ON COMPACT HOMOGENEOUS $G_{2(2)}$-MANIFOLDS

WOLFGANG GLOBKE

(July 3, 2019)

Abstract

We prove that among all compact homogeneous spaces for an effective transitive action of a Lie group whose Levi subgroup has no compact simple factors, the seven-dimensional flat torus is the only one that admits an invariant torsion-free $G_{2(2)}$-structure.

1. Introduction and main results

Let $G$ be a connected Lie group whose Levi subgroup has no compact simple factors. Let $M$ be a seven-dimensional connected compact homogeneous space for $G$, by which we mean $M = G/H$ for some closed uniform subgroup $H$ of $G$, and $G$ acts effectively on $M$. Assume now that there exists a $G$-invariant torsion-free $G_{2(2)}$-structure $(g_M, \varphi_M)$ on $M$, where $G_{2(2)}$ denotes the split real form of the complex exceptional Lie group $G_2^C$. This means $g_M$ is a pseudo-Riemannian metric of signature $(4,3)$, and $\varphi_M$ is a certain parallel three-form whose stabilizer on each tangent space is the group $G_{2(2)}$.

In this article we will show the following:

**Theorem A.** Let $M$ be a compact seven-dimensional homogeneous space for a Lie group $G$ whose Levi subgroup does not have compact simple factors. If $M$ has a $G$-invariant torsion-free $G_{2(2)}$-structure, then $G = M = \mathbb{R}^7/\mathbb{Z}^7$ is a flat torus. In particular, the holonomy group of $M$ is trivial.

The proof of this theorem makes use of results by Banes, Globke and Zeghib [1] to reduce it to the case of a Lie group with bi-invariant metric. Then it follows from the next theorem:

Wolfgang Globke is supported by the Austrian Science Fund FWF grant I 3248.
Theorem B. Let $G$ be a seven-dimensional Lie group and $\Gamma$ a uniform lattice in $G$. If $M = G/\Gamma$ has a $G$-invariant torsion-free $G_{2(2)}$-structure whose associated metric pulls back to a bi-invariant metric on $G$, then $G = M = \mathbb{R}^7_3/\mathbb{Z}^7$ is a flat torus. In particular, the holonomy group of $M$ is trivial.

In Section 2 we use a result by Globke and Nikolayevsky [5] to reduce the problem to nilpotent Lie groups. The nilpotence of $G$ then implies that $\varphi_M$ induces an $\text{Ad}(G)$-invariant three-form on the Lie algebra of $G$. We then investigate in Section 3 the obstructions for nilpotent Lie algebras with invariant scalar products to be contained in $g_{2(2)}$. Combining these results, we prove Theorems A and B in Section 4.

Contrasting our theorems here, there are many examples of homogeneous spaces for compact Lie groups that admit non-trivial invariant $G_{2(2)}$-structures. Lê and Munir [8] established a classification of these spaces. In the Riemannian $G_{2}$-case, this is a complete classification of compact homogeneous $G_{2}$-manifolds. See the references in [8] for further related results.

Other existence results in a setting similar to ours were obtained, for example, by Fino and Luján [4], who determine $G_{2(2)}$-structures on compact nilmanifolds $\Gamma\backslash G$, or equivalently, left-invariant $G_{2(2)}$-structures on seven-dimensional nilpotent Lie groups $G$. Note that, despite the authors calling these structures “invariant”, the metrics on these quotients are not $G$-invariant. In fact, the additional assumption made in [4] that the metric is definite on the center of $G$ prohibits the pulled-back metric on $G$ to be bi-invariant, which is necessary for the metric on $\Gamma\backslash G$ to be $G$-invariant (unless $G$ is abelian to begin with).

Another related result is the classification of indecomposable indefinite symmetric spaces with $G_{2(2)}$-structures by Kath [7]. All of these turn out to be non-compact quotients of nilpotent Lie groups with a bi-invariant metric, and their holonomy groups are three-dimensional and abelian.

Acknowledgement I would like to thank Thomas Leistner for helpful discussions of holonomy groups, and also the anonymous referee for many helpful suggestions that improved the readability of the paper.

Notations and conventions A Lie group or Lie algebra is called $k$-step nilpotent if the $k$th term in its descending central series is trivial, but the $(k - 1)$st term is not.

For a Lie algebra $\mathfrak{g}$ with subalgebra $\mathfrak{h}$ we let $\text{ad}(\mathfrak{g})$ denote the adjoint representation of $\mathfrak{g}$, and when clarity requires it we write $\text{ad}_{\mathfrak{h}}(\mathfrak{g})$ for the adjoint action of $\mathfrak{h}$ on $\mathfrak{g}$ to distinguish it from the adjoint representation of $\mathfrak{h}$ on itself. A similar notation is used for Lie groups.

A Lie algebra is called metric if it has an invariant scalar product. The vector space $\mathbb{R}^n$, equipped with a scalar product of signature $(n - s, s)$, is denoted by $\mathbb{R}^n_s$. 
2. Reduction to nilpotent groups

In this section we will show that for our purposes it is sufficient to consider nilpotent Lie groups.

**Lemma 2.1.** Let $M$ be a compact homogeneous space for a Lie group $G$ whose Levi subgroup does not have compact simple factors. Suppose $G$ acts effectively on $M$. If $M$ has a $G$-invariant pseudo-Riemannian metric, then $M = G/\Gamma$ for some uniform lattice $\Gamma$ in $G$, and in particular $\dim G = \dim M$. Moreover, the pseudo-Riemannian metric on $M$ is induced by a bi-invariant metric on $G$.

**Proof.** Write $M = G/H$ for a closed uniform subgroup $H$ of $G$. Via pullback to $G$, $g_M$ induces a symmetric bilinear form on the Lie algebra of $G$ whose kernel is the Lie algebra of $H$. Baues, Globke and Zeghib [1, Theorem A] showed that this bilinear form is $\text{Ad}(G)$-invariant, so that its kernel is an ideal. By the effectivity of the $G$-action, this ideal, and hence the identity component of $H$, must be trivial. This means $H$ is a uniform lattice in $G$, so that $\dim G = \dim M$. By the invariance of the bilinear form on the Lie algebra, the metric on $M$ is induced by a bi-invariant metric on $G$. 

The existence of a torsion-free $G_{2(2)}$-structure $(g_M, \varphi_M)$ on a manifold $M$ means that the three-form $\varphi_M$ is parallel and is thus preserved by the holonomy group at every point $p \in M$. The stabilizer of $(\varphi_M)_p$ in $\text{GL}(T_p M)$ is $G_{2(2)}$, which means $\text{Hol}(g_M) \subseteq G_{2(2)}$. Moreover, the metric $g_M$ of the $G_{2(2)}$-structure has vanishing Ricci curvature (Bonan [3]).

**Lemma 2.2.** Let $G$ be a seven-dimensional connected Lie group with a bi-invariant metric $g_G$, and $\Gamma$ a uniform lattice in $G$. Let $M = G/\Gamma$ and let $g_M$ be the metric induced on $M$ by $g_G$. If $g_M$ is Ricci-flat, then:

1. $G$ is nilpotent.
2. The connected holonomy group of $g_M$ is $\text{Hol}(g_M) \cong \text{Ad}_q([G, G])$.

In particular, this holds if $g_M$ is the metric of a torsion-free $G_{2(2)}$-structure $(g_M, \varphi_M)$ on $M$, and in this case $\text{Ad}_q(G)$ is a subgroup of $G_{2(2)}$.

**Proof.** The bi-invariance of $g_G$ implies that the Ricci tensor, restricted to the left-invariant vector fields on $G$, is proportional to the Killing form of $G$. Since $g_M$, and hence $g_G$, is Ricci-flat, the Killing form of $G$ is zero, which means $G$ is solvable. Moreover, the Ricci-flatness implies that $M$ is an Einstein manifold. It was shown by Globke and Nikolayevsky [5, proof of Theorem 1.3] that a solvable Lie group acting transitively on a compact
pseudo-Riemannian Einstein manifold of dimension less or equal to seven is nilpotent. So $G$ is nilpotent.

As a Lie group with bi-invariant metric, the curvature tensor on $G$ is given by $R(X,Y)Z = \frac{1}{4}[[X,Y],Z]$ for any left-invariant vector fields $X,Y,Z$ on $G$. The Ambrose-Singer Theorem (cf. Besse [2, Theorem 10.58]) now implies that the connected holonomy group of $G$ is $\text{Hol}(\mathfrak{g}_G) \cong \text{Ad}_{\mathfrak{g}}([G,G])$. Since $G$ is a covering space of $M$, $\text{Hol}(\mathfrak{g}_G) \cong \text{Hol}(\mathfrak{g}_M)$ (cf. Besse [2, 10.16]).

Suppose $(\mathfrak{g}_M, \varphi_M)$ is a torsion-free $G_2$-structure on $M$. Then $\mathfrak{g}_M$ and $\mathfrak{g}_G$ are Ricci-flat, so all of the above applies. The three-form $\varphi_M$ pulls back to a left-invariant three-form $\varphi_G$ on $G$ that is right-invariant under $\Gamma$. This means the induced three-form $\varphi_\mathfrak{g}$ on $\mathfrak{g}$ is $\text{Ad}_{\mathfrak{g}}(\Gamma)$-invariant. But the lattice $\text{Ad}_{\mathfrak{g}}(\Gamma)$ in the nilpotent Lie group $\text{Ad}_{\mathfrak{g}}(G)$ is Zariski-dense and $\varphi_\mathfrak{g}$ is a polynomial expression, hence $\varphi_\mathfrak{g}$ is $\text{Ad}_{\mathfrak{g}}(G)$-invariant. Since the real algebraic group $G_{2(2)}$ is the stabilizer of $\varphi_\mathfrak{g}$, this means $\text{Ad}_{\mathfrak{g}}(G)$ is a subgroup of $G_{2(2)}$.

3. Nilpotent metric Lie algebras

3.1. Nilpotent metric Lie algebras in low dimensions

Let $\mathfrak{n}$ be a nilpotent Lie algebra with invariant scalar product $\langle \cdot, \cdot \rangle$ of signature $(p,q)$. Let $\mathfrak{z}(\mathfrak{n})$ denote the center of $\mathfrak{n}$. Set

$$j = \mathfrak{z}(\mathfrak{n}) \cap [\mathfrak{n}, \mathfrak{n}].$$

This is a totally isotropic ideal in $\mathfrak{n}$. Also, $j^i$ is an ideal in $\mathfrak{n}$ that contains $[\mathfrak{n}, \mathfrak{n}]$ and $\mathfrak{z}(\mathfrak{n})$. We have vector space decompositions

$$\mathfrak{n} = j^* \oplus j^i, \quad j^i = \mathfrak{w} \oplus j,$$

where $j^*$ is totally isotropic, dually paired with $j$ via $\langle \cdot, \cdot \rangle$ and orthogonal to $\mathfrak{w}$, and $\langle \cdot, \cdot \rangle$ has signature $(p - \dim j, q - \dim j)$ on $\mathfrak{w}$.

The decomposition (3.2) is helpful in understanding the algebraic structure of Lie algebras with invariant scalar products. The following is a simple yet very useful property of the ideal $j$.

**Lemma 3.1.** $\mathfrak{n}$ is abelian if and only if $j = 0$.

**Proof.** If $\mathfrak{n}$ is abelian, then clearly $j = 0$. If $\mathfrak{n}$ is not abelian, its descending central series eventually intersects $\mathfrak{z}(\mathfrak{n})$ non-trivially, which means $j \neq 0$.

**Lemma 3.2.** If $\dim \mathfrak{n} \leq 4$, then $\mathfrak{n}$ is abelian.
and invariance of $\langle \cdot, \cdot \rangle$, these dimensions imply $j = \langle j^*, w \rangle \perp j^*$, contradicting the definition of $j^*$.

Now assume $\dim n = 4$ and $n$ is not abelian. If $\dim j = 2$, then $n = j^* \oplus j$ and invariance of $\langle \cdot, \cdot \rangle$ implies $[n, n] = [j^*, j^*] \perp j^*$, but also $[j^*, j^*] \subset j$, a contradiction. This leaves the case $\dim j = 1$. Here, invariance and $\dim j^* = 1$ imply $[j^*, w] \subseteq w$. By nilpotence of $n$, $[w, w] \subseteq j$, and since $j^*$ is dually paired with $j$, it follows that $j^*$ acts non-trivially on $w$. But invariance then requires $[j^*, w] = w$, contradicting the nilpotence of $n$.

With regard to Lemma 3.2, we are interested in the question when for non-abelian $n$ of dimension seven, $ad_n(n)$ is contained in $g_2(2)$. So let us now further assume that $\dim n = 7$ and that $n$ is $k$-step nilpotent. Since it is possible that $n$ is decomposable, meaning it can be further decomposed into an orthogonal direct sum $n = n_1 \times n_0$ of ideals, we are also interested in non-abelian nilpotent Lie algebras $n_1$ of dimension $\dim n_1 \leq 7$ with an invariant scalar product.

As is evident from Kath’s classification [6, Theorem 4.7], the Examples 3.3 to 3.5 below are the only non-abelian nilpotent Lie algebras $n_1$ of dimension less than eight with an invariant scalar product that cannot be further decomposed into orthogonal direct sums of ideals. We use the following notation: If $d = \dim j$, let $a_1, \ldots, a_d \in j^*$, $w_1, \ldots, w_{n-2d} \in w$ and $z_1, \ldots, z_d \in j$ be bases of the respective subspaces in (3.2), such that the $a_i$ and $z_j$ are dual bases to each other with respect to $\langle \cdot, \cdot \rangle$. The number $\varepsilon = \pm 1$ depends on whether $p \geq q$ (then $\varepsilon = 1$) or $p < q$ (then $\varepsilon = -1$).

**Example 3.3.** Let $\dim n_1 = 7$, $\dim j = 2$, with bracket relations

\[
[a_1, a_2] = w_1, \quad [a_1, w_1] = w_2, \quad [a_1, w_2] = -\varepsilon w_3, \quad [a_1, w_3] = -z_2, \\
[a_2, w_1] = 0, \quad [a_2, w_2] = 0, \quad [a_2, w_3] = z_1, \\
w_1, w_2 = \varepsilon z_1, \quad w_1, w_3 = 0, \quad w_2, w_3 = 0,
\]

where the scalar product on $w$ is given by

$\langle w_1, w_1 \rangle = \langle w_1, w_2 \rangle = \langle w_2, w_3 \rangle = \langle w_3, w_3 \rangle = 0, \quad \langle w_1, w_3 \rangle = 1, \quad \langle w_2, w_2 \rangle = \varepsilon$.

We denote this Lie algebra by $n_i$. Here, $n_i$ is three-step nilpotent, $\dim w = 3$, and the algebra $ad_n(w)$ and three-dimensional and abelian.

**Example 3.4.** Let $\dim n_1 = 6$, $\dim j = 3$, with non-zero bracket relations

\[
[a_1, a_2] = z_3, \quad [a_2, a_3] = z_1, \quad [a_3, a_1] = z_2.
\]

We denote this Lie algebra by $n_i$. Here, $n_i$ is two-step nilpotent and $w = 0$. The invariant scalar product has split signature $(3, 3)$. 

Proof. The claim is trivial for $\dim n \leq 2$. Suppose first that $\dim n = 3$. By (3.2) and Lemma 3.1, if $n$ was not abelian, then $\dim j = \dim j^* = \dim w = 1$. With the invariance of $\langle \cdot, \cdot \rangle$, these dimensions imply $j = \langle j^*, w \rangle \perp j^*$, contradicting the definition of $j^*$.
EXAMPLE 3.5. Let \( \dim n_1 = 5 \), \( \dim j = 2 \), with non-zero bracket relations

\[
[a_1, a_2] = w, \quad [a_1, w] = \varepsilon z_2, \quad [a_2, w] = \varepsilon z_1
\]

We denote this Lie algebra by \( n_{\text{mill}} \). Here, \( n_{\text{mill}} \) is three-step nilpotent, \( \dim w = 1 \). The signature of \( n_{\text{mill}} \) is \((3, 2)\) or \((2, 3)\), depending on \( \varepsilon \).

3.2. Nilpotent subalgebras of \( \mathfrak{g}_2(2) \) The Lie algebra \( \mathfrak{so}(n, \langle \cdot, \cdot \rangle) \) of skew-symmetric linear maps for \( \langle \cdot, \cdot \rangle \) can be identified with \( \mathfrak{so}_{4,3} \). Since \( \langle \cdot, \cdot \rangle \) is invariant we have \( \text{ad}(n) \subset \text{det}(n) \cap \mathfrak{so}_{4,3} \).

The exceptional simple Lie algebra \( \mathfrak{g}_2(2) \) is also a subalgebra of \( \mathfrak{so}_{4,3} \). It is the stabilizer subalgebra in \( \mathfrak{so}_{4,3} \) of a certain three-form \( \varphi \) on \( n \). In a suitable Witt basis of \( n \) with respect to \( \langle \cdot, \cdot \rangle \), we identify \( \mathfrak{g}_2(2) \) with the following Lie subalgebra of \( \mathfrak{so}_{4,3} \):

\[
\mathfrak{g}_2(2) = \begin{pmatrix}
    u_7 & u_9 & u_{10} & u_{12} & u_{13} & u_{14} & 0 \\
    u_1 & u_8 & u_{11} & \frac{u_{10}}{2} & -\frac{u_{14}}{2} & 0 & -u_{14} \\
    u_2 & u_3 & u_7 - u_8 & \frac{u_{10}}{2} & 0 & \frac{u_{12}}{4} & -u_{13} \\
    u_4 & 4u_2 & -4u_1 & 0 & \frac{u_{10}}{2} & -\frac{u_{12}}{4} & -u_{12} \\
    u_5 & -2u_4 & 0 & 4u_1 & u_8 - u_7 & -u_{11} & -u_9 \\
    u_6 & 0 & 2u_4 & -4u_2 & -u_3 & -u_8 & -u_9 \\
    0 & -u_6 & -u_5 & -u_4 & -u_2 & -u_1 & -u_7
\end{pmatrix}
\begin{pmatrix}
u_1, \ldots, u_{14} \in \mathbb{R} \end{pmatrix}
\]

(this matrix representation is borrowed from Leistner, Nurowski and Sagerschmidt [9], with some adjustments to the parameter labelling).

Any strictly triangular subalgebra of \( \mathfrak{g}_2(2) \) is contained in a maximal triangular subalgebra of \( \mathfrak{g}_2(2) \). All maximal triangular subalgebras of \( \mathfrak{g}_2(2) \) are conjugate to each other by \( G_{22} \), so we may assume the strictly triangular subalgebra \( \text{ad}(n) \) is conjugate to a subalgebra of

\[
m = \begin{pmatrix}
    0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
    u_1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
    u_2 & u_3 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
    u_4 & 4u_2 & -4u_1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
    u_5 & -2u_4 & 0 & 4u_1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
    u_6 & 0 & 2u_4 & -4u_2 & -u_3 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
    0 & -u_6 & -u_5 & -u_4 & -u_2 & -u_1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0
\end{pmatrix}
\begin{pmatrix}
u_1, \ldots, u_6 \in \mathbb{R} \end{pmatrix} \quad (3.3)
\]

In fact, this subalgebra \( m \) is a maximal strictly triangular subalgebra of a Borel subalgebra of \( \mathfrak{g}_2(2) \), and hence a conjugate of \( \text{ad}(n) \) is contained in \( m \).

LEMMA 3.6. Let \( A \) be the matrix in \( \mathbb{KK} \). Suppose \( \text{rk} A \leq 2 \). Then \( u_1 = 0 \), and in addition one of the following holds,

(a) either \( u_2 = u_4 = 0 \),

(b) or \( u_2 \neq 0 \), \( u_4 \neq 0 \) and \( u_3 = \frac{4u_2^2}{u_4} \), \( u_5 = -\frac{u_2^2}{2u_2} \).
Proof. If $u_1 \neq 0$, then columns one, three, four and six are linearly independent. So assume henceforth $u_1 = 0$, that is,

$$
A = \begin{pmatrix}
0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 \\
u_2 & u_3 & 0 & 0 & 0 & 0 & 0 \\
u_4 & 4u_2 & 0 & 0 & 0 & 0 & 0 \\
u_5 & -2u_4 & 0 & 0 & 0 & 0 & 0 \\
u_6 & 0 & 2u_4 & -4u_2 & -u_3 & 0 & 0 \\
0 & -u_6 & -u_5 & -u_4 & -u_2 & 0 & 0
\end{pmatrix}.
$$

First, assume $u_2 = 0$. Then columns one, two, three, four are linearly independent, unless also $u_4 = 0$. This is case (a).

Next, assume $u_2 \neq 0$. If $u_4 = 0$, we see that columns one, two and four are linearly independent. So assume also $u_4 \neq 0$. Given $\text{rk } A = 2$, the subcolumns

$$
\begin{pmatrix} u_3 \\ u_5 \end{pmatrix} \quad \text{and} \quad \begin{pmatrix} 4u_2 \\ -2u_4 \end{pmatrix}
$$

must be linearly dependent. So add $-u_3$ times the first column of $A$ to its second column, and obtain the identities $4u_2 - \frac{u_3 u_4}{u_2} = 0$ and $-2u_4 - \frac{u_3 u_5}{u_2} = 0$. By solving for $u_3$ and $u_5$ we obtain

$$
u_3 = \frac{4u_2^2}{u_4}, \quad u_5 = -\frac{u_3^2}{2u_2}.$$

Plugging this into $A$ we can verify directly that $\text{rk } A = 2$. This is case (b). \qed

Remark. Note that condition (a) in Lemma 3.6 is necessary but not sufficient for $\text{rk } A = 2$. Also, the condition $\text{rk } A \leq 2$ already implies $\text{rk } A = 2$ for the non-zero matrices in case (a) or (b).

Below, we use the notation $A(u_3, u_5, u_6)$ for matrices of case (a) in Lemma 3.6 and $B(u_2, u_4, u_6)$ for matrices of case (b),

$$
A(u_3, u_5, u_6) = \begin{pmatrix}
0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 \\
u_3 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 \\
u_5 & 0 & 0 & 0 & 0 & 0 & 0 \\
u_6 & 0 & 0 & 0 & -u_3 & 0 & 0 \\
0 & -u_6 & -u_5 & 0 & 0 & 0 & 0
\end{pmatrix},
$$

$$
B(u_2, u_4, u_6) = \begin{pmatrix}
0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 \\
u_2 & 4u_2^2/u_4 & 0 & 0 & 0 & 0 & 0 \\
u_4 & 4u_2 & 0 & 0 & 0 & 0 & 0 \\
u_2^2/2u_2 & -2u_4 & 0 & 0 & 0 & 0 & 0 \\
u_6 & 0 & 2u_4 & -4u_2 & -4u_2^2/u_4 & 0 & 0 \\
0 & -u_6 & u_2^2/2u_2 & -u_4 & -u_2 & 0 & 0
\end{pmatrix}, \quad u_2, u_4 \neq 0.
$$
**Lemma 3.7.** The maximal nilpotent subalgebra $m$ of $g_{2(2)}$ does not contain a three-dimensional Lie subalgebra $b$ consisting only of matrices of rank two (and zero).

**Proof.** Rank two matrices in $m$ belong to one of the two types described in Lemma 3.6. First, assume $b$ contains only matrices of the form $A(u_3, u_5, u_6)$. In order to be of rank two, one of the parameters $u_3, u_5, u_6$ must be zero in each element of $b$. But the set of matrices with this property is a finite union of two-dimensional subspaces, contradicting $\dim b = 3$.

So assume $b$ contains a non-zero matrix $B(u_2, u_4, u_6)$. If $b$ contains two elements $B_1 = B(u_2, u_4, u_6), B_2 = B(v_2, v_4, v_6)$ that are not multiples of each other, then one of $u_2 + v_2 \neq 0$ or $u_4 + v_4 \neq 0$ holds. The sum $B_{12} = B_1 + B_2$ is

$$B_{12} = \begin{pmatrix}
0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 \\
u_2 + v_2 & \frac{4u_2^2}{u_4} + \frac{4v_2^2}{v_4} & 0 & 0 & 0 & 0 \\
u_4 + v_4 & \frac{4u_4}{u_2} + \frac{4v_4}{v_2} & 0 & 0 & 0 & 0 \\
-\frac{u_2^2}{2u_2} - \frac{v_2^2}{2v_2} & -2u_4 - 2v_4 & 0 & 0 & 0 & 0 \\
u_6 + v_6 & 0 & 2u_4 + 2v_4 & -4u_2 - 4v_2 & -\frac{4u_2^2}{u_4} - \frac{4v_2^2}{v_4} & 0 \\
0 & -u_6 - v_6 & \frac{u_4^2}{2u_2} + \frac{v_6^2}{2v_2} & -u_4 - v_4 & -u_2 - v_2 & 0
\end{pmatrix}.$$

If $\text{rk} \ B_{12} = 2$, then, since one of $u_2 + v_2$ and $u_4 + v_4$ is non-zero, both must be non-zero ($B_{12}$ is case (b) of Lemma 3.6). Set $w_2 = u_2 + v_2, u_4 = u_2 + v_4$. By Lemma 3.6, entry (3, 2) of $B_{12}$ must be $w_3 = \frac{4w_2^2}{u_4} = 4\frac{u_2^2 + 2u_2v_2 + v_2^2}{u_4}$. But this entry is $\frac{4u_2^2}{u_4} + \frac{4v_2^2}{v_4}$, and the resulting equation $4u_2^2 + 2u_2v_2 + v_2^2 = \frac{4u_2^2}{u_4} + \frac{4v_2^2}{v_4}$ simplifies to $u_2v_2 - u_4v_2 = 0$. Solving for $v_2$ and plugging back into $B(v_2, v_4, v_6)$ shows that

$$B_1 - \frac{u_4}{v_4}B_2 = A(0, 0, u_6 - \frac{u_4}{v_4}v_6).$$

If this is zero, then $B_1$ is a multiple of $B_2$, in contradiction to our assumption.

So $b$ contains $B_1$ and $A(0, 0, 1)$ as basis elements, and all other elements $B(v_2, v_4, v_6) \in b$ lie in the two-dimensional subspace $U$ spanned by those two elements. Since $\dim b = 3$, there exists a third basis vector of $b$ of the form $B(u_2, u_4, u_6) + A(w_3, w_5, 0)$ for some $u_2, u_4 \neq 0$, and at least one of $w_3$ or $w_5$ is non-zero, for otherwise the element lies in the subspace $U$. But then the resulting matrix cannot be of rank two, as it is neither of type (a) nor type (b) in Lemma 3.6. In fact, it is not of type (a) since $u_2 \neq 0$, and for type (b), the entries $u_3, u_5$ are functions of $u_2, u_4$, which prohibits adding a non-zero term $w_3$ or $w_5$.

In conclusion, a Lie subalgebra with the properties required for $b$ does not exist in $m$. \qed
Lemma 3.8. Let $\mathfrak{n}$ be a seven-dimensional two-step nilpotent Lie algebra with an invariant scalar product of index three. Then $\text{ad}(\mathfrak{n})$ is not contained in $\mathfrak{g}_{2(2)}$.

Proof. The invariance of $\langle \cdot, \cdot \rangle$ and two-step nilpotence of $\mathfrak{n}$ imply $\mathfrak{g}(\mathfrak{n}) = \mathfrak{w} \oplus \mathfrak{j}$ and $[\mathfrak{n}, \mathfrak{n}] = [j^*, j^*] = j$. In particular, $\dim \text{ad}(\mathfrak{n}) = \dim j^* = \dim j$. By assumption, $j \neq 0$, hence $\dim j = 3$. In fact, if $\dim j^* \leq 2$, then $[j^*, j^*] = 0$ due to the invariance of $\langle \cdot, \cdot \rangle$, a contradiction. Also by invariance, $\text{im ad}(x) = x^* \cap j$ for all non-zero $x \in j^*$. So $\text{rk ad}(x) = 2$ for all non-zero $x \in j^*$.

If $\text{ad}(\mathfrak{n})$ is contained in $\mathfrak{g}_{2(2)}$, then it is a nilpotent triangular subalgebra, and as such contained in a maximal nilpotent triangular subalgebra. This means $\text{ad}(\mathfrak{n})$ is conjugate to a three-dimensional abelian subalgebra of $\mathfrak{m}$ in (3.3) consisting of rank two matrices (and zero). But by Lemma 3.7, such a subalgebra cannot exist in $\mathfrak{m}$. \qed

Lemma 3.9. Let $\mathfrak{n}$ be a seven-dimensional nilpotent but non-abelian Lie algebra with an invariant scalar product of index three. Then $\text{ad}(\mathfrak{n})$ is not contained in $\mathfrak{g}_{2(2)}$.

Proof. If $\text{ad}(\mathfrak{n})$ is contained in $\mathfrak{g}_{2(2)}$, then it is a nilpotent triangular subalgebra, and as such contained in a maximal nilpotent subalgebra. This means $\text{ad}(\mathfrak{n})$ is conjugate to a subalgebra of the maximal nilpotent subalgebra $\mathfrak{m}$ of $\mathfrak{g}_{2(2)}$ given by (3.3). The possibilities for $\mathfrak{n}$ are covered by the examples in Section 3, up to some abelian factor. We use the notation from these examples.

Suppose first that $\mathfrak{n}$ is indecomposable. Then $\mathfrak{n}$ must be the Lie algebra $\mathfrak{n}_1$ from Example 3.3. Now $\text{ad}_{\mathfrak{n}}(\mathfrak{m})$ is a three-dimensional abelian subalgebra of $\text{ad}_{\mathfrak{n}_1}(\mathfrak{n}_1)$, generated by the elements $\text{ad}(w_i)$, $i = 1, 2, 3$. From the commutator relations of $\mathfrak{n}_1$ it follows that the image of every non-zero $Q \in \text{ad}_{\mathfrak{n}_1}(\mathfrak{m})$ is the span of $z_1$ and $Q \alpha_1$. Hence $\text{rk } Q = 2$ for all non-zero $Q$. Now Lemma 3.7 tells us that such a subalgebra does not exist in $\mathfrak{m}$ (alternatively, this case could be excluded by comparison with Kath’s classification result [7, Theorem 6.8]).

Suppose now that $\mathfrak{n}$ is decomposable, that is, an orthogonal direct sum $\mathfrak{g} = \mathfrak{n}_0 \times \mathfrak{n}_0$ of non-zero metric Lie algebras. We may assume $\dim \mathfrak{n}_1 > \dim \mathfrak{n}_0$. Then $1 \leq \dim \mathfrak{n}_0 \leq 4$, so that $\mathfrak{n}_0$ is abelian by Lemma 3.2. If $\mathfrak{n}_1$ is not abelian, then $5 \leq \dim \mathfrak{n}_1 \leq 6$. This leaves $\mathfrak{n}_0$ and $\mathfrak{n}_1$ from Examples 3.4 and 3.5 as possibilities for $\mathfrak{n}_1$. Since $\mathfrak{n}_0 \times \mathfrak{R}$ is two-step nilpotent, its adjoint representation cannot be contained in $\mathfrak{g}_{2(2)}$ by Lemma 3.8.

So assume $\mathfrak{n} = \mathfrak{n}_0 \times \mathfrak{n}_0$. By the relations in Example 3.5, the algebra $\text{ad}(\mathfrak{n})$ is three-dimensional, spanned by $\text{ad}(\alpha_1)$, $\text{ad}(\alpha_2)$ and $\text{ad}(\alpha_3)$. Furthermore, it follows that the image of a linear combination $Q = \alpha_1 \text{ad}(\alpha_1) + \alpha_2 \text{ad}(\alpha_2) + \beta \text{ad}(\alpha_3)$ equals $\text{span } \{\alpha_1 w - \beta \varepsilon z_1, \alpha_2 \varepsilon z_1 - \alpha_1 \varepsilon z_2\}$. So $\text{rk } Q = 2$ for all non-zero $Q \in \mathfrak{h}$. We can now apply Lemma 3.7 to conclude that $\text{ad}(\mathfrak{n})$ is not contained in $\mathfrak{g}_{2(2)}$. \qed
4. Proofs of the main theorems

Proof (Theorem B). In this situation, Lemma 2.2 applies. This means $G$ is nilpotent, $\dim G = 7$ and $\text{ad}(g)$ is a subalgebra of $g_{2(2)}$. But by Lemma 3.9 this is not possible unless $g$ and hence $G$ is abelian. Since $G$ acts effectively on $M = G/\Gamma$, the lattice $\Gamma$ must be trivial, which implies that $G$ itself is compact. This means $G = M$ is a torus $\mathbb{R}^3/\mathbb{Z}^7$.

Proof (Theorem A). By Lemma 2.1 the group $G$ has dimension seven and $M = G/\Gamma$ for some uniform lattice $\Gamma$ in $G$, and the metric $g_M$ on $M$ is induced by a bi-invariant metric $g_G$ on $G$. Now we are in the situation of Theorem B which concludes the proof.
