STATISTICAL UNBOUNDED CONVERGENCE IN BANACH LATTICES

ZHANGJUN WANG, ZILI CHEN, AND JINXI CHEN

Abstract. Several recent papers investigated unbounded and statistical versions of order convergence and topology convergence in locally solid Riesz space. In this paper, we study the statistical unbounded order and topology convergence in Riesz spaces and Banach lattices. In particular, we study the relationship of those convergence and characterize order continuous, KB, reflexive Banach lattices in terms of these convergence.

1. Introduction

Riesz space has been studied in [1,2], and for more details of Banach lattices, we can read [3,4].

The unbounded convergence has study in [5-10,13], it is different on order unbounded sets with common convergence. A sequence \((x_n)\) in Riesz space \(E\) is unbounded order convergent\((uo-convergent for short)\) to \(x\) if \(|x_n - x| \land u \xrightarrow{uo} 0\) for all \(u \in E_+\). A sequence \((x_n)\) in Banach lattice \(E\) is unbounded norm convergent\((un-convergent for short)\) to \(x\) if \(|x_n - x| \land u \xrightarrow{∥∥} 0\) for all \(u \in E_+\). A sequence \((x_n)\) in Banach lattice \(E\) is unbounded absolute weak convergent\((uaw-convergent for short)\) to \(x\) if \(|x_n - x| \land u \xrightarrow{w} 0\) for all \(u \in E_+\). A sequence \((x_n)\) in Banach lattice \(E\) is unbounded absolute weak star convergent\((uaw\*-convergent for short)\) to \(x'\), if \(|x'_n - x'| \land u' \xrightarrow{w*} 0\) for all \(u' \in E'_+\).

Statistical order convergence and statistical norm(weak) convergence will be the basic tool of our study in [11,12]. Let \(K\) be a set of positive integers. The natural density of \(K\) is defined by

\[
\delta(K) = \lim_{n \to \infty} \frac{1}{n} |\{k \in K : k \leq n\}|
\]

2010 Mathematics Subject Classification. 46B42, 46A40.

Key words and phrases. Riesz space, Banach lattice, statistical unbounded order convergence, statistical unbounded norm convergence, statistical unbounded absolute weak convergence, statistical unbounded absolute weak* convergence.
where \(|k \in K : k \leq n|\) denotes the number of elements of \(K\) not exceeding \(n\). If \(\delta(K)\) exists, then \(\delta(K^c) = 1 - \delta(K)\), where \(K^c\) is the complement of the set \(K\) in \(N\).

If \((x_n)\) is a sequence such that \((x_n)\) satisfies property \(P\) for all \(n\) except a set of natural density zero, then we say that \((x_n)\) satisfies property \(P\) for almost all \(n\) and we abbreviate this by \(a.a.n\).

A sequence \((x_n)\) in \(E\) is statistically monotone increasing (in short, \(smi\)) if there exists a set \(K = \{n_1 < n_2 < \ldots\} \subset N\) such that \(\delta(K) = 1\) and \((x_{n_k})\) is increasing. A statistically monotone decreasing (in short, \(smd\)) sequence is defined similarly. In this case, we write \(x_n \uparrow^{st}\) and \(x_n \downarrow^{st}\), respectively. A \(smi\) or \(smd\) sequence will be called a statistically monotonic sequence. Let \((x_n)\) be a sequence in \(E\). If there exists a set \(K = \{n_1 < n_2 < \ldots\} \subset N\) such that \(\delta(K) = 1\), \((x_{n_k})\) is increasing and \(\sup_{k \in N} x_{n_k} = x\) for some \(x \in E\), then we write \(x_n \uparrow^{st} x\). Similarly, if \((x_{n_k})\) is decreasing and \(\inf_{k \in N} x_{n_k} = x\), then we write \(x_n \downarrow^{st} x\). If \(x_n \uparrow^{st} x\) or \(x_n \downarrow^{st} x\), then \((x_n)\) is statistically monotone convergent to \(x\).

A sequence \((x_n)\) in \(E\) is statistically order convergent to \(x \in E\) provided that there exists a sequence \((p_n)\) such that \(p_n \downarrow^{st} 0\) and a set \(K = \{n_1 < n_2 < \ldots\} \subset N\) with \(\delta(K) = 1\) such that \(|x_n - x| \leq p_n\) for every \(n \in K\). In this case, we have \(\delta\{n \in N : |x_n - x| \not\in p_n\} = 0\), and we write \(x_n \rightarrow^{st-ord} x\). We call \(x\) the statistical order limit of \((x_n)\).

A sequence \((x_n)\) in Banach space \(E\) is statistically norm convergent to \(x \in E\) provided that \(\delta\{n \in N : \|x_n - x\| \geq \epsilon\} = 0\) for all \(\epsilon > 0\). We write \(x_n \rightarrow^{st-norm} x\). We call \(x\) the statistical norm limit of \((x_n)\). A sequence \((x_n)\) in \(E\) is statistically weak convergent to \(x \in E\) provided that \(\delta\{n \in N : |f(x_n - x)| \geq \epsilon\} = 0\) for all \(\epsilon > 0\), \(f \in E'\). We write \(x_n \rightarrow^{st-w} x\). We call \(x\) the statistical weak limit of \((x_n)\).

Now, we study the convergence by unbounded and statistical versions. We can outline our work as follows. In Section 2, the concepts of statistical unbounded order convergence in a Riesz space are introduced, and some main results are obtained. In Section 4, In Section 3, we introduce the concept of statistically unbounded norm convergence, statistically unbounded absolute weak convergence and statistical unbounded absolute weak* convergence in Banach lattices, then we describe order continuous Banach lattices, \(KB\)-spaces and reflexive Banach lattices.

2. STATISTICAL UNBOUNDED ORDER CONVERGENCE

we study a new convergence in Riesz space.
Definition 2.1. A sequence \((x_n)\) in \(E\) is statistically unbounded order convergent to \(x \in E\) provided that there exists a sequence \((p_n)\) such that \(p_n \downarrow 0\) and a set \(K = \{ n_1 < n_2 < \ldots \} \subset N\) with \(\delta(K) = 1\) such that \(|x_n - x| \wedge u \leq p_n\) for every \(n \in K\) and \(u \in E_+\). In this case, we have \(\delta\{ n \in N : |x_n - x| \wedge u \not\leq p_n \} = 0\), and we write \(x_n \stackrel{st}{\rightarrow} \) for the statistical unbounded order limit of \((x_n)\). We call \(x\) the statistical unbounded order limit of \((x_n)\).

Proposition 2.2. (1) \(st\)-uo-limits are unique;
(2) \(st\)-uo-limits is linear;
(3) \(x_n \stackrel{st}{\rightarrow} x\) iff \((x_n - x) \stackrel{st}{\rightarrow} 0\);
(4) if \(x_n \stackrel{st}{\rightarrow} x\), then \(|x_n| \stackrel{st}{\rightarrow} |x|\).

Proof. (1): Let \((x_n)\) be a sequence in \(E\) such that \(x_n \stackrel{st}{\rightarrow} x\) and \(x_n \not\stackrel{st}{\rightarrow} y\). Then we can find sequences \((p_n)\) and \((q_n)\) such that \(p_n \downarrow 0\) and \(q_n \downarrow 0\), and a set \(K = \{ n_1 < n_2 < \ldots \} \subset N\) with \(\delta(K) = 1\) such that

\[|x_{n_k} - x| \wedge u \leq p_{n_k} \downarrow 0, |x_{n_k} - y| \wedge u \leq q_{n_k} \downarrow 0.\]

Thus, we get

\[0 \leq |x - y| \wedge u \leq |x_{n_k} - x| \wedge u + |x_{n_k} - y| \wedge u \leq p_{n_k} + q_{n_k}\]

for every \(k \in N\) and \(u \in E_+\), which shows that \(x = y\);
(2) and (3): obviously;
(4): according to \(|x_n| - |x| \wedge u \leq |x_n - x| \wedge u\), we have the conclusion.

It is similar to [11, Theorem 7], the Squeeze law holds for statistical unbounded order convergence.

Proposition 2.3. Let \(E\) be a Riesz space; \((x_n)\), \((y_n)\) and \((z_n)\) be sequences in \(E\) such that \(x_n \leq y_n \leq z_n\) for all \(n \in K \subset N\) with \(\delta(K) = 1\), \(x_n \stackrel{st}{\rightarrow} x\) and \(z_n \stackrel{st}{\rightarrow} x\). Then \(y_n \stackrel{st}{\rightarrow} x\).

The \(st\)-uo-convergence preserve disjoint property.

Proposition 2.4. Let \(x_n \stackrel{st}{\rightarrow} x\) and \(x_n \perp y\ a.a.n\), then \(x \perp y\).

Proof. Since \(x_n \perp y\ a.a.n\). Then we have \(|x_n| \wedge |y| = 0\) for \(a.a.n\). Since \(x_n \stackrel{st}{\rightarrow} x\), we have \(|x_n| \stackrel{st}{\rightarrow} |x|\) and thus \(|x_n| \wedge |y| = 0\). It follows that \(|x| \wedge |y| = 0\).

In general, any subsequence of a convergent sequence is convergent, but it does not hold for \(st\)-uo-convergence.
Example 2.5. In $l_p$, $(1 < p < +\infty)$, let $(e_n)$ be the standard basis, and

$$ x_n = \begin{cases} \sum_{i=1}^{k} e_i, & n = k^2 (k \in N); \\ e_n, & \text{otherwise.} \end{cases} $$

Since $(e_n)$ is disjoint sequence, $(x_n)$ is statistical unbounded order convergent to 0. But the subsequence $(x_{k^2})$ does not.

Order convergence is statistical order convergence, similarly, $uo$-convergence implies st-$uo$-convergence, but the converse does not hold. In Example 2.5, $(x_n)$ is statistical unbounded order convergent to zero, but $(x_n)$ is not $uo$-convergent.

When does the st-$uo$-convergence imply $uo$-convergence?

In fact, statistical unbounded order convergence is different with unbounded order convergence on a index set which has zero density.

Proposition 2.6. Let $E$ be a Riesz space and $(x_n)$ be a sequence in $E$. Then $(x_n)$ is statistically unbounded order convergent to $x \in E$ if and only if there is another sequence $(y_n)$ such that $x_n = y_n$ for a.a.n and which is unbounded order convergent to the same limit $x$.

Proof. $\Rightarrow$: According to definition.

$\Leftarrow$: Assume that $x_n = y_n$ for a.a.n and $y_n \xrightarrow{uo} x$. Then there exists a sequence $(p_n) \downarrow 0$ (hence $p_n \downarrow_{st} 0$) and $|y_n - x| \wedge u \leq p_n$ for every $u \in E_+$. Thus, we can write

$$ \{n \leq m : |x_n - x| \wedge u \nleq p_n\} \subset \{|n \leq m : x_n \neq y_n\} \cup \{n \leq m : |y_n - x| \wedge u \nleq p_n\}. $$

Since $y_n \xrightarrow{uo} x$, the second set on the right side is empty. Hence we have $\delta \{n \in N : |x_n - x| \wedge u \nleq p_n\} = 0$, i.e. $x_n \xrightarrow{st-u(o)} x$. $\Box$

Proposition 2.7. If $(x_n)$ is monotone, then $uo$-convergence and st-$uo$-convergence agree.

Proof. Assume that $x_n \uparrow$ and $x_n \xrightarrow{st-u(o)} x$, then there exists a $K \subset N, \delta(K) = 1$ such that $x_k \xrightarrow{uo} x$ for $k_i \in K \subset N, i \in N$, hence $\sup_{i \in N} x_k = x$. For $j_i \in K^c, i \in N$, since $x_ji \uparrow$, so we have $x_ji \uparrow \leq x$, factly, if $x_ji > x$, then there exists a $k_0$ such that $x_{k_0} \geq x_{j_0} > x$, it is contradiction. And since we can find $k_i$ and $j_i$ such that $x_{k_i} \leq x_{j_i} \leq x$, by $\sup_{i \in N} x_k = x$, it follow that $\sup_{i \in N} x_ji = x$, hence $x_{j_i} \xrightarrow{uo} x$ for $j_i \in K^c$, so $x_n \xrightarrow{uo} x$ for $n \in N$. $\Box$

Similarly, st-$ord$-convergence implies st-$uo$-convergence, but the converse does not hold. In Example 2.5, $(x_n)$ is statistical unbounded order convergent to zero, but $(x_n)$ is not statistical order convergent.
It is natural to ask when the \textit{st-uO}-convergence imply \textit{st-ord}-convergence? By [7,Theorem 3.10], in \textit{\sigma}-order complete and \textit{\sigma}-laterally complete Riesz space, \((x_n)\) is \textit{uo}-Cauchy iff it is \textit{ord}-convergent. So, for Riesz space \(E\) with the property, \((x_n)\) is \textit{st-uO}-Cauchy iff it is \textit{st-ord}-convergent.

For order bounded sequence, the \textit{st-uO}-convergence is the same as \textit{st-ord}-convergence. In fact, it holds on weaker condition.

Let \(E\) be a Riesz space and \((x_n)\) be a sequence in \(E\). Then \((x_n)\) is statistically order bounded if there exists an order interval \([x, y]\) such that \(\delta\{n \in \mathbb{N} : x_n \notin [x, y]\} = 0\).

It is clear that an order bounded sequence is statistically order bounded, but the converse does not hold in general.

**Example 2.8.** In \(l_\infty\), let \((e_n)\) be the unit vectors, and

\[
x_n = \begin{cases} 
  ne_n, & n = k^2 (k \in \mathbb{N}); \\
  e_n, & \text{otherwise.}
\end{cases}
\]

\((x_n)\) is statistically order bounded sequence, but it is not order bounded.

**Proposition 2.9.** Let \((x_n)\) be statistically order bounded sequence in Riesz space \(E\) and \(x_n \overset{st-uO}{\longrightarrow} x\), then \(x_n \overset{st-ord}{\longrightarrow} x\).

**Proof.** Since \(x_n \overset{st-uO}{\longrightarrow} x\), therefore, \(x_n \overset{uo}{\longrightarrow} x\) for a.a.n. And since \((x_n)\) is statistically order bounded sequence, then there exists \(u \in E_+\) such that \(\delta\{n \in \mathbb{N} : \|\lambda x_n\| > C\} = 0\). It was shown in [7,Corollary 3.6] that every disjoint sequence is \textit{uo}-null, hence it is \textit{st-uO}-null.

Now, we describe \(KB\) space by statistical unbounded order convergence.

A sequence \((x_n)\) is said to be statistical unbounded order Cauchy, if the sequence \((x_n - x_m)\) \textit{st-uO}-converges to 0.

Let \(E\) be a Banach space and \((x_n)\) be a sequence in \(E\). Then \((x_n)\) is statistically norm bounded if for any \(C \in \mathbb{R}^+\) there exists a \(\lambda > 0\) such that \(\delta\{n \in \mathbb{N} : \|\lambda x_n\| > C\} = 0\).

It is clear that an norm bounded sequence is statistically norm bounded, but the converse does not hold in general. In Example 2.9, \((x_n)\) is statistically norm bounded sequence, but it is not norm bounded.

**Theorem 2.10.** Let \(E\) be an order continuous Banach lattice. The following are equivalent:
(1): $E$ is KB space;
(2): every norm bounded $\text{uo}$-Cauchy sequence in $E$ is $\text{uo}$-convergent;
(3): every statistically norm bounded $\text{st}$-$\text{uo}$-Cauchy sequence in $E$ is $\text{st}$-$\text{uo}$-convergent.

Proof. (1) $\Rightarrow$ (2): By [5, Theorem 4.7];
(2) $\Rightarrow$ (3): Obviously;
(3) $\Rightarrow$ (2): Assume that $E$ is not KB space, then $E$ contains a sublattice lattice isomorphic to $c_0$. Let $(x_n)$ be a sequence in $c_0$, and
$$x_n = \begin{cases} ne_n, & n = k^2 (k \in \mathbb{N}); \\ \sum_{i=1}^{n} e_i, & \text{otherwise}. \end{cases}$$
$(x_n)$ is statistically norm bounded and $\text{st}$-$\text{uo}$-Cauchy sequence in $E$ but it is not $\text{st}$-$\text{uo}$-convergent. $\square$

Weak convergence is statistical weak convergence. Weak convergent sequence is norm bounded, hence it is statistically norm bounded. Conversely, it does not hold. In Example 2.5, $(x_n)$ is statistical weak convergent to zero and statistically norm bounded, but it is not convergent weakly.

Let $E$ be a Banach space, $E$ is said to have statistical weak convergent property (STW property, for short) if $(x_n)$ is statistically norm bounded and $x_n \xrightarrow{\text{st-uo}} 0$ in $E$, then $x_n \xrightarrow{\text{w}} 0$.

Let $E$ be a Banach space, $E$ is said to have statistical weak* convergent property (STW* property, for short) if $(x'_n)$ is statistically norm bounded and $x'_n \xrightarrow{\text{st-uo}*} 0$ in $E'$, then $x'_n \xrightarrow{\text{w*}} 0$.

Now, we study order continuous Banach lattices by $\text{st}$-$\text{uo}$-convergence.

**Theorem 2.11.** Let $E$ be an Banach lattice.

1. $E$ has order continuous norm;
2. for any statistically norm bounded sequence $(x'_n)$ in $E'$, if $x'_n \xrightarrow{\text{st-uo}} 0$, then $x'_n \xrightarrow{\text{st-\sigma(E',E)}} 0$;
3. for any statistically norm bounded sequence $(x'_n)$ in $E'$, if $x'_n \xrightarrow{\text{st-uo}} 0$, then $x'_n \xrightarrow{\text{st-|\sigma(E',E)}} 0$.

Then (1) $\Rightarrow$ (2) $\iff$ (3) hold, and in addition, if $E$ has STW* property, all are equivalent.

Proof. Since $x'_n \xrightarrow{\text{st-uo}} 0 \iff |x'_n| \xrightarrow{\text{st-uo}} 0$, it is clear that (2) $\iff$ (3).

(1) $\Rightarrow$ (2): Assume that $E$ has order continuous norm, by [6, Theorem 2.1], for any norm bounded sequence $(x'_n)$ in $E'$ satisfying $x'_n \xrightarrow{\text{uo}}$
0, then \( x'_n \xrightarrow{\text{st-un}} 0 \). Since it is different with statistical on a index set which has zero density, hence for any statistically norm bounded sequence \((x'_n)\) if \( x'_n \xrightarrow{\text{st-uo}} 0 \), then \( x'_n \xrightarrow{\text{st-\sigma(E',E)}} 0 \).

(2) \( \Rightarrow \) (1): For any norm bounded disjoint sequence \((x'_n)\) in \( E' \), obviously, it is statistically norm bounded and uo-null, hence it is st-uo-null, so \( x'_n \xrightarrow{\text{st-\sigma(E',E)}} 0 \). Since \( E \) has STW*C property, \((x'_n)\) is weak* convergent to zero. By [4, Corollary 2.4.3], \( E \) has order continuous norm. □

3. Statistical unbounded convergence in Banach lattices

Now, we study the statistical unbounded convergence in Banach lattice. It is similar to [8,10,13], we introduce some new convergences in Banach lattices.

**Definition 3.1.** A sequence \((x_n)\) in Banach lattice \( E \) is statistically unbounded norm convergent to \( x \in E \) provided that 

\[
\delta\{n \in N : \|x_n - x\wedge u\| \geq \epsilon\} = 0 \text{ for all } \epsilon > 0 \text{ and } u \in E_+.
\]

We write \( x_n \xrightarrow{\text{st-un}} x \). We call \( x \) the statistical unbounded norm limit of \((x_n)\).

A sequence \((x_n)\) in Banach lattice \( E \) is statistically unbounded absolute weak convergent to \( x \in E \) provided that 

\[
\delta\{n \in N : f(|x_n - x| \wedge u) \geq \epsilon\} = 0 \text{ for all } \epsilon > 0, f \in E'_+ \text{ and } u \in E_+.
\]

We write \( x_n \xrightarrow{\text{st-uaw}} x \). We call \( x \) the statistical unbounded absolute weak limit of \((x_n)\).

A sequence \((x'_n)\) in dual Banach lattice \( E \) is statistically unbounded absolute weak star convergent to \( x' \in E \) provided that 

\[
\delta\{n \in N : (|x'_n - x'| \wedge u')(x) \geq \epsilon\} = 0 \text{ for all } \epsilon > 0, x \in E_+ \text{ and } u' \in E_+.
\]

We write \( x_n \xrightarrow{\text{st-uaw*}} x \). We call \( x' \) the statistical unbounded absolute weak star limit of \((x'_n)\).

Similarly to Proposition 2.2, we have the following results.

**Proposition 3.2.** (1) st-un-limits are unique;

(2) st-un-limits is linear;

(3) \( x_n \xrightarrow{\text{st-un}} x \) iff \( (x_n - x) \xrightarrow{\text{st-un}} 0 \);

(4) if \( x_n \xrightarrow{\text{st-un}} x \), then \( |x_n| \xrightarrow{\text{st-un}} |x| \).

The st-uaw-convergence and st-uaw*-convergence have analogic conclusions.

In general, any subsequence of a convergent sequence is convergent, but it does not hold for st-un-convergence, st-uaw-convergence and st-uaw*-convergence.
Example 3.3. In \( L_p[0, 1] \) \((1 < p < +\infty)\), let

\[
x_n(t) = \begin{cases} 
0, & t \not\in \left[ \frac{1}{2^n}, \frac{1}{2^{n-1}} \right]; \\
1, & t \in \left[ \frac{1}{2^n}, \frac{1}{2^{n-1}} \right]. 
\end{cases}
\]

and

\[
y_n = \begin{cases} 
\sum_{i=1}^{n} ix_i, & n = k^2 (k \in N); \\
2^n x_n, & \text{otherwise.} 
\end{cases}
\]

\((y_n)\) is statistical unbounded norm (absolute weak, absolute weak star) convergent to zero, but \((x_{k^2})\) does not.

Norm (weak, weak*) convergence is statistical norm (weak, weak*) convergence, similarly, \(un(uaw, uaw^*)\)-convergence implies \(st-un(uaw, uaw^*)\)-convergence, but the converse does not hold. In Example 3.3, \((y_n)\) is \(st-un(st-uaw, st-uaw^*)\)-convergent, but it is not \(un(uaw, uaw^*)\)-convergent.

Under what conditions, does the \(st-un(st-uaw, st-uaw^*)\)-convergence implies \(un(uaw, uaw^*)\)-convergence? In fact, \(st-un(st-uaw, st-uaw^*)\)-convergence is different with \(un(uaw, uaw^*)\)-convergence on a index set which has zero density.

Lemma 3.4. Let \( E \) be a Riesz space and \((x_n)\) be a sequence in \( E \). Then \((x_n)\) is \(st-un(uaw, uaw^*)\)-convergent to \( x \in E \) if and only if there is another sequence \((y_n)\) such that \( x_n = y_n \) for a.a.n and which is \(un(uaw, uaw^*)\)-convergent to the same limit \( x \).

Proposition 3.5. For monotonic sequence, then

(1) \(un\)-convergence and \(st-un\)-convergence agree.
(2) \(uaw\)-convergence and \(st-un\)-convergence agree.
(3) \(uaw^*\)-convergence and \(st-uaw^*\)-convergence agree.

Proof. (1): By [4, Proposition 1.1.6(3)], every convergent sequence monotone has supremum which is the limit of norm convergence. Now, assume that \( 0 \leq x_n \uparrow \) and \( x_n \xrightarrow{un} x \). Since \((|x_n| \land u)\) is increasing sequence and convergent to \( x \) for all \( u \in E_* \), hence \( x = \sup_{n \in N} x_n \).

According to proof of Proposition 2.7, if a sequence \((x_n)\) in a Banach lattice \( E \) is monotone and statistical unbounded norm convergent to \( x \in E \), then \( x = \sup_{n \in N} x_n \).

Now, assume that \( x_n \xrightarrow{st-un} x \) and \((x_n)\) is monotone, we have \( x = \sup_{n \in N} x_n \). Hence there exists \((k_j)\) be a strictly increasing sequence of natural numbers so that \( x_{k_j} \xrightarrow{un} x \) with \((k_j)_{j \in N} = K \subset N, \delta(K) = \).
1. Let any \( \epsilon > 0, \ u \in E_+ \), choose a natural number \( j_0 \) such that \( \| |x_{j_0} - x| \wedge u \| < \epsilon \). Then, for any \( n > k_{j_0} \), we have
\[
0 \leq |x - x_n| \wedge u \leq |x - x_{k_{j_0}}| \wedge u
\]
This shows \( \| |x - x_n| \wedge u \| \leq \| |x - x_{k_{j_0}}| \wedge u \| < \epsilon \).
Hence, \( x_n \xrightarrow{\text{un}} x \).

(2): Suppose that \( (x_n) \) is an increasing convergent sequence and \( x_n \xrightarrow{\text{uaw}} x \). Since \( x_m - x_n \in E_+ \) for all \( m \geq n \), because lattice operation of uaw-convergence is continuous, so \( (x_m - x_n)(m) = (x_m - x_n)^+ \xrightarrow{\text{uaw}} (x - x_n)^+ \), hence \( x - x_n \geq 0 \) for all \( n \). If \( x \) is not supremum, then assume that \( y \in E \) such that \( x_n \leq y \leq x \) for all \( n \in N \), it follows that
\[
x_n = x_n \wedge y \xrightarrow{\text{uaw}} x \wedge y = y
\]
Hence, \( y = x \), so \( x = \sup_{n \in N} x_n \).

According to proof of Proposition 2.7, if a sequence \( (x_n) \) in a Banach lattice \( E \) is monotone and statistical unbounded absolute weak convergent to \( x \in E \), then \( x = \sup_{n \in N} x_n \).

Now, let \( x_n \xrightarrow{\text{uaw}} x \) and \( (x_n) \) be monotone, we have \( x = \sup_{n \in N} x_n \). Hence there exists \( (k_j) \) be a strictly increasing sequence of natural numbers so that \( x_{k_j} \xrightarrow{\text{uaw}} x \) with \( (k_j)_{j \in N} = K \subset N, \delta(K) = 1 \). Let any \( \epsilon > 0, \ u \in E_+ \) and \( f \in E'_+ \), choose a natural number \( j_0 \) such that \( f(|x_{j_0} - x| \wedge u) < \epsilon \). Then, for any \( n > k_{j_0} \), we have
\[
0 \leq |x - x_n| \wedge u \leq |x - x_{k_{j_0}}| \wedge u
\]
This shows
\[
0 \leq f(|x - x_n| \wedge u) \leq f(|x - x_{k_{j_0}}| \wedge u) < \epsilon
\]
Hence, \( x_n \xrightarrow{\text{uaw}} x \).

(3): It is similar to (2). \( \square \)

**Lemma 3.6.** In an order continuous Banach lattice, st-uo-convergence implies st-un-convergence.

Next, we describe \( KB \) space by statistical unbounded norm convergence. According to Theorem 2.10, we have the following result.

**Theorem 3.7.** Let \( E \) be an order continuous Banach lattice. The following are equivalent:

(1) \( E \) is \( KB \) space;

(2) every norm bounded uo-Cauchy sequence in \( E \) is un-convergent;

(3) every statistically norm bounded st-uo-Cauchy sequence in \( E \) is st-un-convergent.

When does the st-un(st-aw, st-aw*)-convergence implies st-n(st-aw, st-aw*)-convergence?

In fact, for statistically order bounded sequences, st-un-convergence and statistical norm convergence agree. The st-uaw-convergence and st-uaw*-convergence have analogous results.

According to [9, theorem 2.3], the following holds.

**Proposition 3.8.** Let \(E\) be a Banach lattice with strong order unit, then \((x_n)\) in \(E\) is st-norm convergence if and only if it is st-un-convergence.

By [10, Lemma 2], every disjoint sequence is uaw-null, hence it is st-uaw-null, moreover it is st-uaw*-null.

Now, we can describe order continuous and reflexive Banach lattice by statistical unbounded convergence.

**Theorem 3.9.** Let \(E\) be an Banach lattice.

1. \(E\) has order continuous norm;
2. for any statistically norm bounded sequence \((x'_n)\) in \(E'\), if \(x'_n \overset{st-\sigma(E',E)}{\longrightarrow} 0\), then \(x'_n \overset{st-\sigma(E',E)}{\longrightarrow} 0\);
3. for any statistically norm bounded sequence \((x'_n)\) in \(E'\), if \(x'_n \overset{st-\sigma(E',E)}{\longrightarrow} 0\), then \(x'_n \overset{st-\sigma(E',E)}{\longrightarrow} 0\).

Then (1) \(\Rightarrow\) (2) \(\Leftrightarrow\) (3) hold, and in addition, if \(E\) has STW* C property, all are equivalent.

**Proof.** Since \(x'_n \overset{st-\sigma(E',E)}{\longrightarrow} 0\), then \(\left|x'_n\right| \overset{st-\sigma(E',E)}{\longrightarrow} 0\), it is clear that (2) \(\Leftrightarrow\) (3).

1. \(\Rightarrow\) (2): Suppose that \(E\) has order continuous norm, by [13, Theorem 2.15], for any norm bounded sequence \((x'_n)\) in \(E'\) satisfying \(x'_n \overset{uaw*}{\longrightarrow} 0\), then \(x'_n \overset{\sigma(E',E)}{\longrightarrow} 0\). Since it is different with statistical on a index set which has zero density, so for any statistically norm bounded sequence \((x'_n)\) if \(x'_n \overset{st-\sigma(E',E)}{\longrightarrow} 0\), then \(x'_n \overset{st-\sigma(E',E)}{\longrightarrow} 0\).
2. \(\Rightarrow\) (1): For any norm bounded disjoint sequence \((x'_n)\) in \(E'\), by Corollary 4.15, it is statistically norm bounded and st-uo-null, so \(x'_n \overset{st-\sigma(E',E)}{\longrightarrow} 0\). Since \(E\) has STW* C property, \((x'_n)\) is weak* convergent to zero. By [4,Corollary 2.4.3], \(E\) has order continuous norm. \(\Box\)

**Theorem 3.10.** Let \(E\) be an Banach lattice.

1. \(E'\) has order continuous norm;
(2) for any statistically norm bounded sequence \((x_n)\) in \(E\), if \(x_n \xrightarrow{st-uaw} 0\), then \(x_n \xrightarrow{st-\sigma(E,E')} 0\);

(3) for any statistically norm bounded sequence \((x_n)\) in \(E\), if \(x_n \xrightarrow{st-uaw} 0\), then \(x_n \xrightarrow{st-|\sigma|(E,E')} 0\).

Then \((1) \Rightarrow (2) \Leftrightarrow (3)\) hold, and in addition, if \(E\) has STWC property, all are equivalent.

Proof. Similarly.

Corollary 3.11. For AM-space or atomic and order continuous Banach lattice with order continuous dual, the st-uaw-convergence and st-w-convergence are agrees.

Proof. Since AM-space and atomic Banach lattice with order continuous norm has lattice operation weakly sequence continuous property, so st-w-convergence implies st-uaw-convergence. For the reverse, the dual space of AM-space is AL-space which is order continuous, hence st-uaw-convergence implies st-w-convergence.

Theorem 3.12. For Banach lattice \(E\). The following are equivalent:

1. \(E\) is reflexive;
2. every statistically norm bounded st-uaw-Cauchy sequence in \(E\) is statistical weakly convergent.
3. every statistically norm bounded st-un-Cauchy sequence in \(E\) is statistical weakly convergent.
4. every statistically norm bounded st-uo-Cauchy sequence in \(E\) is statistical weakly convergent.

Proof. (1) \Rightarrow (2): Since \(E\) is reflexive, then \(E\) and \(E'\) are KB space, so we have every statistically norm bounded st-uaw-Cauchy sequence in \(E\) is statistical weakly Cauchy. Since \(E\) is KB-space, so it is statistical weakly convergent.

(2) \Rightarrow (1): We show that \(E\) contains no lattice copies of \(c_0\) or \(l_1\). Suppose that \(E\) contains a sublattice isomorphic to \(l_1\). The \((x_n)\) of \(l_1\) which is in Example 3.3, it is st-uaw convergent to zero and statistically norm bounded but it is not statistical weakly convergence. Suppose that \(E\) contains a sublattice isomorphic to \(c_0\), the \((x_n)\) of \(c_0\) which is in the proof of Theorem 3.14, it is st-uaw-Cauchy sequence, but it is not weakly convergence. So we have the conclusion.

(2) \Rightarrow (3): Since \(un\)-convergence implies \(uaw\)-convergence, so we have the conclusion.

(3) \Rightarrow (1): \(E\) contains no sublattice isomorphic to \(c_0\) or \(l_1\), the proof is similarly to (2) \Rightarrow (1).
(1) ⇔ (4): the proof is similar to (1) ⇔ (2). □
