ON SINGULAR POINTS AND OSCILLATORY INTEGRALS

TOSHIO NAGANO AND NAOYA MIYAZAKI

Dedicated to Emeritus Professor Hideki Omori on his 80th birthday

Abstract. In this note, we generalize the Fresnel integrals using oscillatory integral, and then we obtain an extension of the stationary phase method.

1. Introduction

In the present note, we study a method for an asymptotic expansion of the following integral

\[ I(\lambda) := \int_{\mathbb{R}^n} e^{i\lambda \phi(x)} a(x) dx \]

as a real positive parameter \( \lambda \to \infty \). For the purpose we first give a summary of the original method relating to theory of asymptotic expansion in §2. In particular, the stationary phase method is known as a method for an asymptotic expansion of an oscillatory integral of a phase function with a non-degenerate critical point.

In §3, we extend the Fresnel integrals by changing of a path for integration in the well-known proof using Cauchy’s integral theorem. Next, according to oscillatory integral, we also obtain further generalization of the Fresnel integrals.

Furthermore, in §4, we establish finer generalization of the stationary phase method.

As mentioned as above, the several proofs of the Fresnel integrals are known ([17] I p.326, II p.85, 245, etc.). In particular, we are interested in the proof of applying Cauchy’s integral theorem to a function \( e^{-i z^2} \) on the domain surrounded by a fan with the center at the origin of Gaussian plane ([10]). By changing the fan used in the proof, we can generalize the Fresnel integrals in the following way:

\[ I_{p,q}^\pm := \int_0^\infty e^{\pm izp} x^{q-1} dx = p^{-1} e^{\pm i \frac{q}{2p}} \Gamma \left( \frac{q}{p} \right) , \]

where \( \Gamma \) is the Gamma function. This equalities hold for \( p > q > 0 \) (Lemma 3.1). Moreover, by making a sense of these integrals via oscillatory integral, we obtain

\[ \tilde{I}_{p,q}^\pm := \lim_{\varepsilon \to +0} \int_0^\infty e^{\pm izp} x^{q-1} \chi(\varepsilon x) dx = p^{-1} e^{\pm i \frac{q}{2p}} \Gamma \left( \frac{q}{p} \right) , \]

Key words and phrases. Fresnel integral, oscillatory integral, stationary phase method, asymptotic expansion.

The first author was supported by Tokyo University of Science Graduate School doctoral program scholarship and an exemption of the cost of equipment from 2016 to 2018 and would like to thank to Professor Minoru Ito for giving me an opportunity of studies and preparing the environment.
where $\chi \in \mathcal{S}(\mathbb{R})$ with $\chi(0) = 1$. This equalities hold for $p > 0$ and $q > 0$ (Theorem 2.3 (i)). These results can be considered as an extension of the case of $\lambda = q - 1$ and $\xi = 1$ in the Fourier transform of Gel’fand-Shilov generalized function $\mathcal{F}[x_+^q](\xi)$ with $\lambda \in \mathbb{C} \setminus \{-1\}$ (\cite{8} p.170):

$$\mathcal{F}[x_+^q](1) := \lim_{\tau \to +0} \int_0^\infty e^{i\tau x} e^{-\tau x} dx = e^{\frac{i\pi q}{2}} \Gamma(q)(1 + i0)^{-q},$$

where $\text{Re}\tau > 0$. By our results, we can become to treat the oscillatory integrals for a phase function with a degenerate critical point expressed by positive real power. And then, using the result obtained as above, we give an extention of the stationary phase method in one variable (Theorem 2.4 (iv)).

To the end of §1, we remark notation which will be used in this note:

$\alpha = (\alpha_1, \ldots, \alpha_n) \in (\mathbb{Z} \geq 0)^n$ is a multi-index with a length $|\alpha| = \alpha_1 + \cdots + \alpha_n$, and then, we use $x^\alpha = x_1^{\alpha_1} \cdots x_n^{\alpha_n}$, $\alpha! = \alpha_1! \cdots \alpha_n!$, $\partial_x^\alpha = \partial_{x_1}^{\alpha_1} \cdots \partial_{x_n}^{\alpha_n}$ and $D_x^\alpha = D_x^{\alpha_1} \cdots D_x^{\alpha_n}$, where $\partial_x^j = \frac{\partial}{\partial x_j}$ and $D_x^j = \frac{1}{j!} \partial_x^j$ for $x = (x_1, \ldots, x_n)$.

$C^\infty(\mathbb{R}^n)$ is the set of complex-valued $C^\infty$ functions on $\mathbb{R}^n$. $C^\infty_0(\mathbb{R}^n)$ is the set of all $f \in C^\infty(\mathbb{R}^n)$ with compact support. $\mathcal{S}(\mathbb{R}^n)$ is the Schwartz space of rapidly decreasing $C^\infty$ functions on $\mathbb{R}^n$, that is, the Fréchet space of all $f \in C^\infty(\mathbb{R}^n)$ such that $
abla_{x \in \mathbb{R}^n} |x^\beta \partial_x^\alpha f(x)| < \infty$ for any multi-indexes $\alpha, \beta \in (\mathbb{Z} \geq 0)^n$.

$O$ means a Landau’s symbol, that is, $f(x) = O(g(x))$ ($x \to a$) if $|f(x)/g(x)|$ is bounded as $x \to a$ for functions $f$ and $g$.

## 2. Preliminary

In this section, we recall the oscillatory integrals and the original stationary phase method.

**Definition 2.1.** Let $\lambda \geq 1$ and let $\phi$ be a real-valued $C^\infty$ function on $\mathbb{R}^n$ and $a \in C^\infty(\mathbb{R}^n)$. If there exists

$$\tilde{I}_\phi[a](\lambda) := O_s \int_{\mathbb{R}^n} e^{\lambda \phi(x)} a(x) dx := \lim_{\varepsilon \to +0} \int_{\mathbb{R}^n} e^{i\lambda \phi(x)} a(x) \chi(\varepsilon x) dx$$

independent of $\chi \in \mathcal{S}(\mathbb{R}^n)$ with $\chi(0) = 1$ and $0 < \varepsilon < 1$, then we call $\tilde{I}_\phi[a](\lambda)$ an oscillatory integral where we call $\phi$ (resp. $a$) a phase function (resp. an amplitude function).

If we suppose a certain suitable conditions for $\phi$ and $a$, then we can show $\tilde{I}_\phi[a](\lambda)$ exists independent of $\chi$ and $\varepsilon$. The fundamental properties are the following (cf. \cite{13} p.47.):

**Proposition 2.2.** Assume that $\chi \in \mathcal{S}(\mathbb{R}^n)$ with $\chi(0) = 1$. Then

(i) $\chi(\varepsilon x) \to 1$ uniformly on any compact set in $\mathbb{R}^n$ as $\varepsilon \to +0$.

(ii) For each multi-index $\alpha \in (\mathbb{Z} \geq 0)^n$, there exists a positive constant $C_\alpha$ independent of $0 < \varepsilon < 1$ such that for $x \in \mathbb{R}^n$

$$|\partial_x^\alpha \chi(\varepsilon x)| \leq C_\alpha (1 + |x|^2)^{-|\alpha|/2}.$$

(iii) For any multi-index $\alpha \in (\mathbb{Z} \geq 0)^n$ with $\alpha \neq 0$, $\partial_x^\alpha \chi(\varepsilon x) \to 0$ uniformly in $\mathbb{R}^n$ as $\varepsilon \to +0$.

Next we recall the Fresnel integrals (cf. \cite{10} p.23.).
Proposition 2.3. The following integrals, which called Fresnel integrals, hold:

$$\int_{-\infty}^{\infty} e^{\pm ix^2} dx = \sqrt{\pi} e^{\pm i \frac{\pi}{4}},$$

where double signs $\pm$ in same order.

Next we summarize the Fourier transforms of rapidly decreasing $C^\infty$ functions.

Definition 2.4. Let $f \in S(\mathbb{R}^n)$. Then we define by $\hat{f} = \mathcal{F}[f]$ the Fourier transform of $f$ as

$$\mathcal{F}[f](\xi) := \frac{1}{(2\pi)^{\frac{n}{2}}} \int_{\mathbb{R}^n} e^{-i\langle x, \xi \rangle} f(x) dx,$$

where $\langle x, \xi \rangle := \sum_{k=1}^{n} x_k \xi_k$ for $x = (x_1, \ldots, x_n)$ and $\xi = (\xi_1, \ldots, \xi_n) \in \mathbb{R}^n$.

If $A$ is a real symmetric non-singular $n \times n$ matrix, then the Fourier transform of $e^{i(1/2)\langle Ax, x \rangle}$ is given in the following way (cf. [8], [9], [3], [7], [5]).

Proposition 2.5. Let $A$ be a real symmetric non-singular $n \times n$ matrix with $p$ positive and $n-p$ negative eigenvalues.

(i) If $A = \pm 1$ for $n = 1$, then

$$\mathcal{F}[e^{\pm i \frac{1}{2} x^2}](\xi) = e^{\pm i \frac{\pi}{4}} e^{\mp i \frac{1}{2} \xi^2},$$

where double signs $\pm, \mp$ in same order.

(ii) If $n \geq 1$, then

$$\mathcal{F}[e^{i \frac{1}{2} \langle Ax, x \rangle}](\xi) = \frac{e^{i \frac{1}{2} \text{sgn} A} |\det A|^{-\frac{1}{2}}}{|\det A|^{\frac{1}{2}}} e^{-i \frac{1}{2} \langle A^{-1} \xi, \xi \rangle},$$

where $\text{sgn} A := p - (n - p)$.

By Proposition 2.5, we can obtain an asymptotic expansion of the oscillatory integral with a non-degenerate quadratic phase $\phi(x) = (1/2)\langle Ax, x \rangle$ in the following way.

Proposition 2.6. Suppose that $\lambda \geq 1$, $a \in S(\mathbb{R}^n)$ and $A$ is a real symmetric non-singular $n \times n$ matrix. Then, there exists a positive constant $C$ such that for any $N \in \mathbb{N}$

$$\int_{\mathbb{R}^n} e^{i \frac{1}{2} A (x, x)} a(x) dx$$

$$= (2\pi)^{\frac{n}{2}} \frac{e^{i \frac{1}{2} \text{sgn} A}}{|\det A|^{\frac{1}{2}}} \sum_{k=0}^{N-1} \frac{1}{k!} \left(-i \frac{1}{2} \langle A^{-1} D_x, D_x \rangle \right)_x^k a(x) \lambda^{-k - \frac{n}{2}} + R_N(\lambda)$$

and

$$|R_N(\lambda)| \leq (2\pi)^{\frac{n}{2}} \frac{C}{|\det A|^{N+\frac{n}{2}}} \frac{1}{N!} \left( \sum_{|\alpha| \leq 2(N+n)} \int_{\mathbb{R}^n} |\partial_x^\alpha a(x)| dx \right) \lambda^{-N - \frac{n}{2}}.$$
Lemma 2.7. Let $\phi$ be a real-valued $C^\infty$ function on a neighborhood of $\bar{x}$ in $\mathbb{R}^n$ such that $\bar{x}$ is an only non-degenerate critical point of $\phi$, that is, if and only if $\nabla \phi(\bar{x}) = 0$, and $\det \text{Hess}(\bar{x}) \neq 0$. Then there exist neighborhoods $U$ of $\bar{x}$ and $V$ of $0$ in $\mathbb{R}^n$ and $C^\infty$ diffeomorphism $\Phi: V \to U$ such that $x = \Phi(y)$ for $x = (x_1, \ldots, x_n) \in U$ and $y = (y_1, \ldots, y_n) \in V$ and

$$\phi(x) - \phi(\bar{x}) = \frac{1}{2}(y_1^2 + \cdots + y_p^2 - y_{p+1}^2 - \cdots - y_n^2),$$

where $\text{Hess}(\bar{x}) := (\partial^2 \phi(\bar{x})/\partial x_i \partial x_j)_{i,j=1,\ldots,n}$ is Hessian matrix of $\phi$ at $\bar{x}$ with “$p$” positive and “$n - p$” negative eigenvalues.

The second one is for an estimation of the remainder of an asymptotic expansion for an oscillatory integral ([8], [9]).

Lemma 2.8. Let $\lambda \geq 1$ and $a \in S(\mathbb{R}^n)$ and let $\phi$ be a real-valued $C^\infty$ function on $\mathbb{R}^n$ with $|\nabla \phi(x)| \geq d > 0$ for $x \in \text{suppa}$. Then for each $N \in \mathbb{N}$, there exists a positive constant $C_N$ such that

$$\left| \int_{\mathbb{R}^n} e^{\lambda \phi(x)} a(x) dx \right| \leq C_N (\lambda d^2)^{-N}.$$

We are now in a position to state the stationary phase method ([8], [9], [3], [5]).

Theorem 2.9. Suppose that $\lambda \geq 1$, $a \in S(\mathbb{R}^n)$ and $\phi$ is a real-valued $C^\infty$ function on a neighborhood of $\bar{x}$ in $\mathbb{R}^n$ such that $\bar{x}$ is an only non-degenerate critical point of $\phi$. Then there exist neighborhoods $U$ of $\bar{x}$ and $V$ of $0$ in $\mathbb{R}^n$ and $C^\infty$ diffeomorphism $\Phi: V \to U$ such that $x = \Phi(y)$ for $x = (x_1, \ldots, x_n) \in U$ and $y = (y_1, \ldots, y_n) \in V$, and for each $N \in \mathbb{N}$, there exists a positive constant $C_N$ such that

$$\int_{\mathbb{R}^n} e^{\lambda \phi(x)} a(x) dx = (2\pi)^{\frac{n}{2}} \frac{e^{i\frac{\pi}{4} \text{sgnHess}(\bar{x})}}{|\det \text{Hess}(\bar{x})|^\frac{1}{4}} e^{i\lambda \phi(\bar{x})} \times \sum_{k=0}^{N-1} \frac{1}{k!} \left(-\frac{1}{2}\text{Hess}(\bar{x})^{-1}D_y, D_y\right)^k \left|_{y=0} \{a \circ \Phi\}(y)\lambda^{-k-\frac{n}{2}} + R_N(\lambda) \right|$$

and

$$|R_N(\lambda)| \leq C_N \lambda^{-N-\frac{n}{2}},$$

where $J_\Phi(y) := \det(\partial x_j/\partial y_k)_{j,k=1,\ldots,n}$ is a Jacobian of $\Phi$.

3. Generalized Fresnel Integrals

In this section, we consider a generalization of the Fresnel integrals.

Lemma 3.1. Assume that $p > q > 0$. Then we have

$$I_{p,q} := \int_0^\infty e^{\pm iz^p} z^{q-1} dz = p^{-1} e^{\pm i\frac{\pi}{4}} \Gamma\left(\frac{q}{p}\right),$$

where $\Gamma$ is the Gamma function and double signs are in same order.

Proof. Apply Cauchy’s integral theorem to a homeomorphic function $e^{iz^p} z^{q-1}$ on the domain with the boundary $\sum_{j=1}^4 C_j$ defined by $C_1 := \{z = r \in \mathbb{C} | 0 < \varepsilon \leq r \leq R\}$, $C_2 := \{z = Re^{i\theta} \in \mathbb{C} | 0 \leq \theta \leq \pi/2p\}$, $C_3 := \{z = \varepsilon e^{i(\pi/2p)} \in \mathbb{C} | -R \leq s \leq -\varepsilon\}$ and $C_4 := \{z = \varepsilon e^{-i\tau} \in \mathbb{C} | -\pi/2p \leq \tau \leq 0\}$. \qed
If \( q \geq p > 0 \), we can make a sense of (3.1) as oscillatory integrals. In order to show this, we prepare the following lemma.

**Lemma 3.2.** Assume that \( p > 0 \) and \( q > 0 \). Let \( \chi \in \mathcal{S}(\mathbb{R}) \) with \( \chi(0) = 1 \) and \( 0 < \varepsilon < 1 \). Then we have

(i) For each \( k \in \mathbb{Z}_{\geq 0} \), there exist the following independent of \( \chi \) and \( \varepsilon \)

\[
\lim_{\varepsilon \to +0} \int_{0}^{\infty} e^{\pm ixp} x^{q-1} \frac{d^k}{dx^k} \chi(\varepsilon x) dx.
\]

(ii) If \( k \neq 0 \), then

\[
\lim_{\varepsilon \to +0} \int_{0}^{\infty} e^{\pm ixp} x^{q-1} \frac{d^k}{dx^k} \chi(\varepsilon x) dx = 0.
\]

(iii) If \( p > q \), then

\[
\tilde{I}_{p,q}^\pm := Os \int_{0}^{\infty} e^{\pm ixp} x^{q-1} dx = \int_{0}^{\infty} e^{\pm ixp} x^{q-1} dx = I_{p,q}^\pm.
\]

Double signs \( \pm \) in same order.

**Proof.** Dividing this integral by cutoff function \( \varphi \) which has its compact support around the origin in \( \mathbb{R} \). Repeating application of a differential operator \( L = \frac{1}{px^{p-1}} \frac{d}{dx} \) to \( e^{\pm ixp} \) on the support of \( 1 - \varphi \) and integration by parts make the order of integrand descend to be integrable in the sense of Lebesgue. Application of Lebsgue’s dominant convergence theorem with Proposition 3.2 completes the proof. \( \square \)

By Lemmas 3.1 and 3.2 we obtain the following theorem.

**Theorem 3.3.** Assume that \( p, q \in \mathbb{C} \).

(i) If \( p > 0 \) and \( q > 0 \), then

\[
\tilde{I}_{p,q}^\pm := Os \int_{0}^{\infty} e^{\pm ixp} x^{q-1} dx = p^{-1} e^{\pm i \pi/2} \Gamma\left( \frac{q}{p} \right).
\]

(ii) The \( \tilde{I}_{p,q}^\pm \) can be extended non-zero meromorphic on \( \mathbb{C} \) with poles of order 1 at \( q = -pj \) for \( j \in \mathbb{N} \) as to \( q \) for each \( p > 0 \), and meromorphic on \( \mathbb{C} \setminus \{0\} \) with poles of order 1 at \( p = -q/j \) for \( j \in \mathbb{N} \) as to \( p \) for each \( q > 0 \) by analytic continuation.

Double signs \( \pm \) in same order. We call \( \tilde{I}_{p,q}^\pm \) “generalized Fresnel integrals”.

**Proof.** When \( p > q \), applying Lemma 3.2(iii) and Lemma 3.1 give (i). When \( q \geq p \), repeating use of integration by part combining with Lemma 3.1 show (i). Using analytic continuation of the Gamma function with (i) proves (ii). \( \square \)

Using the theorem above, we can extend the Euler Beta function as follow.

**Proposition 3.4.** Assume that \( p_j > 0 \) and \( q_j \in \mathbb{C} \setminus \{0\} \) for \( j = 1, 2, 3 \). Let

\[
\tilde{B}(p_1, p_2; q_1, q_2, q_3) := e^{\pm i \pi} \left( \frac{q_1 + q_2 - q_3}{q_3} \right) \frac{p_1 p_2}{p_3} \tilde{I}_{p_1,q_1}^\pm \tilde{I}_{p_2,q_2}^\pm \tilde{I}_{p_3,q_3}^\pm
\]

Then

\[
\tilde{B}(1, 1, 1; q_1, q_2, q_1 + q_2) = B(q_1, q_2),
\]

where \( B(x, y) \) is the Euler Beta function and double signs \( \pm \) in same order.
4. An Extension of the Stationary Phase Method

In this section, we consider an extension of the stationary phase method in one variable according to the generalized Fresnel integrals developed above.

**Theorem 4.1.** Let \( p > 0, \lambda \geq 1 \) and \( a \in \mathcal{S}(\mathbb{R}) \).

(i) If \( q > 0 \), then
\[
I_{p,q}^\pm[a](\lambda) := \int_0^\infty e^{\pm i\lambda x^p} x^{q-1} a(x) dx
\]
is absolutely convergent.

(ii) If \( q > p \), then there exists a positive constant \( C_q \) such that
\[
|I_{p,q}^\pm[a](\lambda)| \leq C_q \lambda^{-\frac{q-1}{2}+1}.
\]

(iii) If \( p > 0 \), then for any \( N \in \mathbb{N} \) such that \( N + 1 \geq p \),
\[
\int_0^\infty e^{\pm i\lambda x^p} a(x) dx = p^{-1} \sum_{k=0}^{N-1} e^{\pm i\frac{k+1}{p}} \frac{\Gamma\left(\frac{k+1}{p}\right)}{k!} \lambda^{-\frac{k+1}{p}} a^{(k)}(0) + O\left(\lambda^{-\frac{N+1}{p}+1}\right).
\]

(iv) If \( m \in \mathbb{N} \), then for any \( N \in \mathbb{N} \) such that \( N + 1 \geq m \),
\[
\int_{-\infty}^{\infty} e^{\pm i\lambda x^m} a(x) dx = m^{-1} \sum_{k=0}^{N-1} \left( e^{\pm i\frac{k+1}{m}} + (-1)^k e^{\pm (-1)^m i\frac{k+1}{m}} \right)
\times \frac{\Gamma\left(\frac{k+1}{m}\right)}{k!} \lambda^{-\frac{k+1}{m}} a^{(k)}(0) + O\left(\lambda^{-\frac{N+1}{m}+1}\right).
\]

Double signs \( \pm \) in same order.

**Proof.** (i) Put \( f(x) = e^{i\lambda x^p} x^{q-1} a(x) \), then \( f(x) = O(x^\alpha) \) \((x \to +0)\) when \( \alpha = q - 1 > -1 \) and \( f(x) = O(x^\beta) \) \((x \to \infty)\) when \( \beta = q - 1 - (q+1) < -1 \). This shows (i). According to integration by part, we show the second assertion (ii). As to (iii), first we divide this integral into the principal part and the remainder term by Taylor expansion of \( a \) at 0. And then applying Theorem 4.1 (i) after using change of variable \( y = \lambda^{1/p} x \) in the former and applying (ii) in the latter completes the proof. (iv) If the variable is negative, we first change a variable \( x = -y \). Then (iii) proves (iv). \( \square \)

To the end of the present note, we note that we obtain asymptotic expansion of oscillatory integral in several variables with not only the Morse type phase function but also singular types for examples \( A, E \)-phase functions. For details, see [15].
