Hamiltonian hyperkähler manifold, let \(\pi : \mu^{-1}(0) \rightarrow M//K\) be the quotient map, and let \(S \subseteq M//K\) be an orbit-type piece. Then:

(i) \(S\) is a topological manifold, \(\pi^{-1}(S)\) is a smooth submanifold of \(M\), and there is a unique smooth structure on \(S\) such that \(\pi^{-1}(S) \rightarrow S\) is a smooth submersion.

(ii) There is a unique hyperkähler structure \((g_S, J_S, K_S)\) on \(S\) such that the pullbacks of the Kähler forms \(\omega_1, \omega_3, \omega_K\) to \(\pi^{-1}(S)\) are the restrictions of the Kähler forms \(\omega_1, \omega_3, \omega_K\) of \(M\).

Our formulation of this theorem is slightly stronger than the one in the cited paper since we have added a uniqueness part in (ii), characterizing the hyperkähler structures. We will need this stronger version, so, for completeness, we provide a full proof of Theorem 1.1 in §2.5.

The question of whether this partition is a topological stratification (Definition 2.4) was left open in Dancer–Swann’s work; even the frontier condition was not known. The issue is that the arguments used by Sjamaar–Lerman [39] in the symplectic case is based on the local normal form for the moment map [12, 29], which has no hyperkähler equivalent. Indeed, the local normal form for the moment map implies the Darboux theorem, so a hyperkähler equivalent would give a local model describing all three symplectic forms simultaneously and hence they could not carry any local information. But the three symplectic forms collectively determine the Riemannian metric, which does carry local information: the curvature. Nevertheless:

Theorem 1.2. Let \((M, K, \mu)\) be an integrable tri-Hamiltonian hyperkähler manifold. Then, the orbit-type partition of \(M//K\) is a topological stratification.

In fact, we will show that this partition is a Whitney stratification (Definition 2.7) with respect to some complex-analytic structure.

The idea of the proof is to use the close relationship between hyperkähler geometry and complex-symplectic geometry. Namely, \(M//K\) is isomorphic to a symplectic reduction in the category of complex-analytic spaces, and we can adapt Sjamaar–Lerman’s arguments to this setting.

More precisely, let \(G := K_C\) and suppose, without loss of generality, that the action is integrable with respect to the complex structure \(I\). Note that we can always arrange this by rotating \((I, J, K)\) by an element of \(SO(3)\). Let \(\mu_I, \mu_J, \mu_K\) be the three components of the hyperkähler moment map \(\mu\) and let \(\mu_R := \mu_I\) and \(\mu_C := \mu_J + i\mu_K\). Then, \(\mu_C : M \rightarrow g^*\), where \(g := \text{Lie}(G)\), is a holomorphic moment map for the action of \(G\) on \(M\) with respect to the \(I\)-holomorphic complex-symplectic form \(\omega_C := \omega_J + i\omega_K\). Moreover, by letting

\[
M^{\mu_C-\text{ss}} := \{ p \in M : \overline{G \cdot p} \cap \mu_R^{-1}(0) \neq \emptyset \}
\]

\[
\mu_C^{-1}(0)^{\mu_C-\text{ss}} := \mu_C^{-1}(0) \cap M^{\mu_C-\text{ss}},
\]

we have \(\mu^{-1}(0) \subseteq \mu_C^{-1}(0)^{\mu_C-\text{ss}}\) and, by a result of Heinzner–Loose [18], this inclusion descends to a homeomorphism \(M//K \cong \mu_C^{-1}(0)^{\mu_C-\text{ss}}//G\), where // is a categorical quotient in the category of complex-analytic spaces (we will review Heinzner–Loose’s work in §2.4). Thus, it suffices to get a local normal form for the complex part \(\mu_C\) of the moment map, and this is one of the main technical results of this paper.

To state this normal form, let \(p \in \mu^{-1}(0)\) and let \(V := (T_p(G \cdot p))^{\omega_C}/T_p(G \cdot p)\), where \((\cdot)^{\omega_C}\) is the complex-symplectic complement. Then, \(V\) is a complex-symplectic
Then, there is a complex-Hamiltonian manifold \((M, 1, \omega_C, G, \mu_C)\) completely determined in a neighbourhood of \(p\) by the representation of \(H\) on \(V\). More precisely, there is a canonical structure of a complex-Hamiltonian manifold on the associated vector bundle \(G \times_H (\mathfrak{h}^0 \times V)\) (see §3.2), which gives the local model:

**Theorem 1.3.** Let \((M, K, \mu)\) be an \(l\)-integrable tri-Hamiltonian hyperkähler manifold. Let \(G \coloneqq K_C, p \in \mu^{-1}(0), H \coloneqq G_p, V \coloneqq (T_p(G \cdot p))^{\omega C}/T_p(G \cdot p)\). Then, there is a \(G\)-saturated neighbourhood of \(p\) in \(M^{\mu_{ss}}\) which is isomorphic as a complex-Hamiltonian \(G\)-manifold to a \(G\)-saturated neighbourhood of \([1, 0, 0]\) in \(G \times_H (\mathfrak{h}^0 \times V)\).

Here, a \(G\)-**saturated** subset of a \(G\)-space \(X\) is a subset \(A\) such that \(\overline{g \cdot a} \subseteq A\) for all \(a \in A\). See Losev [28] for a similar result in the algebraic setting.

This local form enables us to study the structure of the quotient:

**Theorem 1.4.** Let \((M, K, \mu)\) be an \(l\)-integrable tri-Hamiltonian hyperkähler manifold and let \(G \coloneqq K_C\). For each orbit-type strata \(S \subseteq M///K\), let \((\mathfrak{g}_S, I_S, J_S, K_S)\) be its hyperkähler structure as in Theorem 1.1. Let \(\mu_S \coloneqq \mu I\) and \(\mu_C \coloneqq \mu I + i\mu_K\).

(i) **Complex-analytic structure.** The inclusion \(\mu^{-1}(0) \subseteq \mu^{-1}(0)^{\mu\text{-ss}}\) descends to a homeomorphism \(M///K \cong \mu^{-1}(0)^{\mu\text{-ss}}//G\) and hence \(M///K\) inherits the structure \(\mathcal{O}_I\) of a complex-analytic space. Moreover, the orbit-type partition is a complex-analytic Whitney stratification with respect to \(\mathcal{O}_I\) and is compatible with the complex structures \(I_S\) on the strata.

(ii) **Holomorphic Poisson structure.** There is a unique holomorphic Poisson bracket on \(\mathcal{O}_I\) such that the inclusion of each orbit-type piece \(S \hookrightarrow M///K\) is holomorphic Poisson with respect to \(\omega_{J_S} + i\omega_{K_S}\).

(iii) **Real Poisson structure.** The first Kähler forms \(\omega_S\) are compatible with a stratified symplectic structure in the sense of Sjamaar–Lerman, i.e. there is a subalgebra \(C^\infty(M///K)\) of the algebra of real-valued continuous functions, together with a Poisson bracket, such that the inclusion of each orbit-type piece \(S \hookrightarrow M///K\) is smooth and Poisson with respect to \(\omega_S\).

(iv) **Local model.** Let \(q \in M///K\). Take a point \(p \in \mu^{-1}(0)\) above \(q\), let \(H \coloneqq G_p, V \coloneqq (T_p(G \cdot p))^{\omega C}/T_p(G \cdot p),\) where \(\omega_C \coloneqq \omega I + i\omega_K\), and let \(\Phi_V : V \to \mathfrak{h}^*\) be the moment map \(\Phi_V(v)(x) = \frac{1}{2}\omega_C(xv, v)\). Then, \(H\) is a complex reductive group and \(q\) has a neighbourhood biholomorphic with respect to \(\mathcal{O}_I\) to a neighbourhood of \(0\) in the GIT quotient \(\Phi_V^{-1}(0)//H = \text{Spec} \mathbb{C}[\Phi_V^{-1}(0)^H]\). Moreover, this biholomorphism respects the orbit-type stratifications and holomorphic Poisson brackets on both sides.

**Remark 1.5.** (i) and (iii) imply that \(M///K\) is a stratified Kähler space in the sense of Huebschmann [22, Definition 3.1].

**Remark 1.6.** Using Kempf–Ness type theorems, there are many situations where \(M///K\) is isomorphic to a GIT quotient \(\mu_C^{-1}(0)//L G\) for some linearisation \(L\), i.e. when \(\mu_C^{-1}(0)^{\mu_{ss}}\) coincides with the set of \(L\)-semistable points. In that case, the sheaf \(\mathcal{O}_I\) is simply the underlying complex-analytic structure. For example, this is the case for hyperkähler quotients of \(T^*G\) by closed subgroups of \(K \times K\) [33], where \(T^*G\) has the hyperkähler structure found by Kronheimer [26]. See also [32] for a study of the resulting partition in some family of examples.
Remark 1.7. The complex-symplectic GIT quotients $\Phi_{V}^{-1}(0)/H$ which appear as local models in this theorem have been well studied in the literature. For example, it is known that if $H$ is abelian then $\Phi_{V}^{-1}(0)/H$ is normal [2]. In particular, Theorem 1.4(iv) implies that hyperkähler quotients by compact tori are normal.

1.3. Organization of the paper. In §2 we give background material on stratified spaces and reduction, in §3 we prove Theorem 1.3, and in §4 we prove Theorem 1.4.

Acknowledgements. This work was done mainly during the author’s PhD at the University of Oxford. I thank Prof. Andrew Dancer, my supervisor, for his guidance.

2. Preliminaries

This section gives background material on stratified spaces, symplectic reduction, quotients of complex-analytic spaces, and the links between these notions. We start with a review of the theory of topologically stratified spaces and explain the work of Sjamaar–Lerman [39] on singular symplectic reduction. We then discuss links with complex-analytic geometry, reviewing work of Heinzner–Loose [18] and Sjamaar [38]. We also recall Dancer–Swann’s construction [5] of the hyperkähler structures on the orbit-type pieces of a singular hyperkähler quotient and prove Theorem 1.1.

2.1. Stratified spaces. Stratified spaces are topological spaces which can be partitioned into manifolds which “fit together nicely”. The underlying object for this theory is thus the following:

Definition 2.1. A partitioned space is a pair $(X, P)$ where $X$ is a topological space and $P$ is a partition of $X$, i.e. a collection of non-empty disjoint subsets of $X$ whose union is $X$. The elements of $P$ are called the pieces. An isomorphism between two partitioned spaces $(X, P)$ and $(Y, Q)$ is a homeomorphism $f : X \rightarrow Y$ such that for all $S \in P$ there exists $T \in Q$ such that $f(S) = T$.

Just like manifolds are topological spaces satisfying additional conditions, stratified spaces are partitioned spaces with additional conditions imposed. The first step is the following notion.

Definition 2.2 ([7, §1.1]). A decomposed space is a partitioned space $(X, P)$ such that $X$ is second countable and Hausdorff, and the following conditions hold:

- **Manifold condition.** Each piece is a topological manifold in the subspace topology.
- **Local condition.** $P$ is locally finite and its pieces are locally closed.
- **Frontier condition.** For all $S, T \in P$, if $S \cap T \neq \emptyset$ then $S \subseteq T$.

Remark 2.3. If $(X, P)$ is a decomposed space, then there is a natural relation on $P$ given by $S \leq T$ if $S \subseteq T$. It follows from the local closedness of the strata that this relation is a partial order. Moreover, the frontier condition is equivalent to

$$\overline{S} = \bigcup_{T \leq S} T,$$

for all $S \in P$.

This notion is sometimes incorporated in the definition of decomposed space, namely we fix a poset $\mathcal{I}$ and say that an $\mathcal{I}$-decomposed space is a topologically stratified space $(X, P)$ with an isomorphism $P \cong \mathcal{I}$ of posets.

Decomposed spaces can be rather pathological: for example, the topologist’s sine curve
is a perfectly valid one with two strata. Roughly speaking, stratified spaces avoid such pathologies by requiring that every point has a neighbourhood which retracts continuously onto it. We also impose that this neighbourhood is compatible with the partition in some sense. To make this precise, we need a few extra notions.

First, the \textit{dimension} of a decomposed space \((X, \mathcal{P})\) is

\[
\dim(X, \mathcal{P}) := \sup \{ \dim S : S \in \mathcal{P} \}.
\]

Given two partitioned spaces \((X, \mathcal{P})\) and \((Y, \mathcal{Q})\), their \textit{cartesian product} is the partitioned space \((X \times Y, \mathcal{P} \times \mathcal{Q})\) where \(\mathcal{P} \times \mathcal{Q} = \{S \times T : S \in \mathcal{P}, T \in \mathcal{Q}\}\). If \((X, \mathcal{P})\) and \((Y, \mathcal{Q})\) are decomposed spaces, then so is \((X \times Y, \mathcal{P} \times \mathcal{Q})\), and \(\dim(X \times Y, \mathcal{P} \times \mathcal{Q}) = \dim(X, \mathcal{P}) + \dim(Y, \mathcal{Q})\). Next, the \textit{cone} over a partitioned space \((X, \mathcal{P})\) is the partitioned space \((CX, \mathcal{C}P)\) where \(CX\) is the open cone over \(X\), i.e.

\[
CX := (X \times [0, \infty))/\{(p, 0) \sim (q, 0), \text{ for all } p, q \in X\}
\]

and \(\mathcal{C}P\) is the natural partition of \(CX\) given by \(\mathcal{C}P := \{S \times (0, \infty) : S \in \mathcal{P}\} \cup \{\text{vertex}\}\). The cone over a decomposed space \((X, \mathcal{P})\) is itself a decomposed space and has dimension \(\dim(CX, \mathcal{C}P) = \dim(X, \mathcal{P}) + 1\). A topologically stratified space is defined inductively as a decomposed space \((X, \mathcal{P})\) which is locally isomorphic to \(\mathbb{R}^n\) times a cone over a lower-dimensional topologically stratified space:

\textbf{Definition 2.4} ([7, 39]). A zero-dimensional topologically stratified space is any countable set of points with the discrete topology and with any partition. A \textit{topologically stratified space} is a finite-dimensional decomposed space \((X, \mathcal{P})\) such that every point \(p \in X\) has a neighbourhood isomorphic as a partitioned space to \(\mathbb{R}^n \times CL\) for some \(n \geq 0\) and some compact topologically stratified space \(L\), by a map sending \(p \mapsto \{0\} \times \{\text{vertex}\}\).

For example, one-dimensional topologically stratified spaces are locally modelled on cones over finite sets of points, i.e. they are graphs:

\[
\begin{array}{c}
\begin{array}{c}
\vdots \\
\text{one-dimensional local models}
\end{array}
\end{array}
\]

\[
a \text{one-dimensional topologically stratified space}
\]

Then, two-dimensional topologically stratified spaces are locally modelled on cones over graphs, etc. Also, manifolds with corners are special cases.

A typical way of proving that a decomposed space \((X, \mathcal{P})\) is a topologically stratified space is by the Whitney conditions [43].

\textbf{Definition 2.5.} Let \(S\) and \(T\) be two disjoint smooth submanifolds of \(\mathbb{R}^n\). We say that \(S\) is \textit{regular} over \(T\) if the following two conditions hold:

- \textbf{Whitney Condition A.} If \(x_i \in S\) is a sequence converging to \(y \in T\) and the sequence of subspaces \(T_{x_i} S \subseteq \mathbb{R}^n\) converges (in the Grassmannian) to \(V \subseteq \mathbb{R}^n\), then \(T_y T \subseteq V\).
• **Whitney Condition B.** If \( x_i \in S \) and \( y_i \in T \) are two sequences converging to \( y \in T \) in such a way that that the sequence of lines \( \mathbb{R}(x_i - y_i) \subseteq \mathbb{R}^n \) converges to \( l \in \mathbb{RP}^{n-1} \) and the subspaces \( T_x, S \to V \subseteq \mathbb{R}^n \), then \( l \subseteq V \).

A **Whitney stratification** of a subset \( X \) of \( \mathbb{R}^n \) is a decomposition \( \mathcal{P} \) of \( X \) into smooth submanifolds of \( \mathbb{R}^n \) such that \( S \) is regular over \( T \) for all \( S, T \in \mathcal{P} \).

We have (see e.g. Goresky–MacPherson [7, Ch. 1, §1.4] or Mather [31]):

**Proposition 2.6.** **Whitney stratifications are topological stratifications in the sense of** Definition 2.4. \( \square \)

Although Whitney stratifications are initially defined in \( \mathbb{R}^n \), the definition is purely local and is invariant under diffeomorphisms [31, §2]. In particular, it makes sense for complex-analytic spaces:

**Definition 2.7.** A **complex-analytic Whitney stratified space** is a complex-analytic space \((X, \mathcal{O}_X)\) together with a decomposition \( \mathcal{P} \) of \( X \) into complex submanifolds satisfying Whitney conditions A and B.

2.2. **Smooth manifold quotients.** Let \( K \) be a compact Lie group acting smoothly on a smooth manifold \( M \). Then, the quotient \( M/K \) is a topologically stratified space with respect to a natural partition by orbit-types. To define this partition, for each subgroup \( H \subseteq K \), let \((H)\) be the conjugacy class of \( H \) in \( K \). We say that \( p \in M \) has **orbit-type** \((H)\) if its stabilizer subgroup \( K_p \) is in \((H)\). Denote the set of points of orbit-type \((H)\) by

\[
M_{(H)} := \{ p \in M : K_p \in (H) \}.
\]

The **orbit-type partition** is the partition whose pieces are the connected components of the sets \( M_{(H)}/K \) for \( H \subseteq K \). This is a topological stratification as a consequence of the slice theorem for proper group actions (see e.g. [6, Theorem 2.7.4]).

2.3. **Stratified symplectic spaces.** A **Hamiltonian manifold** is a triple \((M, K, \mu)\), where \( M \) is a symplectic manifold, \( K \) a compact Lie group acting on \( M \) by symplectomorphisms, and \( \mu : M \to \mathfrak{t}^* \) a \( K \)-equivariant moment map. Sjamaar–Lerman [39] generalized the Marsden–Weinstein theorem [30] by showing that the orbit-type partition of \( M/\mu K := \mu^{-1}(0)/K \) is a topological stratification (even though \( \mu^{-1}(0) \) is not a smooth manifold) and that each piece has a canonical symplectic structure.

Moreover, these symplectic structures are compatible with a Poisson bracket on an appropriate substitute for the algebra of smooth functions. More precisely, let \( C^\infty(M/\mu K) \) be \( \mathbb{R} \)-algebra of continuous functions on \( M/\mu K \) which descend from smooth \( K \)-invariant functions on \( M \). Then, there is a unique Poisson bracket on \( C^\infty(M/\mu K) \) such that the inclusion of each symplectic stratum \( S \hookrightarrow M/\mu K \) is a smooth Poisson map.

Hence, the main result of [39] is that singular symplectic reductions are examples of the following notion:

**Definition 2.8** (Sjamaar–Lerman [39]). A **stratified symplectic space** is a topologically stratified space \((X, \mathcal{P})\) with a symplectic structure on each stratum, a subalgebra \( C^\infty(X) \) of the \( \mathbb{R} \)-algebra of continuous functions on \( X \), and a Poisson bracket on \( C^\infty(X) \) such that for each stratum \( S \in \mathcal{P} \) the inclusion \( S \hookrightarrow X \) is a Poisson map, i.e. for all \( f, g \in C^\infty(X) \) the restrictions \( f|_S, g|_S \) are smooth and \( \{ f|_S, g|_S \} = \{ f, g \}|_S \).
We recall the construction of the symplectic forms on the orbit-type pieces of $M/K$ [39, Theorem 3.5], as this will be useful for our discussion on hyperkaehler quotients. For a closed subgroup $H \subseteq K$, let $M_H$ be the set of points $p \in M$ whose stabilizer is precisely $H$. Then, the connected components of $M_H$ are smooth symplectic submanifolds of $M$ (of possibly different dimensions) and the group $L := N_K(H)/H$ (where $N_K(H)$ is the normalizer of $H$ in $K$) is compact and acts freely on $M_H$ by preserving the symplectic forms. Now, $\frak{t}^* := \text{Lie}(\frak{t})^*$ can be identified with a subspace of $\frak{t}^*$, namely, $\frak{h}^* \cap (\frak{t}^*)^H$, where $\frak{h}^*$ is the annihilator of $\frak{h} := \text{Lie}(H)$ and $(\frak{t}^*)^H$ is the set of points fixed by $H$. Moreover, if $M_H'$ denotes the union of the connected components of $M_H$ which intersect $\mu^{-1}(0)$, then $\mu$ restricts to a moment map $\mu_H : M'_H \to \frak{t}^*$ for the action of $L$ on $M'_H$. Since this action is free, each connected component of $M_H/\mu_HL = \mu^{-1}(0)/L$ is a smooth symplectic manifold by the standard Marsden–Weinstein theorem [30]. Then, the inclusion $\mu_H^{-1}(0) \subseteq \mu^{-1}(0)/H$ descends to a homeomorphism $M_H/\mu_HL \cong \mu^{-1}(0)/H/K$, and this endows each connected component of $\mu^{-1}(0)/H/K$ with a symplectic structure. Furthermore, the pullback of each symplectic form to the corresponding connected component of $\mu^{-1}(0)/H$ (which is a smooth submanifold of $M$) is the restriction of the symplectic form of $M$.

2.4. Kähler quotients. A Hamiltonian Kähler manifold is a Hamiltonian manifold $(M, K, \mu)$ with a $K$-invariant Kähler structure compatible with the symplectic form. If $K$ acts freely, then $M/K$ has a Kähler structure compatible with the reduced symplectic form (see e.g. [21, Theorem 3.1]). More generally, each symplectic stratum in Sjamaar–Lerman’s stratification is Kähler. To see this, it suffices to note that for each closed subgroup $H \subseteq K$, the space $M_H$ of points with stabiliser $H$ is now a complex submanifold of $M$ and hence is Kähler. Thus, the connected components of $M_H/\mu_HL$ (where $\mu_H$ and $L$ are as in §2.3) are Kähler manifolds, and the homeomorphism $M_H/\mu_HL \cong \mu^{-1}(0)/H/K$ gives the desired Kähler structures.

But we can say much more about the holomorphic aspect of $M/K$ when the action is integrable, i.e. extends to a holomorphic action of $G := K_C$, as shown by Sjamaar [38] and Heinzner–Loose [18]. Indeed, $M/K$ is homeomorphic to a categorical quotient $M^{wss}/G$ in the category of complex-analytic spaces, or more precisely, an analytic Hilbert quotient: the complex-analytic analogue of GIT quotients. Good expositions can be found in Heinzner–Huckleberry [15, 16] or Greb [9, §2–3]; we summarise the main points in this section. See also [41, §2.4] [8, §2] [10, §2] [9, §1] [14, §0] [19] [17] [18].

2.4.1. Analytic Hilbert quotients.

Definition 2.9. Let $(X, \mathcal{O}_X)$ be a complex-analytic space and $G$ a complex reductive group acting holomorphically on $X$. An analytic Hilbert quotient of $X$ by $G$ is a complex-analytic space $(Y, \mathcal{O}_Y)$ together with a $G$-invariant surjective holomorphic map $\pi : X \to Y$ such that:

(i) the map $\pi : X \to Y$ is locally Stein, i.e. $Y$ has a cover by Stein open sets whose preimages are Stein;

(ii) $\mathcal{O}_Y = (\pi_*\mathcal{O}_X)^G$.

An important consequence of this definition is that, if it exists, an analytic Hilbert quotient is a categorical quotient for complex-analytic spaces. In particular, it is
unique up to biholomorphisms. We denote it

$$X//G := \text{the analytic Hilbert quotient of } X \text{ by } G \text{ (if it exists)}.$$ 

Topologically, $X//G$ is the quotient of $X$ by the equivalence relation $x \sim y$ if $G \cdot x \cap G \cdot y \neq \emptyset$ and $\pi : X \to X//G$ is the corresponding quotient map. The space $X//G$ can also be viewed as the set of closed $G$-orbits, i.e. by defining the set of \textbf{polystable} points

$$X^{\text{ps}} := \{ x \in X : \text{the orbit } G \cdot x \text{ is closed in } X \},$$

the inclusion $X^{\text{ps}} \subseteq X$ descends to a bijection $X^{\text{ps}}/G \to X//G$. In particular, for every $p \in X//G$, there is a unique closed $G$-orbit in the fibre $\pi^{-1}(p) \subseteq X$.

\textbf{Example 2.10} (GIT quotients). Let $X$ be a complex affine variety, $G$ a complex reductive group acting algebraically on $X$, and consider the affine GIT quotient $X//G := \text{Spec } \mathbb{C}[X]^G$ together with the morphism $X \to X//G$ induced by the inclusion $\mathbb{C}[X]^G \to \mathbb{C}[X]$. Then, the analytification of $X \to X//G$ is an analytic Hilbert quotient $[13, \S 6.4]$. More generally, since complex affine varieties are Stein, the analytification of any GIT quotient is an analytic Hilbert quotient.

We will later need the following properties of analytic Hilbert quotients:

\textbf{Proposition 2.11.} Let $\pi : X \to X//G$ be an analytic Hilbert quotient.

(i) An open set $U \subseteq X$ is $G$-saturated if and only if it is saturated with respect to $\pi$. In that case, $U//G := \pi(U)$ is open in $X//G$ and the restriction $U \to U//G$ is an analytic Hilbert quotient.

(ii) If $Y \subseteq X$ is a $G$-invariant closed complex-analytic subspace, then $Y//G := \pi(Y)$ is a closed complex-analytic subspace of $X//G$ and the restriction $Y \to Y//G$ is an analytic Hilbert quotient. \hfill $\square$

For (i) see [19, \S 2 Remark and \S 1 Corollary] and for (ii) see [19, \S 1(ii)].

2.4.2. The Heinzner–Loose theorem. Just as for GIT quotients, the question of existence of analytic Hilbert quotients is a subtle one. In complete analogy, for an action of a complex reductive group $G$ on a complex-analytic space $X$, there does not always exist an analytic Hilbert quotient, but in good cases, one can find a large open subset of $X$ on which the quotient exists. For GIT, this set depends on a choice of a linearisation, and for analytic Hilbert quotients, it depends on a choice of a moment map for the action of a maximal compact subgroup $K \subseteq G$, as we now explain.

Let $(M, K, \mu)$ be an integrable Hamiltonian Kähler manifold and let $G := K_{\mathbb{C}}$.

Define the set of $\mu$-\textbf{semistable} points by

$$M^{\mu-\text{ss}} := \{ p \in M : G \cdot p \cap \mu^{-1}(0) \neq \emptyset \}$$

and the set of $\mu$-\textbf{polystable} points by

$$M^{\mu-\text{ps}} := \{ p \in M : G \cdot p \text{ is closed in } M^{\mu-\text{ss}} \}.$$

\textbf{Theorem 2.12} (Heinzner–Loose [18]). The set $M^{\mu-\text{ss}}$ is a $G$-invariant open subset of $M$ and the analytic Hilbert quotient $M^{\mu-\text{ss}}//G$ exists. For all $p \in M$, we have

$$p \in M^{\mu-\text{ps}} \iff G \cdot p \cap \mu^{-1}(0) \neq \emptyset.$$

Moreover, the inclusion $\mu^{-1}(0) \to M^{\mu-\text{ss}}$ descends to a homeomorphism $M//_{\mu} K \to M^{\mu-\text{ss}}//G$. Also, for every $p \in M^{\mu-\text{ps}}$ we have $G_p = (K_p)_{\mathbb{C}}$, so $G_p$ is a complex reductive group. \hfill $\square$
**Remark 2.13.** Special cases of Theorem 2.12 were known long before [18]. See, for example, Guillemin–Sternberg [11, §4] and Kirwan [25, §7.5]. It was also obtained independently by Sjamaar [38] under an additional assumption on the moment map. This result can be thought of as an “analytic” version of the Kempf–Ness theorem.

**Remark 2.14.** Heinzner–Loose [18] do not mention analytic Hilbert quotients directly, but the above theorem can be deduced from their proofs. The reformulation which we gave can be found in Heinzner–Huckleberry [14, §0].

The main ingredient in the proof of Heinzner–Loose’s theorem is the Holomorphic Slice Theorem. We briefly review it here, since we will use it later. If \( H \) is a complex Lie subgroup of a complex Lie group \( G \) and \( S \) is a complex \( H \)-manifold, we denote by \( G \times H S \) the quotient of \( G \times S \) by the \( H \)-action \( h \cdot (g, x) = (gh^{-1}, h \cdot x) \). Since the \( H \)-action is free and proper, there is a unique complex manifold structure on \( G \times H S \) such that \( G \times S \rightarrow G \times H S \) is a holomorphic submersion.

**Definition 2.15.** Let \( G \) be a complex reductive group acting holomorphically on a complex manifold \( M \). A **holomorphic slice** at a point \( p \) in \( M \) is a \( G_p \)-invariant complex submanifold \( S \subseteq M \) containing \( p \) such that \( G \cdot S \) is open in \( M \) and the map

\[
G \times G_p S \rightarrow G \cdot S, \quad [g, x] \mapsto g \cdot x
\]

is a \( G \)-equivariant biholomorphism.

**Theorem 2.16** (Holomorphic Slice Theorem [18, §2.7] [38, Theorem 1.12]). Let \((M, K, \mu)\) be an integrable Hamiltonian Kähler manifold. Then, there exists a holomorphic slice at every point \( p \in M^{\mu-ps} \).

**Remark 2.17.** In [18], this is stated only for points \( p \in M \) such that \( \mu(p) \) is fixed by the coadjoint action, but since \( M^{\mu-ps} = G \cdot \mu^{-1}(0) \) we deduce the above version.

This theorem enables us to study \( G \)-equivariant local properties of the complex manifold \( M \) near a closed orbit of \( M^{\mu-ss} \) by the local model \( G \times G_p S \). This was used by Heinzner–Loose to prove the existence of the analytic Hilbert quotient.

### 2.4.3. Stratification of analytic Hilbert quotients

Let \( \pi : X \rightarrow X//G \) be an analytic Hilbert quotient (e.g. a GIT quotient). Then, as in §2.2, the orbit space \( X^{ps}/G \) has a partition by \( G \)-orbit-types, i.e. the pieces are the connected components of the sets \((X^{ps})_{(H)}//G \) for \( H \subseteq G \). Then, the bijection \( X^{ps}/G \rightarrow X//G \) defines a natural partition on \( X//G \) which we call the **\( G \)-orbit-type partition**. Equivalently, the orbit-type of a point \( p \in X//G \) is defined to be the orbit-type of the unique closed orbit in \( \pi^{-1}(p) \).

If \((M, K, \mu)\) is a Hamiltonian Kähler manifold, then \( M//\mu K \cong M^{\mu-ss}//G \) is an analytic Hilbert quotient and hence has a \( G \)-orbit-type partition. But it also has the \( K \)-orbit-type partition of Sjamaar–Lerman. Moreover, each stratum in the \( K \)-orbit-type partition is a Kähler manifold, and hence has a complex structure. The next result shows that these partitions and complex structures are the same.

**Theorem 2.18** (Sjamaar [38, Theorem 2.10]).

(i) The homeomorphism \( M//\mu K \rightarrow M^{\mu-ss}//G \) is an isomorphism of partitioned spaces.

(ii) The \( G \)-orbit-type strata of \( M^{\mu-ss}//G \) are complex submanifolds.
(iii) Let $S$ be a $K$-orbit-type stratum in $M//K$ and $S'$ the corresponding $G$-orbit-type stratum in $M^{\text{ss}}//G$. Then, the restriction $S \to S'$ is a biholomorphism with respect to Kähler structure on $S$ and the complex structure on $S'$ obtained from (ii).

\[\square\]

Remark 2.19. (iii) is not stated in this way in [38], but is part of the proof.

Remark 2.20. As explained earlier, Sjamaar [38] obtained Heinzner–Loose’s Theorem 2.12 independently, but under an additional assumption on the moment map which he called admissibility. He then stated Theorem 2.18 under the same assumption, but his proof relies only on the validity of Theorem 2.12 but not on the admissibility of the moment map.

2.5. Hyperkähler quotients. The goal of this section is to prove Theorem 1.1. We follow Dancer–Swann [5], refining slightly their arguments to get the uniqueness part of the theorem. The proof is similar to the construction of the Kähler structures on the orbit-type strata of a Kähler quotient explained in §2.4.

We use the notation and terminology of the introduction (§1.2). Let $(M, K, \mu)$ be a tri-Hamiltonian hyperkähler manifold and let $S \subseteq M//K$ be an orbit-type piece. Then, $S$ is a connected component of a set of the form $\mu^{-1}(0)(H)//K$ for some closed subgroup $H \subseteq K$. The set $M_H$ of points with stabiliser $H$ is now a hyperkähler submanifold of $M$ and $\mu$ restricts to a hyperkähler moment map $\mu_H : M_H \to \mathfrak{t}^* \otimes \mathbb{R}^3 \subseteq \mathfrak{t}^* \otimes \mathbb{R}^3$ for the free action of $L := N_K(H)/H$ on the union $M_H$ of the connected components of $M_H$ intersecting $\mu^{-1}(0)$. Hence, the connected components of $M_H//L = \mu_H^{-1}(0)/L$ are smooth hyperkähler manifolds by the usual hyperkähler quotient construction [21, Theorem 3.2]. Moreover, the inclusion $\mu_H^{-1}(0) \subseteq \mu^{-1}(0)(H)$ descends to a homeomorphism $M_H//L \to \mu^{-1}(0)(H)//K$ and hence endows each connected component of $\mu^{-1}(0)(H)//K$ with a hyperkähler structure. To show that this map is indeed a homeomorphism and also to characterise the hyperkähler structures, we will need the following lemma. This result is implicit in Sjamaar–Lerman [39] and Dancer–Swann [5], but we give a short proof for completeness.

Lemma 2.21. Let $K$ be a compact Lie group acting smoothly on a smooth manifold $M$, let $H$ be a closed subgroup of $K$, and let $L = N_K(H)/H$. Then, $M_H$ and $M_{(H)}$ are smooth submanifolds of $M$, and the quotients $M_H//L$ and $M_{(H)}//K$ are topological manifolds with unique smooth structures such that the quotients maps $M_H \to M_H//L$ and $M_{(H)} \to M_{(H)}//K$ are smooth submersions. Moreover, the inclusion $M_H \hookrightarrow M_{(H)}$ descends to a diffeomorphism $M_H//L \to M_{(H)}//K$.

Proof. This follows easily from the slice theorem for proper group actions. The map $M_H//L \to M_{(H)}//K$ is bijective, so everything reduces to local statements. Hence we may assume (by the slice theorem) that $M = K \times W$ for some representation $W$ of $H$. Then, $M_H = L \times W_H$, $M_{(H)} = K/H \times W_H$, and $W_H$ is a linear subspace of $W$ (the set of fixed points of $H$), so $M_H$ and $M_{(H)}$ are smooth submanifolds of $M$. Moreover, $M_H//L = W_H$ and the quotient map $M_H \to M_H//L$ is the projection $L \times W_H \to W_H$ and hence is a smooth submersion. Similarly, the quotient map $M_{(H)} \to M_{(H)}//K$ is the projection $K/H \times W_H \to W_H$. Under these identifications, the map $M_H//L \to M_{(H)}//K$ is the identity map $W_H \to W_H$.

Proof of Theorem 1.1. Let $S \subseteq M//K$ be an orbit-type piece. Let $Z := \mu^{-1}(0)$ so that $S$ is a connected component of $Z_{(H)}//K$ for some $H \subseteq K$. As explained
above, $Z_H$ is a smooth submanifold of $M_H$ and $Z_H/L$ is a hyperkähler manifold, where $L := N_K(H)/K$. Now, $Z_H/L$ is a smooth submanifold of $M_H/L$ and its image under the diffeomorphism $M_H/L \to M_{(H)}/K$ is $Z_{(H)}/K$, so the latter is also smooth. Hence, by the transversality theorem applied to $M_{(H)} \to M_{(H)}/K$, $Z_{(H)}$ is a smooth submanifold of $M_{(H)}$ and $Z_{(H)} \to Z_{(H)}/K$ is a smooth submersion. Note that $\pi^{-1}(S)$ is open in $Z_{(H)}$, so it is also a smooth submanifold and the restriction $\pi^{-1}(S) \to S$ is a smooth submersion. Moreover, $\pi^{-1}(S)$ has pure dimension since $S$ is connected and all fibres are diffeomorphic to $K/H$.

To prove the claim about the hyperkähler structure, let $\eta, \eta, \eta_K$ be the Kähler forms on $Z_{(H)}/K$ induced by the diffeomorphism $Z_H/L \to Z_{(H)}/K$ and consider the commutative diagram

$$
\begin{array}{ccc}
Z_H & \xrightarrow{i} & Z_{(H)} \\
\downarrow\rho & & \downarrow\pi \\
Z_H/L & \xrightarrow{\varphi} & Z_{(H)}/K.
\end{array}
$$

We want to show that $\pi^*\eta = j^*\omega_1$ and similarly for $J$ and $K$. By construction, we have $i^*\pi^*\eta = \rho^*\varphi^*\eta = i^*j^*\omega_1$ and hence $\pi^*\eta$ and $j^*\omega_1$ agree on $T_pZ_H$ for all $p \in Z_H$. Note that since $d\varphi_p$ and $d\rho_p$ are surjective we have $T_pZ_{(H)} = T_pZ_H + \ker d\varphi_p$. Thus, to prove that $\pi^*\eta$ and $j^*\omega_1$ agree on $T_pZ_{(H)}$ it suffices to show that if $u \in \ker d\varphi_p$ and $v \in T_pZ_{(H)}$ then $\pi^*\eta(u,v) = j^*\omega_1(u,v)$. Clearly, $\pi^*\eta(u,v) = 0$ since $d\pi_p(u) = 0$. To show that also $j^*\omega_1(u,v) = 0$, note that $\ker d\varphi_p = T_p(K \cdot p)$ so $u = x^\#$ for some $x \in t$ and hence $\omega_1(u,v) = i_x \omega_1(v) = d\langle \mu_x, x \rangle(v) = 0$ since $v \in T_pZ_{(H)} \subseteq \ker d\mu_p$. Hence, $\pi^*\eta$ and $j^*\omega_1$ agree on $T_pZ_{(H)}$ for all $p \in Z_H$ and since they are $K$-invariant and $K \cdot Z_H = Z_{(H)}$ we conclude that $\pi^*\eta = j^*\omega_1$. The same argument also shows that $\pi^*\eta_J = j^*\omega_J$ and $\pi^*\eta_K = j^*\omega_K$. Since a hyperkähler structure is completely determined by its three symplectic forms (e.g. $I = \omega_K^{-1}\omega_J$), this proves the proposition.

3. A LOCAL NORMAL FORM FOR THE UNDERLYING COMPLEX-HAMILTONIAN MANIFOLD

3.1. Overview. The goal of this section is to prove Theorem 1.3, which establishes a local normal form for the underlying complex-Hamiltonian manifold of a tri-Hamiltonian hyperkähler manifold analogous to the local normal form of Guillemin–Sternberg [12] and Marle [29].

Throughout this section, $(M, K, \mu)$ is an $I$-integrable tri-Hamiltonian hyperkähler manifold and $G := K_C$. Then, $\omega_C := \omega_I + i\omega_K$ is a complex-symplectic form on $(M, I)$ and $\mu_C := \mu_I + i\mu_K : M \to \mathfrak{g}$ is a holomorphic moment map for the action of $G$ on $(M, I, \omega_C)$ (see [21, §3(D)]). We call $(M, I, \omega_C, G, \mu_C)$ the underlying complex-Hamiltonian manifold of $(M, K, \mu)$.

Let $\mu_R := \mu_I$ so that $(M, K, \mu_R)$ is an integrable Hamiltonian Kähler manifold as in §2.4. In particular, we have the sets $M^{\mu_C-ss}$ and $M^{\mu_C-ps}$ as in §2.4.2, and we will use the notations

$$
\mu_C^{-1}(0)^{\mu_C-ss} := \mu_C^{-1}(0) \cap M^{\mu_C-ss} \quad \text{and} \quad \mu_C^{-1}(0)^{\mu_C-ps} := \mu_C^{-1}(0) \cap M^{\mu_C-ps}.
$$

The idea of the local normal form for the moment map is to show that in a neighbourhood of a point $p \in \mu^{-1}(0)$, the underlying complex-Hamiltonian manifold
(M, l, ωC, G, μC) is completely determined by the representation of H := Gp on the complex-symplectic slice
\[ V := (T_p(G \cdot p))^{ac}/T_p(G \cdot p). \]

By the Holomorphic Slice Theorem 2.16, the orbit G \cdot p is embedded in M, so the tangent space \( T_p(G\cdot p) \) is well-defined. We have \( T_p(G\cdot p) \subseteq \ker(\text{d}\mu_C)_p = (T_p(G\cdot p))^{ac} \) and hence V is a well-defined complex-symplectic vector space. Moreover, H := Gp = (Kp)C (by Theorem 2.12), so H is a complex reductive group acting linearly on V and preserving its complex-symplectic form. In other words, p determines a complex-symplectic representation \( \rho : H \to \text{Sp}(V, \omega_C) \). The goal of Theorem 1.3 is to construct a complex-Hamiltonian manifold E from G and p which is isomorphic to a neighbourhood of p in (M, I, ωC, G, μC). The construction of E is the same as the one used by Guillemin–Sternberg [12], but in a complex-symplectic setting; see also [39, §2] and [28].

In §3.2 we recall the constructing of the local model E. In §3.3, we prove a holomorphic version of the Darboux–Weinstein theorem which we will need for the proof of Theorem 1.3. In §3.4, we reformulate the Holomorphic Slice Theorem in a way that is more suitable for our purpose. Finally, we prove Theorem 1.3 in §3.5.

3.2. The local model. Let G be a complex reductive group, H a reductive subgroup of G, and (V, ωC) a complex-symplectic representation of H. Then, \( T^*G \) has the canonical complex-symplectic form \( -d\theta \), where \( \theta \) is the tautological holomorphic 1-form. We identify \( T^*G \) with \( G \times g^* \) via left translation, i.e. via the biholomorphism
\[ G \times g^* \to T^*G, \quad (g, \xi) \mapsto (dL_{g^{-1}})^*(\xi), \]
where \( L_{g^{-1}} : G \to G \) is left multiplication by \( g^{-1} \).

Recall that a Lie group action on any manifold lifts to a Hamiltonian action on the cotangent bundle. By considering the action of \( G \times G \) on G by left and right multiplications (i.e. \( (a, b) \cdot g := agb^{-1} \)) its lift to \( T^*G = G \times g^* \) is \( (a, b) \cdot (g, \xi) = (agb^{-1}, \text{Ad}_g^* \xi) \), and the moment map is
\[ T^*G \to g^* \times g^*, \quad (g, \xi) \mapsto (\text{Ad}_g^* \xi, -\xi) \]
(see e.g. [1, §4.4]). The representation H → Sp(V, ωC) can also be viewed as a complex-Hamiltonian H-manifold with moment map \( \Phi_V : V \to h^* \), \( \Phi_V(v)(x) = \frac{i}{2} \omega_C(xv, v) \). Thus, there is an Hamiltonian action of H on \( T^*G \times V \), where H acts on \( T^*G \) as the subgroup \( 1 \times H \subseteq G \times G \) and on V by the given representation. Let E be the complex-symplectic reduction of \( T^*G \times V \) by H. Since the action of H on \( T^*G \times V \) is free and proper, E is a complex-symplectic manifold. Moreover, the Hamiltonian action of \( G \times 1 \) on \( T^*G \) descends to a Hamiltonian action of G on E, making E into a complex-Hamiltonian G-manifold.

We can also rewrite E in a more convenient form where the complex moment map for the G-action is explicit. First, note that the complex moment map for the action of H on \( T^*G \times V \) is
\[ \lambda : T^*G \times V \to h^*, \quad \lambda(g, \xi, v) = \Phi_V(v) - \xi|_h. \]
Take a Hermitian inner-product on g invariant under the maximal compact subgroup \( K \subseteq G \) and let \( m \) be the orthogonal complement to h in g. This defines an H-equivariant isomorphism \( h^* \cong m^* \subset g^* \) so we can view \( \Phi_V \) as taking values in \( g^* \). Then, the map
\[ G \times h^* \times V \to \lambda^{-1}(0), \quad (g, \xi, v) \mapsto (g, \xi + \Phi_V(v), v) \]
is a biholomorphism. The $H$-action on $\lambda^{-1}(0)$ corresponds to the $H$-action on $G \times h^0 \times V$ given by $h \cdot (g, \xi, v) = (gh^{-1}, \text{Ad}_h^* \xi, h \cdot v)$, so $E$ is the holomorphic vector bundle

\begin{equation}
E = G \times_H (h^0 \times V)
\end{equation}

over $G/H$. In this setup, the Hamiltonian $G$-action is

\begin{equation}
G \times E \to E, \quad a \cdot [g, \xi, v] = [ag, \xi, v]
\end{equation}

and the complex moment map is

\begin{equation}
\kappa : G \times_H (h^0 \times V) \to \mathfrak{g}^*, \quad [g, \xi, v] \mapsto \text{Ad}_g^* \xi + \Phi_V(v).
\end{equation}

We summarise this discussion in the following proposition.

**Proposition 3.1.** Let $G$ be a complex reductive group, $H$ a reductive subgroup of $G$, and $V$ a complex-symplectic representation of $H$. Then, the complex-symplectic manifold (3.3) with the action (3.4) and moment map (3.5) is a complex-Hamiltonian manifold.

**Remark 3.2.** Dancer–Swann [4] showed that $E$ is a tri-Hamiltonian hyperkähler manifold whose underlying complex-Hamiltonian manifold is the one described above.

### 3.3. Holomorphic Darboux–Weinstein Theorem

The Darboux–Weinstein theorem [42] is a standard result in symplectic geometry which says that if two symplectic forms $\omega_0$ and $\omega_1$ on a manifold $M$ agree on a submanifold $N \subseteq M$, then we can find a diffeomorphism $f$ on a neighbourhood of $N$ such that $f^* \omega_1 = \omega_0$. There is also an equivariant version of the theorem, where if $\omega_0$, $\omega_1$ and $N$ are invariant under the action of a compact Lie group, then $f$ can be taken to be equivariant.

By the tubular neighbourhood theorem, it suffices to prove the result when $M$ is a vector bundle and $N$ the zero-section, and this is indeed how Weinstein’s original proof goes [42]. In the holomorphic setting, there is no tubular neighbourhood theorem, but we can still adapt Weinstein’s proof to formulate a similar statement on holomorphic vector bundles:

**Theorem 3.3.** Let $G$ be a group acting on a holomorphic vector bundle $E$ by bundle automorphisms (not necessarily fixing the base). Let $\omega_0$ and $\omega_1$ be two $G$-invariant complex-symplectic forms on a $G$-invariant neighbourhood $U$ of the zero-section $Z \subseteq E$ such that $\omega_0|_Z = \omega_1|_Z$. Then, there are $G$-invariant neighbourhoods $U_0$ and $U_1$ of $Z$ in $U$ and a $G$-equivariant biholomorphism $f : U_0 \to U_1$ such that $f^* \omega_1 = \omega_0$ and $f|_Z = 1|_Z$.

**Remark 3.4.** Here $\omega_1|_Z$ is the restriction of $\omega_1$ to $(\Lambda^2 T^* E)|_Z$ (this is not the same as the pullback to $Z$).

The rest of this subsection is devoted to the proof of this theorem. Let us first briefly sketch how we will proceed. The first step is to get a “Poincaré lemma” for the retraction of $U$ onto $Z$, i.e. to construct an explicit homotopy operator $I : \Omega^k(U) \to \Omega^{k-1}(U)$ between the identity map and $\pi^*$, where $\pi : U \to U, v \mapsto 0 \cdot v$. Then, $\alpha = I(\omega_0 - \omega_1)$ is a 1-form on $U$ and, for $t$ small enough, $\omega_t := \omega_0 + t(\omega_1 - \omega_0)$ is non-degenerate, so we get a time-dependent holomorphic vector field $X_t = \omega_t^{-1}(\alpha)$ on a neighbourhood of $Z$. The proof concludes by showing that the time-dependent flow of $X$ gives a biholomorphism with the desired properties.
Let us now construct the homotopy operator. Let $\mathbb{D}$ be the closed unit disc centred at $0$ in $\mathbb{C}$ and let $U \subseteq E$ be as in Theorem 3.3. By shrinking $U$ if necessary, we may assume that it is preserved by $\mathbb{D}$, i.e., $zu \in U$ for all $z \in \mathbb{D}$ and $u \in U$. Let

$$W := \{(z, u) \in \mathbb{C} \times U : zu \in U\}.$$ 

Then, $W$ is open in $\mathbb{C} \times U$ and $\mathbb{D} \times U \subseteq W$. Let

$$\lambda : W \longrightarrow U, \quad (z, u) \longmapsto zu,$$

and for each $z \in \mathbb{D}$ let

$$\iota_z : U \longrightarrow W, \quad u \longmapsto (z, u).$$

Let $\Omega^k(U)$ be the space of holomorphic $k$-forms on $U$. Then, for all $\omega \in \Omega^k(U)$, we have a family of holomorphic $(k-1)$-forms $\iota_z^* i_{\partial_z} \lambda^* \omega \in \Omega^{k-1}(U)$ depending holomorphically on $z \in \mathbb{D}$, where $i_{\partial_z}$ is the interior product with the vector field $\partial_z := \frac{\partial}{\partial z}$ on $W \subseteq \mathbb{C} \times E$. Hence, we have a linear operator

$$I : \Omega^k(U) \longrightarrow \Omega^{k-1}(U), \quad I\omega := \int_0^1 (\iota_z^* i_{\partial_z} \lambda^* \omega) dz.$$ 

Let $\pi : U \rightarrow U$ be the projection onto the zero-section.

**Proposition 3.5.** We have $d(I\omega) + I(d\omega) = \omega - \pi^* \omega$ for all $\omega \in \Omega^k(U)$, i.e. $I$ is a homotopy operator between the identity map and $\pi^*$.

**Proof.** We have

$$d(I\omega) + I(d\omega) = \int_0^1 \iota_z^* (d\iota_{\partial_z} \lambda^* \omega + i_{\partial_z} d\lambda^* \omega) dz = \int_0^1 (\iota_z^* L_{\partial_z} \lambda^* \omega) dz.$$ 

Now, the flow $\theta_t$ of $\partial_z$ is $\theta_t(z, u) = (z + t, u) = \iota_{z+t}(u)$, so $\theta_1 \circ \iota_0 = \iota_t$. Hence

$$\iota_z^* L_{\partial_z} \lambda^* \omega = \iota_0^* \theta_1^* L_{\partial_z} \lambda^* \omega = \iota_0^* \theta_1^* \lambda^* \omega = \frac{d}{dt} \iota_0^* \theta_t^* \lambda^* \omega,$$

so we get

$$d(I\omega) + I(d\omega) = \int_0^1 \frac{d}{dt} \iota_0^* \theta_t^* \lambda^* \omega dt = \iota_0^* \theta_1^* \lambda^* \omega - \iota_0^* \theta_0^* \lambda^* \omega = \omega - \pi^* \omega. \quad \square$$

The following observation will be useful.

**Lemma 3.6.** Let $\omega \in \Omega^k(U)$ and let $p \in Z$. If $\omega_p = 0$ then $(I\omega)_p = 0$.

**Proof.** For all $v \in (T_pU)^{k-1}$, we have $(\iota_z^* i_{\partial_z} \lambda^* \omega)_p(v) = \omega_z p(d\lambda(\partial_z), d\lambda(dt_z(v))) = 0$ since $zp = p$ as $p \in Z$. Thus, $(\iota_z^* i_{\partial_z} \lambda^* \omega)_p = 0$ for all $z$ and hence $(I\omega)_p = 0$. \quad \square

**Proof of Theorem 3.3.** Let $\eta = \omega_1 - \omega_0$ and let $\alpha = -I\eta \in \Omega^1(U)$. Then, $\eta = -d\alpha$ by Proposition 3.5. Since $\eta$ is $G$-invariant, it follows from the definition of $I$ that $\alpha$ is also $G$-invariant. Moreover, since $\eta|_Z = 0$ we have $\alpha|_Z = 0$ by Lemma 3.6.

For each $z \in \mathbb{C}$, define a $G$-invariant holomorphic 2-form on $U$ by $\omega_z = \omega_0 + z\eta$. We have $\omega_z|_Z = \omega_0|_Z$, so in particular, $\omega_z|_Z$ is non-degenerate for all $(z, p) \in \mathbb{C} \times Z$. Let $\mathbb{D}_r$ be the open disc of radius $r$ centred at $0$ in $\mathbb{C}$. By compactness of $\mathbb{D}_2$, we can find a neighbourhood $U' \subseteq U$ of $Z$ such that $\omega_z|_{U'}$ is non-degenerate for all $(z, p) \in \mathbb{D}_2 \times U'$. Moreover, by $G$-invariance of $\omega_z$, we can take $U'$ to be $G$-invariant. Thus, we may assume that $\omega_z|_{U'}$ is non-degenerate for all $(z, p) \in \mathbb{D}_2 \times U$. In particular, the maps

$$\hat{\omega}_z : TU \longrightarrow T^* U, \quad v \longmapsto \omega_z(v, \cdot)$$
are vector bundle isomorphisms for all \( z \in \mathbb{D}_2 \). Define a holomorphic family of vectors fields on \( U \) by
\[
X : \mathbb{D}_2 \times U \to TU, \quad (z, p) \mapsto (\hat{\alpha}_p).
\]

Let \( J = \mathbb{D}_2 \cap \mathbb{R} = (-2, 2) \) and let \( \psi : \mathcal{E} \to U \) be the smooth time-dependent flow of the restriction \( X|_{J \times U} \). That is, \( \mathcal{E} \) is the open subset of \( J \times J \times M \) such that for all \((t_0, p) \in J \times M \), the map \( \psi(t_0, p)(t) := \psi(t, t_0, p) \) is the maximally extended integral curve of \( X|_{J \times U} \) starting at \((t_0, p)\). From the general theory of smooth time-dependent flows (see e.g. [27, Theorem 9.48]), for all \((t_1, t_0) \in J \times J \) the set
\[
U(t_1, t_0) := \{ p \in U : (t_1, t_0, p) \in \mathcal{E} \}
\]
is open, and the map
\[
\psi(t_1, t_0) : U(t_1, t_0) \to U(t_0, t_1), \quad p \mapsto \psi(t_1, t_0, p)
\]
is a diffeomorphism. Moreover, since \( X \) is holomorphic, \( \psi(t_1, t_0) \) is a biholomorphism (this follows from the holomorphic dependence of solutions to linear systems of ODEs on the initial conditions; see e.g. [3, Ch. 1, §8]). Since \( \alpha|_Z = 0 \) we have \( X|_{(t_0, p)} = 0 \) for all \((t_0, p) \in J \times Z \), and hence \( \psi(t_1, t_0, p) = p \) for all \((t_1, t_0, p) \in J \times J \times Z \). In particular, \( J \times J \times Z \subseteq \mathcal{E} \), so \( U(1, 0) \) and \( U(0, 1) \) contain \( Z \). We claim that the biholomorphism \( \psi_1,0 : U_{1,0} \to U_{0,1} \) is the one we need. First, since \( \omega \) and \( \omega_1 \) are \( G \)-invariant, so is \( X \). Hence, \( U_{1,0} \) and \( U_{0,1} \) are \( G \)-invariant, and \( \psi_1,0 \) is \( G \)-equivariant. Moreover, from [27, Proposition 22.15] we have for all \( t_1 \in J \),
\[
\frac{d}{dt} \bigg|_{t=t_1} \psi^*_{t_1,0} \omega_1 = \psi^*_{t_1,0} \left( L_{X_{t_1}} \omega_{t_1} + \frac{d}{dt} \bigg|_{t=t_1} \omega_{t_1} \right) = \psi^*_{t_1,0} \left( i_{X_{t_1}} d\omega_{t_1} + d|_{t=t_1} X_{t_1} \omega_{t_1} + \eta \right) = 0.
\]
Thus, \( \psi^*_{t_1,0} \omega_1 = \psi^*_{0,0} \omega_0 = \omega_0 \).

3.4. Linearisation of the Holomorphic Slice Theorem. In this subsection, we explain how to put the Holomorphic Slice Theorem 2.16 in a form which will be more convenient for our purpose. First, we want to linearise the slice and realise neighbourhoods of orbits in \( M \) as neighbourhoods of zero-sections of vector bundles.

**Proposition 3.7.** Let \((M, K, \mu)\) be an integrable Hamiltonian Kähler manifold, let \( p \in M^{\mu\text{-ss}} \), let \( G := K_C \), let \( H := G_p \), and let \( W := T_p M / T_p (G \cdot p) \). Then, there is an open ball \( B \) centred at 0 in \( W \), a \( G \)-invariant neighbourhood \( U \) of \( p \) in \( M \), and a \( G \)-equivariant biholomorphism \( G \times H / (H \cdot B) \to U \) mapping \([1, 0] \) to \( p \).

**Proof.** This is an intermediate step in Sjamaar’s proof of the Holomorphic Slice Theorem: see the top of p. 101 in [38]. It can also be proved by linearising the action of \( G_p \) on the slice \( S \) at \( p \) [38, Theorem 1.21].

It will be important to know that the open set \( U \) of the preceding proposition can be taken to be \( G \)-saturated. First, we have:

**Proposition 3.8.** Let \((M, K, \mu)\) be an integrable Hamiltonian Kähler manifold and let \( p \in M^{\mu\text{-ss}} \). Then, every \( G \)-invariant neighbourhood of \( p \) contains a neighbourhood of \( p \) which is \( G \)-saturated in \( M^{\mu\text{-ss}} \).

**Proof.** Our argument is similar to [20, Remark 14.24]. As observed in [19, Remark 1.1], the quotient map \( \pi : M^{\mu\text{-ss}} \to M^{\mu\text{-ss}}//G \) sends \( G \)-invariant closed subsets to closed subsets. Let \( U \) be a \( G \)-invariant neighbourhood of \( p \) in \( M^{\mu\text{-ss}} \). Then,
$C := M^{\mu-ss} - U$ is a $G$-invariant closed subset of $M^{\mu-ss}$, so $\pi(C)$ is closed in $M^{\mu-ss}/G$. Moreover, since $G \cdot p$ is closed in $M^{\mu-ss}$, we have $\pi(p) \notin \pi(C)$. Hence, $\pi^{-1}(M^{\mu-ss}/G - \pi(C))$ is a $G$-saturated neighbourhood of $p$ contained in $U$. □

The set $H \cdot B$ in Proposition 3.7 is also $H$-saturated [40, Corollary 4.9] and it follows that $G \times_H (H \cdot B)$ is $G$-saturated in $G \times_H W$. We can then restate the Holomorphic Slice Theorem in the following form:

**Theorem 3.9.** Let $(M, K, \mu)$ be an integrable Hamiltonian Kähler manifold. Let $p \in M^{\mu-ss}$, let $G := K \subseteq$, let $H := G_p$, and let $W := T_pM/T_p(G \cdot p)$. Then, there is a $G$-saturated neighbourhood $U$ of $p$ in $M^{\mu-ss}$, a $G$-saturated neighbourhood $U'$ of the zero-section of the vector bundle $G \times_H W$, and a $G$-equivariant biholomorphism $U' \to U$ mapping $[1, 0]$ to $p$.

**Proof.** Let $\varphi : G \times_H (H \cdot B) \to U$ be the biholomorphism of Proposition 3.7. By Proposition 3.8, there is a $G$-saturated neighbourhood $U'$ of $p$ contained in $U$. Let $B' \subseteq B$ be an open ball sufficiently small so that $U := \varphi(G \times_H (H \cdot B')) \subseteq U'$. Then, $U''$ is $G$-saturated. □

### 3.5. Proof of the Complex-Hamiltonian Local Normal Form.

We now complete the proof of Theorem 1.3. The first step is to have an explicit expression for the complex-symplectic form $\eta_G$ of the local model $E = G \times_H (\mathfrak{h}^\ast \times V)$ at the point $q = [1, 0, 0]$. Note that $G_q = H$, so $H$ acts linearly on $T_qE$. Since the $G$-action is Hamiltonian, this is a complex-symplectic representation of $H$ on $T_qE$. Recall that $\mathfrak{m} \subseteq \mathfrak{g}$ is the orthogonal complement to $\mathfrak{h}$.

**Proposition 3.10.** We have $T_qE \cong \mathfrak{m} \times \mathfrak{m}^\ast \times V$ as complex-symplectic $H$-representations, where $\mathfrak{m} \times \mathfrak{m}^\ast$ has the canonical symplectic form $(\langle x, \varphi \rangle, \langle y, \psi \rangle) \mapsto \psi(x) - \varphi(y)$. Moreover, $T_q(G \cdot q) \cong \mathfrak{m} \times 0 \times 0$ under this isomorphism.

**Proof.** The canonical symplectic form on $T^*G = G \times \mathfrak{g}^\ast$ at $T(g, \xi)(T^*G) = \mathfrak{g} \times \mathfrak{g}^\ast$ is

$$
\langle (x, \varphi), (y, \psi) \rangle \mapsto \psi(x) - \varphi(y) + \xi([x, y])
$$

(see e.g. [1, Proposition 4.4.1]). In particular, if $\tilde{q} := (1, 0, 0) \in T^*G \times V$, the symplectic form on $T^*G \times V$ at $T_q(T^*G \times V) = \mathfrak{g} \times \mathfrak{g}^\ast \times V$ is

$$
\langle (x, \varphi, u), (y, \psi, v) \rangle \mapsto \psi(x) - \varphi(y) + \omega_G(u, v).
$$

Now, we have $d\lambda_\tilde{q}(x, \xi, v) = -\xi|_{\mathfrak{h}}$, so the tangent space to $\lambda^{-1}(0)$ at $\tilde{q}$ is $\mathfrak{g} \times \mathfrak{h}^\circ \times V$. Moreover, $T_q(H \cdot \tilde{q}) = \mathfrak{h} \times 0 \times 0$, so

$$
T_q(\lambda^{-1}(0)/H) = T_q\lambda^{-1}(0)/T_q(G \cdot \tilde{q}) = \mathfrak{g}/\mathfrak{h} \times \mathfrak{h}^\circ \times V.
$$

Identifying $\mathfrak{g}/\mathfrak{h}$ with $\mathfrak{m}$ and $\mathfrak{h}^\circ$ with $\mathfrak{m}^\ast$ gives the result. □

**Lemma 3.11.** Let $H \to \text{Sp}(R, \omega)$ be a complex-symplectic representation and $S \subseteq R$ an $H$-invariant isotropic subspace. Then, $R/S \cong S^\ast \times S^\omega/S$ as $H$-modules.

**Proof.** Let $R \to S^\ast$ be the composition of the isomorphism $R \to R^\ast$ induced by $\omega$ with the restriction map $R^\ast \to S^\ast$. Let $R \to S^\omega$ be the projection along the $H$-invariant complement of $S^\omega$ in $R$ (by complete reducibility). These maps give an $H$-equivariant surjective map $R \to S^\ast \times S^\omega/S$ with kernel $S^\omega \cap S$. Since $S$ is isotropic, we have $S^\omega \cap S = S$. □
Proof of Theorem 1.3. Since $T_p(G \cdot p) \cong g/\mathfrak{h}$ is isotropic in $T_pM$, Lemma 3.11 implies that $T_p^2M/T_p(G \cdot p) \cong \mathfrak{h}^\circ \times V$, where $V$ is the complex-symplectic slice at $p$. Thus, by Theorem 3.9, there is a $G$-saturated neighbourhood of $p$ in $M^{\mu_{\mathbb{R}}\text{-ss}}$ which is $G$-equivariantly biholomorphic to a $G$-saturated neighbourhood of $q = [1, 0, 0]$ in $E = G \times_H (\mathfrak{h}^\circ \times V)$. Note that by Proposition 3.10, $T_q(G \cdot q)$ is also isotropic with respect to the canonical complex-symplectic form on $E$. Note also that any $G$-invariant neighbourhood of the zero-section $0_E = G \cdot q$ of $E$ contains a $G$-saturated neighbourhood, namely $G \times_H (H \cdot B)$ for a sufficiently small ball $B$. Hence, it suffices to show that, for any two $G$-invariant complex-symplectic forms $\omega_C$ and $\eta_C$ on a $G$-invariant neighbourhood of the zero-section $0_E = G \cdot q$ in $E$ such that $T_q0_E$ is isotropic with respect to both, there is a $G$-equivariant biholomorphism on a possibly smaller neighbourhood of $0_E$ which pulls back $\eta_C$ to $\omega_C$. By the holomorphic version of the Darboux–Weinstein given in Theorem 3.3, it suffices to find such a biholomorphism that makes them match on $0_E$. This can be reduced to a linear algebraic problem, as we now explain. The proof is inspired from [28, Proposition 2].

Since $T_q0_E \subseteq T_qE$ is isotropic with respect to both $\omega_C$ and $\eta_C$, [28, Lemma 6] says that there exists an $H$-equivariant linear isomorphism $\varphi : T_qE \rightarrow T_qE$ which restricts to the identity on $T_q0_E$ and such that $\varphi^*\eta_C = \omega_C$. We have $T_qE = m \times m^* \times V$ and $T_q0_E = m \times 0 \times 0$, so $\varphi$ is of the form

$$\varphi : m \times m^* \times V \rightarrow m \times m^* \times V, \quad \varphi(x, \xi, v) = (x + A(\xi, v), B(\xi, v)),$$

where $A : m^* \times V \rightarrow m$ and $B : m^* \times V \rightarrow m^* \times V$ are some linear maps, with $B$ invertible. Then,

$$\psi : E \rightarrow E, \quad \psi([g, \xi, v]) = [ge^{A(\xi, v)}, B(\xi, v)]$$

is a $G$-equivariant biholomorphism with $d\psi_q = \varphi$. In particular, $\psi^*\eta_C|_q = \omega_C|_q$ and, since $\omega_C$ and $\eta_C$ are $G$-invariant and $\psi$ is $G$-equivariant, this implies that $\psi^*\eta_C|_{g \cdot q} = \omega_C|_{g \cdot q}$ for all $g \in G$, i.e., $\psi^*\eta_C|_{0_E} = \omega_C|_{0_E}.$

We can now apply Theorem 3.3, which shows the existence of a $G$-equivariant complex-symplectic isomorphism $f : U \rightarrow U'$ such that $f(p) = q$, where $U$ is a $G$-saturated neighbourhood of $p$ in $M^{\mu_{\mathbb{R}}\text{-ss}}$ and $U'$ a $G$-saturated neighbourhood of $q$ in $E$. It remains to show that $\kappa \circ f = \mu_C$. Since $(\kappa \circ f)(p) = 0 = \mu_C(p)$ and since moment maps are unique up to a constant (see e.g. [37, Ch. 26]) it suffices to show that $\kappa \circ f$ is a moment map for the $G$-action on $M^{\mu_{\mathbb{R}}\text{-ss}}$. This follows from the fact that $f$ is a $G$-equivariant complex-symplectic isomorphism. \hfill \Box

4. Stratification of singular hyperkähler quotients

The goal of this section is to prove Theorem 1.4, describing the structure of singular hyperkähler quotients. Throughout this section, $(M, K, \mu)$ will be a fixed $1$-integrable tri-Hamiltonian hyperkähler manifold.

4.1. Complex-analytic structure. Let us first explain how the results on analytic Hilbert quotients of §2.4 help us define a complex-analytic structure on $M//K$. We use the notation of §3; in particular, $G := K_C$, $\mu_C := \mu_J + i\mu_K$, and $\mu_R := \mu_I$. First, note that $\mu_C^{-1}(0)^{\mu_{\mathbb{R}}\text{-ss}} := \mu_C^{-1}(0) \cap M^{\mu_{\mathbb{R}}\text{-ss}}$ is a $G$-invariant closed complex-analytic subspace of $M^{\mu_{\mathbb{R}}\text{-ss}}$. Hence, by Proposition 2.11(ii), its image $\mu_C^{-1}(0)^{\mu_{\mathbb{R}}\text{-ss}}//G$ in $M^{\mu_{\mathbb{R}}\text{-ss}}//G$ is a closed complex-analytic subspace, and the restriction

$$\mu_C^{-1}(0)^{\mu_{\mathbb{R}}\text{-ss}} \rightarrow \mu_C^{-1}(0)^{\mu_{\mathbb{R}}\text{-ss}}//G$$
is an analytic Hilbert quotient. Note that the space \( \mu_{C}^{-1}(0) \mu_{K}^{-ss} \) has a \( G \)-orbit-type partition as in §2.4.3 and \( M//K \) has a \( K \)-orbit-type partition into hyperkähler manifolds by Theorem 1.1. Moreover, by Heinzner–Loose’s Theorem 2.12 and Sjamaar’s Theorem 2.18(i), we have \( \mu_{C}^{-1}(0) \subseteq \mu_{C}^{-1}(0) \mu_{K}^{-ss} \), and this inclusion descends to an isomorphism

\[
M//K \to \mu_{C}^{-1}(0) \mu_{K}^{-ss} // G
\]

of partitioned spaces. In particular, \( M//K \) has the structure of a complex-analytic space. We denote the structure sheaf by \( \mathcal{O} \).

We have shown the first part Theorem 1.4(i); it remains to show that the orbit-type partition of \( M//K \) is a complex-analytic Whitney stratification with respect to this sheaf \( \mathcal{O} \) and is compatible with the complex structures \( I_{S} \) on the pieces. This will be shown later as a consequence of the local model Theorem 1.4(iv), which we show next.

### 4.2. Linear hyperkähler quotients

Let us first consider the case of a linear hyperkähler quotient. Let \( V \) be a quaternionic vector space, i.e. a real vector space endowed with three endomorphisms \( I,J,K \) such that \( I^{2} = J^{2} = K^{2} = IJK = -1 \). Then, \( V \cong \mathbb{H}^{n} \) for some \( n \), so we may endow \( V \) with a real inner-product \( \langle \cdot, \cdot \rangle \) such that \( I,J,K \) are skew-symmetric. This makes \( V \) into a hyperkähler manifold, with Kähler forms \( \omega(u,v) = \langle hu, v \rangle \), etc. Let \( L \) be a compact Lie group acting linearly on \( V \) by preserving \( \langle \cdot, \cdot \rangle \) and \( I,J,K \). Then, there is a hyperkähler moment map, namely

\[
\phi : V \to \Gamma \otimes \mathbb{R}^{3}, \quad \phi(v)(x_{1}, x_{2}, x_{3}) = \frac{1}{2}(\omega_{I}(x_{1}v,v), \omega_{J}(x_{2}v,v), \omega_{K}(x_{3}v,v)).
\]

Moreover, the \( L \)-action extends to an \( l \)-complex-linear action of \( H := L_{C} \), and the underlying complex-Hamiltonian manifold is \((V, \omega_{C}, H, \Phi_{V})\), where \( \omega_{C} := \omega_{I} + i\omega_{K} \) and \( \Phi_{V} \) is the canonical moment map \( \Phi_{V}(v)(x) = \frac{1}{2}\omega_{C}(xv,v) \). By the Kempf–Ness theorem [24], every point in \( V \) is \( \phi_{l} \)-semistable (see e.g. [35, Proposition 3.9]), so the complex-analytic space \((V//_{\phi_{l}} L, \mathcal{O}_{l})\) is simply the analytification of the affine GIT quotient \( \Phi_{V}^{-1}(0)//H = \text{Spec} \mathbb{C}[\Phi_{V}^{-1}(0)]^{H} \).

Conversely, if \( H \) is any complex reductive group and \( H \to \text{Sp}(V, \omega_{C}) \) is a complex-symplectic representation (e.g. a complex-symplectic slice) then \( V \cong \mathbb{C}^{2n} \cong \mathbb{H}^{n} \) for some \( n \), so we may endow \( V \) with the structure of a quaternionic vector space invariant under the action of a maximal compact subgroup \( L \) of \( H \) (by averaging). Hence, the GIT quotient \( \Phi_{V}^{-1}(0)//H \) can always be viewed as a hyperkähler quotient.

### 4.3. Local model

We now prove the first part of Theorem 1.4(iv) which gives a local model for the complex-analytic structure \( \mathcal{O}_{l} \). It will be shown later that there is a holomorphic Poisson bracket on \( \mathcal{O}_{l} \) (Theorem 1.4(ii)) compatible with this model.

Let \( q \in M//K \) and let \( p \in \mu_{-1}(0) \) be a point above \( q \). Let \( H := G_{p} \) and let \( V := (T_{p}(G \cdot p))^{ss} / T_{p}(G \cdot p) \) be the complex-symplectic slice at \( p \). Let \( \Phi_{V} : V \to \mathfrak{h}^{*} \) be the canonical moment map. We want to show that \( q \) has a neighbourhood \( U \) which is isomorphic as a complex-analytic and partitioned space to a neighbourhood \( U' \) of 0 in the GIT quotient \( \Phi_{V}^{-1}(0)//H \). However, note that the natural partition of \( \Phi_{V}^{-1}(0)//H \) is by \( H \)-orbit-types rather than \( G \)-orbit-types. To show that the biholomorphism \( U \to U' \) is an isomorphism of partitioned spaces, we will first need to show that once we refine the partitions into the connected components of the pieces, the \( G \)-orbit-type partition of \( \Phi_{V}^{-1}(0)//H \) (i.e. saying that two points
Lemma 4.1. Let \((M, K, \mu)\) be a Hamiltonian Kähler manifold and let \(\tilde{K}\) be a compact Lie group containing \(K\) as a Lie subgroup. Then, the \(K\)- and \(\tilde{K}\)-orbit-type partitions of \(M//\mu K\) coincide. Moreover, if \((M, K, \mu)\) is integrable, then the \(K_C\)- and \(\tilde{K}_C\)-orbit-type partitions of \(M^{\mu \text{ss}}//K_C\) also coincide.

Proof. Let \(X = \mu^{-1}(0)\) and let \(\pi : X \to X/K\) be the quotient map. Let \(S \subseteq X/K\) be a \(\tilde{K}\)-orbit-type piece, i.e. a connected component of a set of the form \(X_{(H)_\tilde{K}}/K\) for some closed subgroup \(H \subseteq K\), where \((H)_\tilde{K}\) is the conjugacy class of \(H\) in \(\tilde{K}\). We have \(S = \pi(T)\) for some connected component \(T\) of \(X_{(H)_\tilde{K}}\). Fix \(x \in T\). We want to show that if \(y \in T\) then \(K_x\) and \(K_y\) (which are conjugate in \(\tilde{K}\)) are in fact conjugate in \(K\). Let

\[
A := \{y \in T : K_y \text{ is conjugate to } K_x \text{ in } K\}.
\]

It suffices to show that \(A\) is both open and closed in \(T\). Closed: Let \(y \in \overline{A} \cap T\) and write \(y = \lim_{n \to \infty} y_n\) with \(y_n \in A\). Then, there exist \(k_n \in K\) such that \(k_n K_x k_n^{-1} = K_{y_n}\) for all \(n\). Since \(K\) is compact, we may assume that \(\lim_{n \to \infty} k_n = k\) for some \(k \in K\). Then, \(k K_x k^{-1} \subseteq K_y\) by continuity of the action. Moreover, \(k K_x k^{-1}\) and \(K_y\) are isomorphic since they are conjugate in \(\tilde{K}\) and since they have finitely many connected components, the inclusion \(k K_x k^{-1} \subseteq K_y\) implies that \(k K_x k^{-1} = K_y\). Thus, \(A\) is closed. Open: Let \(y \in A\). By Palais [36, Corollary 2 on p. 313] there is a neighbourhood \(V\) of \(y\) in \(X\) such that if \(z \in V\) then \(K_z\) is conjugate (in \(K\)) to a subgroup of \(K_y\). Then, \(V \cap T\) is a neighbourhood of \(y\) in \(T\) and \(V \cap T \subseteq A\), so \(A\) is open in \(T\).

The second statement amounts to show that if \(H\) and \(L\) are two closed subgroups of a compact Lie group \(R\), then \(H\) and \(L\) are conjugate in \(R\) if and only if \(H_C\) and \(L_C\) are conjugate in \(R_C\). This follows from Mostow’s decomposition, as explained by Sjamaar [38, Proof of Theorem 2.10, first paragraph].

Now, by picking a quaternionic structure on the complex-symplectic slice \(V\) as explained in §4.2, we can apply this result to \((V, K_p, \phi_0)\) and infer that the \(G\)- and \(H\)-orbit-type partitions of \(\Phi_{V^{-1}}(0)//H\) coincide. This will be used for the last part of the following result.

Proposition 4.2. Let \(q \in M//K\). Take a point \(p \in \mu^{-1}(0)\) above \(q\), let \(H := G_p = (K_p)\_C\), and let \(V := (T_p(G \cdot p))^{\text{ss}}/T_p(G \cdot p)\). Then, there is a neighbourhood \(U\) of \(q\) in \(M//K\), an open ball \(B \subseteq V\) around \(0\), and a biholomorphism (with respect to \(O\)) from \(U\) to the image of \((H \cdot B) \cap \Phi_{V^{-1}}(0)\) in the GIT quotient \(\Phi_{V^{-1}}(0)//H = \text{Spec } \mathbb{C}[\Phi_{V^{-1}}(0)]^H\) which maps \(q\) to the image of \(0 \in \Phi_{V^{-1}}(0)\). Moreover, this biholomorphism is an isomorphism of partitioned spaces.

Proof. Let \(E = G \times_H (\mathfrak{h}^0 \times V)\). Since \(H\) is reductive and acts freely on \(G \times (\mathfrak{h}^0 \times V)\), \(E\) is an affine variety. Moreover, the moment map \(\kappa : E \to \mathfrak{g}^*\) is algebraic, so \(\kappa^{-1}(0)\) is an affine variety in \(E\) and we can consider the GIT quotient \(\kappa^{-1}(0)//G = \text{Spec } \mathbb{C}[\kappa^{-1}(0)]^G\). We claim that \(\kappa^{-1}(0)//G \cong \Phi_{V^{-1}}(0)//H\) as affine varieties. Indeed, we have \(\kappa^{-1}(0) = G \times_H \Phi_{V^{-1}}(0)\), so the inclusion \(\Phi_{V^{-1}}(0) \to \kappa^{-1}(0) : v \mapsto [1, v]\) descends to a morphism \(\psi : \Phi_{V^{-1}}(0)//H \to \kappa^{-1}(0)//G\). Also, the projection
\( \kappa^{-1}(0) = G \times_H \Phi^{-1}_V(0) \to \Phi^{-1}_V(0) / H \) onto the second factor descends to a morphism 
\( \kappa^{-1}(0) / G \to \Phi^{-1}_V(0) / H \) which is an inverse of \( \psi \).

Now, for an element \([g,v] \in G \times_H \Phi^{-1}_V(0) = \kappa^{-1}(0)\) we have \( G_{[g,v]} = gHg^{-1} \), so \( \psi \) is an isomorphism of partitioned spaces with the \( G \)-orbit-type partitions on both sides. As explained above, Lemma 4.1 implies that the \( G \)-orbit-type partition on \( \Phi^{-1}_V(0) / H \) coincides with the \( H \)-orbit-type partition.

By the local normal form (Theorem 1.3), there are \( G \)-saturated neighborhoods \( U \subseteq M^{\mu_{C}C} \) and \( U' \subseteq E \) of \( p \) and \([1,0,0]\), and an isomorphism \( f : U \to U' \) of complex-Hamiltonian \( G \)-manifolds. Note that \( U' \) can be taken to be of the form \( U' = G \times_H (H \cdot B) \) for some open ball \( B \) around zero in \( m^* \times V \) (this is how \( U' \) was constructed in the proof). Then, \( W \) is an \( H \) in \( \mu_{C}^{-1}(0)^{\mu_{C}C} \) a \( G \)-saturated open subset of \( \mu_{C}^{-1}(0)^{\mu_{C}C} \), and so is \( W' \) in \( \kappa^{-1}(0) \) in \( \kappa^{-1}(0) \). Moreover, by Proposition 2.11(i), the image \( W / G \) of \( W \) in \( \mu_{C}^{-1}(0)^{\mu_{C}C} / G \) is open and \( W \to W / G \) is an analytic Hilbert quotient. Similarly, \( W' / G \subseteq \kappa^{-1}(0) / G \) is an analytic Hilbert quotient. Since \( f : U \to U' \) is a \( G \)-equivariant biholomorphism with \( \kappa \circ f = \mu_{C} \), it restricts to a \( G \)-equivariant biholomorphism \( W \to W' \) and hence to a biholomorphism \( W / G \to W' / G \) which respects the \( G \)-orbit-type partitions. Moreover, under the isomorphism \( \kappa^{-1}(0) / G \cong \Phi^{-1}_V(0) / H \) above we have an isomorphism \( W' / G \cong (H \cdot B \cap \Phi^{-1}_V(0)) / H \) of complex-analytic and partitioned spaces.

\[ 4.4. \textbf{The orbit-type pieces are complex submanifolds.} \] As a first application of Proposition 4.2, we will show that the pieces in the orbit-type partition of \( M / K \) are complex submanifolds with respect to \( O \); this is one of the requirements in the definition of complex-analytic Whitney stratifications.

We shall achieve this by describing the orbit-type partition of \( \Phi^{-1}_V(0) / H \), where \( H \) is a complex reductive group, \( \Phi : H \to \text{Sp}(V, \omega_C) \) a complex-symplectic representation, and \( \Phi_V : V \to \mathfrak{h}^* \) the canonical moment map. The set \( V^H \) of fixed points of \( H \) is a complex-symplectic subspace, so \( V = W \oplus V^H \), where \( W \) is the symplectic complement. Then, \( W \) is complex-symplectic and \( H \)-invariant, so it provides a complex-symplectic representation of \( H \). The moment map \( \Phi_W : W \to \mathfrak{h}^* \) associated with this representation is simply the restriction of \( \Phi_V \) to \( W \), so we have the decomposition

\[ \Phi^{-1}_V(0) / H = (\Phi^{-1}_W(0) / H) \times V^H. \]

For each \( L \subseteq H \), let \( (\Phi^{-1}_W(0) / H)_{(L)} \) be the image of \( \Phi^{-1}_W(0) / H \) under the bijection \( \Phi^{-1}_W(0) / H \to \Phi^{-1}_W(0) / H \). Then, the pieces of the orbit-type partition of \( \Phi^{-1}_V(0) / H \) are the connected components of the sets of the form \( (\Phi^{-1}_W(0) / H)_{(L)} \times V^H \).

\[ \text{Lemma 4.3.} \quad \text{The orbit-type piece of} \quad \Phi^{-1}_V(0) / H \quad \text{containing} \quad 0 \quad \text{is} \quad \{0\} \times V^H. \]

\[ \text{Proof.} \quad \text{Note that} \quad V_{(H)} = V^H \quad \text{since} \quad v \in V \quad \text{and} \quad H_v = gHg^{-1} \quad \text{for some} \quad g \in H, \quad \text{then} \quad gHg^{-1} \subseteq H, \quad \text{and since} \quad gHg^{-1} \quad \text{and} \quad H \quad \text{are isomorphic Lie groups with finitely many connected components this implies} \quad gHg^{-1} = H \quad \text{and hence} \quad H_v = H. \quad \text{In particular,} \quad W_{(H)} = W \cap V^H = 0, \quad \text{so the piece containing} \quad 0 \quad \text{is} \quad (\Phi^{-1}_W(0) / H)_{(H)} \times V^H = \{0\} \times V^H. \]

\[ \text{Proposition 4.4.} \quad \text{The orbit-type pieces of} \quad M / K \quad \text{are non-singular complex-analytic subspaces with respect to} \quad O. \]
Proof. By Lemma 4.3 and Proposition 4.2, the embedding of a $K$-orbit-type piece in $M///K$ is locally biholomorphic to the embedding of $\{0\} \times V^H$ in $(\Phi^{1}_H(0)///H) \times V^H$. \hfill \Box

4.5. Compatibility with the hyperkähler structures. Let $S \subseteq M///K$ be an orbit-type piece. Then, by Proposition 4.4, $S$ is a complex manifold. But also, $S$ has a complex structure $I_S$ as part of its hyperkähler structure $(g_S, I_S, J_S, K_S)$ of Theorem 1.1. We want to show that those are equal, or in other words:

**Proposition 4.5.** The inclusion $S \hookrightarrow M///K$ is holomorphic with respect to $I_S$ and $O_I$.

Proof. We want to show that the composition $S \hookrightarrow M///K \rightarrow \mu^{-1}_C(0)ss ///G$ is a closed complex-analytic subspace of $M^{ss} ///G$, it suffices to show that the composition $S \hookrightarrow \mu^{-1}_C(0)ss ///G \rightarrow M^{ss} ///G$ is holomorphic, which is the same as the composition $S \hookrightarrow M///K \hookrightarrow M///\mu_R K \rightarrow M^{ss} ///G$. The set $S$ is a connected component of $\mu^{-1}(0)/(H)/K$ for some $H \subseteq K$. Hence, $S$ is a subset of a connected component $T$ of $\mu^{-1}(0)/(H)/K$. Moreover, $T$ is a stratum in the Kähler quotient $M///\mu_R K$ and, from the definition of the Kähler structure on $T$ given in §2.4 and the definition of $I_S$ given above, the inclusion $S \hookrightarrow T$ is holomorphic. Hence, it suffices to show that the composition $T \hookrightarrow M///\mu_R K \rightarrow M^{ss} ///G$ is holomorphic, and this follows from Theorem 2.18(iii). \hfill \Box

4.6. The frontier condition. At this point we have shown Theorem 1.4(i) except for the fact that the orbit-type partition is a Whitney stratification. In this section we prove the first step, which is that this partition is a decomposition in the sense of Definition 2.2 (this is a requirement in the definition of Whitney stratified spaces). Since $K$ is compact, $\mu^{-1}(0)/K$ satisfies the local condition, so it only remains to show the frontier condition. This will be achieved by the local model of Proposition 4.2, so we first need to discuss how the frontier condition can be inferred locally.

Given a partitioned space $(X, \mathcal{P})$ we will denote by $\mathcal{P}^\circ$ the refinement of $\mathcal{P}$ obtained by separating every piece of $\mathcal{P}$ into its connected components. In particular, the orbit-type partition of $M///K$ which we are considering is the refinement $\mathcal{P}^\circ$ of $\mathcal{P} := \{\mu^{-1}(0)(K_p)/K : p \in \mu^{-1}(0)\}$. Also, we will say that a partitioned space $(X, \mathcal{P})$ is **conical** at a stratum $S \in \mathcal{P}$ if $S \subseteq \overline{T}$ for all $T \in \mathcal{P}$.

The following lemma provides a local criterion for partitioned spaces to satisfy the frontier condition.

**Lemma 4.6.** Let $(X, \mathcal{P})$ be a partitioned space. Suppose that every point $x \in X$ has a neighbourhood $U$ such that if $S$ is the stratum containing $x$, then $S \cap U$ is connected and $(\mathcal{P}|_U)^\circ$ is conical at $S \cap U$. Then, $\mathcal{P}^\circ$ satisfies the frontier condition.

Proof. Let $S, T \in \mathcal{P}$ and let $S = \bigsqcup_i S_i, T = \bigsqcup_j T_j$ be their connected components. Suppose that $S_{i_0} \cap \overline{T_{j_0}} \neq \emptyset$ for some $i_0, j_0$. We want to show that $S_{i_0} \subseteq \overline{T_{j_0}}$. The set $R := S_{i_0} \cap \overline{T_{j_0}}$ is closed in $S_{i_0}$, so it suffices to show that $R$ is also open in $S_{i_0}$. Let $x \in R$. Take a neighbourhood $U$ of $x$ in $X$ such that $S \cap U$ is connected and $(\mathcal{P}|_U)^\circ$ is conical at $S \cap U$. We claim that $S_{i_0} \cap U \subseteq R$, or equivalently, $S_{i_0} \cap U \subseteq \overline{T_{j_0}}$. If $T \cap U = \bigsqcup_k C_k$ are the connected components of $T \cap U$, then, since $(\mathcal{P}|_U)^\circ$ is conical at $S \cap U$, we have $S \cap U \subseteq \overline{C_k}$ for all $k$. But the set of connected components of
$T \cap U$ is the union of the set of connected components of $T_j \cap U$ for all $j$, so there exists $k_0$ such that $C_{k_0} \subseteq T_{j_0} \cap U$ and hence $S_{k_0} \cap U \subseteq S \cap U \subseteq C_{k_0} \subseteq T_{j_0}$. □

Proposition 4.7. The orbit-type partition of $M///K$ satisfies the frontier condition and hence is a decomposition.

Proof. Let $q \in M///K$, let $V$, $H$, and $B \subseteq V$ be as in Proposition 4.2, and let $U = (H \cdot B) \cap \Phi^{-1}_V(0)//H$. We denote by $[v]$ the image of a point $v \in \Phi^{-1}_V(0)$ in the GIT quotient $\Phi^{-1}_V(0)//H$. Then, $q$ has a neighbourhood isomorphic to $U$ as partitioned spaces, with an isomorphism sending $q$ to $[0]$. Let $\mathcal{P}$ be the orbit-type partition of $\Phi^{-1}_V(0)//H$ and let $S \in \mathcal{P}$ be the piece containing $[0]$. By Lemma 4.6, it suffices to show that $S \cap U$ is connected and $(\mathcal{P}|_U)^c$ is conical at $S \cap U$. By Lemma 4.3, $S = \{(0)\} \times V^H$ so $S \cap U = \{(0)\} \times (V^H \cap B)$ is connected. To show that $(\mathcal{P}|_U)^c$ is conical at $S \cap U$, let $T' \in (\mathcal{P}|_U)^c$. Then, $T'$ is a connected component of $T \cap U$, where $T := (\Phi^{-1}_V(0)//H)_L \times V^H$ for some $L \subseteq H$. We need to show that $S \cap U \subseteq T'$. Let $([0],v) \in S \cap U$, where $v \in V^H \cap B$. Take any point $([w],u)$ of $T'$, where $w \in (\Phi^{-1}_V(0)//H)|_L$, $u \in V^H$, and $w + u \in H \cdot B$. It suffices to find a continuous path $\gamma : [0,1] \to T \cap U$ such that $\gamma(1) = ([w],u)$ and $\lim_{t \to 0} \gamma(t) = ([0],v)$. Let $h \in H$ be such that $w + u \in h^{-1} \cdot B$. Then, $hw + u \in B$. We also have $v \in B$, so there exists $t_0 > 0$ small enough so that $t_0 hw + v \in B$ and hence $t_0 w + v \in H \cdot B$. Now, $\Phi_V(tw) = t^2 \Phi_V(w) = 0$ and hence $([tw],v) \in T \cap U$ for all $t > 0$. Moreover, since $B$ is convex, the straight line from $t_0 w + v$ to $w + u$ will stay in $(H \cdot B) \cap ((\Phi^{-1}_V(0)//H)|_L \times V^H)$ and hence $([t_0 w],v)$ and $([w],u)$ are in the same path component $T'$ of $T \cap U$. □

4.7. Whitney conditions. We show that the orbit-type partition of $M///K$ is a complex-analytic Whitney stratification with respect to $\mathcal{O}_1$ and hence a stratification in the sense of Definition 2.4. In particular, this completes the proof of Theorem 1.4(i). Our proof is similar to that of Sjamaar–Lerman [39, §6]. Let us first recall the following result of Whitney.

Lemma 4.8 (Whitney [43, Lemma 19.3]). Let $S$ and $T$ be disjoint complex submanifolds of a complex-analytic space $X$ with $S \subseteq T$ and $\dim S < \dim T$. There is a (possibly empty) complex-analytic subspace $A$ of $S$ with $\dim A < \dim S$ such that $T$ is regular over $S \setminus A$. □

Corollary 4.9. Let $X$ be a complex-analytic space and $T \subseteq X$ a complex submanifold with $\dim T > 0$. Then, $T$ is regular over $\{x\}$ for all $x \in T \setminus T$. □

Proof. Use Lemma 4.8 with $S = \{x\}$. □

Proposition 4.10. The orbit-type partition of $M///K$ is a complex-analytic Whitney stratification with respect to $\mathcal{O}_1$. In particular, it is a stratification in the sense of Definition 2.4.

Proof. By Proposition 4.2, the problem reduces to checking Whitney conditions for the $H$-orbit-type partition of $\Phi^{-1}_V(0)//H$ at $[0]$. By §4.4, we have $\Phi^{-1}_V(0)//H = (\Phi^{-1}_W(0)//H) \times V^H$ and hence it suffices to check Whitney condition for $\Phi^{-1}_W(0)//H$ at $[0]$. But the piece containing $[0]$ is the singleton $\{0\}$, so this follows from Corollary 4.9. □
4.8. **Poisson structure.** We now show Theorem 1.4(ii), which says that there is a natural Poisson bracket on \(\mathcal{O}_1\) making \(M///K\) a stratified symplectic space as in Sjamaar–Lerman’s work (§2.3) but in a complex-analytic sense.

The definition of the Poisson bracket on \(\mathcal{O}_1\) is as follows. Let \(U \subseteq M///K\) be open, let \(f,g \in \mathcal{O}_1(U)\) and let \(q \in U\). To define \(\{f,g\}(q)\), let \(S \subseteq M///K\) be the orbit-type stratum containing \(q\) and let \((g_S, I_S, J_S, K_S)\) be its hyperkähler structure. Then, \((\omega_S)_c := \omega_{I_S} + i \omega_{K_S}\) is a complex-symplectic form on \((S, I_S)\). By Proposition 4.5, the restrictions \(f|_{S\cap U}, g|_{S\cap U}\) are \(I_S\)-holomorphic, and hence we can take their Poisson bracket \(\{f,g\}(q) := f|_{S\cap U} \cdot g|_{S\cap U}\). This defines a function \(\{f,g\} : U \to \mathbb{C}\) pointwise, and the goal is to show that it is holomorphic, i.e., \(\{f,g\} \in \mathcal{O}_1(U)\).

In what follows, we identify \(S\) with a \(G\)-orbit-type stratum in \(\mu^{-1}_c(0)\mu_{\text{i ss}}//G\), i.e. \(S\) is a connected component of \((\mu^{-1}_c(0)\mu_{\text{i ss}}//G)(H)\) for some reductive subgroup \(H \subseteq G\). By the definition of the \(G\)-orbit-type partition, the map \((\mu^{-1}_c(0)\mu_{\text{i ss}}//G)(H) \to (\mu^{-1}_c(0)\mu_{\text{i ss}}//G)(H)\) is surjective (note that on the left-hand side we use polystable points), so \(S\) is the image under the quotient map \(\mu^{-1}_c(0)\mu_{\text{i ss}}//G\) of an open subset \(Z\) of \((\mu^{-1}_c(0)\mu_{\text{i ss}}//G)(H)\).

**Lemma 4.11.** The set \(Z\) is a complex submanifold of \(M\), the map \(\pi : Z \to S\) is a holomorphic submersion, and \(\pi^*(\omega_S)_c = i^*\omega_c\) where \(i : Z \hookrightarrow M\).

**Proof.** By the local normal form (Theorem 1.3), the embedding of \(Z\) in \(M\) is locally biholomorphic to the embedding of \(G/H \times V^H\) in \(G \times_H (h^0 \times V)\) and \(\pi\) is locally biholomorphic to the projection \(G/H \times V^H \to V^H\). This proves the first and second assertions. For the third assertion, we first note that, since the pullbacks of the symplectic forms \(\omega_{I_S}, \omega_{I_0}, \omega_{K_S}\) on \(\mu^{-1}(0)(H)\) are the restrictions of the symplectic forms \(\omega_I, \omega_J, \omega_K\) on \(M\), we have \(j^*(\pi^*(\omega_S)_c) = j^*(i^*\omega_c)\) where \(j : \mu^{-1}(0)(H) \hookrightarrow Z\). Since \(j\) descends to a diffeomorphism \(\mu^{-1}(0)(H)/K \to (\mu^{-1}_c(0)\mu_{\text{i ss}}//G)(H)\) we get that for all \(p \in \mu^{-1}(0)(H)\), \(T_pZ = T_p\mu^{-1}(0)(H) + T_p(G/p)\). Hence, the result follows by the same argument as in the proof of Theorem 1.1 given in §2.5. \(\square\)

**Lemma 4.12.** Let \(f : U \to \mathbb{C}\) be a holomorphic \(G\)-invariant function on an open set \(U \subseteq M\), and let \(\Xi_f\) be the holomorphic vector field on \(U\) dual to \(df\) under \(\omega_c\). Then, \(\Xi_f\) is tangent to \(Z\), i.e., \(\Xi_f(p) \in T_pZ\) for all \(p \in Z \cap U\).

**Proof.** Let \(m = h^\perp\) as in §3.2. By the local normal form we may assume that \(M = G \times_H (m^* \times V), p = [1,0,0]\) and \(Z = G/H \times V^H\). By Lemma 3.10, \(T_pM = m \times m^* \times V, Z = m \times 0 \times V^H,\) and \(T_p(G/p) = m \times 0 \times 0\). Let \((x,\xi,v) := \Xi_f(p) \in m \times m^* \times V\). Then, \(df_p(y,v,w) = \eta(x) - \xi(y) + \omega_c(v,w)\) for all \((y,\eta,w) \in m \times m^* \times V\). Since \(f\) is \(G\)-invariant, we have \(df_p(m \times 0 \times 0) = 0\), so \(\xi = 0\). Also, \(G\)-equivariance implies that for all \(w \in V\) and \(h \in H\) we have \(df_h(0,0,h\cdot w) = df_h(0,0,w)\), so \(\omega_c(v,h\cdot w) = \omega_c(v,w)\). Since \(\omega_c\) is \(H\)-invariant, this implies \(\omega_c(h^{-1}v - v, w) = 0\) for all \(w \in V\) and \(h \in H\), so \(v \in V^H\). Thus, \(\Xi_f(p) = (y,0,v) \in m \times 0 \times V^H = T_pZ\). \(\square\)

**Lemma 4.13.** For all open set \(U \subseteq M///K\) and \(f,g \in \mathcal{O}_1(U)\), we have \(\{f,g\} \in \mathcal{O}_1(U)\).

**Proof.** We identify \(M///K\) with \(\mu^{-1}_c(0)\mu_{\text{i ss}}//G\). Let \(\Pi : \mu^{-1}_c(0)\mu_{\text{i ss}} \to \mu^{-1}_c(0)\mu_{\text{i ss}}//G\) be the quotient map. Then, \(\{f,g\} \in \mathcal{O}_1(U)\) if and only if the pullback \(\Pi^*\{f,g\} : \Pi^{-1}(U) \to \mathbb{C}\) is holomorphic. This is a local statement, so we may assume that \(\Pi^{-1}(U) = \mu^{-1}_c(0)\mu_{\text{i ss}} \cap U'\) for some \(G\)-invariant open set \(U' \subseteq M\mu_{\text{i ss}}\) such that
Π∗f and Π∗g extend to holomorphic G-invariant functions ˜f, ˜g : U′ → C. Then, it suffices to show that Π∗{f, g} = {˜f, ˜g}|Π−1(U). As ˜f, ˜g and ωC are G-invariant, so is {˜f, ˜g}. Thus, it suffices to show that Π∗{f, g}(p) = {˜f, ˜g}(p) for every polystable point p ∈ Π−1(U) ∩ µ−1 C (0)μ−1-π. We have p ∈ Z for some Z as above. Let S = Π(Z), π = Π|Z : Z → S and i : Z → M, as before. Then, we have dπ(Ξf(p)) = Ξf(π(p)), where Ξf is the Hamiltonian vector field of f on U ∩ S, since for all v ∈ TpZ,

\[(ωS)c(dπ(Ξf(p)), dπ(v)) = ωC(Ξf(p), v) = dическое{f}(v) = df(π)(dπ(v)) = (ωS)c(Ξf(π(p)), dπ(v)).\]

Thus,

\[\{f, g\}(\Pi(p)) := (ωS)c(Ξf(π(p)), Ξf(π(p))) = (ωS)c(\{dπ(Ξf(p)), dπ(Ξf(p))\}) = (ωC)(Ξf(p), Ξf(π(p))) = (f, g)(p).\]

So Π∗{f, g} = {˜f, ˜g}|Π−1(U) and hence {f, g} ∈ O(\U).

By construction, the Poisson bracket is uniquely determined by the property that the inclusions of the strata are Poisson maps. Thus, we have show Theorem 1.4(ii).

4.9. Compatibility of the local model. We now show the remaining part of Theorem 1.4(iv), which is that the local model is compatible with the holomorphic Poisson bracket constructed in the previous section.

Let H be a complex reductive group and H → Sp(V, ωC) a complex-symplectic representation. Then, as explained in §4.2, we can view the affine GIT quotient V0 := ΦV−1(0)//H as a hyperkähler quotient. Hence, if O\V0 denotes the underlying complex-analytic structure of V0, then (V0, O\V0) together with the H-orbit-type partition is a complex-analytic Whitney stratified space with a holomorphic Poisson bracket (which does not depend on the choice of quaternionic structure). Recall from Proposition 4.2 that ΦV−1(0)//H provides a local model for the complex-analytic structure of M//K. Here we show that ΦV−1(0)//H is also a local model for the Poisson structure.

**Proposition 4.14.** The biholomorphism of Proposition 4.2 is compatible with the holomorphic Poisson brackets.

**Proof.** Since the local normal form for (M, K, μ) is an isomorphism of complex-symplectic manifolds, we only need to show that the isomorphism κ−1(0)//G = ΦV−1(0)//H of affine varieties in the proof of Proposition 4.2 respects the Poisson brackets. This follows from the fact that V is a complex-symplectic submanifold of H via the embedding ϵ : V → G ×H (h×V), v → [1, 0, v] and that the isomorphism descends from this map. □

4.10. Real Poisson structure. We now prove Theorem 1.4(iii), i.e. we show that M//K has the structure of a stratified symplectic space (Definition 2.8) compatible with the first Kähler forms.

Let C∞(M//K) be the subalgebra of the R-algebra of continuous functions on M//K consisting functions descending from smooth K-invariant functions on M. In other words, f ∈ C∞(M//K) if and only if there exists F ∈ C∞(M)K such that π∗f = F|µ−1(0), where π : µ−1(0) → M//K is the quotient map.

**Lemma 4.15.** The inclusion S ↪ M//K of an orbit-type stratum is a smooth map, i.e. for all f ∈ C∞(M//K), f|S is a smooth function on S.
Proof. Let $F \in C^\infty(M)^K$ be such that $f \circ \pi = F|_{\mu^{-1}(0)}$. Recall that, by Theorem 1.1, $\pi^{-1}(S)$ is a smooth submanifold of $M$ and the restriction $\pi^{-1}(S) \to S$ is a surjective submersion. Hence, $F|_{\pi^{-1}(S)}$ descends to a unique smooth function $S \to \mathbb{R}$, which is just $f|_S$. \hfill \Box

Hence, we can define a Poisson bracket pointwise as in [39] by letting

$$\{f, g\}(x) := \{f|_S, g|_S\}_{\omega_S}(x),$$

where $S$ is the unique orbit-type stratum containing $x$ and $\{\cdot, \cdot\}_{\omega_S}$ is the real Poisson bracket on $S$ induced by $\omega_S$. It only remains to show that $\{f, g\} \in C^\infty(M//K)$ (the Leibniz rule and Jacobi identity follow from that of $\{\cdot, \cdot\}_{\omega_S}$).

**Proposition 4.16.** For all $f, g \in C^\infty(M//K)$ we have $\{f, g\} \in C^\infty(M//K)$.

Proof. First note that $(M, K, \mu_K)$ is a Hamiltonian manifold as in §2.3, so Sjamaar–Lerman’s original theorem holds, i.e. $M//\mu_K$ is endowed with a Poisson $\mathbb{R}$-algebra $C^\infty(M//\mu_K)$ defined analogously. By definition, the inclusion $M//K \hookrightarrow M//\mu_K$ is smooth with respect to $C^\infty(M//K)$ and $C^\infty(M//\mu_K)$.

Now, let $f, g \in C^\infty(M//K)$, so that $f \circ \pi = F|_{\mu^{-1}(0)}$ and $g \circ \pi = G|_{\mu^{-1}(0)}$ for some $F, G \in C^\infty(M)^K$. Let $\tilde{\pi} : \mu_K^{-1}(0) \to M//\mu_K$ be the quotient map. Then, $F|_{\mu_K^{-1}(0)} = \tilde{f} \circ \tilde{\pi}$ and $G|_{\mu_K^{-1}(0)} = \tilde{g} \circ \tilde{\pi}$, for some $\tilde{f}, \tilde{g} \in C^\infty(M//\mu_K)$. Note that $\tilde{f}|M//K = f$ and $\tilde{g}|M//K = g$. Let $x \in M//K$, let $S$ be the stratum containing $x$, and let $\tilde{S}$ be the stratum of $M//\mu_K$ containing $x$. Then, by construction of the hyperkähler structure on $S$ (see §2.5), $S$ is a Kähler submanifold of $\tilde{S}$. In particular, $\{f, g\}(x) = \{f|_S, g|_S\}_S(x) = \{\tilde{f}|_{\tilde{S}}, \tilde{g}|_{\tilde{S}}\}_{\tilde{S}}(x) = \{\tilde{f}, \tilde{g}\}(x)$. Hence, $\{f, g\} = \{\tilde{f}, \tilde{g}\}|_{M//K} \in C^\infty(M//K)$ since $\{\tilde{f}, \tilde{g}\} \in C^\infty(M//\mu_K)$.
