TURÁN NUMBER OF DISJOINT TRIANGLES IN 4-PARTITE GRAPHS

JIE HAN AND YI ZHAO

Abstract. Let \( k \geq 2 \) and \( n_1 \geq n_2 \geq n_3 \geq n_4 \) be integers such that \( n_4 \) is sufficiently larger than \( k \). We determine the maximum number of edges of a 4-partite graph with parts of sizes \( n_1, \ldots, n_4 \) that does not contain \( k \) vertex-disjoint triangles. For any \( r > t \geq 3 \), we give a conjecture on the maximum number of edges of an \( r \)-partite graph that does not contain \( k \) vertex-disjoint cliques \( K_t \). We also determine the largest possible minimum degree among all \( r \)-partite triangle-free graphs.

1. Introduction

A graph \( G \) is called \( F \)-free if \( G \) does not contain any copy of \( F \) as a subgraph. Let \( K_t \) denote a complete graph on \( t \) vertices. In 1941, Turán [7] proved that \( T_{n,t} \), the balanced complete \( t \)-partite graph on \( n \) vertices which was later named as the Turán graph, has the maximum number of edges among all \( K_t ` \) free graphs (the case \( t = 2 \) was previously solved by Mantel [5]). Turán’s result initiates the study of Extremal Graph Theory, which is now a substantial area of research. Note that Turán problems become very hard in hypergraphs. For example, despite many efforts and recent developments, we still do not know the Turán number for tetrahedron in a 3-uniform hypergraph.

Let \( kK_t \) denote \( k \) disjoint copies of \( K_t \). Simonovits [6] studied the Turán problem for \( kK_t \) and showed that when \( n \) is sufficiently large, the (unique) extremal graph on \( n \) vertices is the join of \( K_{k-1} \) and the Turán graph \( T_{n-k+1,t-1} \).

In this paper we consider Turán problems in multi-partite graphs. Let \( K_{n_1,n_2,\ldots,n_r} \) denote the complete \( r \)-partite graph on parts of size \( n_1, n_2, \ldots, n_r \). This variant of the Turán problem was first considered by Zarankiewicz [9], who was interested in the case when forbidding \( K_{s,t} \) in \( K_{a,b} \).

Formally, given graphs \( H \) and \( F \), we define \( \text{ex}(H,F) \) as the maximum number of edges in an \( F \)-free subgraph of \( H \). Chen, Li and Tu [2] determined \( \text{ex}(K_{n_1,n_2},kK_2) \) and De Silva, Heyse and Young [3] later showed that \( \text{ex}(K_{n_1,\ldots,n_r},kK_2) = (k-1)(n_1 + \cdots + n_r-1) \) for \( n_1 \geq \cdots \geq n_r \). Recently, De Silva, Heyse, Kapilow, Schenfisch and Young [4] determined \( \text{ex}(K_{n_1,\ldots,n_r},kK_r) \) and raised the question of determining \( \text{ex}(K_{n_1,\ldots,n_r},kK_t) \) when \( r > t \).

Problem 1.1. [4] Determine \( \text{ex}(K_{n_1,\ldots,n_r},kK_t) \) when \( r > t \).

Very recently, Bennett, English and Talandra-Fisher [1] gave an exact answer to this problem for \( k = 1 \). For any \( I \subseteq [r] \), write \( n_I := \sum_{i \in I} n_i \).

Theorem 1.2. [1] The extremal number \( \text{ex}(K_{n_1,\ldots,n_r},K_t) \) is equal to

\[
\max_{\mathcal{P}} \sum_{I \neq \emptyset, I \in \mathcal{P}} n_I \cdot n_I',
\]

where the maximum is taken over all partitions \( \mathcal{P} \) of \( [r] \) into \( t-1 \) parts.

Yi Zhao is partially supported by NSF grant DMS 1700622.
The authors of [1] again asked for the solution of Problem 1.1 for $k \geq 2$. In this paper we solve Problem 1.1 for $r = 4$ and $t = 3$ when all $n_i$’s are sufficiently large. For positive integers $n_1 \geq n_2 \geq n_3 \geq n_4$, we define a function

$$g(n_1, n_2, n_3, n_4) := \max\{ (n_1 + n_4)(n_2 + n_3) + (k - 1)n_1, n_1(n_2 + n_3 + n_4) + (k - 1)(n_2 + n_3) \}.$$ 

For arbitrary positive integers $a, b, c, d$, we define $g(a, b, c, d)$ to be the function value corresponding to the non-ascending order of $a, b, c, d$. That is, $g(a, b, c, d) = g(a_1, a_2, a_3, a_4)$, where $a_1 \geq a_2 \geq a_3 \geq a_4$ and \{a_1, a_2, a_3, a_4\} = \{a, b, c, d\} as two multisets.

**Theorem 1.3.** Given $k \geq 1$, there exists $N$ such that if $G$ is a $kK_3$-free $4$-partite graph with parts of sizes $n_1 \geq n_2 \geq n_3 \geq n_4 \geq N$, then $e(G) \leq g(n_1, n_2, n_3, n_4)$. In other words, $ex(K_{n_1, n_2, n_3, n_4}, kK_3) \leq g(n_1, n_2, n_3, n_4)$.

The bound in Theorem 1.3 is tight due to two constructions $G_1$ and $G_2$ below. Note that a subgraph of $G_2$ was given by De Silva et al. [4] as a potential extremal construction; Wagner [8] realized that $G_1$ was a better construction for the $n_1 = n_2 = n_3 = n_4$ case. Let $n_1 \geq n_2 \geq n_3 \geq n_4 \geq k$. We define two $4$-partite graphs with parts $V_1, \ldots, V_4$ such that $|V_i| = n_i$. Fix a set $Z$ of $k - 1$ vertices in $V_4$. Let

$$G_1 := K_{V_1 \cup V_4, V_2 \cup V_3} \cup K_{Z, V_1} \text{ and } G_2 := K_{V_1, V_2 \cup V_3 \cup V_4} \cup K_{Z, V_2 \cup V_3},$$

where $K_{V_1, \ldots, V_r}$ denotes the complete $r$-partite graph with parts $V_1, \ldots, V_r$. Note that both $G_1$ are $G_2$ are $kK_3$-free. Moreover, $e(G_1) = (n_1 + n_4)(n_2 + n_3) + (k - 1)n_1$ and $e(G_2) = n_1(n_2 + n_3 + n_4) + (k - 1)(n_2 + n_3)$. Note that $e(G_2) \geq e(G_1)$ if and only if $n_1 \geq n_2 + n_3$ and equality holds when $n_1 = n_2 + n_3$.

Our proof uses a progressive induction on the total number of vertices and standard induction on $k$, which uses Theorem 1.2 as the base case.

We conjecture an answer to Problem 1.1 in general, which includes all aforementioned results [1–3] and Theorem 1.3.

**Conjecture 1.4.** Given $r > t \geq 3$ and $k \geq 2$, let $n_1, \ldots, n_r$ be sufficiently large. For $I \subseteq [r]$, write $m_I := \min_{i \in I} n_i$. Given a partition $P$ of $[r]$, let $n_P := \max_{I \in P} \{n_I - m_I\}$. The Turán number $ex(K_{n_1, \ldots, n_r}, kK_t)$ is equal to

$$\max_P \left\{ (k - 1)n_P + \sum_{I \neq I' \in P} n_I \cdot n_{I'} \right\}, \quad (1.1)$$

where the maximum is taken over all partitions $P$ of $[r]$ into $t - 1$ parts.

The bound (1.1) is achieved by the following graph. Given integers $k, t$ and $n_1, \ldots, n_r$ with $r > t$ and $n_i \geq k$ for all $i$, let $P$ be a partition of $[r]$ into $t - 1$ parts that maximizes (1.1). Let $G$ be an $r$-partite graph whose parts have sizes $n_1, \ldots, n_r$. Partition $G$ into $t - 1$ parts according to $P$, namely, let $V_I = \bigcup_{i \in I} V_i$ for every $I \in P$ and include all edges between $V_I$ and $V_{I'}$ for all $I \neq I' \in P$. In addition, let $I_0 \in P$ maximizing $n_I - m_I$ and let $V_{I_0}$ be the smallest part in $V_{I_0}$. We choose a set $Z \subseteq V_{I_0}$ of $k - 1$ vertices and add all edges between $Z$ and $V_{I_0} \setminus V_{I_0}$.

At last, it is also natural to consider the minimum degree condition for this type of problems. We include the following result on triangle-free multi-partite graphs, which has an elementary proof. Given an $r$-partite graph $G$ with parts of sizes $n_1, \ldots, n_r$, an optimal bipartition of $G$ is a bipartition $I, I'$ of $[r]$ such that $\min\{n_I, n_{I'}\}$ is maximized among all bipartitions of $[r]$. 
Theorem 1.5. Let $G$ be an $r$-partite graph with an optimal bipartition $I_1, I_2$. If $\delta(G) > \min\{n_{I_1}, n_{I_2}\}$, then $G$ contains a triangle.

Proof. Let $n' := \min\{n_{I_1}, n_{I_2}\}$ and $n'' := \max\{n_{I_1}, n_{I_2}\}$. Towards a contradiction, we assume that $\delta(G) > n'$ and $G$ is triangle-free. Denote the parts of $G$ by $V_1, \ldots, V_r$ and for any $I \in [r]$, write $V_I = \bigcup_{i \in I} V_i$. We consider the following maximum

$$\max_{v \in V(G), I \subseteq [r]: |V_I| \leq n'} d(v, V_I).$$

Suppose $v$ and $I$ achieve such a maximum. Since $|V_I| \leq n'$ and $d(v) > n'$, $v$ has a neighbor not in $V_I$. Denote this vertex by $w$ and assume $w \in V_i$. Observe that we must have $|V_I| + |V_i| > n'$—otherwise we can add $i$ to $I$ and obtain a bigger degree $d(v, V_{I \cup \{i\}})$, contradicting the maximality of $v$ and $I$. Let $J := [r] \setminus (I \cup \{i\})$. We must have $|V_J| \leq n'$—otherwise $I \cup \{i\}$ is a bipartition of $[r]$ with $|V_I| + |V_J| > n'$, contradicting that $I_1, I_2$ is optimal.

Since $w$ cannot be adjacent to any other neighbor of $v$ (because $G$ is triangle-free), we know that $d(w, V_I) \leq |V_I| - d(v, V_I)$. Since $d(w) > n'$, we have

$$d(w, V_J) > n' - d(w, V_I) \geq n' - |V_I| + d(v, V_I).$$

On the other hand, since $|V_I| \leq n'$, the maximality of $v$ and $I$ implies that $d(w, V_J) \leq d(v, V_J)$. Together with the lower bound for $d(w, V_J)$, it implies that $|V_I| > n'$, a contradiction. \hfill $\square$

Notation. Let $G = (V, E)$ be a graph and $A, B \subseteq V$ be disjoint sets. Let $e(A) := e(G[A])$ be the number of edges of $G$ in $A$ and $e(A, B)$ be the number of edges of $G$ with one end in $A$ and the other in $B$. Moreover, let $G \backslash A := G[V \backslash A]$. Denote by $e(A; G) := e(G) - e(G \backslash A)$, the number of edges of $G$ incident to $A$. For vertices $x, y$ and $z$, we often write $xyz$ for $\{x, y, z\}$. We sometimes abuse this notation by using $xy \in A \times B$ to indicate that $x \in A$ and $y \in B$.

2. The progressive induction

To prove Theorem 1.3, we will use the progressive induction, which is an induction without the base case. Here we state the lemma on progressive induction by Simonovits [6].

Lemma 2.1. [6] For $n \in \mathbb{N}$, let $\mathcal{A}_n$ be finite subsets such that $\mathcal{A}_n \cap \mathcal{A}_m = \emptyset$ whenever $n \neq m$. Let $\mathcal{A} = \bigcup_{n=1}^{\infty} \mathcal{A}_n$. Let $B$ be a condition or property defined on $\mathcal{A}$ (namely, the elements of $\mathcal{A}$ may satisfy or not satisfy $B$). Let $\Delta(a) : \mathcal{A} \rightarrow \mathbb{N}$ be a function such that

(a) $\Delta(a) = 0$ whenever $a$ satisfies $B$, and

(b) there is an $M_0$ such that if $n > M_0$ and $a \in \mathcal{A}_n$, then either $a$ satisfies $B$ or there exist $n'$ with $n/2 < n' < n$ and $a' \in \mathcal{A}_{n'}$ such that $\Delta(a) < \Delta(a')$.

Then there exists an $n_0$ such that whenever $n > n_0$, every $a \in \mathcal{A}_n$ satisfies $B$.

Below is a sketch of the proof of Lemma 2.1. Let $s = \max \Delta(a)$ among all $a \in \mathcal{A}_1 \cup \cdots \cup \mathcal{A}_{M_0}$. By (b) and standard induction, we can derive that $\Delta(a) \leq s$ for all $a \in \mathcal{A}$. Let $n_0 = 2^s M_0$ and assume $n > n_0$. If some $a \in \mathcal{A}_n$ does not satisfy $B$, then by (b), there exists $a_1 \in \mathcal{A}_{n_1}$ for some $n_1 > n/2 > 2^{s-1} M_0$ such that $\Delta(a_1) > \Delta(a)$, in particular, $\Delta(a_1) \geq 1$ (thus $a_1$ does not satisfy $B$ because of (a)). Applying (b) repetitively, we find $a_2, \ldots, a_{s+1}$ such that $a_i \in \mathcal{A}_{n_i}$ for some $n_i > 2^{s-i} M_0$ and $\Delta(a_i) \geq i$. In particular, $\Delta(a_{s+1}) \geq s + 1$, a contradiction.

When applying the progressive induction to prove Theorem 1.3, we let $\mathcal{A}_n$ be the collection of all $kK_3$-free 4-partite graphs whose parts have sizes $n_1, \ldots, n_4$ such that $n = n_1 + \cdots + n_4$ and

$$n_4 \geq 4k.$$ (2.1)
Let $A = \bigcup A_n$. Define $B$ as the property that $e(G) \leq g(n_1, n_2, n_3, n_4)$ and $\Delta(G) := \max\{0, e(G) - g(n_1, n_2, n_3, n_4)\}$. Thus (a) holds. Suppose that some $G \in A_n$ does not satisfy $B$. In order to derive (b), we consider a set $T \subseteq V(G)$ of size at most two and let $n_1', n_2', n_3', n_4'$ denote the sizes of the parts of $G \setminus T$. Then $\Delta(G) < \Delta(G \setminus T)$ is equivalent to
\[ e(G) - g(n_1, n_2, n_3, n_4) < e(G \setminus T) - g(n_1', n_2', n_3', n_4'). \]
Then $\Delta(G) < \Delta(G \setminus T)$ is equivalent to $e(T; G) < g(n_1, n_2, n_3, n_4) - g(n_1', n_2', n_3', n_4')$. Thus, when proving Theorem 1.3 by contradiction, we may assume that for all sets $T \subseteq V(G)$ of size at most two,
\[
e(T; G) \geq g(n_1, n_2, n_3, n_4) - g(n_1', n_2', n_3', n_4'). \quad (2.2)
\]

3. Proof of Theorem 1.3

We prove Theorem 1.3 in this section. We will use a progressive induction on $n_1 + \cdots + n_4$ and a standard induction on $k$. We assume that $k \geq 2$, as the case $k = 1$ has been proved in Theorem 1.2. We also assume that $G$ is maximal, that is, if we add any additional edge to $G$, then $kK_3 \subseteq G$. So $G$ contains at least $k - 1$ disjoint triangles.

The main difficulty in the proof is that, when we delete a set $T \subseteq V(G)$, the order of the part sizes of $G \setminus T$ may not follow that of $G$. For instance, suppose $n_1 < n_2 + n_3$ and $T = \{v\} \subseteq V_1$. If $n_1 > n_2$, then the order of the part sizes of $G \setminus T$ is $n_1 - 1 \geq n_2 \geq n_3 \geq n_4$, the same as that of $G$. By (2.2), we may assume that for every $v \in V_1$,
\[ d(v) = e(T; G) \geq g(n_1, n_2, n_3, n_4) - g(n_1 - 1, n_2, n_3, n_4) = n_2 + n_3 + k - 1, \]
which matches the degree of the vertices in $V_1$ in the extremal graph $G_1$. However, when $n_1 = n_2 > n_3 \geq n_4$, the order of the part sizes of $G \setminus T$ is $n_2 \geq n_1 - 1 \geq n_3 \geq n_4$, and we can only derive $d(v) \geq n_1 + n_4$ from (2.2). Another complication comes from the fact that there are two possible extremal graphs. Even under the assumption that $n_1 \leq n_2 + n_3$, we still have to consider the possibility of $n'_1 > n'_2 + n'_3$ in $G \setminus T$, where $n'_1, n'_2, n'_3, n'_4$ are the part sizes of $G \setminus T$.

Even though a case analysis is unavoidable, we study the structure of $G$ and use it to simplify the presentation. An edge of $G$ is called rich if it is contained in at least $k$ triangles whose third vertices are located in the same part of $V(G)$. We show that every triangle of $G$ must contain a rich edge but $G$ contains at most $6k^2$ rich edges. Let $Z$ be the set of vertices incident to at least one rich edge. Thus, not only $G \setminus Z$ is triangle-free (which would be true for any $Z$ that contains a copy of $(k - 1)K_3$), but also every edge in $G \setminus Z$ is not contained in any triangle of $G$ because such a triangle would not contain any rich edge. Then by counting the edges of $G$, we show that we can always apply the progressive induction or the standard induction.

We will use the following simple fact.

**Fact 3.1.** Let $G$ be a 4-partite graph with parts $V_1, \ldots, V_4$ and let $x \in V_1$ and $y \in V_2$. Let $n_i := |V_i|$ for $i \in [4]$. Then $x$ and $y$ have at least $d(x) + d(y) - \sum_{i \in [4]} n_i$ common neighbors in $G$. In particular, if $x$ and $y$ have no common neighbor, then $d(x) + d(y) = \sum_{i \in [4]} n_i$ implies that $xy \in E(G)$, $V_2 \subseteq N(x)$ and $V_1 \subseteq N(y)$.

**Proof.** Note that $d(x, V_3 \cup V_4) = d(x) - d(x, V_2) \geq d(x) - n_2$ and $d(y, V_3 \cup V_4) = d(y) - d(y, V_1) \geq d(y) - n_1$. Let $m$ denote the number of common neighbors of $x$ and $y$. Then $m \geq d(x, V_3 \cup V_4) + d(y, V_3 \cup V_4) - n_3 - n_4 \geq d(x) + d(y) - \sum_{i \in [4]} n_i$. So the first part of the fact follows. In particular, if $m = 0$, then $d(x) + d(y) \leq \sum_{i \in [4]} n_i$. Moreover, if the equality holds, then the inequalities in previous calculations must be equalities. In particular, $d(x, V_2) = n_2$ and $d(y, V_1) = n_1$, which also imply that $xy \in E(G)$. \qed
The proof of Theorem 1.3 consists of two cases.

3.1. **The case** $n_1 > n_2 + n_3$. First note that when $n_1 \geq n_2 + n_3$, our goal is to prove $e(G) \leq n_1(n_2 + n_3 + 4) + (k - 1)(n_2 + n_3)$. Since $n_1 - 1 \geq n_2 + n_3$, we have

$$g(n_1, n_2, n_3, n_4) - g(n_1 - 1, n_2, n_3, n_4) = n_2 + n_3 + 4.$$ 

If there is a vertex $v \in V_1$ such that $d(v) < n_2 + n_3 + 4$, then we can delete this vertex and apply progressive induction. Otherwise, we know that $G[V_1, V_2 \cup V_3 \cup V_1]$ is complete, and thus $G[V_2 \cup V_3 \cup V_4]$ does not contain a matching of size $k$. The result of [3] or a simple induction on $k^1$ yields that $e(G[V_2 \cup V_3 \cup V_4]) \leq (k-1)(n_2 + n_3)$. This shows $e(G) \leq n_1(n_2 + n_3 + 4) + (k-1)(n_2 + n_3)$, as desired.

3.2. **The case** $n_1 \leq n_2 + n_3$. Towards a contradiction, assume that

$$e(G) > g(n_1, n_2, n_3, n_4) = (n_1 + n_4)(n_2 + n_3) + (k-1)n_1.$$ 

(3.1)

Given a set $T \subseteq V(G)$ of at most two vertices, let $n'_1, n'_2, n'_3$ and $n'_4$ denote the sizes of the parts of $G \setminus T$. By (2.2), we assume that

$$e(T; G) \geq (n_1 + n_4)(n_2 + n_3) + (k-1)n_1 - g(n'_1, n'_2, n'_3, n'_4).$$ 

(3.2)

Now that $e(\{v\}; G) = d(v)$ if $T = \{v\}$ and $e(\{x, y\}; G) = d(x) + d(y) - 1$ if $T = \{x, y\} \in E(G)$.

Below we collect some useful assumptions we can make by the progressive induction.

(A) for any $v \in V_1$, 

(A1) $d(v) \geq n_2 + n_3 + k - 1$, if $n_1 > n_2$,

(A2) $d(v) \geq n_1 + n_4$, if $n_1 = n_2$;

(B) for any $v \in V_i, i = 2, 3$,

(B1) $d(v) \geq n_1 + n_4$, if $n_i > n_4$ and $n_1 < n_2 + n_3$,

(B2) $d(v) \geq n_2 + n_3$, otherwise;

(C) for any $v \in V_4$, $d(v) \geq n_2 + n_3$.

(D) Assume that $n_1 > n_3$ and $n_2 > n_4$. Then for two vertices $x, y \in V_1$, $y \in V_2$, the part sizes of $G \setminus \{x, y\}$ are $n_1 - 1 \geq n_2 - 1, n_3 \geq n_4$, and we have

$$e(xy; G) \geq (n_1 + n_4)(n_2 + n_3) + (k-1)n_1 - ((n_1 + n_4 - 1)(n_2 + n_3 - 1) + (k-1)(n_1 - 1))$$

$$\geq \sum_{i=4} n_i + k - 2.$$

In addition, if $xy \in E(G)$, then we have $d(x) + d(y) \geq \sum_{i=4} n_i + k - 1 > \sum_{i=4} n_i$.

(E) Assume that $n_1 < n_2 + n_3$. Then for two vertices $x \in V_2, y \in V_4$, the part sizes of $G \setminus \{x, y\}$ are $n_1 \geq \{n_2 - 1, n_3 \geq n_4 - 1$, and we have

$$e(xy; G) \geq (n_1 + n_4)(n_2 + n_3) + (k-1)n_1 - ((n_1 + n_4 - 1)(n_2 + n_3 - 1) + (k-1)n_1)$$

$$\geq \sum_{i=4} n_i - 1.$$

In addition, if $xy \in E(G)$, then we have $d(x) + d(y) \geq \sum_{i=4} n_i$.

To illustrate the cases for $G \setminus \{v\}$, let us list all the possibilities for the $g$ function of $G \setminus \{v\}$. Recall that we have $n_1 \leq n_2 + n_3$ in this case.

(1) If $n_1 > n_2$, then $g(n_1 - 1, n_2, n_3, n_4) = (n_1 - 1 + n_4)(n_2 + n_3) + (k - 1)(n_1 - 1)$; 

\(^1If there is a vertex of degree at least $2k - 1$, then we can delete it and apply induction; otherwise, as the size of the maximum matching is $k - 1$, there are at most $2(k - 1)(2k - 1) \leq (k - 1)(n_2 + n_3)$ edges (using $k \ll n_3 \leq n_2$).
(2) if \( n_1 = n_2 > n_4 \), then \( g(n_1 - 1, n_2, n_3, n_4) = (n_1 + n_4)(n_2 + n_3 - 1) + (k - 1)n_1 \);

(3) if \( n_1 = n_4 \), then \( g(n_1 - 1, n_2, n_3, n_4) = (n_1 + n_4 - 1)(n_2 + n_3) + (k - 1)n_1 \);

(4) \( g(n_1, n_2, n_3, n_4 - 1) = (n_1 + n_4 - 1)(n_2 + n_3) + (k - 1)n_1 \).

Next, for \( i = 2, 3, 4 \),

(5) if \( n_1 < n_2 + n_3 \) and \( n_i > n_4 \), then \( g(n_1, n_i - 1, n_5 - i, n_4) = (n_1 + n_4)(n_2 + n_3 - 1) + (k - 1)n_1 \);

(6) if \( n_i = n_4 \), then \( g(n_1, n_i - 1, n_5 - i, n_4) = (n_1 + n_4 - 1)(n_2 + n_3) + (k - 1)n_1 \);

(7) if \( n_1 = n_2 + n_3 \) and \( n_i > n_4 \), then \( g(n_1, n_i - 1, n_5 - i, n_4) = n_1(n_2 + n_3 + n_4 - 1) + (k - 1)(n_2 + n_3 - 1) \).

By (3.2) and straightforward calculations we see that (1) implies (A1), (2) and (3) imply (A2) and (4) implies (C). Similarly, (5) implies (B1) and (6) and (7) imply (B2).

Recall that an edge \( xy \in E(G) \) is rich if \( x \) and \( y \) have at least \( k \) common neighbors in some vertex class. If \( d(x) + d(y) \geq \sum_{i \in [4]} n_i + 2k - 1 \), then by Fact 3.1, \( x \) and \( y \) have at least \( 2k - 1 \) common neighbors and thus at least \( k \) common neighbors in one part. Therefore \( xy \) is rich.

Let \( R \subseteq G \) be the 4-partite graph whose edges are the rich edges of \( G \), and let \( Z = \bigcup_{e \in R} e \). We have the following claim.

**Claim 3.2.** The following assertions hold:

(i) every vertex is contained in at most \( k - 1 \) edges of \( R \) whose other ends are located in the same vertex class; in particular, the maximum degree of \( R \) is at most \( 3k - 3 \);

(ii) \( e(R) \leq 2(k - 1)(3k - 3) = 6(k - 1)^2 \) and \( |Z| \leq 6(k - 1)^2 + 2(k - 1) \leq 6k^2 \);

(iii) every triangle in \( G \) contains an edge in \( R \).

**Proof.** To see (ii), first note that if \( R \) has a matching of size \( k \), then we can greedily build \( k \) vertex-disjoint triangles by extending each rich edge in the matching. Therefore, the largest matching in \( R \) is of size at most \( k - 1 \) and consequently, \( R \) has a vertex cover of size at most \( 2(k - 1) \). Together with (i), we derive (ii).

For (i), we claim that if there is a vertex \( v \) incident to \( k \) rich edges to another class, then we can delete this vertex and proceed induction. Indeed, given any copy \( S \) of \( (k - 1)K_3 \) in \( G \backslash \{v\} \), by the assumption, we can pick a rich edge in \( G \backslash S \) that contains \( v \) and then extend this rich edge to a triangle that does not intersect \( S \). This gives a \( kK_3 \) in \( G \), a contradiction. Thus, we infer that \( G \backslash \{v\} \) is \( (k - 1)K_3 \)-free. So we can bound \( e(G \backslash \{v\}) \) by the inductive hypothesis. By comparing (1) and (7) above, we obtain

\[
e(G \backslash \{v\}) \leq \max\{(n_1 + n_4 - 1)(n_2 + n_3) + (k - 2)n_1, (n_1 + n_4)(n_2 + n_3 - 1) + (k - 2)n_1\}.
\]

Moreover, for the maximum above, if \( v \in V_4 \), then the first term must achieve the maximum, and \( d_G(v) \leq n_1 + n_2 + n_3 \); otherwise, we have \( d_G(v) \leq n_1 + n_2 + n_4 \). It is easy to check that \( e(G) = e(G \backslash \{v\}) + d_G(v) \leq (n_1 + n_4)(n_2 + n_3) + (k - 1)n_1 \) holds for all cases, contradicting (3.1).

For (iii), let \( T \) be a triangle in \( G \) and consider \( G \backslash T \). By induction, we may have four possibilities

- \( e(G \backslash T) \leq (n_1 + n_4 - 1)(n_2 + n_3 - 2) + (k - 2)n_1 \),
- \( e(G \backslash T) \leq (n_1 + n_4 - 2)(n_2 + n_3 - 1) + (k - 2)(n_1 - 1) \),
- \( e(G \backslash T) \leq (n_1 - 1)(n_2 + n_3 + n_4 - 2) + (k - 2)(n_2 + n_3 - 2) \), or
- \( e(G \backslash T) \leq n_1(n_2 + n_3 + n_4 - 3) + (k - 2)(n_2 + n_3 - 2) \).

In the first two cases, (3.1) implies

\[
e(T; G) > \sum_{i \in [4]} n_i + \min\{n_1 + n_4, n_2 + n_3\} + n_1 - 2 \geq \frac{3}{2} \sum_{i \in [4]} n_i + n_4 - 2. \tag{3.3}
\]
For the third case, we must have $n_1 = n_2 + n_3$. Note that we can rewrite \((n_1 - 1)(n_2 + n_3 + n_4 - 2) + (k - 2)(n_2 + n_3 - 2) = (n_2 + n_3 - 1)(n_1 + n_4 - 2) + (k - 2)(n_1 - 2)\). So we get the upper bound as in the second case, and thus (3.3) holds. For the last case, we must have $n_2 + n_3 - 1 \leq n_1 \leq n_2 + n_3$. If $n_1 = n_2 + n_3 - 1$, then similarly we can rewrite \(n_1(n_2 + n_3 + n_4 - 3) + (k - 2)(n_2 + n_3 - 2) = (n_2 + n_3 - 1)(n_1 + n_4 - 2) + (k - 2)(n_1 - 1)\) and get the upper bound as in the second case, and thus (3.3) holds. Otherwise $n_1 = n_2 + n_3 \geq 2n_4$, and we infer \((5/2)n_1 \geq n_1 + n_2 + n_3 + n_4 = \sum_{i \in \{4\}} n_i\). Thus, \((15/4)n_1 \geq (3/2) \sum_{i \in \{4\}} n_i\). By (3.1), we get

\[
e(T; G) > (n_1 + n_4)(n_2 + n_3) + (k - 1)n_1 - n_1(n_2 + n_3 + n_4 - 3) - (k - 2)(n_2 + n_3 - 2)
\]

\[\geq 4n_1 + k - 2 = \frac{15}{4} n_1 + \frac{n_4}{2} + k - 2 \geq \frac{3}{2} \sum_{i \in \{4\}} n_i + \frac{n_4}{2} + k - 2.
\]

By (2.1), \(e(T; G) \geq (3/2) \sum_{i \in \{4\}} n_i + n_4/2 + k - 2\) holds for all cases.

Let $T = xyz$ and note that $d(x) + d(y) + d(z) = e(T; G) + 3$. By averaging, without loss of generality, we may assume that

\[
d(x) + d(y) \geq \frac{2}{3} \left( \frac{3}{2} \sum_{i \in \{4\}} n_i + \frac{n_4}{2} + k + 1 \right) \geq \sum_{i \in \{4\}} n_i + 2k - 1,
\]

as (2.1). Thus, $xy$ is rich and we are done. \(\square\)

For two disjoint sets $A, B \subseteq V(G)$, write $d(A, B) = e(A, B)/(|A||B|)$, as the density of the bipartite graph with parts $A$ and $B$. A pair of classes $(V_i, V_j)$ is called full if $d(V_i \setminus Z, V_j) = d(V_j \setminus Z, V_i) = 1$; $(V_i, V_j)$ is called empty if $e(V_i \setminus Z, V_j) = e(V_i, V_j \setminus Z) = 0$. We have the following observation:

**Observation 3.3.** For distinct $i, j, t \in \{4\}$, if $d(V_i \setminus Z, V_j) = d(V_j \setminus Z, V_i) = 1$, then $(V_j, V_t)$ must be empty because any edge in $(V_j, V_t)$ but not in $(V_j \cap Z, V_t \cap Z)$ will create a triangle with at most one vertex in $Z$, contradicting (iii). In particular, if both $(V_i, V_j)$ and $(V_i, V_t)$ are full, then $(V_j, V_t)$ is empty.

**Claim 3.4.** Fix $i \neq j \in \{4\}$. If $d(x) + d(y) \geq \sum_{i \in \{4\}} n_i$ for every edge $xy \in V_i \times V_j$, then either

- $e(V_i \setminus Z, V_j \setminus Z) = 0$ or
- $d(V_i \setminus Z, V_j) = d(V_j \setminus Z, V_i) = 1$, and $d(x) + d(y) = \sum_{i \in \{4\}} n_i$.

Moreover, if $d(x) + d(y) > \sum_{i \in \{4\}} n_i$ for every edge $xy \in V_i \times V_j$, then $(V_i, V_j)$ is empty.

**Proof.** Assume that \{i, j, t, l\} = \{4\}. Suppose there is an edge $xy \in G[V_i \setminus Z, V_j \setminus Z]$. Note that if $x$ and $y$ have a common neighbor $z$, then as $x, y \notin Z$, none of the edges of $xyz$ can be in $R$, contradicting (iii). Thus, $x$ and $y$ have no common neighbor. By Fact 3.1, $d(x) + d(y) \leq \sum_{i \in \{4\}} n_i$. If $d(x) + d(y) \geq \sum_{i \in \{4\}} n_i$, by Fact 3.1, $d(V_j, V_i) = n_j$ and $d(y, V_i) = n_i$. Repeated applications of this observation on these edges imply that for any $xy \in V_i \times V_j$ such that at least one of them is not in $Z$, $xy \in E(G)$, that is, $d(V_j, V_i) = d(V_i \setminus Z, V_j \setminus Z) = 1$.

Moreover, if $d(x) + d(y) > \sum_{i \in \{4\}} n_i$ for every edge $xy \in V_i \times V_j$, we obtain a contradiction with the inequalities above and thus $e(V_i \setminus Z, V_j \setminus Z) = 0$. Now suppose there is an edge $xy \in (V_i \cap Z) \times (V_j \setminus Z)$. As $d(x) + d(y) > \sum_{i \in \{4\}} n_i$, $x$ and $y$ have some common neighbors in $V_i \cup V_j$. But since $y \notin Z$, by (iii), their common neighbors must be in $(V_i \cup V_j) \cap Z$. By $e(V_i \setminus Z, V_j \setminus Z) = 0$, we know that $N(y) \cap V_i \subseteq V_i \cap Z$. All together, we obtain that $d(x) + d(y) \leq n_j + n_t + n_l + |Z| \leq \sum_{i \in \{4\}} n_i$, a contradiction. By symmetry, we obtain $e(V_i \setminus Z, V_j) = e(V_i, V_j \setminus Z) = 0$, namely, $(V_i, V_j)$ is empty. \(\square\)
After these preparations, we return to the proof by dividing into cases depending on the inequalities in \( n_1 \geq n_2 \geq n_3 \geq n_4 \).

**Case 1.** \( n_1 > n_3 \) and \( n_2 > n_4 \). In this case, by (D), we have \( d(x) + d(y) > \sum n_i \) for every edge \( xy \in V_1 \times V_2 \). By Claim 3.4, \((V_1, V_2)\) is empty. Thus, for any \( x \in V_1 \setminus Z \), we have \( d(x) \leq n_3 + n_4 < \min\{n_2 + n_3, n_1 + n_4\} \), contradicting (A1) or (A2).

**Case 2.** \( n_1 = n_2 = n_3 \geq n_4 \).

Write \( n_1 = n_2 = n_3 = n \) and note that \( n_1 < n_2 + n_3 \). In this case, by (E) and the similarity of \( V_1, V_2, \) and \( V_3 \), we have \( d(x) + d(y) \geq \sum n_i \) for every edge \( xy \in (V_1 \cup V_2 \cup V_3) \times V_4 \). Moreover, for any \( x \in V_4 \), by (C) we have \( d(x) \geq 2n \). So at least two of \((V_1, V_4), (V_2, V_4), \) and \((V_3, V_4)\) must be full. Without loss of generality, assume \((V_1, V_4)\) and \((V_2, V_4)\) are full. By Observation 3.3, \((V_1, V_2)\) is empty. Next, we claim that \((V_3, V_4)\) is empty. Indeed, let \( x \in V_2 \setminus Z \) and by (B), we have \( d(x) \geq \min\{2n, n + n_4\} = n + n_4 \). Since \((V_1, V_2)\) is empty, we have that \( d(x, V_1) = 0 \) and thus \( d(x) \leq n + n_4 \). Thus, \( d(x) = n + n_4 \) and in particular \( d(x, V_2) = n \). Since this holds for every \( x \in V_2 \setminus Z \), we obtain \( d(V_2 \setminus Z, V_3) = 1 \). Thus \((V_3, V_4)\) is empty by Observation 3.3. Together with (ii), we infer

\[
e(G) = e(Z) + e(V \setminus Z; G) < |Z|^2 + (n_1 + n_2)(n_3 + n_4) < (n_1 + n_2)(n_3 + n_4) + (k - 1)n_1,
\]

contradicting (3.1).

**Case 3.** \( n_1 > n_2 = n_3 = n_4 \).

Let \( n_2 = n_3 = n_4 = n \) and thus \( n_1 \leq 2n \). First assume that there is a vertex \( y \in V_2 \cup V_3 \cup V_4 \) such that \( d(y) \geq n_1 + n + k \). It follows that \( d(y, V_1) \geq d(y) - 2n \geq k \). So let us take \( x_1, \ldots, x_k \in N(y) \cap V_1 \). By (A1), we have \( d(x_j) \geq 2n + k - 1 \). Thus, we infer that \( d(x_j) + d(y) \geq n_1 + 3n + 2k - 1 \), and thus \( x_jy \in E(R) \) for each \( j \in [k] \). However, this contradicts (i). So for every \( y \in V_2 \cup V_3 \cup V_4 \) we have \( d(y) \leq n + n + k - 1 \). On the other hand, we know that \( d(x) \leq 3n \) for any \( x \in V_1 \).

Let \( e \in E(R) \) be a rich edge. By definition, given any set \( S \subseteq V(G) \) that spans a copy of \((k - 1)K_3\), \( e \) must intersect \( S \), as otherwise we can find a triangle which contains \( e \) and does not intersect \( S \), a contradiction. This implies that \( G \setminus e \) is \((k - 1)K_3\)-free and below we seek to apply induction on \( G \setminus e \).

We next assume that there is a rich edge \( xy \in V_1 \times (V_2 \cup V_3 \cup V_4) \). Note that

\[
g(n_1, n, n, n) - g(n_1 - 1, n, n, n - 1)
= (n_1 + n)2n + (k - 1)n_1 - ((n_1 + n - 2)2n + (k - 2)(n_1 - 1))
= n_1 + 4n + k - 2.
\]

By the maximum degree condition, we have \( e(xy; G) = d(x) + d(y) - 1 \leq n_1 + 4n + k - 2 \). So we can apply induction. Thus, we may assume that there is no rich edge from \( V_1 \times (V_2 \cup V_3 \cup V_4) \).

Now we show that there is no triangle intersecting \( V_1 \). Suppose to the contrary, there is one such triangle \( xyz \) and without loss of generality, assume that \( xyz \in V_1 \times V_2 \times V_3 \). Note that

\[
g(n_1, n, n, n) - g(n_1 - 1, n, n - 1, n - 1)
= (n_1 + n)2n + (k - 1)n_1 - ((n_1 + n - 2)(2n - 1) + (k - 2)(n_1 - 1))
= 2n_1 + 5n + k - 4.
\]

Thus, if \( e(xyz; G) \leq 2n_1 + 5n + k - 4 \), then we can apply induction. So we may assume that \( d(x) + d(y) + d(z) = e(xyz; G) + 3 \geq 2n_1 + 5n + k \). Since \( d(y) \leq n_1 + n + k - 1 \), we obtain that \( d(x) + d(z) \geq n_1 + 4n + 1 \). This implies that \( x \) and \( z \) have at least \( n + 1 \geq 2k - 1 \) common neighbors, namely, \( xz \in E(R) \). This contradicts the conclusion of the previous paragraph.
As we have assumed that $G$ is maximal and $k \geq 2$, $G$ contains a triangle. By the conclusion of the previous paragraph, the triangle must be in $V_2 \cup V_3 \cup V_4$. Moreover, by (iii), such a triangle must contain an edge $xy \in E(R)$. Without loss of generality, suppose $xy \in V_2 \times V_3$. We first assume that $n_1 = 2n$. Note that
\[
g(2n, n, n, n) - g(2n, n, n - 1, n - 1) = 2n \cdot 3n + 2n(k - 1) - (2n(3n - 2) + (k - 2)(2n - 1))
= 6n + k - 2.
\]
Thus, if $e(xy; G) \leq 6n + k - 2$, then we can apply induction. So we may assume that $d(x) + d(y) = e(xy; G) + 1 \geq 6n + k$. However, this implies that $|N(x) \cap N(y) \cap V_1| \geq k > 0$, contradicting that there is no triangle intersecting $V_1$. At last, assume $n_1 < 2n$. Note that
\[
g(n_1, n, n, n) - g(n_1, n, n - 1, n - 1)
= (n_1 + n)2n + (k - 1)n_1 - ((n_1 + n - 1)(2n - 1) + (k - 2)(n_1 - 1))
= 2n_1 + 3n + k - 3.
\]
By the maximal degree condition, we have $e(xy; G) < d(x) + d(y) \leq 2(n_1 + n + k - 1) < 2n_1 + 3n + k - 3$. So we are done by induction.

The proof is completed.

4. Concluding remarks

In this paper we solved Problem 1.1 for $r = 4$ and $t = 3$ when all $n_i$’s are large. The idea in our proof should be helpful for proving Conjecture 1.4. However, to determine the maximum in (1.1), there are quite a few cases to consider even when $r = 5$ and $t = 3$. Indeed, suppose $n_1 \geq n_2 \geq \cdots \geq n_5$ and $(I, I')$ is the bipartition of $[5]$ that attained the maximum in (1.1). Assume $1 \in I$. Depending on the values of $n_1, \ldots, n_5$, it is possible to have

$I = \{1\}$ or $\{1, 2\}$ or $\{1, 3\}$ or $\{1, 4\}$ or $\{1, 5\}$ or $\{1, 4, 5\}$.

Another open problem is to find the smallest $N$ such that Theorem 1.3 holds. By examining the proof of Theorem 1.3 and revising Lemma 2.1 (because (b) actually holds for $n - 2 \leq n' < n$ in our proof), our proof gives $N = \Omega(k^3)$. It is interesting to know whether one can reduce $n_0$ to a linear function of $k$.

At last, it is also natural to consider the extension of Theorem 1.5 to other cliques $K_t$, $t \geq 4$.

Conjecture 4.1. Let $G$ be an $r$-partite graph whose parts have sizes $n_1, \ldots, n_r$. If
\[
\delta(G) > \max_{P} \min_{I \in \mathcal{P}} n_{[r] \setminus I},
\]
where the maximum is over all partitions $P$ of $[r]$ into $t - 1$ parts, then $G$ contains a copy of $K_t$.
