ABOUT BREDON MOTIVIC COHOMOLOGY OF A FIELD

MIRCEA VOINEAGU

Abstract. We prove that, over a perfect field, Bredon motivic cohomology can be computed by Suslin-Friedlander complexes of equivariant equidimensional cycles. Partly based on this result we completely identify Bredon motivic cohomology of a quadratically closed field and of a euclidian field in weights 1 and \( \sigma \). We also prove that Bredon motivic cohomology of an arbitrary field in weight 0 with integer coefficients coincides (as abstract groups) with Bredon cohomology of a point.

1. Introduction

Motivated by Voevodsky’s definition of motivic cohomology, we introduced in [7] (together with J.Heller and P.A. Ostvaer) an equivariant generalization of motivic cohomology called Bredon motivic cohomology for \( G \)-equivariant smooth schemes over a field \( k \) and for a finite group \( G \). In a subsequent paper [8] (together with J.Heller and P.A. Ostvaer), we extended this definition to an equivariant motivic cohomology bigraded by a pair of virtual \( C_2 \)-representations and defined in the \( \mathbb{Z}/2 \)-equivariant stable \( A^1 \)-homotopy category.

We proved in [8] that for a smooth \( C_2 \)-scheme \( X \) over the field of complex numbers there is a natural cycle map into Bredon cohomology of \( X(\mathbb{C}) \), which in a certain range of indexes becomes an isomorphism with finite coefficients. This result allows us to obtain partial computations of Bredon motivic cohomology groups of a complex variety in terms of Bredon cohomology of its complex points. However, apart from applications of this theorem, there is a lack of computations of Bredon motivic cohomology groups.

In this paper we give complete computations of Bredon motivic cohomology groups with integer coefficients in weight 0 of an arbitrary field. We also compute Bredon motivic cohomology of a field of characteristic zero with integer coefficients of bi-index given by one-dimensional \( \mathbb{Z}/2 \)-representations. We also give complete computations for quadratically closed fields and euclidian fields of characteristic
zero in weights 1 and \( \sigma \). The strategy to prove the results in weights 1 and \( \sigma \) (see section 5) is to show that Bredon motivic cohomology can be computed by Suslin-Friedlander complexes of equivariant equidimensional cycles (see section 3). This together with a result of Nie [17] gives a computation of the Bredon cohomology of a field of characteristic zero in bidegree \((a + 2q\sigma, b + q\sigma)\) (see Proposition 3.4). Using this computation and after a careful analysis of the maps that appear in the i.e.s. given by the cofiber sequence \( C_{2+} \rightarrow S^0 \rightarrow S^\sigma \) we complete the computation of Bredon motivic cohomology with integer coefficients in weights 1 and \( \sigma \) of certain fields (see section 5 Theorems 5.7, 5.10, 5.8, 5.11).

A consequence of this computation is that Bredon motivic cohomology with \( \mathbb{Z}/2 \) coefficients of a quadratically closed field of characteristic zero in weights 1 and \( \sigma \) coincides (as abstract groups) with Bredon cohomology of a point with integer coefficients. For this see Corollary 5.12 and Corollary 5.9.

For example, in weight 1 with \( \mathbb{Z}/2 \)-coefficients we have the following (see Corollary 5.9):

**Theorem 1.1.** Let \( k \) be a field of characteristic zero. If \( k \) is a quadratically closed field or a euclidian field we have

\[
H^{n+\sigma,1}_{C_2}(k, \mathbb{Z}/2) = \begin{cases} 
\mathbb{Z}/2 \oplus k^*/k^{*2} & 0 \leq -a \leq p-1 \\
\mathbb{Z}/2 \oplus k^*/k^{*2} & 2 < a \leq -p \\
\mathbb{Z}/2 & a = 2 \leq -p, 0 \leq -a = p \\
k^*/k^{*2} & a = 1 < p, 2 < a = -p + 1 \\
0 & \text{otherwise}
\end{cases}
\]

Notice that in the case of a quadratically closed field (for example any algebraically closed field such as \( \mathbb{C} \)) \( k^*/k^{*2} = 0 \) and in the case of a euclidian field (for example \( \mathbb{R} \)) \( k^*/k^{*2} \simeq \mathbb{Z}/2 \).

We know that \( H^{1,1}(k, \mathbb{Z}) = K^1_{\text{mot}}(k) = k^* \) ([9], [11]). As a generalization of this result we have the following result for Bredon motivic cohomology (Corollary 5.6):

**Theorem 1.3.** For an arbitrary field \( k \) of characteristic zero we have \( H^{\sigma,\sigma}_{C_2}(k, \mathbb{Z}) = \mathbb{Z}/2, H^{1,\sigma}_{C_2}(k, \mathbb{Z}) = k^{*2}, H^{\sigma,1}_{C_2}(k, \mathbb{Z}) = \mathbb{Z}/2 \) and \( H^{1,1}_{C_2}(k, \mathbb{Z}) = k^* \).

In section 4 we analyze the cohomology groups of the shift complexes \( Z_{\text{top}}(n\sigma)(k) \) and \( Z_{\text{top}}(n)(k) \) for an arbitrary field \( k \). We obtain computations for weight 0 Bredon motivic cohomology with integer coefficients of a field.

As a consequence, we obtain that Bredon motivic cohomology with integer coefficients in weight 0 of an arbitrary field coincides (as abstract groups) with Bredon cohomology of a point with integer coefficients. In conclusion, with \( \mathbb{Z}/2 \)-coefficients we have:

**Theorem 1.4.** For an arbitrary field \( k \) we have

\[
H^{n+\sigma,0}_{C_2}(k, \mathbb{Z}/2) = \begin{cases} 
\mathbb{Z}/2 & 0 \leq -a \leq p \\
\mathbb{Z}/2 & 1 < a \leq -p \\
0 & \text{otherwise}
\end{cases}
\]

In section 3 we show that Suslin-Friedlander complexes of \( C_2 \)-equivariant equidimensional cycles compute Bredon motivic cohomology over a perfect field (see Theorem 3.1). In section 6 we discuss Borel motivic cohomology of a field in weights 0, 1 and \( \sigma \).
Notation and Conventions. We let $G = \mathbb{Z}/2$ and we view it as a group scheme over $k$ via $G = \mathcal{U}spec(k)$. Sometimes we write $C_2$ for the same group. We let $GSch/k$ be the category of $G$–equivariant separated quasi-projective schemes with $G$-equivariant morphisms of schemes and $GSm/k$ be its subset of smooth $G$-equivariant quasi-projective schemes over $k$.

We write $A(V) = Spec(Sym(V^\vee))$ for the affine $k$-scheme associated to a $k$-vector space $V$ and $\mathbb{P}(V) = Proj(A(V))$ for the projective scheme.

We denote $S_x = \{ g \in G | gx = x \} = G/Gx$ the set-theoretical stabilizer of a point $x$ and $Gx = G \times S_x \{ x \}$ the orbit of a point $x$. In general for a $Z \subset X$ we write $GZ = \cup_{g \in G} gZ$ for the orbit of $Z$.

For an abelian group $G$ we write $\mathbb{Z}G = \{ g \in G | 2g = 0 \}$. We write $k[G] = 1 + \sigma$ for the regular $C_2$–representation. We denote by $\sigma$ the real $C_2$-representation given by $\mathbb{R}$ with the $-1$ action. We denote by $S^\sigma$ the sphere associated to the $C_2$–representation $\sigma$ and in general by $SV$ the topological sphere associated to the $C_2$-representation $V$.

We use the following notation for indexes in $RO(G)$-graded Bredon cohomology $H_B^{p,q}(X,Z) := H_B^{p,q,G}(X,Z)$ for any virtual $C_2$–representation $V = p + q\sigma$. We write $H^{n,q}(X)$ for the motivic cohomology of the scheme $X$.

Acknowledgements: The author would like to thank Jeremiah Heller for many useful discussions. The author would also like to thank the University of Illinois at Urbana-Champaign, where the final stages of this project were completed. The author thanks the referee for many useful comments.

2. Preliminaries

Let $V$ be a $C_2$-representation and

$$T^V := \mathbb{P}(V \oplus 1)/\mathbb{P}(V) \simeq \mathbb{A}(V)/\mathbb{A}(V) \setminus \{ 0 \}$$

be the motivic representation sphere with the isomorphism in the $C_2$–equivariant $\mathbb{A}^1$–homotopy category ([1], [6], [8]). For $n \geq 0$ we write $T^nV = T^V \wedge \ldots \wedge T^V$ with $n$ copies of $T^V$ in the right term. More generally we have $T^V \oplus W = T^V \wedge W$ for any two $C_2$-representations $V$ and $W$.

We have by definition that

$$A(V) := a_{\text{eNis}}C_*A_{tr,C_2}(T^V)[-2a - 2b\sigma]$$

is the Bredon motivic complex associated to the $C_2$–representation $V = a + b\sigma$. Here $A_{tr,C_2}(X) = Cor_k(-, X)^{C_2} \otimes A$ and $a_{\text{eNis}}$ is a sheafification in equivariant Nisnevich topology ([1], [7], [4]). Here $Cor_k(X,Y)^{C_2}$ is the free abelian group generated by elementary equivariant correspondences. An equivariant elementary correspondence from $X$ to $Y$ is a correspondence of the form $Z = Z + g_1Z + g_2Z + \ldots + g_nZ$ where $Z$ is an elementary correspondence (finite and surjective over a connected component of $X$) and $g_i$ range over a set of coset representatives for $Stab(Z) = \{ g \in G | gZ = Z \}$.
The equivariant Nisnevich topology is the smallest Grothendieck topology containing the elementary Nisnevich covers \( \{ U \to X, Y \to X \} \) associated to the equivariant distinguished square in \( C_2\text{Sch}/k \)

\[
\begin{array}{ccc}
W & \to & Y \\
\downarrow & & \downarrow \\
U & \to & X.
\end{array}
\]

Here \( p : Y \to X \) is an equivariant etale morphism and \( U \hookrightarrow X \) is an equivariant open embedding such that \( (X \setminus U)_{\text{red}} \simeq (Y \setminus W)_{\text{red}} \). According to [7] and [4] an equivariant etale map \( p : Y \to X \) is a \( C_2 \)-equivariant Nisnevich cover if for any \( x \in X \) there is \( y \in Y \) such that \( p(y) = x \), \( k(x) \simeq k(y) \) and the set-theoretical stabilizers coincide \( S_x \simeq S_y \). According to [7] the points in the equivariant Nisnevich topology are Hensel semi-local affine \( C_2 \)-schemes with a single closed orbit. Any semilocal Henselian affine \( C_2 \)-scheme over \( k \) with a single orbit is equivariantly isomorphic to \( \text{Spec}(O_{A,Gx}^k) \), the \( \text{Spec} \) of the henselization of the semilocal ring \( O_{A,Gx} \) where \( A \) is some affine \( C_2 \)-scheme and \( x \in A \).

For a different generalization of Nisnevich topology in the equivariant setting called the fixed point Nisnevich topology see [5]. The fixed point Nisnevich topology is a topology finer than the equivariant Nisnevich topology, but coarser than the equivariant etale topology used by Thomasson [10]. For example if \( X \) is a \( G \)-scheme with free action and \( X^e \) is the same scheme with trivial action then \( X^e \times G \to X \) is a cover in fixed point topology, but not in the equivariant Nisnevich topology [7].

The shift in the definition of Bredon motivic complexes is given by the tensor product in \( D^- (C_2 \text{Cor}_k) \) with the invertible complexes \( Z_{\text{top}}(a + b \sigma) \) associated to any virtual \( C_2 \)-representation \( V = a + b \sigma \) [7]. We have that

\[
Z_{\text{top}}(\sigma) := \text{Cone}(Z_{\text{tr}}(C_2)^{C_2} \to Z_{\text{tr}}(k)^{C_2}) \in D^- (C_2 \text{Cor}_k)
\]

is the complex associated to the sign sphere \( S^\sigma \). Here \( D^- (C_2 \text{Cor}_k) \) is the derived category of bounded above chain complexes of equivariant Nisnevich sheaves with equivariant transfers on \( C_2 \text{Sm}/k \) and it has a tensor product induced by

\[
Z_{\text{tr}}(X)^{C_2} \otimes_{C_2}^\text{tr} Z_{\text{tr}}(Y)^{C_2} := Z_{\text{tr}}(X \times Y)^{C_2}.
\]

For an abelian group \( A \) we have that \( \{ M_{A,n} = Z_{\text{tr}}(C_2)(T^{\text{top}}(C_2)) \} \) defines the Bredon motivic cohomology spectrum \( M_A \) in the stable \( C_2 \)-equivariant motivic homotopy category \( SH_{C_2} \) [8]. The construction of \( SH_{C_2} \) as a stabilization with respect to the motivic sphere \( T^k[C_2] \) is recalled in the appendix of [8] and it initially appeared in [6] as a tool to study Hermitian K-theory of fields. We write \( [-,-]_{SH_{C_2}} \) for maps in \( SH_{C_2} \).

The equivariant \( \mathbb{A}^1 \)-homotopy was introduced initially by Voevodsky [1] in order to understand motivic Eilenberg-Mac Lane spaces. In the \( C_2 \)-equivariant \( \mathbb{A}^1 \)-homotopy category (see [1], [6]) we have the following spheres: the usual sphere \( \mathbb{A}^1 \), with trivial action, the sign sphere \( S^\sigma \) with the conjugation action, the Tate sphere \( S^1 = (\mathbb{A}^1 \setminus \{0\}, 1) \) with the trivial action and the sign Tate sphere \( S^1_\tau = (\mathbb{A}^1 \setminus \{0\}, 1) \) with the action \( x \to x^{-1} \).

Using the notation from [8] we define below the following motivic spheres bi-indexed by virtual \( C_2 \)-representations:

\[
S^{a+\sigma,b+q\sigma} := S^{-b} \wedge S^{(p-q)\sigma} \wedge S^b \wedge S^{q\sigma}.
\]
Notice that this notation is slightly different from the one used in [6] (see [8] for the translation between these two notations). This notion is suitable for comparison of Bredon motivic cohomology and Bredon cohomology as the complex realization of $R_c(S^{n+p\sigma,b+q\sigma}) = S^{n+p\sigma}$, where the right side defines the usual topological sphere associated to the $C_2-$ representation $V = a + p\sigma := \mathbb{R}^a \oplus \mathbb{R}^{-p}$. 

The definition of Bredon motivic cohomology in $SH_{C_2}$ is the following:

**Definition 2.1.** (see [7]) The Bredon motivic cohomology of a motivic $C_2$-spectrum $E$ with coefficients in an abelian group $A$ is defined by

$$\tilde{H}^{a+p\sigma,b+q\sigma}(E, A) := [E, S^{a+p\sigma,b+q\sigma} \wedge M\Delta]_{SH_{C_2}}.$$ 

We call the virtual $C_2$-representation $V = a + p\sigma$ the cohomology index and the virtual $C_2-$representation $W = b + q\sigma$ the weight index.

According to [7] this definition for $E = \sum T_\sigma \varprojlim X_\sigma$, where $X$ is a smooth $C_2-$scheme and the motivic sphere $T_\sigma^{[G]} = T \wedge T^\sigma = S^1 \wedge S_1^\sigma \wedge S^0 \wedge S_0^\sigma$ ((6), (8)), coincides with the definition of Bredon motivic cohomology given by the hypercohomology in equivariant Nisnevich topology (or equivariant Zariski topology [7]) of the Bredon motivic complexes $(A(V))$ defined above.

Based on an equivariant cancellation theorem proved in [7] we can conclude that if $V = b + q\sigma$ is a virtual representation and $W = c + d\sigma$ is a representation such that $V \oplus W$ is an actual $C_2-$representation then for any $C_2-$scheme $X$ we have

$$H^{a+p\sigma,b+q\sigma}(X, Z) = H^{a+p\sigma,b+q\sigma}(X, \wedge T^W, Z(V \oplus W)[2c + (2d + p)\sigma]).$$

For the relationship between the Bredon motivic cohomology and Edidin-Graham equivariant higher Chow groups [3] (which are a generalization of Totaro’s Chow groups of classifying spaces [12]) see [8].

For a pointed motivic $C_2-$space $\chi$ we have that the map in the equivariant $\Lambda^1$-homotopy category

$$C_{2+} \wedge \chi \simeq C_{2+} \wedge \chi^e \to \chi^e$$

induces an isomorphism

$$\tilde{H}^{a+p\sigma,b+q\sigma}(C_2+ \wedge \chi, Z) = H^{a+p\sigma,b+q\sigma}(\chi^e, Z),$$

with $\chi^e$ being the motivic space with the forgotten action [8] and the right side is given by the usual motivic cohomology. If the $C_2$-scheme $X$ has trivial action then according to [8] we have that $H^{a,b}_{C_2}(X, Z) = H^{a,b}(X, Z)$. Proposition 3.3 in section 3 gives a slight generalization of this last result. If $X$ is a smooth quasi-projective $C_2-$scheme with free $C_2$-action then $H^{n,m}_{C_2}(X, A) = H^{n,m}(X/C_2, A)$ [8].

In the stable equivariant $\Lambda^1-$homotopy category there is the following motivic isotropy sequence

$$\mathbf{E}Z/2_+ \to S^0 \to \mathbf{E}Z/2$$

defined as a colimit of $C_2-$homotopy cofiber sequences

$$\Lambda(n\sigma) \setminus \{0\}_+ \to S^0 \to S^{2n\sigma,n\sigma} = S^0_\sigma \wedge S^0_t.$$ 

By definition $\mathbf{E}Z/2 = \text{colim}_n \Lambda(n\sigma) \setminus \{0\}$. The first map is induced by the projection $\Lambda(n\sigma) \setminus \{0\} \to \text{Spec}(k)$. We have that $\mathbf{E}Z/2 = \text{colim}_n S^{n\sigma}_\sigma \wedge S^n_t$. The geometric classifying space is defined as the quotient of $\mathbf{E}Z/2$ by the free $C_2-$action

$$\mathbf{B}Z/2 := \mathbf{E}Z/2/\mathbb{Z}_2 = \text{colim}_n \Lambda(n\sigma) \setminus \{0\}/\mathbb{Z}/2.$$ 

In Proposition 2.9 and Theorem 5.4 in [8] we showed that Bredon motivic cohomology of $\mathbf{E}Z/2$ is periodic of periodicity $(2\sigma - 2, \sigma - 1)$ and that Bredon motivic cohomology of $\mathbf{E}Z/2$ is periodic with periodicities $(\sigma - 1, 0)$ and $(\sigma - 1, \sigma - 1)$. 

In the stable equivariant $\mathbb{A}^1$–homotopy category we have the basic cofiber sequence
\[
C_2^+ \wedge \mathbb{M}_\mathbb{Z} \xrightarrow{p} \mathbb{M}_\mathbb{Z} \xrightarrow{i} S^\sigma \wedge \mathbb{M}_\mathbb{Z}
\]
which gives rise to the natural long exact sequence for any $C_2^+$ scheme $X$.

\[
\cdots \to H^{a-1+(p+1)\sigma, b+q\sigma}_{C_2}(X) \xrightarrow{\delta} H^a_{\mathcal{M}}(X) \xrightarrow{p^*} H^a_{C_2}(X) \xrightarrow{\delta} H^{a+p+1, b+q\sigma}_{C_2}(X) \to \cdots
\]

For a complex scheme $X$, the basic cofiber sequence of the classical equivariant homotopy theory given by $C_2^+ \to S^0 \to S^\sigma$ induces a l.e.s. for the Bredon cohomology of the complex points of $X$. The complex realization $X \to X(\mathbb{C})$ defined on $C_2 Sm/C \to C_2 Top$ extends to a map $SHC_2(\mathbb{C}) \to SMC_2$ between the stable equivariant $\mathbb{A}^1$–homotopy category over $\mathbb{C}$ and the classical stable equivariant homotopy category. According to [8] the complex realization of the motivic spectrum $\mathbb{M}_\mathbb{A}$ gives the spectrum that defines Bredon cohomology. The realization functor also induces a map between the two long exact sequences induced by the cofiber sequence $C_2^+ \to S^0 \to S^\sigma$ in the motivic equivariant homotopy category and in the classical equivariant homotopy category.

The connecting map in the l.e.s. 2.2 is induced by the map
\[
S^\sigma \xrightarrow{\delta} C_2^+ \wedge S^\sigma = C_2^+ \wedge S^1.
\]

**Proposition 2.4.** The composition $S^\sigma \xrightarrow{\delta} C_2^+ \wedge S^\sigma = C_2^+ \wedge S^1 \xrightarrow{p^*} S^\sigma$ where the first map is the connecting map and the second map is induced by $C_2^+ \xrightarrow{p} S^0$ induces multiplication by 2 on Bredon motivic cohomology of a field i.e.
\[
H^a_{C_2}(k, \mathbb{Z}) \xrightarrow{p^*} H^{a+p-1, b+q}(k, \mathbb{Z}) \xrightarrow{\delta^*} H^a_{C_2}(k, \mathbb{Z}) \xrightarrow{\delta} H^{a+p+1, b+q}(X) \to \cdots
\]
is multiplication by 2 for any field $k$.

**Proof.** The map $S^\sigma \xrightarrow{\delta} C_2^+ \wedge S^\sigma$ induces a stable map $S^0 \to C_2^+$ which is Spanier-Whitehead dual to the stable map $C_2^+ \xrightarrow{p} S^0$. □

**Corollary 2.5.** The map on Bredon motivic cohomology induced by $C_2^+ \to S^0$ has a 2-torsion kernel.

**Proof.** According to the above composition we have that if $x \in Ker(p^*)$ then $2x = 0$. □

We also recall that the topological Bredon cohomology groups of a point with $\mathbb{Z}/2$-coefficients are ([2]):
\[
H^a_{Br}(pt, \mathbb{Z}/2) = \begin{cases} 
\mathbb{Z}/2 & 0 \leq -a \leq p \\
\mathbb{Z}/2 & 1 < a \leq -p \\
0 & \text{otherwise}
\end{cases}
\]

With integer coefficients ([2]), we have that if $p > 0$ (the positive cone) and $p$ is even then
\[
H^a_{Br}(pt, \mathbb{Z}) = \begin{cases} 
\mathbb{Z} & a = -p \\
\mathbb{Z}/2 & -p < a \leq 0, a = \text{even} \\
0 & \text{otherwise}
\end{cases}
\]
and if $p > 0$ (the positive cone) and $p$ is odd then
\[ H^{a+p\sigma}_{Br}(pt, \mathbb{Z}) = \begin{cases} \mathbb{Z}/2 & -p < a \leq 0, \, a = \text{even} \\ 0 & \text{otherwise} \end{cases}, \]

and if $p < 0$ (the negative cone) and $p$ is even then
\[ H^{a+p\sigma}_{Br}(pt, \mathbb{Z}) = \begin{cases} \mathbb{Z}/2 & 1 < a < -p, \, a = \text{odd} \\ \mathbb{Z} & a = -p \\ 0 & \text{otherwise} \end{cases}, \]

and if $p < 0$ (negative cone) and $p$ is odd then
\[ H^{a+p\sigma}_{Br}(pt, \mathbb{Z}) = \begin{cases} \mathbb{Z}/2 & 1 < a \leq -p, \, a = \text{odd} \\ 0 & \text{otherwise} \end{cases}. \]

3. Complexes of equivariant equidimensional cycles

We can define a presheaf of $C_2$-equivariant equidimensional cycles on $C_2Sm/k$ for any smooth $C_2$-scheme as in the non-equivariant case:
\[ z_{equi}(T, r)^{C_2}(S) = \text{the free abelian group generated by elementary equivariant } r-\text{equidimensional cycles over } S \times T. \]

An elementary equivariant $r$-equivariant cycle is of the form $\tilde{Z} = Z + g_1Z + \ldots + g_nZ$, where $Z$ is an irreducible closed subvariety of $S \times T$ which is dominant and equidimensional of relative dimension $r$ over a connected component of $S$ and $g_i$ are a set of coset representatives of $\text{Stab}(Z) = \{ g \in G | gZ = Z \}$. We conclude that for a projective or proper smooth $C_2$-scheme $T$ we have $z_{equi}(T, 0)^{C_2} = Z_{tr}(T)^{C_2}$. This is because $z_{equi}(T, 0)(S)$ is the free abelian group generated by closed irreducible subvarieties $Z$ of $S \times T$ which are quasi-finite and dominant over a connected component of $S$ and coincides for a proper or projective $C_2$-scheme $T$ with $Z_{tr}(T)(S)$.

We define Suslin-Friedlander equivariant motivic complexes for a $C_2$-representation $V = a + b\sigma$ to be
\[ Z_{SF}(V) = C_* z_{equi}(A(V), 0)^{C_2}[-2a - 2b\sigma]. \]

This is a complex of sheaves in the equivariant Nisnevich topology on $C_2Sm/k$.

The next theorem states that Suslin-Friedlander equivariant motivic complexes compute Bredon motivic cohomology.

**Theorem 3.1.** Let $k$ be a perfect field and $V$ a $C_2$-representation. Then there is a quasi-isomorphism of complexes of sheaves in the equivariant Zariski topology on $C_2Sm/k$,
\[ Z(V) \simeq Z_{SF}(V). \]

In particular $H^{a+p\sigma, b+q\sigma}(X, \mathbb{Z}) = H^{a, b+q\sigma}_{C_2Nis}(X, Z_{SF}(V)[p\sigma]) = H^{a, b+q\sigma}_{C_2Zar}(X, Z_{SF}(V)[p\sigma])$ for any $C_2$-representation $V = b + q\sigma$.

**Proof.** Let $V = b + q\sigma$ a $C_2$-representation. As in the nonequivariant case (Theorem 16.8 [9]) we let $F_V(U)$ be the free abelian group generated by the equivariant 0-equidimensional (over $U$) closed subvarieties on $U \times A(V)$ that doesn’t touch $U \times 0$.

We have that $F_V(U) \subset z_{equi}(A(V), 0)^{C_2}(U)$. 

We have a commutative diagram in the category of presheaves with equivariant transfers:

\[
\begin{array}{ccccccccc}
0 & \rightarrow & Z_{tr}(\mathbb{P}(V+1) \setminus \{0\})^{C_2} & / & Z_{tr}(\mathbb{P}(V))^{C_2} & \rightarrow & Z_{tr}(\mathbb{P}(V+1))^{C_2} & / & Z_{tr}(\mathbb{P}(V))^{C_2} & \rightarrow & \ker_1 & \rightarrow & 0 \\
0 & \rightarrow & F_V & \rightarrow & z_{equi}(\mathbb{A}(V), 0)^{C_2} & \rightarrow & \ker_2 & \rightarrow & 0.
\end{array}
\]

The vertical maps are injective by construction. The middle map is injective because we have an exact sequence

\[0 \rightarrow Z_{tr}(\mathbb{P}(V))^{C_2} \rightarrow Z_{tr}(\mathbb{P}(V+1))^{C_2} \rightarrow z_{equi}(\mathbb{A}(V), 0)^{C_2}.\]

We see that \(\ker_1(U)\) is free abelian on equivariant correspondences \(Z \subset U \times \mathbb{P}(V+1)\) which touch \(U \times \{0\}\) and \(\ker_2(U)\) is free abelian on the equivariant closed 0-equidimensional \(W \subset U \times \mathbb{A}(V)\) which touch \(U \times \{0\}\). But the middle map is injective on these generators so it implies that \(r\) is injective.

We can prove that the map \(r\) is surjective on semilocal affine Hensel schemes with a single closed orbit. Let \(S\) be such a scheme and \(Z \subset S \times \mathbb{A}(V)\) a 0-equidimensional closed equivariant over \(S\). This means that \(Z\) is quasi-finite over \(S\). This implies that \(Z/C_2 \rightarrow S/C_2\) is quasi-finite over the local affine Hensel scheme \(S/C_2\). This implies that the quotient \(Z/C_2 = Z_1' \sqcup Z_0'\) is a disjoint union of a closed subscheme \(Z'_1\) which is finite and surjective over \(S/C_2\) and a closed subscheme \(Z_0'\) which doesn’t contain any point over the closed point of the local Hensel scheme. Moreover \(Z_0'\) doesn’t intersect \(S/C_2 \times \{0\}\) (see Lemma 16.11 [9]). Let \(p : Z \rightarrow Z/C_2\) be the canonical quotient map which is finite and surjective and \(Z_1 = p^{-1}(Z'_1), Z_0 = p^{-1}(Z'_0)\). This implies that \(Z = Z_0 \sqcup Z_1\). We also have that \(Z_0\) is a closed \(C_2\)-equivariant subscheme which doesn’t intersect \(S \times \{0\}\) and \(Z_1\) is a \(C_2\)-equivariant closed subscheme which is finite and surjective over \(S\).

This implies that \(Z_0\) is an \(C_2\)-equivariant cycle in \(F_V(S)\). It is also clear that \(Z_1\) comes from \(z_{tr}(\mathbb{P}(V+1))^{C_2} / Z_{tr}(\mathbb{P}(V))^{C_2}\) and \(Z = Z_1\) in \(\ker_2\). This implies \(r\) is surjective on semilocal affine Hensel schemes with a single closed orbit.

We have that \(C_1 \ker_1 \simeq C_1 \ker_2\) is a quasi-isomorphism of sheaves in equivariant Zariski topology (see Proposition 3.2 below).

We notice that \(\mathbb{P}(V+1) \setminus \{0\} \hookrightarrow \mathbb{P}(V+1)\) is \(C_2\)-equivariantly \(\mathbb{A}^1\)- homotopy equivalent to the inclusion \(\mathbb{P}(V) \hookrightarrow \mathbb{P}(V+1)\) (see Page 5 [8]) so

\[C_\ast \left(Z_{tr}(\mathbb{P}(V+1) \setminus \{0\})^{C_2} / Z_{tr}(\mathbb{P}(V))^{C_2}\right)

is a chain contractible complex of presheaves.

To conclude the theorem, we notice that \(C_\ast F_V\) is also a chain contractible complex of presheaves. Let \(H\) be the following map \(H_X : F_V(X) \rightarrow F_V(X \times \mathbb{A}^1)\) (with trivial action on \(\mathbb{A}^1\)) given by the equivariant pull-back of cycles \(f : X \times \mathbb{A}(V) \times \mathbb{A}^1 \rightarrow X \times \mathbb{A}(V), f(x, r, t) = (x, rt)\) which is flat on \(X \times \mathbb{A}(V) \setminus \{0\}\). Then \(F_V(i_1) \circ H_X = id\) and \(F_V(i_0) \circ H_X = 0\) which implies that \(C_\ast F_V\) is a chain contractible complex. Here \(i_1\) is the inclusion \(i_1 : X \times \mathbb{A}(V) \rightarrow X \times \mathbb{A}(V) \times \mathbb{A}^1\) with \(i_1(x, t) = (x, t, 1)\) and similarly \(i_0 : X \times \mathbb{A}(V) \rightarrow X \times \mathbb{A}(V) \times \mathbb{A}^1\) with \(i_0(x, t) = (x, t, 0)\).

Notice that we only used equivariant \(\mathbb{A}^1\)- equivalence in order to prove that certain complexes of presheaves are chain contractible complexes.

Using that \(C_\ast\) is an exact functor and using the five lemma we conclude that

\[C_\ast \left(Z_{tr}(\mathbb{P}(V+1))^{C_2} / Z_{tr}(\mathbb{P}(V))^{C_2}\right) \simeq C_\ast \left(z_{equi}(\mathbb{A}(V), 0)^{C_2}\right).\]
Proposition 3.2. Let $k$ be a perfect field. Let $F$ be a presheaf with equivariant transfers such that $F_{e\text{Nis}} = 0$. Then $C_*F_{e\text{Nis}} \simeq 0$ and $C_*F_{\text{Zar}} \simeq 0$.

Proof. We have that $C_*F_{e\text{Nis}} \simeq 0$ iff $(H_i)_{e\text{Nis}} = 0$ where $H_i = H_i(C_*F_{e\text{Nis}}) = 0$ for any $i$. This is obviously true for $i \leq 0$, where for $i = 0$ we used the condition $F_{e\text{Nis}} = 0$. We prove by induction that $(H_i)_{e\text{Nis}} = 0$ for any $i$. Suppose $(H_j)_{e\text{Nis}} = 0$ for any $j < i$. This means that the good truncation at level $i$, $\tau(C_*F_{e\text{Nis}})$ is quasi-isomorphic to $C_*F_{e\text{Nis}}$. We also have that the presheaf $H_i$ is homotopy invariant and then $(H_i)_{e\text{Nis}}$ is homotopy invariant (see Theorem 1.2. [7]). This implies that

$$\text{Hom}_{D^c_{e\text{Nis}}(k)}((C_*F)_{e\text{Nis}}, (H_i)_{e\text{Nis}}[i]) = \text{Hom}_{D^c_{e\text{Nis}}(k)}(F_{e\text{Nis}}, (H_i)_{e\text{Nis}}[i]) = 0,$$

where $D^c_{e\text{Nis}}(k)$ is the derived category of bounded above complexes of equivariant Nisnevich sheaves. This implies that the map in $D^c_{e\text{Nis}}(k)$,

$$C_*F_{e\text{Nis}} \simeq \tau C_*F_{e\text{Nis}} \to (H_i)_{e\text{Nis}}[i]$$

which induces an isomorphism on the $i^{th}$ homology groups is zero. This implies that $(H_i)_{e\text{Nis}} = 0$ and the induction is complete.

We have that $H_i(S) = 0$ for any semilocal Hensel affine with a single closed orbit. In particular $H_i(\bigcup_i \text{Spec}(E_i)) = 0$ with a $\mathbb{Z}/2$-action on the disjoint union and $E_i$ finitely generated field extensions of $k$. For every semilocal affine with a single closed orbit $S$ over $k$ and $S_0$ a $\mathbb{Z}/2$-invariant dense open subscheme we have that $F(S) \to F(S_0)$ for every homotopy invariant presheaf $F$ with equivariant transfers (Theorem 7.13, [7]). Taking the intersection category of all affine $\mathbb{Z}/2$–equivariant open subsets of $S$ we obtain a disjoint union of finitely generated field extensions of $k$. We conclude that $H_i(S) = 0$ for every semi-local affine with a single closed orbit. Notice that any point on a quasi-projective $\mathbb{Z}/2$-variety has an affine invariant open neighborhood. This implies that $(H_i)_{e\text{Zar}} \simeq 0$ which implies $(C_*F)_{e\text{Zar}} \simeq 0$. □

Part of the following proposition is in Proposition 3.15 [8].

Proposition 3.3. Let $X$ be a smooth scheme with trivial $C_2$-action and $V = b+q\sigma$ a $C_2$-representation. Then

$$\phi : H^{a+q\sigma+\rho+b+q\sigma}(X, Z) \simeq H^{a+2b}_{e\text{Nis}}(X, Z(V)[\rho\sigma]).$$

Proof. We also have the functor $(-)^c : (C_2 Sm/k) \to (Sm/k)$ that forgets the $C_2$-action and sends an equivariant Nisnevich cover into a Nisnevich cover of the schemes without action giving a morphism of sites $(-)^c : (Sm/k)_{Nis} \to (C_2 Sm/k)_{C_2 Nis}$. This induces a map on cohomology $\phi : H^{a+q\sigma+\rho+b+q\sigma}(X, Z) \to H^{a+2b}_{e\text{Nis}}(X, Z(V)[\rho\sigma])$. To construct the inverse of this map we look at the inclusion $t : (Sm/k) \to (C_2 Sm/k)$ which gives a morphism of sites $t : (C_2 Sm/k)_{C_2 Nis} \to (Sm/k)_{Nis}$ with $t^*$ an exact functor and $t^*(Z(V)[\rho\sigma]) = Z(V)[\rho\sigma]$ (see Proposition 3.15[8] and Lemma 3.19[7]). From the Leray spectral sequence we have that

$$\psi : H^{a+2b}_{e\text{Nis}}(X, Z(V)[\rho\sigma]) \simeq H^{a+q\sigma+\rho+b+q\sigma}(X, Z) = H^{a+2b}_{e\text{Nis}}(X, Z(V)[\rho\sigma])$$

is an isomorphism; this is the inverse of $\phi$. □
is a decomposition in $DM^-(k)$, where $k$ is a field of characteristic zero. Here $k[C_2] = 1 \oplus \sigma$ is the regular representation of $C_2$.

We conclude that $C_*z_{equi}(A(n\sigma),0)^C_2(n)[2n] = \oplus_{j=0}^{n-1}Z/2(j)[2j] \oplus Z(2n)[4n]$ so

$$C_*z_{equi}(A(n\sigma),0)^C_2 = \oplus_{j=0}^{n-1}Z/2(j)[2j] \oplus Z(n)[2n].$$

**Proposition 3.4.** Let $k$ be a field of characteristic zero and $b,q \geq 0$. Then

$$H^{a+2q,b+q\sigma}_C(k,Z) = \oplus_{j=0}^{q-1}H^{a+2j,j+b}(k,Z/2) \oplus H^{a+2q,b+q}(k,Z).$$

**Proof.** Using Theorem 3.1 we have that

$$H^{a+2q,b+q\sigma}_C(k,Z) = H^{a-2b}(k,C_*z_{equi}(A(V),0)^C_2) =$$

$$= H^{a-2b}(k,C_*z_{equi}(A(q\sigma),0)^C_2(b)[2b]) = H^{a-2b}(k,\oplus_{j=0}^{q-1}Z/2(j+b)[2j+2b] \oplus Z(q+b)[2q+2b]) =$$

$$= \oplus_{j=0}^{q-1}H^{a-2b}(k,Z/2(j+b)[2j+2b]) \oplus H^{a-2b}(k,Z(q+b)[2q+2b]) =$$

$$= \oplus_{j=0}^{q-1}H^{a+2j,j+b}(k,Z/2) \oplus H^{a+2q,b+q}(k,Z).$$

We used that

$$C_*z_{equi}(A(b+q\sigma),0)^C_2 \simeq C_*z_{equi}(A(q\sigma),0)^C_2 \otimes^{tr} C_*z_{equi}(A,b,0) = C_*z_{equi}(A(q\sigma),0)^C_2(b)[2b]$$

for any $b,q \geq 0$. \hfill $\blacksquare$

With $Z/l$--coefficients (the same for $Z/l$) we have (Theorem 5.7 [17]):

$$C_*z(A(n\sigma))^Z/2 \otimes Z/2 = \oplus_{j=0}^{q-1}(Z/2(j)[2j] \oplus Z/2(j)[2j+1]) \oplus Z/2(n)[2n].$$

This implies the following proposition:

**Proposition 3.5.** For any field $k$ of characteristic zero and any $b,q \geq 0$ we have

$$H^{a+2q,b+q\sigma}_C(k,Z/2) = \oplus_{j=0}^{q-1}(H^{a+2j,j+b}(k,Z/2) \oplus H^{a+2j+1,j+b}(k,Z/2)) \oplus$$

$$\oplus H^{a+2q,b+q}(k,Z/2) \simeq \oplus_{j=0}^{a+b}H^{a+j}_C(k,\mu_2^b \otimes j).$$

The statement is also valid with $Z/l$-coefficients.

**Proof.** The first statement follows from V.Voevodsky [14] and the statement with $Z/l$ coefficients follows from M.Rost and V.Voevodsky’s Bloch-Kato theorem [15], [16]. \hfill $\blacksquare$

In the case of $n = 1$ we have $C_*z_{equi}(A(\sigma))^Z/2 \otimes Z/2 = Z/2 \oplus Z/2[1] \oplus Z/2[2]$ and $C_*z_{equi}(A(\sigma))^Z/2 \otimes Z/2[(1)] = Z/2 \oplus Z/2[1] \oplus k^*/k^* \oplus Z/2[2]$. We also have that $C_*z_{equi}(A(\sigma))^Z/2 \simeq Z/2 \oplus O^*[1]$. These remarks are used in Proposition 5.2.

Remark that Proposition 3.5 and Proposition 3.4 are valid for any smooth scheme with a trivial action.

4. **Bredon motivic cohomology of a field in weight 0**

In this section we will compute Bredon motivic cohomology in weight less than or equal to zero of an arbitrary field $k$.

We have the following vanishing theorem for Bredon motivic cohomology groups:

**Proposition 4.1.** For any smooth $C_2$--variety $X$ and any $b+q < 0, b < 0$ we have

$$H^{a+q,b+q\sigma}_C(X,Z) = 0.$$
Proof. We use the motivic isotropy cofiber sequence \( EC_{2^+} \to S^0 \to \tilde{E}C_2 \) and the periodicity of Bredon motivic cohomology of \( \tilde{E}C_2 \) and \( EC_{2^+} \) to obtain

\[
H^{a,b}(\tilde{E}C_2 \times X) = 0 \to H^{a+pσ,b+qσ}(X) \to H^{a+2q+(p-2q)σ,b+q}(EC_{2^+} \times X) = 0.
\]

This implies the vanishing of the statement. The last equality follows from the fact that \( H^{a+pσ,b}(EC_{2^+} \times X) = 0 \) for any \( a, p \) and \( b < 0 \). This is the result of using inductively the l.e.s.

\[
H^{a,b}(EC_{2^+} \times X) = 0 \to H^{a,b}_{C_2}(EC_{2^+} \times X) = 0 \to H^{a+σ,b}_{C_2}(EC_{2^+} \times X) \to H^{a+1,b}_{C_2}(EC_{2^+} \times X) = 0
\]

and the l.e.s.

\[
H^{a-1,b}(EC_{2^+} \times X) = 0 \to H^{a-σ,b}_{C_2}(EC_{2^+} \times X) \to H^{a,b}_{C_2}(EC_{2^+} \times X) = 0 \to H^{a,b}_{C_2}(EC_{2^+} \times X) = 0.
\]

□

Proposition 4.2. Suppose \( b + q < 0 \). Then

\[
H^{a+pσ,b+qσ}(k, A) = H^{a+2qσ,b+qσ}(k, A)
\]

for any abelian group \( A \). When \( A = \mathbb{Z}/2 \) and \( a > b \geq 0 \) or \( a \leq -2 \) we have that

\[
H^{a+pσ,b+qσ}_{C_2}(k, \mathbb{Z}/2) = H^{a+2qσ,b+qσ}_{C_2}(k, \mathbb{Z}/2) = (H^*_c(k, μ^*_2)[τ, u, v]/(u^2 = vτ))^{a-1,b).
\]

Proof. We restrict to the case \( q < 0, b \geq 0 \) because if \( q < 0 \) and \( b < 0 \) we can use Proposition 4.1 to conclude that both groups are zero. Using the cofiber sequence \( C_{2^+} \to S^0 \to S^0 \) and \( b + q < 0 \) we conclude that \( H^{a+pσ,b+qσ}_{C_2}(k, A) = H^{a+2qσ,b+qσ}_{C_2}(k, A) \) for any \( p \) because motivic cohomology is zero in negative weight.

From the definition, it follows that \( H^{a+2qσ,b+qσ}_{C_2}(k, A) = H^{a+σ,b}_{C_2}(T^{-qσ}, A(b)) \). We have a cofiber sequence \( A(-qσ) \setminus \{0\} \to S^0 \to T^{-qσ} \) which implies that

\[
H^{a,b}(k, A) \to H^0_{C_2}(A(-qσ) \setminus \{0\}, A(b)) \to H^{a+σ}_{C_2}(T^{-qσ}, A(b)) \to H^{a+1,b}(k, A)
\]

with \( H^0_{C_2}(A(-qσ) \setminus \{0\}, A(b)) = H^{a,b}_{C_2}(A(-qσ) \setminus \{0\}/C_2, A) \) because \( A(-qσ) \setminus \{0\} \) has a free \( C_2 \)-action.

We know that \( H^{*,σ}(A(-qσ) \setminus \{0\}/C_2, \mathbb{Z}/2) \) is a \( H^{*,σ}(k, \mathbb{Z}/2) = H^*_c(k, μ^*_2)[τ] \)-module generated by \( uv^i \) and \( v^i \) where \( u \) is a \((1,1)\) element and \( v \) is a \((2,1)\) element and \( τ \) is a \((0,1)\) element (Theorem 6.10 [13]). We also have the relation \( u^2 = vτ \).

We can write the equality as

\[
H^{a+pσ,b+qσ}_{C_2}(k, \mathbb{Z}/2) = H^{a+2qσ,b+qσ}_{C_2}(k, \mathbb{Z}/2) = (H^*_c(k, μ^*_2)[τ, u, v]/(u^2 = vτ))^{a-1,b},
\]

for any \( b + q < 0 \) and \( a > b \) or \( a \leq -2 \). □

Proposition 4.3. We have \( \tilde{H}^{a+pσ,0}_{C_2}(\tilde{E}C_2, A) = 0 \) for any \( a, p \) and any abelian group \( A \).

Proof. From the periodicities \((σ−1, σ−1)\) and \((σ−1, 0)\) of \( \tilde{E}C_2 \) (Proposition 2.9 [8]) we have that \( \tilde{H}^{a+pσ,0}_{C_2}(\tilde{E}C_2) = \tilde{H}^{a,0}_{C_2}(\tilde{E}C_2) \). We have from the motivic isotropy sequence that

\[
0 \to \tilde{H}^{a,0}_{C_2}(\tilde{E}C_2) \to H^{a,0}_C(k) \simeq H^{a,0}_{C_2}(EC_2) \to \tilde{H}^{a+1,0}_{C_2}(\tilde{E}C_2) \to 0
\]

because \( H^{a,0}_C(k) = H^{a,0}_C(k) \simeq H^{a,0}_{C_2}(EC_2) = H^{a,0}_{C_2}(BC_2) \) for any \( a \) (which also implies that the left map of the sequence is injective). In the case of \( a ≠ 0 \) both sides of the isomorphism are zero. When \( a = 0 \) the isomorphism is given by the
Proposition 4.4. Let $b+q = 0$, $b \leq 0$. Then $H^{a+\sigma, b+q}_{C_2}(k, \mathbb{Z}) = H^{a+2q+(p-2)\sigma, 0}_{C_2}(k, \mathbb{Z})$.

Proof. We use the motivic isotropy cofiber sequence $\mathcal{E}C_2 \to S^0 \to \mathcal{E}C_2$. Using Proposition 4.3 we get for $b \leq 0$ that

$$\overline{H}^{a,b}_{C_2}(\mathcal{E}C_2) = 0 \to H^{a+\sigma, b+q}_{C_2}(k, \mathcal{E}C_2) \to \overline{H}^{a+1,b}_{C_2}(\mathcal{E}C_2) = 0$$

so we have $H^{a+\sigma, b+q}_{C_2}(k) = H^{a+\sigma, b+q}_{C_2}(\mathcal{E}C_2) = H^{a+2q+(p-2)\sigma, 0}_{C_2}(k)$ from the $(2\sigma - 2, \sigma - 1)$ periodicity of $\mathcal{E}C_2$ and $b+q = 0$. This means that

$$H^{a+\sigma, b+q}_{C_2}(k) = H^{a+2q+(p-2)\sigma, 0}_{C_2}(k) = H^{a+2q+(p-2)\sigma, 0}_{C_2}(k).$$

We will compute below the abelian groups $H^{a+\sigma, 0}_{C_2}(k, \mathbb{Z})$. We have the following i.e.s.

$$\to H^{a+\sigma, 0}_{C_2}(k, \mathbb{Z}) \to H^{a+\sigma+1, 0}_{C_2}(k, \mathbb{Z}) \to H^{a+\sigma, 0}_{C_2}(k, \mathbb{Z}) \to H^{a+\sigma+1, 0}_{C_2}(k, \mathbb{Z}) \to .$$

It implies that $H^{a+\sigma, 0}_{C_2}(k, \mathbb{Z}) \cong H^{a+(a+1)\sigma, 0}_{C_2}(k, \mathbb{Z})$ for any $p \leq -a - 1$ and that $H^{a+\sigma, 0}_{C_2}(k, \mathbb{Z}) \cong H^{a+(a-1)\sigma, 0}_{C_2}(k, \mathbb{Z})$ for any $p \geq -a + 1$. It is enough to compute the groups $H^{a+(a+1)\sigma, 0}_{C_2}(k, \mathbb{Z})$, $H^{a+(a-1)\sigma, 0}_{C_2}(k, \mathbb{Z})$ and $H^{a+(a-1)\sigma, 0}_{C_2}(k, \mathbb{Z})$ for any $a$. We have a i.e.s. between these groups for any $a$

$$0 \to H^{a+(a+1)\sigma, 0}_{C_2}(k, \mathbb{Z}) \to H^{a+(a-1)\sigma, 0}_{C_2}(k, \mathbb{Z}) \to H^{a, 0}_{C_2}(k, \mathbb{Z}) \to .$$

Notice that by definition $H^{a+(a+1)\sigma, 0}_{C_2}(k, \mathbb{Z}) = H^{a+(a-1)\sigma, 0}_{C_2}(k, \mathbb{Z}) = H^{a+1, 0}_{C_2}(k, \mathbb{Z})$ and $H^{a+(a+1)\sigma, 0}_{C_2}(k, \mathbb{Z}) = H^{a+1, 0}_{C_2}(k, \mathbb{Z})$.

Proposition 4.5. We have that $H^{a+(a-1)\sigma, 0}_{C_2}(k, \mathbb{Z}) = 0$ for any $a \geq 1$ or $a = -1$ and $\mathbb{Z}/2$ if $a = 0$. Also $H^{a+(a+1)\sigma, 0}_{C_2}(k, \mathbb{Z}) = 0$ for $a \leq 1$.

Proof. The complex $Z_{top}(n\sigma) = Z_{top}(\sigma) \otimes^fr \ldots \otimes^fr Z_{top}(\sigma)$ with $n > 0$ is a complex of presheaves on the positions $-n, \ldots, -1, 0$ and it satisfies descent in Nisnevich topology on $Sm/k$. Here $Z_{top}(\sigma)$ is the complex $Z_{tr}(C_2)^{C_2} \to Z_{tr}(k)^{C_2}$ on the positions $-1$ and $0$. If $n = 0$ then $Z_{top}(0) = \mathbb{Z}$ on the position zero. If $n < 0$ then $Z_{top}(n\sigma) = Z_{top}(\sigma) \otimes^fr \ldots \otimes^fr Z_{top}(\sigma)$ on the positions $0, 1, \ldots, -n$ with $Z_{top}(\sigma)$ being the complex $Z_{tr}(k)^{C_2} \to Z_{tr}(k)^{C_2}$ on the positions $0, 1$. This implies that $H^{a+(a-1)\sigma, 0}_{C_2}(k) = H^{a+1, 0}_{C_2}(k, Z_{top}(\sigma)) = 0$ if $b \leq 0$ (we wrote $b = -a + 1$). It implies that $H^{a+(a-1)\sigma, 0}_{C_2}(k) = 0$ for $a \geq 1$. If $a = 0$ then $H^{a, 0}_{C_2}(k, \mathbb{Z}) = H^{0, 0}_{C_2}(Z_{top}(\sigma)(k))$ where $Z_{top}(\sigma)(k)$ is the complex $Z \to \mathbb{Z}$ on the positions $-1, 0$. It implies that $H^{a, 0}_{C_2}(k, \mathbb{Z}) = \mathbb{Z}/2$. If $a = -1$ then we have the exact sequence

$$H^{a, 0}_{C_2}(k, \mathbb{Z}) \to H^{a+1, 0}_{C_2}(k, \mathbb{Z}) \to 0 \to H^{a+2, 0}_{C_2}(k, \mathbb{Z}) \to H^{1, 0}_{C_2}(k, \mathbb{Z}) = 0$$

so we conclude that $H^{a+2, 0}_{C_2}(k, \mathbb{Z}) = 0$. 

□
We also have that $H_{C_2}^{a,0}(k) = H_{C_2}^{b,1}(k, Z_{top}(b\sigma)) = 0$ if $b \geq 0$ (we wrote $b = -a - 1$). It implies that $H_{C_2}^{a,0}(k) = 0$ for $a \leq -1$. If $a = 0$ then $H_{C_2}^{0,0}(k, Z) = H_0(Z_{top}(-\sigma)(k)) = 0$ because $Z_{top}(-\sigma)(k)$ is the complex $Z \xrightarrow{id} Z$ on the positions 0 and 1. If $a = 1$ then we have a sequence

$$0 \to H_{C_2}^{-1,0}(k, Z) \to H_{C_2}^{-1,0}(k, Z) = 0 \to H_{C_2}^{0,0}(k, Z) = H^{0,0}(k, Z) = Z$$

so we conclude that $H_{C_2}^{-1,0}(k, Z) = 0$. □

In the next proposition we will study the cohomology of the complexes $Z_{top}(\pm \sigma)$ and $Z_{top}(\pm 2\sigma)$.

**Proposition 4.6.** We have that $H_{C_2}^{a+2\sigma,0}(k, Z) = 0$ if $a \neq -2, 0$ and $H_{C_2}^{2\sigma,0}(k, Z) = Z/2$, $H_{C_2}^{2+2\sigma,0}(k, Z) = Z$. We also have $H_{C_2}^{a,0}(k, Z) = Z$ and $H_{C_2}^{a-2\sigma,0}(k, Z) = 0$ for any $a \neq 2$.

We have $H_{C_2}^{a,0}(k, Z) = Z/2$, $H_{C_2}^{a+\sigma,0}(k, Z) = 0$ for $a \neq 0$ and $H_{C_2}^{a-\sigma,0}(k, Z) = 0$ for any $a$.

**Proof.** We have that $H_{C_2}^{a,0}(k, Z) = H^{a}(Z_{top}(-\sigma)(k))$. If $a = -1$ then the complex is $Z \xrightarrow{2} Z$ on the positions $-1$ and 0 so $H_{C_2}^{1,0}(k, Z) = H^0(Z_{top}(\sigma)(k)) = Z/2$ and $H_{C_2}^{a+\sigma,0}(k, Z) = 0$ for $a \neq 0$. If $a = 1$ then the complex is $Z \xrightarrow{id} Z$ on the positions 0, 1 so $H_{C_2}^{a-\sigma,0}(k, Z) = H^{a}(Z_{top}(\sigma)(k)) = 0$ for any $a$.

Let’s compute the differentials of the complex $Z_{top}(2\sigma)$. We have the projections $q_i : C_i \xrightarrow{} C_{i+1}$ for $i = 0, 1, 2$ and $p : C_2 \xrightarrow{pt}$. They induce the maps $q_i : Z_{tr}(C_i \times C_{i+1}) \xrightarrow{} Z_{tr}(C_{i+1})$ and $q_i : Z_{tr}(C_i \times C_{i+1}) \xrightarrow{} Z_{tr}(C_{i+1})$. The action of $C_2$ on $C_{i+1}$ is $0, 1$ switches the copies of $k$ i.e. $0 \to 1$ and $1 \to 0$ and induces a pointwise action on $Z_{tr}(C_2 \times C_{i+1})$. The map $p : Z_{tr}(C_2 \times C_{i+1}) \xrightarrow{} Z_{tr}(C_2 \times C_{i+1})$ is $p(a) = 2a$ because the map is induced by $p : Z_{tr}(C_2) \xrightarrow{} Z_{tr}(C_2)$. The dual $p^! : Z_{tr}(C_2) \xrightarrow{} Z_{tr}(C_2)$ is given by $p(a) = (a, a)$ which is given by the transpose matrix (1, 1). We look at $q_1^! : Z_{tr}(C_1) \xrightarrow{} Z_{tr}(C_1)$ and $q_2^! : Z_{tr}(C_2) \xrightarrow{} Z_{tr}(C_2)$ we see that $q_1^!(a, b) = (a, b, a, b) = (a, b)(I_2, I_2)$ which on fixed points gives $q_1^!(a) = (a, a)$. Looking at the transpose we obtain that $q_i : Z_{tr}(C_2 \times C_2) \xrightarrow{} Z_{tr}(C_2)$, $q_i(a, b, c, d) = (a + c, b + d) = (a, b, c, d)(I_2, I_2)^T$ implying that on fixed points we get $q_i : Z_{tr}(C_2 \times C_2) \xrightarrow{} Z_{tr}(C_2)$.

In conclusion we have the following complex

$$0 \to Z_{tr}(C_2 \times C_2) \xrightarrow{} Z_{tr}(C_2)^2 \xrightarrow{\oplus Z_{tr}(C_2)^2} Z_{tr}(C_2)^2 \xrightarrow{} 0$$

with the first map of the complex given by $(q_1, -q_2)$ i.e. $g(a, b) = (a + b, -a - b)$ and the second map is $f(a, b) = 2a + 2b = p + p$. It implies that $H_{-2+2\sigma,0}(k, Z) = Z$, $H_{-1+2\sigma,0}(k, Z) = 0$ and $H_{2\sigma,0}(k, Z) = H^{2,0}(k, Z) = Z/2$.

The complex $Z_{top}(2\sigma)$ is the following complex

$$0 \to Z_{tr}(k) \xrightarrow{} Z_{tr}(C_2)^2 \xrightarrow{\oplus Z_{tr}(C_2)^2} Z_{tr}(C_2 \times C_2) \xrightarrow{} 0$$

with the first map being $g(a) = (a, a)$ and the second map $f(a, b) = (a - b, a - b)$. It implies that $H_{2-2\sigma,0}(k, Z) = Z$ and $H^{n-2\sigma,0}(k, Z) = 0$ for $n \neq 2$. 
Notice that we can compute the cohomology of the complexes $Z_{top}(\pm 2\sigma)$ directly from the cohomology of the complexes $Z_{top}(\pm \sigma)$ (without the need to compute the differentials in $Z_{top}(\pm 2\sigma)$). We have the following l.e.s.

$$0 \to H_{C^2}^{-1-2\sigma,0}(k, \mathbb{Z}) \to H_{C^2}^{1-\sigma,0}(k, \mathbb{Z}) = 0 \to H_{C^2}^{0,0}(k, \mathbb{Z}) \to$$

$$\to H_{C^2}^{2-2\sigma,0}(k, \mathbb{Z}) \to H_{C^2}^{2-\sigma,0}(k, \mathbb{Z}) = 0 \to 0.$$  

It implies that $H_{C^2}^{1-2\sigma,0}(k, \mathbb{Z}) = 0$ and $H_{C^2}^{2-2\sigma,0}(k, \mathbb{Z}) = \mathbb{Z}$. In conclusion $H_{C^2}^{2-2\sigma,0}(k, \mathbb{Z}) = 0$ if $a \neq 2$. We have the following l.e.s.

$$0 \to H_{C^2}^{-2+2\sigma,0}(k, \mathbb{Z}) = 0 \to H_{C^2}^{-2+2\sigma,0}(k, \mathbb{Z}) \to H_{C^2}^{0,0}(k, \mathbb{Z}) = \mathbb{Z} \to$$

$$\to H_{C^2}^{1+\sigma,0}(k, \mathbb{Z}) = 0 \to H_{C^2}^{1+2\sigma,0}(k, \mathbb{Z}) = 0.$$  

This implies that $H_{C^2}^{2+2\sigma,0}(k, \mathbb{Z}) = \mathbb{Z}$ and $H_{C^2}^{1+2\sigma,0}(k, \mathbb{Z}) = 0$. We also have $H_{C^2}^{2,0}(k, \mathbb{Z}) = H_{C^2}^{0,0}(k, \mathbb{Z}) = \mathbb{Z}/2$ and $H_{C^2}^{1+2\sigma,0}(k, \mathbb{Z}) = 0$ if $a \neq -2, 0$. \hfill $\Box$

We compute below the negative cone of weight 0 Bredon motivic cohomology.

**Proposition 4.7.** If $n = \text{even} \geq 4$ then

$$H_{C^2}^{m-n\sigma,0}(k, \mathbb{Z}) = \begin{cases} \mathbb{Z}/2 & 3 \leq m < n, m = \text{odd} \\ \mathbb{Z} & m = n \\ 0 & \text{otherwise} \end{cases}.$$  

If $n = \text{odd} \geq 3$ then

$$H_{C^2}^{m-n\sigma,0}(k, \mathbb{Z}) = \begin{cases} \mathbb{Z}/2 & 3 \leq m \leq n, m = \text{odd} \\ 0 & \text{otherwise} \end{cases}.$$  

**Proof.** We compute the negative cone of weight 0 Bredon motivic cohomology by induction.

If $n = 3$ we have a l.e.s

$$0 \to H_{C^2}^{2-3\sigma,0}(k, \mathbb{Z}) \to H_{C^2}^{2-2\sigma,0}(k, \mathbb{Z}) \xrightarrow{f_1} H_{C^2}^{0,0}(k, \mathbb{Z}) \to H_{C^2}^{3-3\sigma,0}(k, \mathbb{Z}) \to H_{C^2}^{3-2\sigma,0}(k, \mathbb{Z}) = 0$$

and because

$$H_{C^2}^{1-\sigma,0}(k, \mathbb{Z}) = 0 \to H_{C^2}^{0,0}(k, \mathbb{Z}) = \mathbb{Z} \simeq H_{C^2}^{2-2\sigma,0}(k, \mathbb{Z}) = \mathbb{Z} \to H_{C^2}^{2-\sigma,0}(k, \mathbb{Z}) = 0$$

we have, according to Proposition 2.4, that $f_1$ is multiplication by 2. It implies $H_{C^2}^{3-3\sigma,0}(k, \mathbb{Z}) = \mathbb{Z}/2$ and $H_{C^2}^{m-3\sigma,0}(k, \mathbb{Z}) = 0$ if $m \neq 3$. We also have the sequence

$$0 \to H_{C^2}^{3-4\sigma,0}(k, \mathbb{Z}) \to H_{C^2}^{3-3\sigma,0}(k, \mathbb{Z}) = \mathbb{Z}/2 \xrightarrow{f_1} H_{C^2}^{0,0}(k, \mathbb{Z}) = \mathbb{Z} \to$$

$$\to H_{C^2}^{4-4\sigma,0}(k, \mathbb{Z}) \to H_{C^2}^{4-3\sigma,0}(k, \mathbb{Z}) = 0$$

which implies that $H_{C^2}^{3-4\sigma,0}(k, \mathbb{Z}) = H_{C^2}^{3-4\sigma,0}(k, \mathbb{Z}) = H_{C^2}^{3-\sigma,0}(k, \mathbb{Z}) = \mathbb{Z}/2$ for any $n \geq 3$ and $H_{C^2}^{m-3\sigma,0}(k, \mathbb{Z}) = H_{C^2}^{m-4\sigma,0}(k, \mathbb{Z}) = 0$ for $m \leq 2$ and $m \geq 5$ and $H_{C^2}^{4-4\sigma,0}(k, \mathbb{Z}) = \mathbb{Z}$. In conclusion

$$H_{C^2}^{n-4\sigma,0}(k, \mathbb{Z}) = \begin{cases} 0 & n \leq 2, n \geq 5 \\ \mathbb{Z}/2 & n = 3 \\ \mathbb{Z} & n = 4 \end{cases}.$$  

We have

$$0 \to H_{C^2}^{4-5\sigma,0}(k, \mathbb{Z}) \to H_{C^2}^{4-4\sigma,0}(k, \mathbb{Z}) = \mathbb{Z} \xrightarrow{f_2} H_{C^2}^{0,0}(k, \mathbb{Z}) = \mathbb{Z} \to$$
and that $H^{0,0}(k, \mathbb{Z}) = \mathbb{Z} \cong H^{4-4\sigma,0}_{C_2}(k, \mathbb{Z}) = \mathbb{Z}$ is an isomorphism from the above i.e.. We conclude that $H^{k,\sigma}_{C_2}(k, \mathbb{Z}) = 0$ if $m = 3, 5$ and $H^{m-5\sigma,0}_{C_2}(k, \mathbb{Z}) = H^{3-4\sigma,0}_{C_2}(k, \mathbb{Z}) = \mathbb{Z}/2$. It also implies that $H^{m-5\sigma,0}_{C_2}(k, \mathbb{Z}) = 0$ for any $m \neq 3, 5$ and $H^{3-5\sigma,0}_{C_2}(k, \mathbb{Z}) = H^{3-4\sigma,0}_{C_2}(k, \mathbb{Z}) = \mathbb{Z}/2$.

We conclude that $\mathbb{C} H^{5,−5\sigma}_{C_2}(k, \mathbb{Z}) \cong H^{5-\sigma,0}_{C_2}(k, \mathbb{Z}) = \mathbb{Z}/2$ and $H^{0,0}(k, \mathbb{Z}) = \mathbb{Z} \cong H^{6-6\sigma}_{C_2}(k, \mathbb{Z})$.

We conclude that $H^{6-6\sigma}(k, \mathbb{Z}) = \mathbb{Z}$, $H^{5-6\sigma}(k, \mathbb{Z}) = \mathbb{Z}/2$, $H^{4-6\sigma}(k, \mathbb{Z}) = 0$, $H^{3-6\sigma}(k, \mathbb{Z}) = \mathbb{Z}/2$ and $H^{m-6\sigma}(k, \mathbb{Z}) = 0$ for $m \leq 2$ and $m \geq 7$.

By induction we conclude that if $n = even \geq 4$ we have $H^{n-n\sigma}(k, \mathbb{Z}) = \mathbb{Z}$, $H^{n-1-n\sigma}(k, \mathbb{Z}) = \mathbb{Z}/2$, $H^{n-2-n\sigma}(k, \mathbb{Z}) = 0$, $H^{n-3-n\sigma}(k, \mathbb{Z}) = \mathbb{Z}/2$, $H^{2-\sigma}(k, \mathbb{Z}) = 0$ and $H^{m-n\sigma}(k, \mathbb{Z}) = 0$ for any $m \leq 2$ or $m \geq n + 1$.

If $n = odd \geq 3$ then $H^{n-n\sigma}(k, \mathbb{Z}) = \mathbb{Z}/2$, $H^{n-1-n\sigma}(k, \mathbb{Z}) = 0$, $H^{n-2-n\sigma}(k, \mathbb{Z}) = \mathbb{Z}/2$, ..., $H^{3-n\sigma}(k, \mathbb{Z}) = \mathbb{Z}/2$ and $H^{m-n\sigma}(k, \mathbb{Z}) = 0$ if $m \leq 2$ or $m \geq n + 1$.

The proof of the above proposition computes completely the negative cone of Bredon motivic cohomology in weight 0 with integer coefficients.

The positive cone of Bredon motivic cohomology in weight 0 with integer coefficients is completely computed in the next corollary:

**Corollary 4.8.** If $n = even \geq 2$ then

$$H^{m+n\sigma,0}_{C_2}(k, \mathbb{Z}) = \begin{cases} \mathbb{Z}/2 & -n < m \leq 0, m = even \\ \mathbb{Z} & m = -n \\ 0 & otherwise \end{cases}$$

If $n = odd \geq 1$ then

$$H^{m+n\sigma,0}_{C_2}(k, \mathbb{Z}) = \begin{cases} \mathbb{Z}/2 & -n < m \leq 0, m = even \\ 0 & otherwise \end{cases}$$

**Proof.** If $n = 3$ we have

$$0 \to H^{−3+2\sigma,0}_{C_2}(k, \mathbb{Z}) = 0 \to H^{−3+3\sigma,0}_{C_2}(k, \mathbb{Z}) \to$$

$$\to H^{0,0}(k, \mathbb{Z}) = \mathbb{Z} \cong H^{0,0}_{C_2}(k, \mathbb{Z}) = \mathbb{Z} \to H^{−1+\sigma,0}(k, \mathbb{Z}) = 0.$$
which implies that $H_{C_2}^{4+4\sigma,0}(k,\mathbb{Z}) = \mathbb{Z}$, $H_{C_2}^{-3+4\sigma,0}(k,\mathbb{Z}) = 0$, $H_{C_2}^{-2+4\sigma,0}(k,\mathbb{Z}) = H_{C_2}^{-2+3\sigma,0}(k,\mathbb{Z}) = \mathbb{Z}/2$, $H_{C_2}^{-1+4\sigma,0}(k,\mathbb{Z}) = 0$ and $H_{C_2}^{4\sigma,0}(k,\mathbb{Z}) = H_{C_2}^{3\sigma,0}(k,\mathbb{Z}) = \mathbb{Z}/2$ and the rest of the groups are zero. In conclusion

$$H_{C_2}^{m+4\sigma,0}(k,\mathbb{Z}) = \begin{cases} \mathbb{Z} & m = -4 \\ \mathbb{Z}/2 & -2 \leq m \leq 0, m = \text{even} \\ 0 & \text{otherwise} \end{cases}.$$ 

In the case of $n = 5$ we have the following

$$0 \to H_{C_2}^{-5+4\sigma,0}(k,\mathbb{Z}) = 0 \to H_{C_2}^{-5+5\sigma,0}(k,\mathbb{Z}) \to \cdots \to H^{0,0}(k,\mathbb{Z}) = \mathbb{Z} \overset{g_2} \to H_{C_2}^{-4+4\sigma,0}(k,\mathbb{Z}) = \mathbb{Z} \to H_{C_2}^{-4+5\sigma,0}(k,\mathbb{Z}) \to 0.$$ 

The map $g_2$ is multiplication by 2 because

$$0 = H_{C_2}^{-4+3\sigma,0}(k,\mathbb{Z}) \to H_{C_2}^{-4+4\sigma,0}(k,\mathbb{Z}) \simeq H^{0,0}(k,\mathbb{Z}) \to H_{C_2}^{-3+3\sigma}(k,\mathbb{Z}) = 0.$$ 

In conclusion $H_{C_2}^{-3+5\sigma,0}(k,\mathbb{Z}) = 0$, $H_{C_2}^{-2+5\sigma,0}(k,\mathbb{Z}) = H_{C_2}^{-2+4\sigma,0}(k,\mathbb{Z}) = \mathbb{Z}/2$, $H_{C_2}^{-1+5\sigma,0}(k,\mathbb{Z}) = 0$ and $H_{C_2}^{5\sigma,0}(k,\mathbb{Z}) = \mathbb{Z}/2$ and the rest are zero. Now by induction we conclude the rest of the cases.

From the discussion above we also conclude:

**Corollary 4.9.** We have

$$H_{C_2}^{a-\alpha\sigma,0}(k,\mathbb{Z}) = \begin{cases} \mathbb{Z} & a = \text{even} \\ 0 & a = \text{odd, } a \leq 1 \\ \mathbb{Z}/2 & a = \text{odd, } a > 1 \end{cases}.$$ 

We also have $H_{C_2}^{a-\alpha\sigma,0}(k,\mathbb{Z}/2) = \mathbb{Z}/2$ for any $a \leq 0$, $a \geq 2$ and zero for $a = 1$.

The above theorems conclude that Bredon motivic cohomology of a field with integer coefficients in weight 0 coincide (as abstract groups) with Bredon cohomology of a point with integer coefficients. We also have the following theorem:

**Theorem 4.10.** Let $k$ be an arbitrary field. Then with $\mathbb{Z}/2$–coefficients we have that

$$H_{C_2}^{a+p\alpha,0}(k,\mathbb{Z}/2) = \begin{cases} \mathbb{Z}/2 & 1 < a \leq -p \\ \mathbb{Z}/2 & 0 \leq -a \leq p \\ 0 & \text{otherwise} \end{cases}.$$ 

5. **Bredon motivic cohomology of a field in weights 1 and $\sigma$**

In this section we assume that $k$ is a field of characteristic zero.

We have the following Bredon motivic cohomology of $\bar{E}C_2$ in weight 1.

**Proposition 5.1.** We have $\bar{H}_{C_2}^{3+p\alpha,1}(\bar{E}C_2,\mathbb{Z}) = 0$ if $a \neq 3$ and $\bar{H}_{C_2}^{3+p\alpha,1}(\bar{E}C_2,\mathbb{Z}) = \mathbb{Z}/2$.

**Proof.** We have that the motivic isotropy sequence gives a l.e.s

$$0 \to \bar{H}_{C_2}^{1,1}(\bar{E}C_2) \to H_{C_2}^{1,1}(k,\mathbb{Z}) = k^* \to H_{C_2}^{1,1}(EC_2,\mathbb{Z}) = k^* \to \bar{H}_{C_2}^{2,1}(\bar{E}C_2,\mathbb{Z}) \to \cdots$$ 

$$\to H_{C_2}^{2,1}(k,\mathbb{Z}) = 0 \to H_{C_2}^{2,1}(EC_2,\mathbb{Z}) \to \bar{H}_{C_2}^{3,1}(\bar{E}C_2,\mathbb{Z}) \to H_{C_2}^{3,1}(k,\mathbb{Z}) = 0.$$
The map $\alpha : k^* = O^*(k) \to k^* = O^*(BC_2)$ is the identity and $H^{2,1}_{C_2}(EC_2, \mathbb{Z}) = H^{2,1}(BC_2, \mathbb{Z}) = \mathbb{Z}/2$ (Corollary 3.5 [12]). It implies that $\tilde{H}^{m,1}_{C_2}(EC_2, \mathbb{Z}) = 0$ if $m \neq 3$ and $\tilde{H}^{3,1}_{C_2}(EC_2, \mathbb{Z}) = \mathbb{Z}/2$. The general result follows from the periodicities of $EC_2$.

**Proposition 5.2.** a) $H^{2,\sigma}_{C_2}(k, \mathbb{Z}) = \mathbb{Z}/2$, $H^{2\sigma-1,\sigma}_{C_2}(k, \mathbb{Z}) = k^*$, $H^{2\sigma+n,\sigma}_{C_2}(k, \mathbb{Z}) = 0$ for any $n \neq 0, -1$.

b) $H^{2,\sigma}_{C_2}(k, \mathbb{Z}/2) = \mathbb{Z}/2$, $H^{2\sigma-1,\sigma}_{C_2}(k, \mathbb{Z}/2) = \mathbb{Z}/2 \oplus k^*/k^{*2}$, $H^{2\sigma-2,\sigma}_{C_2}(k, \mathbb{Z}/2) = \mathbb{Z}/2$ and $H^{2\sigma+n,\sigma}_{C_2}(k, \mathbb{Z}/2) = 0$ for any $n \neq 0, -1, -2$.

**Proof.** From Proposition 3.4 we have

$$H^{2,\sigma}_{C_2}(k, \mathbb{Z}) = H^0(\text{equi}(A(\sigma), 0)C_2(k)) = H^0(\mathbb{Z}/2[0] \oplus k^*[1]) = \mathbb{Z}/2.$$  

With $\mathbb{Z}/2$-coefficients we have

$$H^{2,\sigma}_{C_2}(k, \mathbb{Z}/2) = H^0(\text{equi}(A(\sigma), 0)C_2(k) \otimes \mathbb{Z}/2) = H^0((\mathbb{Z}/2[0] \oplus k^*[1]) \otimes \mathbb{Z}/2) =$$

$$= H^0(\mathbb{Z}/2[0] \oplus \mathbb{Z}/2[1] \oplus k^*[1] \otimes \mathbb{Z}/2) = H^0(\mathbb{Z}/2[0] \oplus \mathbb{Z}/2[1] \oplus \mathbb{Z}/2[2] \oplus k^*/k^{*2}[1]) = \mathbb{Z}/2.$$  

**Proposition 5.3.** a) We have $H^{2,\sigma}_{C_2}(k, \mathbb{Z}) = \mathbb{Z}/2$ and $H^{2\sigma+n,\sigma}_{C_2}(k, \mathbb{Z}) = 0$ for any $n \neq 0$. With $\mathbb{Z}/2$-coefficients we have $H^{2,\sigma}_{C_2}(k, \mathbb{Z}/2) = \mathbb{Z}/2$ and $H^{2\sigma-1,\sigma}_{C_2}(k, \mathbb{Z}/2) = \mathbb{Z}/2$ and $H^{2\sigma+n,\sigma}_{C_2}(k, \mathbb{Z}/2) = 0$ for any $n \neq 0, -1$.

b) $H^{2,\sigma}_{C_2}(k, \mathbb{Z}/2) = k^{*2}$ and $H^{2\sigma}_{C_2}(k, \mathbb{Z}/2) = 0$ for any $n \neq 1$.

With $\mathbb{Z}/2$-coefficients we have

$$H^{2,\sigma}_{C_2}(k, \mathbb{Z}/2) = \begin{cases} \mathbb{Z}/2 & \sqrt{-1} \neq 0 \\ 0 & \text{otherwise} \end{cases}$$

and $H^{1,\sigma}_{C_2}(k, \mathbb{Z}/2) = k^{*2}/k^{*4}$.

In the case $\sqrt{-1} \neq 0$ we have that $k^*/k^{*2} \simeq k^{*2}/k^{*4} = H^{1,\sigma}_{C_2}(k, \mathbb{Z}/2)$. Also $H^{2,\sigma}_{C_2}(k, \mathbb{Z}/2) = 0$ for $n \neq 0, 1$.

**Proof.** a) We have the following l.e.s.

$$H^{0,1}_{C_2}(k, \mathbb{Z}) = 0 \to H^{1,0}_{C_2}(k, \mathbb{Z}) \to H^{2,1}_{C_2}(k, \mathbb{Z}) = k^* \to H^{1,1}_{C_2}(k, \mathbb{Z}) = k^* \to H^{0,1}_{C_2}(k, \mathbb{Z}) = \mathbb{Z}/2 \to H^{2,1}_{C_2}(k, \mathbb{Z}) = 0$$

We have that

$$id : H^{2,1,1}_{C_2}(k, \mathbb{Z}) = H^0_{C_2}(k, O^*) = O^*(k) = k^* \to H^{1,1}_{C_2}(k, \mathbb{Z}) = k^*.$$  

This is because the connecting map $H^{2,1,1}_{C_2}(k, \mathbb{Z}) = H^{-1}_{C_2}(k, Z(\sigma)[2\sigma]) = H^{-1}_{C_2}(k, O^*[1] \oplus \mathbb{Z}/2[0]) = H^0_{C_2}(k, O^*) = k^* \to H^{1,1}_{C_2}(k, \mathbb{Z}) = H^{2,1,1}_{C_2}(k, \mathbb{Z}) = H^{-1}_{C_2}(C_2, Z(\sigma)[2\sigma]) = H^0_{C_2}(C_2, O^*[C_2]) = k^* = \text{the identity map being induced by the diagonal} k^* \to (k^*)^2$$

It implies from the above l.e.s. that $H^{2,1,1}_{C_2}(k, \mathbb{Z}) = 0$ and $H^{2,1,1}_{C_2}(k, \mathbb{Z}) \simeq H^{2,1,1}_{C_2}(k, \mathbb{Z}) = \mathbb{Z}/2$. We also have that

$$0 = H^{-1,1}_{C_2}(k) \to H^{2,2}_{C_2}(k) \to H^{2,2}_{C_2}(k, \mathbb{Z}) = 0$$

which implies $H^{2,2}_{C_2}(k, \mathbb{Z}) = 0$. Similarly $H^{2,2+n}_{C_2}(k, \mathbb{Z}) \simeq H^{2,2+n}_{C_2}(k, \mathbb{Z}) = 0$ for any $n \geq 1$ and $n \leq -2$. 

From the split universal coefficients sequence we have that
\[ H^2\sigma_C(k, \mathbb{Z}/2) = H_C^\sigma(k, \mathbb{Z}) \otimes \mathbb{Z}/2 = \mathbb{Z}/2 \]
and
\[ H^{2-1,\sigma}_C(k, \mathbb{Z}/2) = 2H^\sigma_C(k, \mathbb{Z}) = \mathbb{Z}/2. \]

b) We have
\[ H^0\sigma_C(k, \mathbb{Z}) = 0 \rightarrow H^0\sigma_C(k, \mathbb{Z}) \rightarrow H^\sigma_C(k, \mathbb{Z}) = \mathbb{Z}/2 \rightarrow H^{1,\sigma}_C(k, \mathbb{Z}) = k^* \rightarrow H^{1,\sigma}_C(k, \mathbb{Z}) = 0 \]
\[ H^{1,\sigma}_C(k, \mathbb{Z}) \rightarrow H^{2,\sigma}_C(k, \mathbb{Z}) = 0 \rightarrow H^2\sigma_C(k, \mathbb{Z}) \rightarrow H^{2+1,\sigma}_C(k, \mathbb{Z}) = 0 \rightarrow 0. \]
It implies that \( H^{2+1,\sigma}_C(k, \mathbb{Z}) = 0 \) for any \( n \neq 0, 1 \). The map \( \alpha \) is either injective or zero. We prove that the map \( \alpha \) is an injective map.

We have \( H^1_S(k, \mathbb{Z}/2) = \mathbb{Z}/2 \) and \( H^1_S(k, \mathbb{Z}/2) = 0 \) for any \( i \neq 1 \). This is because we have
\[ H^{n+\sigma,\sigma}_C(k, \mathbb{Z}) = H^n_C(k, (\mathbb{Z}/2)[n] \oplus \mathbb{Z}/2) = H_{n+1}^\sigma(\mathbb{Z}/2, \mathbb{Z}/2). \]
This is zero if \( n \neq 0 \) and \( \mathbb{Z}/2 \) if \( n = 0 \) from point a). We have that \( H^n_C(k, \mathbb{Z}/2) = 0 \) for any \( n \) because the complexes \( Z_{\text{top}}(-\sigma) \) have trivial cohomology (see proof of Proposition 4.5). Obviously \( H^0_S(k, \mathbb{Z}/2) = \mathbb{Z}/2 \) and \( H^0_S(k, \mathbb{Z}/2) = 0 \) for \( n \neq 1 \). The map \( \alpha \) is the inclusion map being given by the forgetting action map
\[ \mathbb{Z}/2 = H^1_S(k, \mathbb{Z}/2) \rightarrow H^1_S(C, \mathbb{Z}/2) = H^1_S(S, \mathbb{Z}/2) = k^*. \]
The injectivity follows from the following diagram:

\[ \begin{align*}
H^0_C(k, \mathbb{Z}/2) & \rightarrow H^0_C(C, \mathbb{Z}/2) \rightarrow H^1_C(S, \mathbb{Z}/2) \rightarrow H^1_C(k, \mathbb{Z}/2) \rightarrow H^1_C(C, \mathbb{Z}/2) \\
\downarrow r & \downarrow p \downarrow \alpha \downarrow q \downarrow \\
H^0_C(C, \mathbb{Z}/2) & \rightarrow H^0_C(C, \mathbb{Z}/2) \rightarrow H^1_C(C, \mathbb{Z}/2) \rightarrow H^1_C(C, \mathbb{Z}/2) \rightarrow H^1_C(C, \mathbb{Z}/2). 
\end{align*} \]

The map \( p \) is injective and the maps \( r \) and \( q \) are bijectives (Lemma 3.19, [7]) which implies that the map \( \alpha \) is injective.

Because we have a short exact sequence of abelian groups
\[ 0 \rightarrow \mathbb{Z}/2 \rightarrow k^* \rightarrow k^* \rightarrow 0 \]
it implies that \( H^1_C(k, \mathbb{Z}) = k^2 \) and \( H^0_C(k, \mathbb{Z}) = 0 \).

We have \( H^0_C(k, \mathbb{Z}/2) = 2H^1_C(k, \mathbb{Z}) = \text{all elements } x^2 \text{ of order 2 in } k^*. \)

It implies that \( H^1_C(k, \mathbb{Z}/2) = \mathbb{Z}/2 \) (if \(-1 \in k^2\)) or \( H^0_C(k, \mathbb{Z}/2) = 0 \) (if \(-1 \notin k^2\)). Also
\[ H^{1-1,\sigma}_C(k, \mathbb{Z}/2) = 2H^\sigma_C(k, \mathbb{Z}) = 0. \]

With \( \mathbb{Z}/2 \)-coefficients we have the l.e.s.
\[ \rightarrow H^{1,\sigma}_C(k, \mathbb{Z}/2) = 0 \rightarrow H^{1-1,\sigma}_C(k, \mathbb{Z}/2) = \mathbb{Z}/2 \rightarrow H^0_C(k, \mathbb{Z}/2) = \mathbb{Z}/2 \rightarrow H^0_C(k, \mathbb{Z}/2) \rightarrow \\
\rightarrow H^1_C(k, \mathbb{Z}/2) = \mathbb{Z}/2 \rightarrow H^1_C(k, \mathbb{Z}/2) = k^*/k^2 \rightarrow H^1_C(k, \mathbb{Z}/2) = 0. \]
If \(-1 \in k^2\) then \( H^{1,\sigma}_C(k, \mathbb{Z}/2) = \mathbb{Z}/2 \) and the map \( \alpha \) is zero which implies \( H^{1,\sigma}_C(k, \mathbb{Z}/2) = k^*/k^2 \). If \(-1 \notin k^2\) then \( H^{1,\sigma}_C(k, \mathbb{Z}/2) = 0 \) and the map \( \alpha \) is injective and from the short exact sequence
\[ 0 \rightarrow \mathbb{Z}/2 \rightarrow k^*/k^2 \rightarrow H^1_C(k, \mathbb{Z}/2) \rightarrow 0, \]
we have
we have that \( H^{1+\sigma}_C(k, \mathbb{Z}/2) = k^* / k^{*4} \) with the connecting homomorphism \( \delta \) being multiplication by 2.

**Proposition 5.5.** a) \( H^{0,1}_C(k, \mathbb{Z}) = \mathbb{Z}/2, \ H^{\sigma+1,1}_C(k, \mathbb{Z}) = k^* / k^{*2}, \ H^{\sigma+n,1}_C(k, \mathbb{Z}) = 0 \) for \( n \neq 0, 1 \).

b) \( H^{\sigma}_C(k, \mathbb{Z}/2) = \mathbb{Z}/2 \oplus k^* / k^{*2}, \ H^{\sigma+1}_C(k, \mathbb{Z}/2) = k^* / k^{*2}, \ H^{\sigma-1}_C(k, \mathbb{Z}/2) = \mathbb{Z}/2, \ H^{\sigma+n}_C(k, \mathbb{Z}/2) = 0 \) for \( n \neq 0, -1, 1 \).

**Proof.** We have a l.e.s.

\[
H^{0,1}(k, \mathbb{Z}) = 0 \to H^{0,1}_C(k, \mathbb{Z}) = 0 \to H^{\sigma+1,1}_C(k, \mathbb{Z}) \to H^{1,1}(k, \mathbb{Z}) = k^* \delta \to \\
\delta \to H^{1+\sigma,1}_C(k, \mathbb{Z}) = k^* \to H^{1+\sigma,1}_C(k, \mathbb{Z}) \to \\
\to H^{2,1}(k, \mathbb{Z}) = 0 \to H^{2,1}_C(k, \mathbb{Z}) = 0 \to H^{2+\sigma,1}_C(k, \mathbb{Z}) \to \\
\to H^{3,1}(k, \mathbb{Z}) = 0 \to H^{3,1}_C(k, \mathbb{Z}) = 0 \to H^{3+\sigma,1}_C(k, \mathbb{Z}) \to
\]

We obtain \( H^{\sigma+n,1}_C(k, \mathbb{Z}) = 0 \) for \( n \neq 0, 1 \).

We prove now that the connecting map \( \delta \) is the multiplication by 2. According to Proposition 2.4 the composition

\[
H^{1,1}_C(k, \mathbb{Z}) \to H^{1,1}(k, \mathbb{Z}) \delta \to H^{1,1}(k, \mathbb{Z})
\]

is multiplication by 2. We have the following l.e.s.

\[
0 \to H^{2-\sigma,1}_C(k, \mathbb{Z}) \to H^{1,1}_C(k, \mathbb{Z}) \to H^{1,1}(k, \mathbb{Z}) \to H^{2-\sigma,1}_C(k, \mathbb{Z}) \to 0.
\]

Using the motivic isotropy sequence and the periodicity of Bredon motivic cohomology of \( \mathbb{E} \mathbb{Z} / 2 \) (see also Proposition 6.1) we obtain from Proposition 5.3 that

\[
H^{1-\sigma,1}_C(k, \mathbb{Z}) = H^{1-\sigma,1}_C(\mathbb{E} \mathbb{Z} / 2, \mathbb{Z}) = H^{\sigma-1,\sigma}_C(\mathbb{E} \mathbb{Z} / 2, \mathbb{Z}) = H^{\sigma-1,\sigma}_C(k, \mathbb{Z}) = 0.
\]

We also have that

\[
0 \to H^{2-\sigma,1}_C(k, \mathbb{Z}) \to H^{2-\sigma,1}_C(\mathbb{E} \mathbb{Z} / 2) \to \mathbb{Z}/2 \to H^{3-\sigma,1}_C(k, \mathbb{Z}) = 0
\]

with \( H^{2-\sigma,1}_C(\mathbb{E} \mathbb{Z} / 2) = H^{\sigma,\sigma}_C(\mathbb{E} \mathbb{Z} / 2) = H^{\sigma,\sigma}_C(k, \mathbb{Z}) = \mathbb{Z}/2 \). It implies that \( H^{2-\sigma,1}_C(k, \mathbb{Z}) = 0 \) and thus the map \( H^{1,1}_C(k, \mathbb{Z}) \to H^{1,1}(k, \mathbb{Z}) \) is an isomorphism. This implies that the connecting map \( \delta \) is multiplication by 2.

We obtain \( H^{1,1}_C(k, \mathbb{Z}) = k^* / k^{*2} \) and \( H^{1,1}_C(k, \mathbb{Z}) = \mathbb{Z}/2 \).

With \( \mathbb{Z}/2 \)-coefficients we have that

\[
H^{\sigma}_C(k, \mathbb{Z}/2) = H^{\sigma}_C(k, \mathbb{Z}) \otimes \mathbb{Z}/2 \oplus 2H^{1+\sigma,1}_C(k, \mathbb{Z}) = \mathbb{Z}/2 \oplus k^* / k^{*2}.
\]

We also have \( H^{1+\sigma,1}_C(k, \mathbb{Z}/2) = H^{1+\sigma,1}_C(k, \mathbb{Z}) \otimes \mathbb{Z}/2 \oplus 2H^{2+\sigma,1}_C(k, \mathbb{Z}) = k^* / k^{*2} \) and \( H^{1+\sigma,1}_C(k, \mathbb{Z}/2) = H^{1+\sigma,1}_C(k, \mathbb{Z}) \otimes \mathbb{Z}/2 \oplus 2H^{1+\sigma,1}_C(k, \mathbb{Z}) = \mathbb{Z}/2 \). The rest of groups are obviously zero.

In conclusion we have:

**Corollary 5.6.** For any field \( k \) of char\( (k) = 0 \) we have

\[
H^{\sigma}_C(k, \mathbb{Z}) = \mathbb{Z}/2, \ H^{1,1}_C(k, \mathbb{Z}) = k^* / k^{*2}, \ H^{1,1}_C(k, \mathbb{Z}) = \mathbb{Z}/2, \ H^{1,1}_C(k, \mathbb{Z}) = k^*.
\]

With \( \mathbb{Z}/2 \)-coefficients we have \( H^{\sigma}_C(k, \mathbb{Z}/2) = \mathbb{Z}/2, \ H^{1,1}_C(k, \mathbb{Z}/2) = k^* / k^{*2}, \ H^{1,1}_C(k, \mathbb{Z}/2) = k^* / k^{*2} \).
In the following theorem we compute the positive cone of Bredon motivic cohomology of a quadratically closed field or an euclidian field (of characteristic zero).

**Theorem 5.7.** Let \( k \) be a quadratically closed field or an euclidian field. If \( n \geq 2 \) is even, then

\[
H^n_{\mathbb{C}^2}(k, \mathbb{Z}) = \begin{cases} 
  k^* & m = n-1 \\
  k^*/k^{*2} & \quad -1 \leq m < n-1, m = odd \\
  \mathbb{Z}/2 & \quad 0 \leq m < n-1, m = even \\
  0 & \quad \text{otherwise}
\end{cases}
\]

If \( n \geq 1 \) is odd, then

\[
H^n_{\mathbb{C}^2}(k, \mathbb{Z}) = \begin{cases} 
  k^*/k^{*2} & \quad -1 \leq m < n-1, m = odd \\
  \mathbb{Z}/2 & \quad 0 \leq m < n-1, m = even \\
  0 & \quad \text{otherwise}
\end{cases}
\]

**Proof.** We have the following l.e.s.

\[
0 \to H^{2\sigma-1,1}_{\mathbb{C}^2}(k, \mathbb{Z}) \to H^{1,1}(k, \mathbb{Z}) = k^* \xrightarrow{\alpha} H^\sigma_{\mathbb{C}^2}(k, \mathbb{Z}) = \mathbb{Z}/2 \to H^{2\sigma-1,1}_{\mathbb{C}^2}(k, \mathbb{Z}) \to H^{2,1}(k, \mathbb{Z}) = 0.
\]

Here \( H^{2,1}_{\mathbb{C}^2}(k, \mathbb{Z}) = \mathbb{Z}/2 \) from Proposition 5.5. The composition \( H^\sigma_{\mathbb{C}^2}(k, \mathbb{Z}) \to H^\sigma_{\mathbb{C}^2}(C_2, \mathbb{Z}) \to H^\sigma_{\mathbb{C}^2}(k, \mathbb{Z}) \) is multiplication by 2 (the vertical maps in the diagram below are given by forgetting the action):

\[
\begin{array}{ccc}
\tilde{H}^{2\sigma,1}_{\mathbb{C}^2}(S^\sigma) & \xrightarrow{\tilde{\alpha}} & \tilde{H}^{2\sigma,1}_{\mathbb{C}^2}(C_2 + S^1) \\
\downarrow & & \downarrow \\
\tilde{H}^{2,1}_{\mathcal{M}}(S^1) & \xrightarrow{\tilde{\alpha}} & \tilde{H}^{2,1}_{\mathcal{M}}(S^1 \lor S^1) \\
\downarrow & & \downarrow \\
\tilde{H}^{2,1}_{\mathcal{M}}(S). & & \tilde{H}^{2,1}_{\mathcal{M}}(S^1) \\
\end{array}
\]

The first upper horizontal map is induced by the fold map \( C_2 + S^\sigma \to S^\sigma \) and the second is induced by the pinch map \( S^\sigma \to C_+ \lor S^1 \).

It implies that the homomorphism \( \alpha : k^* \to \mathbb{Z}/2 \) has the property that \( \alpha(1) = \alpha(-1) = 1 \). If \( k \) is quadratically closed (i.e. \( k = k^2 \)) then \( \alpha \) is the zero map. If \( k \) is an euclidian field (i.e. formally real and \( k^*/k^{*2} \approx \mathbb{Z}/2 \)) it implies that the map \( \alpha \) is zero. Indeed suppose that \( \alpha \) is surjective. Then \( H = Ker(\alpha) \) is a subgroup of index 2 of \( k^* \) that contains \( k^{*2} \). It implies that \( H = k^{*2} \), but \( -1 \in H \) because \( \alpha(-1) = 0 \). This is contradiction because \( k \) is formally real.

Then we have \( H^{2\sigma,1}_{\mathbb{C}^2}(k, \mathbb{Z}) \simeq H^{\sigma,1}_{\mathbb{C}^2}(k, \mathbb{Z}) = \mathbb{Z}/2 \) and \( H^{2\sigma-1,1}_{\mathbb{C}^2}(k, \mathbb{Z}) = k^* \). By induction we have \( H^{\sigma,1}_{\mathbb{C}^2}(k, \mathbb{Z}) \simeq H^{\sigma,1}_{\mathbb{C}^2}(k, \mathbb{Z}) = \mathbb{Z}/2 \) for any \( n \geq 1 \). We also have \( H^{\sigma+1,1}_{\mathbb{C}^2}(k, \mathbb{Z}) = H^{\sigma+1,1}_{\mathbb{C}^2}(k, \mathbb{Z}) = k^*/k^{*2} \).

According to the sequence

\[
H^{n-1+s,1}_{\mathbb{C}^2}(k, \mathbb{Z}) \to H^{(n-1)\sigma+s,1}_{\mathbb{C}^2}(k, \mathbb{Z}) \to H^{n\sigma+s,1}_{\mathbb{C}^2}(k, \mathbb{Z}) \to H^{n+s,1}_{\mathbb{C}^2}(k, \mathbb{Z})
\]

and by induction we obtain that \( H^{\sigma+n,1}_{\mathbb{C}^2}(k, \mathbb{Z}) = 0 \) if \( s \geq 2 \) and \( n \geq 1 \). This follows from \( H^{n\sigma+s,1}_{\mathbb{C}^2}(k, \mathbb{Z}) = 0 \) if \( n = 0 \) and \( s \geq 2 \). We also have

\[
0 \to H^{2\sigma-2,1}_{\mathbb{C}^2}(k, \mathbb{Z}) = 0 \to H^{2\sigma-2,1}_{\mathbb{C}^2}(k, \mathbb{Z}) \to H^{1,1}(k, \mathbb{Z}) \to H^{2\sigma-1,1}_{\mathbb{C}^2}(k, \mathbb{Z}) \to H^{3\sigma-1,1}_{\mathbb{C}^2}(k, \mathbb{Z}) \to 0.
\]
The map $\psi$ is multiplication by 2 because we have from the above that
\[ H_{C_2}^{2,1}(k, \mathbb{Z}) = 0 \to H_{C_2}^{2\sigma - 1,1}(k, \mathbb{Z}) \simeq H_{C_2}^{1,1}(k, \mathbb{Z}) \to 0 \]
and the map on the $(3, 1)$–motivic cohomology induced by $S^1 \wedge S^1 \to S^1 \wedge S^1 \vee S^1 \wedge S^1 \to S^1 \wedge S^1$ is given by multiplication by 2. This is shown in the diagram below where the vertical maps are forgetting action maps and the lower horizontal composition is the multiplication by 2.

\[
\begin{array}{c}
\xymatrix{
\tilde{H}^{3\sigma,1}(S^\sigma \wedge S^1) \ar[r] \ar[d]_{\cong} & \tilde{H}^{3\sigma,1}(S^\sigma \wedge S^1 \wedge C_2) \ar[r]^{\psi} & \tilde{H}^{3\sigma,1}(S^\sigma \wedge S^1) \\
\tilde{H}^{3,1}(S^1 \wedge S^1) \ar[r] \ar[d] \ar[u]_{\cong} & \tilde{H}^{3,1}(S^1 \wedge S^1 \vee S^1 \wedge S^1) \ar[r] & \tilde{H}^{3,1}(S^1 \wedge S^1).
}
\end{array}
\]

In conclusion we have $H_{C_2}^{3\sigma,2,1}(k, \mathbb{Z}) = \mathbb{Z}/2$ and $H_{C_2}^{3\sigma,1,1}(k, \mathbb{Z}) = k^*/k^{*2} = H_{C_2}^{n\sigma,1,1}(k, \mathbb{Z})$ for any $n \geq 3$. According to the above sequences we have
\[ H_{C_2}^{2\sigma - s,1}(k, \mathbb{Z}) = H_{C_2}^{\sigma,1}(k, \mathbb{Z}) = 0 \]
for any $s \geq 2$. We have $H_{C_2}^{3\sigma - s,1}(k, \mathbb{Z}) = H_{C_2}^{2\sigma - s,1}(k, \mathbb{Z}) = 0$ for any $s \geq 3$. We have
\[ 0 \to H_{C_2}^{3\sigma - 3,1}(k, \mathbb{Z}) = 0 \to H_{C_2}^{3\sigma - 3,1}(k, \mathbb{Z}) \to H_{C_2}^{1,1}(k, \mathbb{Z}) \to H_{C_2}^{3\sigma - 2,1}(k, \mathbb{Z}) \to H_{C_2}^{3\sigma - 2,1}(k, \mathbb{Z}) \to 0 \]
The middle map $H_{C_2}^{1,1}(k, \mathbb{Z}) = k^* \to H_{C_2}^{3\sigma - 2,1}(k, \mathbb{Z}) = \mathbb{Z}/2$ is zero from the argument above. We use that the map $H_{C_2}^{3\sigma - 2,1}(k, \mathbb{Z}) = 0 \to H_{C_2}^{3\sigma - 2,1}(k, \mathbb{Z}) \to H^{1,1}(k, \mathbb{Z})$ is injective and that we have the following commutative diagram with the lower horizontal composition being multiplication by 2.

\[
\begin{array}{c}
\xymatrix{
\tilde{H}^{4\sigma - 2,1}(S^\sigma) \ar[r] \ar[d] & \tilde{H}^{4\sigma - 2,1}(C_2 + S^1) \ar[r] & \tilde{H}^{4\sigma - 2,1}(S^\sigma) \\
\tilde{H}^{3,1}(S^1) \ar[r] \ar[d] & \tilde{H}^{3,1}(S^1 \vee S^1) \ar[r] & \tilde{H}^{3,1}(S^1).}
\end{array}
\]

Then we have $H_{C_2}^{4\sigma - 3,1}(k, \mathbb{Z}) = k^*$ and $H_{C_2}^{4\sigma - 2,1}(k, \mathbb{Z}) = \mathbb{Z}/2$. We have $H_{C_2}^{4\sigma - s,1}(k, \mathbb{Z}) = H_{C_2}^{3\sigma - s,1}(k, \mathbb{Z}) = 0$ for any $s \geq 4$.

Let $n$ be even. By induction we have $H_{C_2}^{n\sigma - m,1}(k, \mathbb{Z}) = k^*/k^{*2}$ if $-1 \leq m < n - 1$, $m$ odd and $H_{C_2}^{n\sigma - n + 1,1}(k, \mathbb{Z}) = k^*$ and $H_{C_2}^{n\sigma - m,1}(k, \mathbb{Z}) = \mathbb{Z}/2$ for $0 \leq m < n - 1$, $m$ even.

Let $n$ be odd. Then $H_{C_2}^{n\sigma - m,1}(k, \mathbb{Z}) = k^*/k^{*2}$ if $-1 \leq m \leq n - 2$, $m$ odd and $H_{C_2}^{n\sigma - m,1}(k, \mathbb{Z}) = \mathbb{Z}/2$ if $-1 \leq m \leq n$, $m$ even.

The negative cone in weight 1 of Breton motivic cohomology of a formally real field or a quadratically closed field of characteristic zero is computed below.

**Theorem 5.8.** Let $k$ be a formally real field or a quadratically closed field.
If $n \geq 2$ is even then
\[
H_{C_2}^{n - n\sigma,1}(k, \mathbb{Z}) = \begin{cases} 
  k^* & m = n + 1 \\
  k^*/k^{*2} & 2 < m \leq n, \text{ even} \\
  \mathbb{Z}/2 & 2 < m \leq n, \text{ odd} \\
  0 & \text{otherwise}
\end{cases}
\]
If $n \geq 1$ is odd then

$$H_{C_2}^{m-n\sigma,1}(k, \mathbb{Z}) = \begin{cases} k^*/k^{\sigma^2} & 2 < m \leq n + 1, m = \text{even} \\ \mathbb{Z}/2 & 2 < m \leq n + 1, m = \text{odd} \\ 0 & \text{otherwise} \end{cases}$$

If $n = 0$ then $H_{C_2}^{m,1}(k, \mathbb{Z}) = H^{m,1}(k, \mathbb{Z}) = k^*$ if $m = 1$ and $H_{C_2}^{m,1}(k, \mathbb{Z}) = 0$ if $m \neq 1$.

**Proof.** We have that $H_{C_2}^{m-n\sigma,1}(k, \mathbb{Z}) = H_{C_2}^{m,1}(k, \mathbb{Z}) = 0$ for any $m \leq 0$ and $n \geq 0$. We have

$$0 \rightarrow H_{C_2}^{1-\sigma,1}(k, \mathbb{Z}) = 0 \rightarrow H_{C_2}^{1,1}(k, \mathbb{Z}) = k^* \simeq H^{1,1}(k, \mathbb{Z}) = \alpha^* \rightarrow H_{C_2}^{2-\sigma,1}(k, \mathbb{Z}) = 0 \rightarrow 0,$$

from the proof of Proposition 5.5. It implies that $H_{C_2}^{m-\sigma,1}(k, \mathbb{Z}) = 0$ for any $m$. We have

$$H_{C_2}^{2-\sigma,1}(k, \mathbb{Z}) = 0 \rightarrow H^{1,1}(k, \mathbb{Z}) \rightarrow H_{C_2}^{3-2\sigma,1}(k, \mathbb{Z}) \rightarrow 0$$

that implies $H_{C_2}^{3-2\sigma,1}(k, \mathbb{Z}) = k^*$ and $H_{C_2}^{m-2\sigma,1}(k, \mathbb{Z}) = 0$ for $m \neq 3$. It also implies that $H_{C_2}^{2-n\sigma,1}(k, \mathbb{Z}) = 0$ for any $n \geq 1$.

We have

$$0 \rightarrow H_{C_2}^{3-3\sigma,1}(k, \mathbb{Z}) \rightarrow H_{C_2}^{3-2\sigma,1}(k, \mathbb{Z}) = k^* \rightarrow H^{1,1}(k, \mathbb{Z}) = k^* \rightarrow H_{C_2}^{4-3\sigma,1}(k, \mathbb{Z}) \rightarrow 0$$

and the middle map is multiplication by 2 because the composition

$$H_{C_2}^{3-2\sigma,1}(k, \mathbb{Z}) = k^* \rightarrow H^{1,1}(k, \mathbb{Z}) = k^* \simeq H_{C_2}^{3-2\sigma,1}(k, \mathbb{Z}) = k^*$$

is multiplication by 2 from Proposition 2.4.

In conclusion we obtain $H_{C_2}^{3-3\sigma,1}(k, \mathbb{Z}) = \mathbb{Z}/2$ and $H_{C_2}^{4-3\sigma,1}(k, \mathbb{Z}) = k^*/k^{\sigma^2}$ and $H_{C_2}^{n-3\sigma,1}(k, \mathbb{Z}) = 0$ for $n \neq 3, 4$.

If $n = 4$ we have that $H_{C_2}^{m-4\sigma,1}(k, \mathbb{Z}) = H^{m-3\sigma,1}(k, \mathbb{Z})$ for any $m \leq 3$ or $m \geq 6$.

For the rest of the cases we have the following l.e.s.

$$0 \rightarrow H_{C_2}^{4-4\sigma,1}(k, \mathbb{Z}) \rightarrow H_{C_2}^{4-3\sigma,1}(k, \mathbb{Z}) = k^*/k^{\sigma^2} \alpha_1 \rightarrow H^{1,1}(k, \mathbb{Z}) = k^* \rightarrow H_{C_2}^{5-4\sigma,1}(k, \mathbb{Z}) \rightarrow 0.$$
so by Theorem 2.4 we obtain that $\alpha_2$ is multiplication by 2. We conclude that $H_{C_2}^{n-5\sigma,1}(k, \mathbb{Z}) = \mathbb{Z}/2$ and $H_{C_2}^{n-5\sigma,1}(k, \mathbb{Z}) = k^*/k^{*2}$. We also have $H_{C_2}^{n-4\sigma,1}(k, \mathbb{Z}) = H_{C_2}^{n-4\sigma,1}(k, \mathbb{Z})$ for $n \neq 5, 6$.

By induction we have the following:

If $n > 2$ is even then $H_{C_2}^{n+1-\sigma,1}(k, \mathbb{Z}) = k^*$ and $H_{C_2}^{n-\sigma,1}(k, \mathbb{Z}) = k^*/k^{*2}$ for $2 < m \leq n$ even and $H_{C_2}^{m-\sigma,1}(k, \mathbb{Z}) = \mathbb{Z}/2$ with $2 < m < n$, $m$ odd.

If $n > 2$ is odd then $H_{C_2}^{m-\sigma,1}(k, \mathbb{Z}) = k^*/k^{*2}$ for $2 < m \leq n + 1$, $m$ even and $H_{C_2}^{m-\sigma,1}(k, \mathbb{Z}) = \mathbb{Z}/2$ if $2 < m \leq n + 1$, $m$ odd.

The case $n = 0$ follows from the computation of motivic cohomology of a field in weight 1.

Corollary 5.9. Let $k$ be a field of characteristic zero. If $k$ is a euclidian field or a quadratically closed field we have that the positive cone ($n \geq 0$) is

$$H_{C_2}^{n-\sigma,m,1}(k, \mathbb{Z}/2) = \begin{cases} k^*/k^{*2} \oplus \mathbb{Z}/2 & 0 \leq m \leq n - 1 \\ \mathbb{Z}/2 & 0 \leq m = n \\ k^*/k^{*2} & m = -1 < n \\ 0 & \text{otherwise} \end{cases}$$

and the negative cone ($-n < 0$)

$$H_{C_2}^{m-\sigma,n,1}(k, \mathbb{Z}/2) = \begin{cases} k^*/k^{*2} \oplus \mathbb{Z}/2 & 3 \leq m \leq n \\ \mathbb{Z}/2 & m = 2 \leq n \\ k^*/k^{*2} & m = n + 1, n \geq 2 \\ 0 & \text{otherwise} \end{cases}$$

We conclude that for a quadratically closed field the Bredon motivic cohomology of weight 1 with $\mathbb{Z}/2$–coefficients coincides as abstract groups with Bredon cohomology of a point. For a euclidian field like $\mathbb{R}$ we have that $k^*/k^{*2} = \mathbb{Z}/2$.

The negative cone of Bredon motivic cohomology of weight $\sigma$ of a formally real field or a quadratically closed field is computed below. For a quadratically closed field it coincides with the negative cone in weight 1 (see Theorem 5.8). It doesn’t coincide for a formally real field.

Theorem 5.10. Suppose that $k$ is a quadratically closed or a formally real field ($\text{char}(k) = 0$). Then for $n \geq 1$ we have:

If $n \geq 2$ is even then

$$H_{C_2}^{m-\sigma,n,\sigma}(k, \mathbb{Z}) = \begin{cases} k^* & m = n + 1 \\ k^*/k^{*2} & 2 \leq m \leq n, m = \text{even} \\ \mathbb{Z}/2 & 2 < m \leq n, m = \text{odd} \\ 0 & \text{otherwise} \end{cases}$$

If $n \geq 1$ is odd then

$$H_{C_2}^{m-\sigma,n,\sigma}(k, \mathbb{Z}) = \begin{cases} k^*/k^{*2} & 2 \leq m \leq n + 1, m = \text{even} \\ \mathbb{Z}/2 & 2 < m \leq n, m = \text{odd} \\ 0 & \text{otherwise} \end{cases}$$
Proof. We have that $H^n_{C_2}^{-m,m}(k, Z) = H^2_{m,m}(k, Z) = 0$ from l.e.s. for any $n \geq 2$ and $m \geq 0$. We also have
\[H^{-m,1}_{C_2}(k, Z) \to H^{-m,m}_{C_2}(k, Z) \to H_{C_2}^{(-m+1),m}(k, Z) \to H_{C_2}^{-m,m+1}(k, Z)\]
We have $H_{C_2}^{-m,m}(k, Z) = 0 = H_{C_2}^0(k, Z) = 0$ for any $m \geq 0$. Also $H_{C_2}^{n-m,m}(k, Z) = 0$ for any $n \leq 0$ and $m \geq 0$. We have that
\[H^0_{C_2}(k, Z) = 0 \to H^1_{C_2}(k, Z) \to H^1_{C_2}(k, Z) = k^*/ \beta_1 \to H^1_{C_2}(k, Z) = k^* \to H^2_{C_2}(k, Z) = H^2_{C_2}(k, Z) = 0.\]
The map $\beta_1$ is an injective map because $H^1_{C_2}(k, Z) = 0$. This follows from $H^1_{C_2}(k, Z) = H^1_{C_2}(\Z/2, Z) = H^3_{C_2}(\Z/2, Z)$ and the motivic isotropy sequence gives
\[H^2_{C_2}(\Z/2, Z) = H^0_{C_2}(k, Z) = 0 \to \Z/2 \to H^3_{C_2}(\Z/2, Z) = \Z/2 \to H^3_{C_2}(\Z/2, Z) \to 0.\]
It implies that $H^3_{C_2}(\Z/2, Z) = 0$.
In conclusion $\beta_1$ is injective and $H^2_{C_2}(k, Z) = k^*/k^2$. We conclude that $H^2_{C_2}(k, Z) = k^*/k^2$ for $n = 2$ and zero otherwise. We also notice that
\[H^1_{C_2}(k, Z) = H^1_{C_2}(n,\sigma)(k, Z) = 0\]
for any $n \geq 1$.
We have
\[0 \to H^2_{C_2}(k, Z) \to H^1_{C_2}(k, Z) = k^*/k^2 \to H^1_{C_2}(k, Z) = k^* \to H^2_{C_2}(k, Z) = H^2_{C_2}(k, Z) = 0\]
so $H^2_{C_2}(k, Z) = k^*/k^2$ and $H^3_{C_2}(k, Z) = k^*$ because the map $\tau$ is the zero map because $k$ is either a formally real field or a quadratically closed field.

We also have $H^2_{C_2}(k, Z) = 0$ for any $n \neq 2, 3$.
We have
\[0 \to H^3_{C_2}(k, Z) \to H^2_{C_2}(k, Z) = k^* \to H^2_{C_2}(k, Z) = k^* \to H^3_{C_2}(k, Z) \to 0\]
and the map $\tau_1$ is the multiplication by 2 as above so $H^3_{C_2}(k, Z) = \Z/2$ and $H^3_{C_2}(k, Z) = k^*/k^2$. Also $H^2_{C_2}(k, Z) = H^2_{C_2}(k, Z) = k^*/k^2$ and $H^3_{C_2}(k, Z) = 0$ if $n \neq 2, 3, 4$.

For $n = 4$ we have
\[0 \to H^4_{C_2}(k, Z) \to H^4_{C_2}(k, Z) = k^*/k^2 \to H^1_{C_2}(k, Z) = k^* \to H^5_{C_2}(k, Z) = H^5_{C_2}(k, Z) = 0\]
so $H^4_{C_2}(k, Z) = k^*/k^2$ and $H^5_{C_2}(k, Z) = k^*$. This is because the map $\tau_2$ is the zero map as above. Also $H^3_{C_2}(k, Z) = H^3_{C_2}(k, Z) = \Z/2$, $H^4_{C_2}(k, Z) = H^5_{C_2}(k, Z) = k^*/k^2$ and the rest are zero.

By induction we have that if $n$ is even then $H^2_{C_2}(k, Z) = k^*/k^2$, $H^3_{C_2}(k, Z) = Z/k^2$, $H^4_{C_2}(k, Z) = Z/k^2$, $H^5_{C_2}(k, Z) = Z/k^2$, $H^6_{C_2}(k, Z) = Z/k^2$.

If $n$ odd then $H^2_{C_2}(k, Z) = k^*/k^2$, $H^3_{C_2}(k, Z) = Z/k^2$, $H^4_{C_2}(k, Z) = Z/k^2$, $H^5_{C_2}(k, Z) = Z/k^2$, $H^6_{C_2}(k, Z) = Z/k^2$.
Theorem 5.11. Let $k$ be a quadratically closed field or a euclidian field. Then if $n \geq 2$ is even

$$H_{C_2}^{n\sigma-m,\sigma}(k, \mathbb{Z}) = \begin{cases} k^* & m = n-1 \\ k^*/k^{*2} & 1 \leq m < n-1, m = odd \\ \mathbb{Z}/2 & 0 \leq m < n-1, m = even \\ 0 & otherwise. \end{cases}$$

If $n \geq 1$ is odd then

$$H_{C_2}^{n\sigma-m,\sigma}(k, \mathbb{Z}) = \begin{cases} k^*/k^{*2} & 1 \leq m < n-1, m = odd \\ \mathbb{Z}/2 & 0 \leq m < n-1, m = even \\ 0 & otherwise \end{cases}$$

If $n = 0$ then $H^{1,\sigma}(k, \mathbb{Z}) = k^{*2}$ and $H^{m,\sigma}(k, \mathbb{Z}) = 0$ for any $m \neq 1$.

Proof. From Proposition 3.4 we have that $H_{C_2}^{2\sigma-1,\sigma}(k, \mathbb{Z}) = k^*$, $H_{C_2}^{2\sigma,\sigma}(k, \mathbb{Z}) = \mathbb{Z}/2$ and $H_{C_2}^{2\sigma+m,\sigma}(k, \mathbb{Z}) = 0$ for $m \neq -1, 0$. We have

$$0 \to H_{C_2}^{2\sigma-2,\sigma}(k, \mathbb{Z}) = 0 \to H_{C_2}^{3\sigma-2,\sigma}(k, \mathbb{Z}) \to$$

$$H_{C_2}^{1,1}(k, \mathbb{Z}) = k^{*} \to H_{C_2}^{2\sigma-1,\sigma}(k, \mathbb{Z}) = k^{*} \to H_{C_2}^{3\sigma-1,\sigma}(k, \mathbb{Z}) \to 0$$

with the map $\gamma$ is given by multiplication by 2. This follows from the fact that $H_{C_2}^{2\sigma-1,\sigma}(k, \mathbb{Z}) \to H_{C_2}^{1,1}(k, \mathbb{Z})$ is the identity map (Proposition 5.3) and from the following diagram

$$\label{eq:diagram1} \begin{array}{ccc} H_{C_2}^{3\sigma-1,\sigma}(S^\sigma) & \overset{\cong}{\longrightarrow} & H_{C_2}^{3\sigma-1,\sigma}(C_2 + S^1) \overset{\gamma}{\longrightarrow} H_{C_2}^{3\sigma-1,\sigma}(S^\sigma) \\ \cong \downarrow & & \cong \downarrow \\ H_{M}^{2,1}(S^1) & \longrightarrow & H_{M}^{2,1}(S^1 \vee S^1) \longrightarrow H_{M}^{2,1}(S^1). \end{array}$$

Then $H_{C_2}^{3\sigma-2,\sigma}(k, \mathbb{Z}) = \mathbb{Z}/2$ and $H_{C_2}^{3\sigma-1,\sigma}(k, \mathbb{Z}) = k^{*}/k^{*2}$. We also have $H_{C_2}^{3\sigma,\sigma}(k, \mathbb{Z}) = H_{C_2}^{2\sigma,\sigma}(k, \mathbb{Z}) = \mathbb{Z}/2$. For $n = 4$ we have

$$0 \to H_{C_2}^{3\sigma-3,\sigma}(k, \mathbb{Z}) = 0 \to H_{C_2}^{4\sigma-3,\sigma}(k, \mathbb{Z}) \to$$

$$H_{C_2}^{1,1}(k, \mathbb{Z}) = k^{*} \alpha \to H_{C_2}^{3\sigma-2,\sigma}(k, \mathbb{Z}) = \mathbb{Z}/2 \to H_{C_2}^{4\sigma-2,\sigma}(k, \mathbb{Z}) \to 0.$$ 

The map $\alpha$ is zero for a quadratically closed field or a euclidian field because $H_{C_2}^{2\sigma-2,\sigma}(k, \mathbb{Z}) = 0 \to H_{C_2}^{3\sigma-2,\sigma}(k, \mathbb{Z}) = \mathbb{Z}/2 \to H_{C_2}^{4\sigma-2,\sigma}(k, \mathbb{Z})$ is injective and we have the following diagram

$$\begin{array}{ccc} H_{C_2}^{4\sigma-2,\sigma}(S^\sigma) & \longrightarrow & H_{C_2}^{4\sigma-2,\sigma}(C_2 + S^1) \overset{\alpha}{\longrightarrow} H_{C_2}^{4\sigma-2,\sigma}(S^\sigma) \\ \downarrow & & \downarrow \\ H_{M}^{2,1}(S^1) & \longrightarrow & H_{M}^{2,1}(S^1 \vee S^1) \longrightarrow H_{M}^{2,1}(S^1). \end{array}$$

This implies that $H_{C_2}^{4\sigma-3,\sigma}(k, \mathbb{Z}) = k^{*}$ and $H_{C_2}^{4\sigma-2,\sigma}(k, \mathbb{Z}) = \mathbb{Z}/2$. Also $H_{C_2}^{1,\sigma}(k, \mathbb{Z}) = H_{C_2}^{2\sigma,\sigma}(k, \mathbb{Z}) = \mathbb{Z}/2$, $H_{C_2}^{3\sigma-1,\sigma}(k, \mathbb{Z}) = H_{C_2}^{2\sigma-1,\sigma}(k, \mathbb{Z}) = k^{*}/k^{*2}$. For $n = 5$ we have

$$0 \to H_{C_2}^{4\sigma-4,\sigma}(k, \mathbb{Z}) = 0 \to H_{C_2}^{5\sigma-4,\sigma}(k, \mathbb{Z}) \to$$

$$H_{C_2}^{1,1}(k, \mathbb{Z}) = k^{*} \beta \to H_{C_2}^{4\sigma-3,\sigma}(k, \mathbb{Z}) = k^{*} \to H_{C_2}^{5\sigma-3,\sigma}(k, \mathbb{Z}) \to 0.$$
with the map \( \beta \) multiplication by 2 because \( H^{3\sigma-3,\sigma}_{C_2}(k,\mathbb{Z}) = 0 \rightarrow H^{3\sigma-3,\sigma}_{C_2}(k,\mathbb{Z}) \simeq H^{1,1}(k,\mathbb{Z}) \) and we have the following diagram

\[
\begin{array}{ccc}
\tilde{H}^{5\sigma-3,\sigma}_{C_2}(\sigma^2) & \xrightarrow{\cong} & \tilde{H}^{5\sigma-3,\sigma}_{C_2}(C_2 \wedge S^1) \\
& \cong & \\
\tilde{H}^{2,1}_{\mathcal{M}}(S^1) & \xrightarrow{\cong} & \tilde{H}^{2,1}_{\mathcal{M}}(S^1 \vee S^1) \\
\end{array}
\]

with the lower horizontal composition being multiplication by 2. It implies that 
\( H^{5\sigma-4,\sigma}_{C_2}(k,\mathbb{Z}) = \mathbb{Z}/2 \) and \( H^{5\sigma-3,\sigma}_{C_2}(k,\mathbb{Z}) = k^*/k^{\ast^2}. \) By previous computations we obtain 
\( H^{5\sigma-2,\sigma}_{C_2}(k,\mathbb{Z}) = \mathbb{Z}/2, \quad H^{5\sigma-1,\sigma}_{C_2}(k,\mathbb{Z}) = k^*/k^{\ast^2}, \quad H^{5\sigma,\sigma}_{C_2}(k,\mathbb{Z}) = \mathbb{Z}/2. \)

By induction it implies that if \( n \) is even then 
\( H^{n\sigma,\sigma}_{C_2}(k,\mathbb{Z}) = \mathbb{Z}/2, \quad H^{n\sigma-1,\sigma}_{C_2}(k,\mathbb{Z}) = k^*/k^{\ast^2}, \quad \ldots, \quad H^{n\sigma-n/2,\sigma}_{C_2}(k,\mathbb{Z}) = k^*/k^{\ast^2}, \quad H^{n\sigma-n/2+2,\sigma}_{C_2}(k,\mathbb{Z}) = k^*/k^{\ast^2}. \)

If \( n \) is odd then 
\( H^{n\sigma,\sigma}_{C_2}(k,\mathbb{Z}) = \mathbb{Z}/2, \quad H^{n\sigma-1,\sigma}_{C_2}(k,\mathbb{Z}) = k^*/k^{\ast^2}, \quad \ldots, \quad H^{n\sigma-n+1,\sigma}_{C_2}(k,\mathbb{Z}) = k^*/k^{\ast^2}, \quad H^{n\sigma-n+1,\sigma}_{C_2}(k,\mathbb{Z}) = \mathbb{Z}/2. \)

The case \( n = 0 \) was discussed in Proposition 5.3.

\[ \square \]

**Corollary 5.12.** Let \( k \) be a field of characteristic zero and \( n > 0. \) If \( k \) is a euclidian field or a quadratically closed field then the negative cone is

\[
H^{m-n,\sigma}_{C_2}(k,\mathbb{Z}/2) = \begin{cases} 
\frac{k^*/k^{\ast^2} \times \mathbb{Z}/2}{2 \leq m \leq n} & 2 \leq m \leq n \\
\frac{k^*/k^{\ast^2}}{2 \leq m = n + 1, m = 1} & \\
\frac{0}{\text{otherwise}} & 
\end{cases}
\]

and the positive cone is

\[
H^{n,\sigma}_{C_2}(k,\mathbb{Z}/2) = \begin{cases} 
\frac{k^*/k^{\ast^2} \times \mathbb{Z}/2}{1 \leq m \leq n - 1} & 1 \leq m \leq n - 1 \\
\frac{\mathbb{Z}/2}{1 \leq m = n, m = 0} & \\
\frac{0}{\text{otherwise}} & 
\end{cases}
\]

If \( n = 0 \) we have that

\[
H^{0,\sigma}_{C_2}(k,\mathbb{Z}/2) = \begin{cases} 
\frac{\mathbb{Z}/2}{-1 \in k^{\ast^2}} & \\
\frac{0}{-1 \notin k^{\ast^2}} & 
\end{cases}
\]

and \( H^{1,\sigma}_{C_2}(k,\mathbb{Z}/2) = k^*/k^{\ast^4} \) and \( H^{n,\sigma}_{C_2}(k,\mathbb{Z}/2) = 0 \) for \( n \neq 0, 1. \)

**Proof.** Universal coefficients sequence gives a split s.e.s

\[ 0 \rightarrow H^{n,\sigma-m,\sigma}_{C_2}(k,\mathbb{Z}) \otimes \mathbb{Z}/2 \rightarrow H^{n,\sigma-m,\sigma}_{C_2}(k,\mathbb{Z}/2) \rightarrow 2H^{n,\sigma-m+1,\sigma}_{C_2}(k,\mathbb{Z}) \rightarrow 0. \]

We have 
\( H^{n,\sigma-m,\sigma}_{C_2}(k,\mathbb{Z}/2) \simeq H^{n,\sigma-m,\sigma}_{C_2}(k,\mathbb{Z}) \otimes \mathbb{Z}/2 \oplus 2H^{n,\sigma-m+1,\sigma}_{C_2}(k,\mathbb{Z}). \)

Suppose \( n \) is even. If \( 1 \leq m < n - 1 \) and \( m \) odd then \( 0 \leq m - 1 < n - 2 \) with \( m - 1 \) even. Then according to Theorem 5.11 we have 
\( H^{n,\sigma-m,\sigma}_{C_2}(k,\mathbb{Z}/2) \simeq k^* \otimes \mathbb{Z}/2 \oplus \mathbb{Z}/2 \simeq k^* \otimes \mathbb{Z}/2. \)

In the case \( m = n - 1 \) we have that 
\( H^{n,\sigma-m,\sigma}_{C_2}(k,\mathbb{Z}/2) \simeq k^* \otimes k^* \otimes \mathbb{Z}/2 \simeq k^* \otimes k^2 \oplus \mathbb{Z}/2. \)

If \( 2 \leq m < n - 1 \) and \( m \) even then \( 1 \leq m - 1 \leq n - 2 \) with \( m - 1 \) odd. Then 
\( H^{n,\sigma-m,\sigma}_{C_2}(k,\mathbb{Z}/2) \simeq \mathbb{Z}/2 \oplus k^*/k^{\ast^2}. \) If \( 1 \leq m = n \) then 
\( H^{n,\sigma-m,\sigma}_{C_2}(k,\mathbb{Z}/2) \simeq 2k^* \simeq \mathbb{Z}/2 \) and if \( m = 0 \) then 
\( H^{n,\sigma-m,\sigma}_{C_2}(k,\mathbb{Z}/2) \simeq \mathbb{Z}/2. \)

Suppose \( n \) is odd. If \( 1 \leq m < n - 1 \) and \( m \) odd then \( 0 \leq m - 1 < n - 2 \) with \( m - 1 \) even. The decomposition is in this case 
\( H^{n,\sigma-m,\sigma}_{C_2}(k,\mathbb{Z}/2) \simeq k^* \otimes k^2 \oplus \mathbb{Z}/2. \)

If \( 2 \leq m < n - 1 \) and \( m \) even then \( 1 \leq m - 1 \leq n - 2 \) with \( m - 1 \) odd. The
decomposition is in this case \( H^{n-a-m,\sigma}(k,\mathbb{Z}/2) \simeq \mathbb{Z}/2 \oplus k^*/k^{*2} \). If \( 1 \leq m = n \) then
the decomposition is \( H^{n-a-m,\sigma}(k,\mathbb{Z}/2) \simeq \mathbb{Z}/2 \) and if \( m = 0 \) the decomposition is
\( H^{n-a-m,\sigma}(k,\mathbb{Z}/2) \simeq \mathbb{Z}/2 \).

For the negative cone we have
\[
H^{m-n,\sigma}(k,\mathbb{Z}/2) \simeq H^{m-n,\sigma}(k,\mathbb{Z}) \oplus \mathbb{Z}/2 \oplus 2H^{m+1-n,\sigma}(k,\mathbb{Z}).
\]
The result follows from Theorem 5.10. If \( n \geq 2 \) is even then we have the following cases.
If \( 2 \leq m \leq n - 1 \), \( m \) even then \( 2 < m + 1 \leq n \), \( m \) odd and the
decomposition is \( H^{m-n,\sigma}(k,\mathbb{Z}/2) \simeq k^*/k^{*2} \oplus \mathbb{Z}/2 \). If \( 2 < m < n \), \( m \) odd then \( 2 < m+1 < n+1 \), \( m+1 \) even and the decomposition is \( H^{m-n,\sigma}(k,\mathbb{Z}/2) \simeq \mathbb{Z}/2 \oplus k^*/k^{*2} \). If \( 1 \leq m = n + 1 \) then the decomposition is \( H^{m-n,\sigma}(k,\mathbb{Z}/2) \simeq k^*/k^{*2} \). If \( m = 1 \) then
the decomposition is \( H^{m-n,\sigma}(k,\mathbb{Z}/2) \simeq k^*/k^{*2} \).

If \( n \geq 2 \) is odd then we have the following cases. If \( 2 \leq m \leq n \) and \( m \) is even then
the decomposition is \( H^{m-n,\sigma}(k,\mathbb{Z}/2) = k^*/k^{*2} \oplus \mathbb{Z}/2 \). If \( 2 < m \leq n \), \( m \) odd then the decomposition is \( H^{m-n,\sigma}(k,\mathbb{Z}/2) = \mathbb{Z}/2 \oplus k^*/k^{*2} \). If \( m = 1 \) then
\( H^{m-n,\sigma}(k,\mathbb{Z}/2) = k^*/k^{*2} \) and if \( 1 \leq m = n + 1 \) then \( H^{m-n,\sigma}(k,\mathbb{Z}/2) = k^*/k^{*2} \).
\[ \square \]

Notice that for a quadratically closed field the Bredon motivic homology groups
\( H^{a+p,0}(k,\mathbb{Z}/2) \) and \( H^{a+p,\sigma}(k,\mathbb{Z}/2) \) are computed as Bredon homology group
\( H^{a+p,0}_B(pt,\mathbb{Z}/2) \). The positive cones of Bredon motivic homology of weight 1 and \( \sigma \)
of a quadratically closed field coincide (this is true also for the negative cones).

6. **Borel equivariant motivic cohomology in weights 0, 1, \( \sigma \)**

In [8] we extended Edidin-Graham equivariant higher Chow groups to an equivariant theory represented in the stable equivariant \( \mathbb{A}^1 \)-homotopy category and bigraded by virtual \( C_2 \)-representations. In Proposition 4.1 [8] we showed that
\[
CH^b_{EC_2}(X, 2b - a, A) \simeq H^{a,b}_{EC}(X \times EC_2, A)
\]
for any integers \( a, b \) and abelian group \( A \).

It implies that Borel equivariant motivic cohomology groups
\( H^{a+p,\omega,0}(X \times EC_2, A) \) are an extension of Edidin-Graham equivariant higher Chow groups
introduced in [3]. For weights 0, 1, \( \sigma \) and an abelian group \( A \) we have the following computation of the Borel equivariant motivic cohomology of a field:

**Proposition 6.1.**

a) \( H^{a+p,0}_{EC_2}(EC_2, A) = H^{a+p,0}_{EC_2}(k, A) \).

b) \( H^{a+p,\sigma}_{EC_2}(EC_2, A) = H^{a+p,\sigma}_{EC_2}(k, A) \).

c) \( H^{a+p,1}_{EC_2}(EC_2, A) = H^{a+p,1}_{EC_2}(k, A) \) if \( a \neq 2, 3 \).

d) \( H^{a+p,1}_{EC_2}(EC_2, A) = H^{a-2+(p+2)\sigma,\sigma}_{EC_2}(k, A) \) if \( a = 2, 3 \).

**Proof.** For a) we have that the equivariant motivic isotropy sequence
\( EC_2 \rightarrow S^0 \rightarrow \tilde{EC}_2 \) gives the following l.e.s.
\[
H^{a+p,0}_{EC_2}(EC_2, A) = 0 \rightarrow H^{a+p,0}_{EC_2}(k, A) \rightarrow H^{a+p,0}_{EC_2}(EC_2) \rightarrow H^{a+1+p,0}_{EC_2}(\tilde{EC}_2) = 0.
\]
The same motivic sequence gives
\[
H^{2+p,1}_{EC_2}(EC_2, A) \rightarrow H^{3+p,1}_{EC_2}(EC_2, A) \rightarrow H^{3+p,1}_{EC_2}(k, A) \rightarrow H^{3+p,1}_{EC_2}(EC_2).
\]
with $\tilde{H}^{a+p,1}_{C_2}(EC_2, A) = \mathbb{Z}/2$ and $\tilde{H}^{a+p,1}_{C_2}(EC_2, A) = 0$ for $n \neq 3$ (Proposition 5.1).

We have from the same isotropy sequence that $H^{a+p,\sigma}_{C_2}(EC_2, A) = H^{a+p,\sigma}_{C_2}(k, A)$ because of the periodicities of Bredon motivic cohomology of $EC_2$. This implies part b).

We also have a $(2\sigma - 2, \sigma - 1)$ periodicity for Bredon motivic cohomology groups of $EC_2$. This implies part d). □

Edidin-Graham higher Chow groups of $EC_2$ in weight 0 and 1 are $CH^1_{C_2}(EC_2, 0, \mathbb{Z}) = CH^1_{C_2}(BC_2) = \mathbb{Z}/2 = H^{2p,\sigma}_{C_2}(k, \mathbb{Z})$ (from d) above), $CH^1_{C_2}(EC_2, 1, \mathbb{Z}) = k^* = H^{1,1}_{C_2}(k, \mathbb{Z})$ (from c) above) and $CH^0_{C_2}(EC_2, 0, \mathbb{Z}) = \mathbb{Z} = H^{0,0}_{C_2}(k, \mathbb{Z}), CH^0_{C_2}(EC_2, -a, \mathbb{Z}) = 0 = H^{a,0}_{C_2}(k, \mathbb{Z})$, for $a \neq 0$ (from a) above).

Notice that the canonical map $H^{a+p,\sigma,b+q}_{C_2}(k, \mathbb{Z}) \to H^{a+p,\sigma,b+q}_{EC_2}(\mathbb{Z})$ is not necessarily an isomorphism (for example for $a = 2, b = 1, q = 0, p = 0$ the map is $0 \to \mathbb{Z}/2$).
