ON THE QUOT SCHEME Quot_{O_{P^1}/k}^d

CRISTINA BERTONE, STEVEN L. KLEIMAN, AND MARGHERITA ROGGERO

Abstract. We consider the quot scheme Quot_{F^r/P^1/k}^d of locally free quotients of F^r := \bigoplus^r O_{P^1} with Hilbert polynomial p(t) = d. We prove that it is a smooth variety of dimension dr, locally isomorphic to A^{dr}. We introduce a new notion of support for modules in Quot_{F^r/P^1/k}^d, called Hilb-support that allows us to define a natural surjective morphism of schemes \( \xi : Quot_{F^r/P^1/k}^d \to \text{Hilb}^d_{O_{P^1}} \) associating to each module its Hilb-support and study the fibres of \( \xi \) over each k-point \( Z \) of \( \text{Hilb}^d_{O_{P^1}} \). If \( Z = Y_1 + \cdots + Y_n \), with \( Y_j = t_i R_j \), where \( R_1, \ldots, R_n \) are distinct points, the fibre of \( \xi \) over \( Z \) is isomorphic to \( Quot_{F^r \otimes O_{Y_j}/k}^1 \times \cdots \times Quot_{F^r \otimes O_{Y_n}/k}^1 \). We then study the Quot scheme \( Quot_{F^r \otimes O_{Y}/k}^t \) with \( Y = t R \). For \( t = 1 \), \( Quot_{F^r \otimes O_{Y}/k}^1 \) is isomorphic to \( P^{r-1} \), while for \( t \geq 2 \) we prove that it is formed by a main irreducible, reduced and singular component of dimension \( t(r - 1) \) and by some embedded component of lower dimension.

1. Introduction

Let \( k \) be an algebraically closed field of any characteristic. We fix the integers \( r \geq 2 \) and \( d \geq 1 \) and set \( S := k[x, y], P^1 := \text{Proj}(S), F^r := \bigoplus^r S \) and \( F := \bigoplus^r O_{P^1} \).

In the present paper we investigate the Quot scheme parameterizing locally free quotient modules of \( F^r \) having Hilbert polynomial \( d \). We refer to Grothendieck [4] for the definition and construction of the Quot scheme \( Quot_{F^r/P^1/k}^d \). Grothendieck's construction of the Quot scheme yields \( Quot_{F^r/P^1/k}^d \) as a closed subscheme of the Grassmannian \( G_k(d, (d + 1)r) \). For a more detailed treatment, see [6].

In the following, for sake of simplicity, we will identify points of \( Quot_{F^r/P^1/k}^d \) with the corresponding quotient modules and points of \( \text{Hilb}^d_{O_{P^1}} \) with the corresponding subschemes of \( P^1 \).

The only completely already known case is the one with \( d = 1 \): in [5, Proposition 2.2] S. L. Kleiman proved that \( Quot_{F^r/P^1/k}^1 \) is isomorphic to \( P(F^r) \).

We prove that \( Quot_{F^r/P^1/k}^d \) is smooth, rational of dimension \( dr \) (Corollary 4.4) and it is covered by Zariski open affine subsets (Proposition 3.4). For each of them, we describe an explicit isomorphism to \( A^{dr} \) (Corollary 4.3).

Although the above quoted results describe \( Quot_{F^r/P^1/k}^d \) as a uniform object, the geometry of \( Quot_{F^r/P^1/k}^d \) becomes more entangled as soon as one takes into account the algebraic structure of the modules corresponding to its points.

A first aspect that makes some points of \( Quot_{F^r/P^1/k}^d \) substantially different from others is a significant diversity between their schematic supports: for instance, a module whose schematic support is made of simple points is certainly not isomorphic to one whose schematic support is a multiple structure over a point. In order to deepen this observation and exploit it to study \( Quot_{F^r/P^1/k}^d \), we define a natural surjective map \( \xi : Quot_{F^r/P^1/k}^d \to \text{Hilb}^d_{O_{P^1}} \). The starting idea was indeed to associate to a module its schematic support. However, it is easy to find modules in \( Quot_{F^r/P^1/k}^d \) whose schematic support has length \( < d \). This is why we introduce the notion of Hilb-support for the points of \( Quot_{F^r/P^1/k}^d \) (Definition 5.4), and use this notion to define the map \( \xi \) (Definition 5.6).

We then investigate the fibers of \( \xi \), by studying Quot schemes \( Quot_{F^r/Y/k}^t := Quot_{F^r \otimes O_Y/Y/k}^t \) over a 0-dimensional scheme \( Y \) in \( P^1 \), with a special attention to the case \( Y = t R, R \in P^1 \), the

2010 Mathematics Subject Classification. 14C05, 14A15.

Key words and phrases. Quot scheme, Hilbert scheme, support.
one with the main interest for the description of the fibers of \( \xi \). For \( t = 1 \) the fiber is isomorphic to \( \mathbb{P}^{r-1} \), while for \( t \geq 2 \), we prove that \( \text{Quot}^t_{\mathcal{F}_Y/Y/k} \) is a scheme formed by a main component of dimension \( t(r-1) \), which is irreducible and reduced but singular, and by embedded components of lower dimension (Theorem 6.4).

Exploiting the above result we obtain the main result of the paper:

**Theorem 1.1.** Let \( Y = Y_1 + \cdots + Y_n \in \text{Hilb}_{\mathbb{P}^1}^d \) with \( Y_j = t_j R_j \) and \( R_1, \ldots, R_n \) distinct points. The fiber of \( \xi \) over \( Y \) is isomorphic to the product \( \text{Quot}^1_{\mathcal{F}_{Y_1}/Y_1/k} \times \cdots \times \text{Quot}^n_{\mathcal{F}_{Y_n}/Y_n/k} \).

If \( n = d \), then the fiber of \( \xi \) over \( Y \) is isomorphic to the product of \( d \) copies of \( \mathbb{P}^{r-1} \). If \( n \neq d \), then the fiber of \( \xi \) over \( Y \) is irreducible and generically smooth, but has embedded components and its support has singular points.

Several statements of the present paper have a local nature, hence in the proofs we can restrict ourselves to an open subset. We choose a open cover made of subsets of \( \text{Quot}^d_{\mathcal{F}_Y/\mathbb{P}^1/k} \) given by the non-vanishing of suitable Plücker coordinates. On each of these open subsets, a module \( M \) of \( \text{Quot}^d_{\mathcal{F}_Y/\mathbb{P}^1/k} \) is characterized by a \( d \times d \) matrix \( P(M) \) that encodes its structure of \( k[x, y] \)-module (Proposition 4.1). This matrix \( P(M) \) is central in all the present paper. For instance, the definition of Hilb-support of a module in \( \text{Quot}^d_{\mathcal{F}_Y/\mathbb{P}^1/k} \), and hence the definition of \( \xi \), rely on the characteristic polynomial of this matrix \( P(M) \). Furthermore, up to a linear change of coordinates in \( \mathbb{P}^1 \), \( \text{Quot}^d_{\mathcal{F}_Y/Y/k} \) with \( Y = tR \) can be locally described by the condition \( P(M)^t = 0 \); we prove Theorem 6.4 by the consequent local description of \( \text{Quot}^d_{\mathcal{F}_Y/Y/k} \) as a scheme of nilpotent matrices, hence a subscheme of the so-called null-cone (see for some details Lemma 6.1 and Example 6.5).

The arguments we just outlined are developed below not only for \( k \)-points, but for families, as is required for working with the functor of points of the Quot scheme.

The starting point for the results of the present paper are the computational results exposed in [1]: although here we do not directly use those methods, the choice of a suitable open cover and the explicit computation of local and global equations for the Quot scheme with \( t = d = 2 \) gave us inspiration and conjectures for the more general case that we prove in the present paper.

2. NOTATION AND GENERAL SETTING

Let \( k \) be an algebraically closed field of any characteristic. In the following \( A \) will always denote a \( k \)-algebra.

We fix the integers \( r \geq 2 \) and \( d > 0 \) and set \( S_A := A[x, y], \mathbb{P}^1 := \text{Proj}(S_A), F_A^r := \bigoplus^r S_A \) and \( \mathcal{F}_A^r := \bigoplus^r \mathcal{O}_{\mathbb{P}^1} \). If \( A = k \), we will simply write \( S, \mathbb{P}^1, F^r, \mathcal{F}^r \).

We will denote by \( \mathcal{G} \) the Grassmannian \( \mathbb{G}_{d,(d+1)r} \) and by \( \mathcal{G} \) its functor of points.

We refer to Grothendieck [4] for the definition of the Quot scheme \( \text{Quot}^d_{\mathcal{F}_Y/\mathbb{P}^1/k} \) and the Quot functor \( \text{Quot}^d_{\mathcal{F}_Y/\mathbb{P}^1/k} \). The Gotzmann number of the Hilbert polynomial \( p(t) = d \) is \( d \) [2], hence every saturated quotient module \( \mathcal{F}_A^r/V \in \text{Quot}^d_{\mathcal{F}_Y/\mathbb{P}^1/k}(A) \) is uniquely determined by its homogeneous component of degree \( d \), namely by \( (\mathcal{F}_A^r/V)_d = (\bigoplus^r S_{A,d})/V_d \).

In this way we obtain the standard embedding of \( \text{Quot}^d_{\mathcal{F}_Y/\mathbb{P}^1/k} \) in \( \mathcal{G} \) and then in \( \mathbb{P}^{N(r)} \) where \( N(r) = \binom{(d+1)r}{r} - 1 \) [1, Section 7]. Taking in consideration this embedding, in the following we often identify every quotient module \( \mathcal{F}_A^r/V \) in \( \text{Quot}^d_{\mathcal{F}_Y/\mathbb{P}^1/k}(A) \) with its degree \( d \) homogeneous component, namely by the rank \( d \) locally free \( A \)-module \( M := \mathcal{F}_{A,d}/V_d \).

We recall that the support of a \( B \)-module \( D \) is the subscheme of \( \text{Spec}(B) \) defined by the ideal \( \text{Ann}(D) := \{ b \in B \text{ such that } bD = 0 \} \). If \( A \) is a \( k \)-algebra and \( \mathcal{F}_A^r/V \in \text{Quot}^d_{\mathcal{F}_Y/\mathbb{P}^1/k}(A) \), then \( \text{Ann}_{S_A}(\mathcal{F}_A^r/V) \cap A = (0) \) and \( \text{Ann}_{S_A}(\mathcal{F}_A^r/V) \ni (x, y) \), because \( (\mathcal{F}_A^r/V)_m \) is a locally free module of rank \( d \) for every \( m \geq d \). Therefore, the support of \( M = (\mathcal{F}_A^r/V)_d \) is a closed subscheme of \( \mathbb{P}^1 \) of length at most \( d \).

Let \( e_1, \ldots, e_r \) be the standard basis of \( F_A^r \) as an \( S_A \)-module. We choose the following ordered list

\[ \mathcal{B} := [x^d e_1, x^{d-1} ye_1, \ldots, y^d e_1, \ldots, x^d e_r, x^{d-1} ye_r, \ldots, y^d e_r] \]
as a basis for $\bigoplus S_{A,d}$ as an $A$-module; $B_j$ will denote the $j$-th element of this list.

Every free (not simply locally free) quotient module $M \in G(A)$ can be represented by a $d \times (d + 1)r$ matrix $C(M)$, where the rows correspond to the choice of a $A$-basis $u_1, \ldots, u_d$ for $M$. Let us denote by $C_i = (c_{1i}, \ldots, c_{di})^T$, $i = 1, \ldots, (d + 1)r$, the columns of this matrix; then

$$C(M) = [C_1 \ C_2 \ldots \ C_{d+1} | \ldots | C_{(d+1)r-d} \ C_{(d+1)r-d+1} \ldots \ C_{(d+1)r}].$$

Considering the Plücker embedding of $G$ in $\mathbb{P}^{N(r)} = \text{Proj}(\mathbb{Z}[\Delta_{j_1,\ldots,j_d}]_{1 \leq j_1 < \cdots < j_d \leq (d+1)r})$, the minors of $C(M)$ are the Plücker coordinates of $M$: for every $1 \leq j_1 < \cdots < j_d \leq (d + 1)r$, we set $\Delta_{j_1,\ldots,j_d}(M) = \det(C_{j_1} \ldots C_{j_d})$.

We will call the $\nu$-th block of $B$ (resp. of $C(M)$) the subset (resp. submatrix) with indices from $(d + 1)v - d$ to $(d + 1)v$, namely those corresponding to $e_v$. When we want to emphasize the division in blocks of the matrix $C(M)$ we will write it as

$$C(M) = [B_{1,1} \ B_{1,2} \ldots \ B_{1,d+1} | \ldots | B_{r,1} \ B_{r,2} \ldots \ B_{r,d+1}],$$

so that $B_{\ell,j}$ is the $j$-th column of the $\ell$-th block.

If $A$ is not a local ring, then not every module $M \in G(A)$ can be represented by such a matrix; indeed, $M$ must be free (in general, $M$ is only locally free). For this reason, it is useful to work on open sets that cover $G$ and on which every $M$ is free.

3. A suitable open cover of $G$ and of $\text{Quot}^d_{\mathcal{F},/\mathbb{P}^1/k}$

For every $i,j$ with $1 \leq j_1 < \cdots < j_d \leq (d + 1)r$, we will denote by $G_{j_1,\ldots,j_d}$ the open subscheme of $G$ where the Plücker coordinates $\Delta_{j_1,\ldots,j_d}$ are invertible and by $G_{j_1,\ldots,j_d}$ the corresponding open subfunctor of $G$.

Similarly, we will denote by $Q_{j_1,\ldots,j_d}$ the open subscheme $G_{j_1,\ldots,j_d} \cap \text{Quot}^d_{\mathcal{F},/\mathbb{P}^1/k}$ of $\text{Quot}^d_{\mathcal{F},/\mathbb{P}^1/k}$ and by $Q_{j_1,\ldots,j_d}$ the corresponding open subfunctor of $\text{Quot}^d_{\mathcal{F},/\mathbb{P}^1/k}$.

Every $A$-module $M \in G_{j_1,\ldots,j_d}(A)$ is free with basis $B_{j_1}, \ldots, B_{j_d}$. Choosing this basis as $u_1, \ldots, u_d$, the submatrix of $C(M)$ corresponding to columns $j_1, \ldots, j_d$ is the identity matrix.

In particular, we consider a list of positive integers $[i_1, \ldots, i_s]$ with $i_1 \geq \cdots \geq i_s > 0$ and $\sum i_m = d$ and denote by $G_{[i_1,\ldots,i_s]}$ and $Q_{[i_1,\ldots,i_s]}$ the open subsets obtained selecting as $j_1, \ldots, j_d$ the first $i_m$ indices of the $m$-th block for every $m = 1, \ldots, s$.

Example 3.1. Consider $r = 3$, $d = 4$. If we choose $[i_1,i_2] = [2,2]$, this corresponds to $j_1 = 1, j_2 = 2, j_3 = 6, j_4 = 7$.

The $N(r)$ open subschemes $G_{j_1,\ldots,j_d}$ form the standard open cover of $G$ and none of them is contained in the union of the other ones. For a general introduction to such open covers see [3, Section 9.8]. The $G_{j_1,\ldots,j_d}$ are all isomorphic, but the $Q_{[i_1,\ldots,i_s]}$ are not. This is due to the fact that the modules $M$ corresponding to the points of $Q_{[i_1,\ldots,i_s]}$ have a specific module structure related to $[i_1, \ldots, i_s]$.

So we will consider transformations by suitable changes of coordinates in $\mathbb{P}^1$ and suitable change of the basis $B$, transformations that preserve the scheme structure of the $\text{Quot}^d_{\mathcal{F},/\mathbb{P}^1/k}$ and that take quotient modules representing points of $\text{Quot}^d_{\mathcal{F},/\mathbb{P}^1/k}$ to isomorphic quotients.

Below, the variables $x, y$ and the basis $e_1, \ldots, e_r$ are changed via matrices in $\text{GL}_2(k)$ and $\text{GL}_r(k)$.

Notation 3.2. We will denote by $G_{[i_1,\ldots,i_s]}^{*}$ and $G_{[i_1,\ldots,i_s]}^{*}$ (resp., $Q_{[i_1,\ldots,i_s]}^{*}$ and $Q_{[i_1,\ldots,i_s]}^{*}$) the union of the $G_{j_1,\ldots,j_d}$ and $G_{[i_1,\ldots,i_s]}$ (resp., $Q_{j_1,\ldots,j_d}$ and $Q_{[i_1,\ldots,i_s]}$), up to the linear changes described above.

Moreover, we will denote by $G^{*}$ and $Q^{*}$ the union of the open subfunctors $Q_{[i_1,\ldots,i_s]}$ and $G_{[i_1,\ldots,i_s]}$, for every sequence $[i_1, \ldots, i_s]$ and up to the above linear changes.

Remark 3.3. Observe that $Q^{*}(A) = \text{Quot}^d_{\mathcal{F},/\mathbb{P}^1/k}(A)$ for every local $k$-algebra $A$.

Proposition 3.4. In the above setting, we have
\[
\text{Quot}_{\mathcal{F}_r/p^1/k}^d = \bigcup_{i_1 \geq \cdots \geq i_s > 0, \sum i_m = d} Q_{[i_1, \ldots, i_s]}^t.
\]

**Proof.** As it suffices to check the asserted equation locally, we consider a local k-algebra \((A, \mathfrak{m}, K)\). It is sufficient to prove that for every \(M \in \text{Quot}_{\mathcal{F}_r/p^1/k}^d(A)\), there is \([i_1, \ldots, i_s]\) such that \(M \in Q_{[i_1, \ldots, i_s]}^t(A)\). Since we will look for invertible submatrices of \(C(M)\), we can work modulo \(\mathfrak{m}\), namely take \(A = K\) a field.

Up to a change of coordinates in \(GL_2(k)\), we may assume that \(M\) is supported on the open subset \(A_{x, y}^s\) of \(\mathbb{P}^1_K\) where \(x\) does not vanish, so that \(xM \mapsto M\).

Then, after reordering \(e_1, \ldots, e_r\), we may assume that in the first block of \(B\) there is an element \(x^{d-s}y^se_1\) that does not vanish in \(M\), hence we may also assume that \(x^de_1\) does not vanish in \(M\) (recall that in our setting \(x\) is not a zero-divisor). Let \(L_1\) be the \(K\)-vector space in \(M\) generated by \(x^de_1, x^{d-1}y_1e_1, \ldots, y^se_1\), and let \(i_1\) be its dimension; by applying the same argument as above, we may choose \(x^de_1, x^{d-1}y_1e_1, \ldots, x^{d-i_1+1}y^{i_1-1}e_1\) as its basis. Indeed, if \(x^{d-s}y^se_1\) is linearly dependent on \(x^de_1, x^{d-1}y_1e_1, \ldots, x^{d-s}y^se_1\), then the same holds for \(x^{d-s}y^se_1\) for every \(t \geq s\).

If \(i_1 = d\), then \(M \in Q_{[d]}(K)\). Otherwise, after reordering \(e_2, \ldots, e_r\) we may assume that the \(K\)-vector space \(L_2 \leq M\) generated by the elements of the first and second block of \(B\) has dimension \(i_1 + i_2 + i_1\) larger than \(i_1\) and see that \(x^de_1, \ldots, x^{d-i_1}y^{i_1-1}e_1, x^{d-2}e_2, \ldots, x^{d-i_2+1}y^{i_2-1}e_2\) is its basis.

Up to reordering \(e_1, \ldots, e_s\), we obtain \(i_1 \geq \cdots \geq i_s > 0\). Finally, we take as basis \(u_1, \ldots, u_d\) of \(M\) exactly the elements \(x^de_1, x^{d-1}y_1e_1, \ldots, x^{d-i_1}y^{i_1-1}e_1, \ldots, x^{d-2}e_2, \ldots, x^{d-i_2+1}y^{i_2-1}e_2\). Thanks to these choices, \(C(M)\) has an identity submatrix, that we will denote by \(\mathrm{Id}_{[i_1, \ldots, i_s]}\), obtained by taking the first \(i_m\) columns from the \(m\)-th block for \(m = 1, \ldots, s\).

**Corollary 3.5.** A local property holds everywhere on \(\text{Quot}_{\mathcal{F}_r/p^1/k}^d\) if, and only if, it holds on the open subsets \(Q_{[i_1, \ldots, i_s]}\), for every \([i_1, \ldots, i_s]\) such that \(i_1 \geq \cdots \geq i_s > 0\), \(\sum i_m = d\).

4. AN EXPLICIT DESCRIPTION OF \(Q_{[i_1, \ldots, i_s]}(A)\)

Now we give an explicit characterization of the the elements of \(Q_{[i_1, \ldots, i_s]}(A)\).

**Proposition 4.1.** Let \(A\) be a \(k\)-algebra. Let \(M\) be a free \(A\)-module of \(G(A)\) and \(F^s_{A}/V\) the \(S_A\)-module generated by \(M\). Then \(M \in \text{Quot}_{\mathcal{F}_r/p^1/k}^d(A)\) if, and only if, \(\exists u_1, \ldots, u_d \in M\), \(\ell, \ell' \in k[x, y]_1\), and a \(d \times d\) matrix \(P(M)\) with entries in \(A\) such that

1. \(u_1, \ldots, u_d\) are \(A\)-basis for \((F^s_{A}/V)_d\);
2. \(\ell, \ell'\) are a basis for the linear forms in \(k[x, y]\), such that \(\ell u_1, \ldots, \ell u_d\) are \(A\)-basis of \((F^s_{A}/V)_{d+1}\);
3. \([\ell u_1 \cdots \ell u_d] = [\ell u_1 \cdots \ell u_d] P(M)\).

If the above conditions are fulfilled, then multiplication by \(\ell\) : \((F^s_{A}/V)_{\geq d} \rightarrow (F^s_{A}/V)_{\geq d+1}\) is injective and \(\ell^m u_1, \ldots, \ell^m u_d\) is \(A\)-basis of \((F^s_{A}/V)_{m+d}\) for every \(m \geq 1\).

**Proof.** It is obvious that the conditions 1), 2), 3) are sufficient to ensure that \(M\) belongs to \(\text{Quot}_{\mathcal{F}_r/p^1/k}^d(A)\): indeed, these conditions ensure that \(F^s_{A}/V\) is a free \(A\)-module with Hilbert polynomial \(d\).

Now we prove that the three conditions are also necessary, namely that all the modules \(M \in \text{Quot}_{\mathcal{F}_r/p^1/k}^d(A)\) fulfill them.

By Proposition 3.4, it is sufficient to consider \(M \in Q_{[i_1, \ldots, i_s]}(A)\) for any \([i_1, \ldots, i_s]\).

Choose \(u_1, \ldots, u_d\) as in the proof of Proposition 3.4, so that the matrix \(C(M)\) has an identity submatrix \(\mathrm{Id}_{[i_1, \ldots, i_s]}\) and take as \(P(M)\) the only matrix such that \([yu_1 \cdots y u_d] = [x u_1 \cdots x u_d] P(M)\). More explicitly, \(P(M)\) is constructed by taking in the \(m\)-th block the columns \(2, \ldots, i_m + 1\), for every \(m \leq s\), and the first column of each block from \(s + 1\) on. In this way, clearly \(P(M)\) gives the multiplication by \(y/x\) of each element of the basis \(x u_1, \ldots, x u_d\) of \((F^s_{A}/V)_{\geq d+1}\).

We conclude the proof observing that the arguments we applied to \((F^s_{A}/V)_{d+1}\), also apply inductively to \((F^s_{A}/V)_{t}\) for every \(t \geq d + 1\).

We now give few explicit examples for Proposition 4.1.
Example 4.2. We consider $d = 5$, $r \geq d$.
Assume $M \in Q_{[0]}(A)$: we can take $x^5 e_1, x^4 y e_1, \ldots, x y^4 e_1$ as a basis of $M$ (as in the proof of Proposition 3.4), so that the first block $B_1$ of $\text{C}(M)$ contains its first 5 columns an identity matrix. We choose $\ell = x, \ell' = y$, and the matrix $P(M)$ (multiplication by $y$) is

$$P(M) = \begin{bmatrix} 0 & 0 & 0 & b_{1,6} \\ 1 & 0 & 0 & b_{2,6} \\ 0 & 1 & 0 & b_{3,6} \\ 0 & 0 & 1 & b_{4,6} \\ 0 & 0 & 0 & 1 & b_{5,6} \end{bmatrix},$$

where $[b_{1,6}, b_{2,6}, b_{3,6}, b_{4,6}, b_{5,6}]^T = B_{1,6}^T$ is the last column of the first block of $\text{C}(M)$.

Assume now $M \in Q_{[3,2]}(A)$: we can take $x^5 e_1, x^4 y e_1, x^3 y^2 e_1, x^5 e_2, x^5 ye_2$ as a basis of $M$, so that the first block $B_1$ of $\text{C}(M)$ starts with the first three columns of the identity matrix, and the block $B_2$ starts with the 4-th and 5-th columns of the identity matrix. We choose $\ell = x, \ell' = y$, and the matrix $P(M)$ (multiplication by $y$) is in this case

$$P(M) = \begin{bmatrix} 0 & 0 & b_{1,4} & 0 & b_{1,9} \\ 1 & 0 & b_{2,4} & 0 & b_{2,9} \\ 0 & 1 & b_{3,4} & 0 & b_{3,9} \\ 0 & 0 & b_{4,4} & 0 & b_{4,9} \\ 0 & 0 & b_{5,4} & 1 & b_{5,9} \end{bmatrix},$$

where $[b_{1,4}, b_{2,4}, b_{3,4}, b_{4,4}, b_{5,4}]^T = B_{1,4}^T$ and $[b_{1,9}, b_{2,9}, b_{3,9}, b_{4,9}, b_{5,9}]^T = B_{2,3}^T$.

Assume now $M \in Q_{[1,1,1,1,1]}(A)$: we can take $x^5 e_1, x^5 e_2, x^5 e_3, x^5 e_4, x^5 e_5$ as a basis of $M$, so that the $j$-th column of the $j$-th block of $B_j$ of $\text{C}(M)$ is the $j$-th column of the identity matrix, $j = 1, \ldots, 5$. We choose $\ell = x, \ell' = y$, and the matrix $P(M)$ (multiplication by $y$) is in this case

$$P(M) = \begin{bmatrix} b_{1,2} & b_{1,8} & b_{1,14} & b_{1,20} & b_{1,26} \\ b_{2,2} & b_{2,8} & b_{2,14} & b_{2,20} & b_{2,26} \\ b_{3,2} & b_{3,8} & b_{3,14} & b_{3,20} & b_{3,26} \\ b_{4,2} & b_{4,8} & b_{4,14} & b_{4,20} & b_{4,26} \\ b_{5,2} & b_{5,8} & b_{5,14} & b_{5,20} & b_{5,26} \end{bmatrix},$$

where $[b_{1,2+\ell-1}, \ldots, b_{1,5}]^T = B_{1,\ell}^T$ is the 2-nd column of the $\ell$-th block of $\text{C}(M)$, $\ell = 1, \ldots, 5$. Observe that in this case $P(M)$ does not contain any column of the submatrix $\text{Id}_{[1,\ldots, 1]}$.

Corollary 4.3. For every $[i_1, \ldots, i_s]$ as above, the open subset $Q_{[i_1, \ldots, i_s]}(\text{Quot}_d)^d/k$ is isomorphic to the affine space $A^d/k = \text{Spec}(k[w_{h,m}]_{h=1, \ldots, d, m=1, \ldots, r})$.

An explicit isomorphism $\phi_{[i_1, \ldots, i_s]}$ can be obtained associating to $w_{1,m}, \ldots, w_{d,m}$ the entries of the first column in the $m$-th block that does not belong to the chosen identity submatrix $\text{Id}_{[i_1, \ldots, i_s]}$.

Proof. Let $A$ be any $k$-algebra. We now prove that given description of $\phi_{[i_1, \ldots, i_s]}$ gives a bijection function between $Q_{[i_1, \ldots, i_s]}(A)$ and $\text{Hom}_A(A[w_{h,m}]_{h=1, \ldots, d, m=1, \ldots, r}, A)$.

First we observe that the columns to which we associate the variables $w_{1,m}, \ldots, w_{d,m}$ for $m = 1, \ldots, s$ allow us to construct the matrix $P(M)$ of Proposition 4.1, while for $m > s$ we associate to $w_{1,m}, \ldots, w_{d,m}$ the entries of the first column of the $m$-th block.

Therefore, $\phi_{[i_1, \ldots, i_s]}(A)(M)$ encodes both $P(M)$ and the initial column of each block: by repeatedly multiplying the first column of each block by $P(M)$ we get the other columns of that block. Therefore, the map $\phi_{[i_1, \ldots, i_s]}(A)$ is well defined and injective.

Moreover, $\phi_{[i_1, \ldots, i_s]}(A)$ is surjective since, by Proposition 4.1, we may freely choose in $A$ the images of the variables $w_{h,m}$ and get a module $M$ in $Q_{[i_1, \ldots, i_s]}(A)$.

Corollary 4.4. $\text{Quot}_d^d/k$ is smooth, rational of dimension $dr$. 

5. Hilb-support of points of \( \text{Quot}_{\mathcal{F}_T}^d \mathbb{P}^1/k \)

This short section is dedicated to studying the support of every module \( M \in \text{Quot}_{\mathcal{F}_T}^d \mathbb{P}^1/k(A) \) in order to associate to it an element of \( \text{Hilb}^d_{\mathcal{O}_{\mathbb{P}^1}}(A) \).

We have already observed that the support of \( M \) is zero-dimensional of length \( \leq d \). The following example shows that the inequality can be strict.

Example 5.1. Let \( A = k \) and let \( M \) be the degree 2 component of \( k[x, y]/(y)e_1 + k[x, y]/(y)e_2 \). Then \( M \in \text{Quot}_{\mathcal{F}_T}^2 \mathbb{P}^1/k(k) \) and its support is the length 1 subscheme of \( \mathbb{P}^1 \) defined by \( y = 0 \).

Notation 5.2. For every module \( M = (F^r_A)/V \) in \( Q_{\{t_1, \ldots, t_d\}}(A) \), let \( u_1, \ldots, u_d \) be the \( A \)-basis, \( \ell, \ell' \) be the basis of \( k[x, y] \) and \( P(M) \) be the matrix of Proposition 4.1. We will denote by \( \chi_P(M)(T) \) the characteristic polynomial \((-1)^d(T^d - tr(P(M))T^{d-1} + \cdots + \det(P(M))) \) of \( P(M) \) and by \( S_\ell(A) \) the ideal in \( S_{\ell}(A) \).

Proposition 5.3. Let \( A \) be a \( k \)-algebra and \( M = (F^r_A)/V \) be any module in \( Q^r_A(A) \). Then

1) the ideal \( A_M \) only depend on \( M \);
2) \( A_M \subseteq \text{Ann}(F^r_A/V) \);
3) \( A_M = \text{Ann}(F^r_A/V) \) if, and only if \( M \in Q_{\{d\}}^r(A) \).

Proof. As the three properties are local, we may assume that \( A \) is local.

1) If \( M \in Q_{\{t_1, \ldots, t_d\}}(A) \), we can construct a generator of \( A \) considering \( M \) as an element of either \( Q_{\{t_1, \ldots, t_d\}}(A) \) or of \( Q_{\{t'_1, \ldots, t'_d\}}(A) \). In both cases \( \ell = x, \ell' = y \) and the two matrices \( P(M), P'(M) \) are associated by the invertible matrix of basis change from \( [u_1, \ldots, u_d] \) to \( [u'_1, \ldots, u'_d] \), so that they have the same characteristic polynomial.

The same happens if we modify the linear basis for \( k[x, y] \). It is sufficient to check this fact considering the following two special cases.

If \( \ell_1 = x, \ell'_1 = y \) and \( \ell_2 = y, \ell'_2 = x \), then the corresponding matrices \( P_1(M) \) and \( P_2(M) \) are inverse, namely \( P_2(M) = (P_1(M))^{-1} \), so that \( x^d \det(P_1(M) - \frac{y}{x}I) + y^d \det(P_2(M)) = \frac{y}{x}I \) are equal, up to a sign.

If \( \ell_1 = x, \ell'_1 = y \) and \( \ell_2 = x, \ell'_2 = y + cx \) with \( c \in k \), then the corresponding matrices \( P_1(M) \) and \( P_2(M) \) satisfy the equality \( P_2(M) = P_1(M) + cI \), so that \( x^d \det(P_1(M) - \frac{y}{x}I) = (y + cx)^d \det(P_2(M) - \frac{y}{x}I) \).

2) The result is a straightforward consequence of what observed in the proof of Corollary 4.3 and of the well known fact that every matrix is a root of its characteristic polynomial, so that \( \chi_{P(M)}(P(M)) = 0 \). By item 1 we may born ourselves to the case \( \ell' = y, \ell = x \).

For every \( i = 1, \ldots, r \) let \( B_{i,j} \) the \( j \)-th column of the \( i \)-th block of \( C(M) \). Then \( B_{i,j} = P(M)^{i-1}B_{i,1} \). If \( \chi_{P(M)}(T) = a_1 + a_2T + \cdots + a_dT^{d-1} + T^d \), then

\[
a_1B_{i,1} + a_2B_{i,2} + \cdots + a_dB_{i,d} = B_{i,d+1} = 0.
\]

Therefore, in \( M \) we have \( x^d \chi_{P(M)}(y/x)e_i = (a_1x^d + a_2x^{d-1}y + \cdots + a_dxy^{d-1} + y^d)e_i = 0 \), for every \( i = 1, \ldots, r \), hence \( A_M \subseteq \text{Ann}_{A}(F^r_A/V) \). 1

3) Both ideals \( A_M \) and \( \text{Ann}_{A}(F^r_A/V) \) are homogeneous and every polynomial \( f \in S_{\ell}(A), m \geq d \), can be written as \( (a_1x^d + a_2x^{d-1}y + \cdots + a_dxy^{d-1} + y^d)g + x^{m-d}(c_1x^d + c_2x^{d-1}y + \cdots + c_dxy^{d-1}) \) for some \( c_1, \ldots, c_d \in A \). Then, if not empty, the difference \( \text{Ann}_{A}(F^r_A/V) \) should contain some element of the type \( c_1x^d + c_2x^{d-1}y + \cdots + c_dxy^{d-1} \). Recall that in Proposition 4.1 we proved that the multiplication by \( x \) in \( (F^r_A/V)_{\geq d} \) is injective.

If \( F^r_A/V \in Q_{\{d\}}(A) \), then \( u_1 = x^d e_1, \ldots, u_d = xy^{d-1}e_1 \) is a basis of \( M \), so that \( (c_1x^d + c_2x^{d-1}y + \cdots + c_dxy^{d-1})e_1 = c_1u_1 + c_2u_2 + \cdots + c_du_d \) vanish if, and only if, \( c_1 = c_2 = \cdots = c_d = 0 \). Therefore \( \text{Ann}_{A}(F^r_A/V) = A_M \). \( \Box \)
Definition 5.4. Let $A$ be any $k$-algebra and $M$ be any element of $Q^*(A)$. We call Hilb-support of $M$ the scheme $\text{Proj}(A[x, y]/\mathcal{A}_M)$.

We now motivate the name we choose for this new kind of support of a module.

Lemma 5.5. For any $k$-algebra $A$, if $M$ is an element of $Q^*(A)$, then the schematic support $Z$ of $M$ coincides with the Hilb-support if, and only if $M \in Q^*_d(A)$.

In particular, for $A = k$, if $M$ is any module in $\text{Quot}^d_{\mathbb{P}^1/k}(k)$ whose schematic support is a zero-dimensional scheme $Z$ formed by $d$ distinct $k$-points of $\mathbb{P}_1$, then $Z$ is also the Hilb-support.

Proof. In order to prove this statement it is sufficient to improve the proof of Proposition 3.4. Let $M$ be a module $Q^*(A)$: as $k$ is an infinite field, up to a general change of the basis $e_1, \ldots, e_r$ with coefficients in $k$, we can assume that the support of $M$ coincides with the support of the submodule of $M$ generated by $e_1$.

Now, if the support of $M$ does not have degree $d$, then it is not the Hilb-support of $M$. Otherwise $M$ belongs to $Q^*_d(A)$ and we apply Proposition 5.3.

We now give a concrete insight to the notion of Hilb-support, when $A = k$.

Observe that if we take $M_1 \in \text{Quot}^d_{\mathbb{P}^1/k}(k)$, $M_2 \in \text{Quot}^d_{\mathbb{P}^2/k}(k)$, then the Hilb-support of the module $M_1 \oplus M_2 \in \text{Quot}^d_{\mathbb{P}^1 \times \mathbb{P}^2/k}(k)$ is the sum of the Hilb-support of the two modules.

Let $A = k$, $M \in \text{Quot}^d_{\mathbb{P}^1/k}(k)$ and let $Z = \{R_1, \ldots, R_n\}$ be the set-theoretical support of $M$. We denote $I_{R_1}$ the maximal saturated ideal in $S$ defining the point $R_1 \in \mathbb{P}^1$. We consider $\mu_j := \text{dim}_k(M \otimes_S S/I_{R_j})$. In this case, the Hilb-support of $M$ is $\mu_1R_1 + \cdots + \mu_nR_n \in \text{Hilb}^d_{\mathbb{P}^1}(k)$.

Definition 5.6. We define a morphism of schemes $\xi : \text{Quot}^d_{\mathbb{P}^1/k} \to \text{Hilb}^d_{\mathbb{P}^1}$ using open subfunctors. We first define $\xi$ on $Q_{[i_1, \ldots, i_s]}$, for any $[i_1, \ldots, i_s]$:

$$\xi(A) : Q_{[i_1, \ldots, i_s]}(A) \to \text{Hilb}^d_{\mathbb{P}^1}(A), M \mapsto \xi(A)(M) = \mathcal{A}_M,$$

The map $\xi$ is well defined thanks to Proposition 5.3.

Remark 5.7. By definition, the map $\xi$ associate to every $k$-point $M$ of $\text{Quot}^d_{\mathbb{P}^1/k}$ its Hilb-support $Y$, that does not always coincide with the schematic support $Z$ of $M$. Therefore the fibre of $\xi$ over a $k$-point $Y$ of $\text{Hilb}^d_{\mathbb{P}^1}$ is in general a proper subscheme of $\text{Quot}^d_{\mathbb{P}^1/k}$, as shown by the following example. However, we can describe the fibre of $\xi$ over any point $Y$ of $\text{Hilb}^d_{\mathbb{P}^1}$ using Quot schemes over 0-dimensional schemes of $\mathbb{P}^1$.

Example 5.8. For $r = 2$, $d = 2$, consider $Y = R + R'$, with $R \neq R'$. Every module whose Hilb-support is $Y$ is completely determined by its restrictions to $R$ and to $R'$; the condition on the Hilb-support requires that each restriction is locally free with rank 1. Therefore, the fiber of $\xi$ over $Y$ is irreducible and isomorphic to $\mathbb{P}^1 \times \mathbb{P}^1$. However $\text{Quot}^2_{\mathbb{P}^1/Y/k}$ has also two other isolated points, corresponding to the modules $M_1 = \mathcal{O}_R \oplus \mathcal{O}_R$ and $M_2 = \mathcal{O}_{R'} \oplus \mathcal{O}_{R'}$, whose schematic support is $R \subsetneq Y$ (resp. $R' \subsetneq Y$). Observe that $\xi(M_1) = 2R$ and $\xi(M_2) = 2R'$.

Proposition 5.9. Let $Y$ be a degree $d$ 0-dimensional subscheme of $\mathbb{P}^1$

1) If $Y = dR$, then $\xi^{-1}(Y) = \text{Quot}^d_{\mathbb{P}^1/Y/k}$.

2) If $Y = Y_1 + \cdots + Y_n$ with $Y_1 = t_1R_1, \ldots, Y_n = t_nR_n$, where $R_1, \ldots, R_n$ are distinct points, then $\xi^{-1}(Y) = \text{Quot}^1_{\mathbb{P}^1/Y_1/k} \times \cdots \times \text{Quot}^n_{\mathbb{P}^1/Y_n/k}$.

Proof. In the first case, a $k$-point of $\xi^{-1}(Y)$ must have set theoretical support $R$ and have Hilbert polynomial $d$. As already observed, this is equivalent to require that the Hilb-support is $dR$.

In the second case every module $M$ in the fibre of $Y$ is determined by its restriction $M_i$ to tech points $R_i$; by definition of Hilb-support the Hilbert polynomial of the restriction to $R_i$ must be exactly $t_i$; hence, by the previous item, $M_i$ is a point of $\text{Quot}^1_{\mathbb{P}^1/Y_i/k}$.

Due to the previous result, in next section we study the Quot schemes over a 0-dimensional scheme of $\mathbb{P}^1$ whose set theoretical support is a single point.
6. Quot over a 0-dimensional scheme supported on a single point

In the present section we study the modules belonging to Quot^{t,F_Y}/Y/k, Quot scheme defined on Y, 0-dimensional scheme of P^1 supported at a single point.

We denote by I_Y ⊂ S the saturated ideal such that Proj(S/I_Y) = Y, and by O_Y the structural sheaf of Proj(S/I_Y). We set F_Y := \oplus^r O_Y = O_Y e_1 + \cdots + O_Y e_r.

**Definition 6.1.** We will denote by Q^*_{t[i_1...i_s],Y} (resp. Q^*_{t[i_1...i_s],Y}) the open subfunctors (resp. subfunctors) of Quot^{t,F_Y}/Y/k (of Quot^{t,F_Y}/Y/k) defined similarly to Q^*_{[i_1...i_s]} (resp. Q^*_{[i_1...i_s]}) in Quot^{t,C}/P^1/k (resp. Quot^{t,C}/P^1/k).

Every statement concerning an open subset Q^*_{t[i_1...i_s],Y} of Quot^{t,F_Y}/P^1/k also apply to the open subset Q^*_{t[i_1...i_s],Y} of Quot^{t,F_Y}/Y/k, provided that the matrix P(M) of M ∈ Q^*_{t[i_1...i_s]}(A) is a root of the equation defining Y. More explicitly, consider Y = tR with R a single point. Assuming by simplicity that R is defined by y = 0, the condition we have to impose is the vanishing of P(M)^t. Hence, we are interested in studying the following functor.

**Lemma 6.2.** Let P = (w_{ij}) be the t × t matrix with indeterminates entries and let P be the functor from Ring to Sets

\[ A \mapsto \{ t \times t matrices P with entries in A such that P^t = 0 \} \]

and, for every ring homomorphism f : A → B

\[ P = (a_{ij}) ∈ P(A) ↦ f(P) = (f(a_{ij})) ∈ P(B). \]

Then P is the functor of points of the subscheme of k^t = Spec(k[w_{ij}]) defined by the ideal I_P generated by the entries of P^t.

**Proof.** Obvious.  

For every k-algebra A, similarly to what we did in Proposition 3.4 for Q_{[i_1...i_s]}, we can construct Q_{t[i_1...i_s],Y}, as a subscheme of the affine scheme k^{tr}. Consider now the matrix P_{t[i_1...i_s]} having the same shape as the matrix P(M) for M ∈ Q_{t[i_1...i_s],Y}(A) (see Proposition 4.1), and whose entries not in the columns of Id_{t[i_1...i_s]} are parameters w_{h,m}, h = 1, ..., t, m = 1, ..., r. Then Q_{t[i_1...i_s],Y} is defined by

\[ \Spec \left( k[w_{h,m}]_{h=1,...,t, m=1,...,r}/I_{P_{t[i_1...i_s]}} \right), \]

where, depending on the chosen [i_1, ..., i_s], the indeterminates w_{h,m}, h = 1, ..., t, m = 1, ..., r correspond to the suitable entries of P_{t[i_1...i_s]} (as described in in Corollary 4.3), and I_{P_{t[i_1...i_s]}} the ideal generated by the entries of the matrix P_{t[i_1...i_s]}.

Observe that, if t ≤ r, then P_{[1,...,1]} = P (there are no identity columns in P_{[1,...,1]}). The scheme representing the functor P associated to P_{t[i_1...i_s]} is geometrically non-trivial. Indeed, even for t = 2 and P_{[1,1]}, the scheme representing P_{[1,1]} has an isolated singular component and an embedded component.

**Example 6.3.** Consider t = 2 and P_{[1,1]} = P. We can explicitly write I_P ⊂ k[w_{1,1}, w_{1,2}, w_{2,1}, w_{2,2}]:

\[ I_P = (w_{1,1}^2 + w_{1,2}w_{2,1}, (w_{1,1} + w_{2,2})w_{1,2}, (w_{1,1} + w_{2,2})w_{2,1}, w_{2,1}w_{1,2} + w_{2,2}^2). \]

Computing a primary decomposition of it, we see that the scheme W := Spec(k[w_{h,m}, h = 1,2, m = 1,2]/I_P) is formed by an irreducible isolated 2-dimensional component C given by

\[ I_C = (w_{1,1} + w_{2,2}, w_{1,1}w_{2,2} - w_{1,2}w_{2,1}) \]

where w_{1,1} + w_{2,2} = tr(P) and w_{1,1}w_{2,2} - w_{1,2}w_{2,1} = det(P) and an embedded component at the point of C corresponding to the null matrix, given for instance by the ideal

\[ (w_{1,2}, w_{2,1}, w_{1,1}^2, w_{2,2}^2) \]

(computations of a primary decomposition have been made by the Maple software).
Note that $I_C$ is also generated by $w_{1,1} + w_{2,2}$ and $w_{1,2}^2 + w_{1,2}w_{2,1}$, hence $C$ is a quadric cone in a hyperplane of $\mathbb{A}^3$ and the vertex corresponds to the null matrix.

We will now describe $\text{Quot}_Y^{t}_{\mathcal{F}_Y/Y/k}$ with $Y = tR$. For every $M$ free module belonging to $\text{Quot}_Y^{t}_{\mathcal{F}_Y/Y/k}(A)$, if $M$ belongs to several open subsets $\mathcal{Q}^{t}_{[i_1,\ldots,i_j],Y}(A)$, we consider the one given by the largest list of indexes according to lex, because this open subsets allows us to characterize more precisely the geometric features of $\text{Quot}_Y^{t}_{\mathcal{F}_Y/Y/k}$ at $M$. In particular, we will be interested in $\mathcal{Q}^{*}_{[t],Y}$, the one having the lex-largest list of indices.

**Theorem 6.4.** Let $r, t \geq 2$, and let $Y$ be the 0-dimensional degree $t$ scheme $tR$ in $\mathbb{P}^1$. Then $\text{Quot}_Y^{t}_{\mathcal{F}_Y/Y/k}$ is an irreducible non-reduced scheme of dimension $t(r-1)$. Its singular locus is contained in the complementary of $\mathcal{Q}^{*}_{[t],Y}$, while $\mathcal{Q}^{*}_{[t],Y}$ is locally isomorphic to $\mathbb{A}^{t(r-1)}$.

**Proof.** As always, we assume that $R$ is the point of $\mathbb{P}^1$ given by $y = 0$, so that $tR$ is given by $y^t = 0$.

We first prove the statement concerning $\mathcal{Q}^{*}_{[t],Y}$ showing that $\mathcal{Q}^{*}_{[t],Y}$ is isomorphic to $\mathbb{A}^{t(r-1)}$. Arguing as in the proof of Corollary 4.3, we see that the modules in $\mathcal{Q}^{*}_{[t],Y}(A)$ are parameterized by $t \cdot r$ parameters (the entries of the column $t + 1$ in the first block and the entries of first column in each following block of $C(M)$). Moreover, the matrix $\mathbf{P}_{[t]}$ is formed by the columns $2,\ldots,t$ of the $t \times t$ identity matrix and by the last column of the first block of $C(M)$, as follows

$$
\mathbf{P}_{[t]} = \begin{bmatrix}
0 & 0 & \ldots & 0 & w_{1,1} \\
1 & 0 & \ldots & 0 & w_{2,1} \\
0 & 1 & \ldots & 0 & w_{3,1} \\
\vdots & \vdots & \ddots & \vdots & \vdots \\
0 & 0 & \ldots & 1 & w_{t-1,1} \\
0 & 0 & \ldots & 0 & w_{1,1}
\end{bmatrix}
$$

where the symbols for the entries of the last column are chosen coherently with (6.1).

As in (6.1), the ideal of $k[w_{h,m}]_{h=1,\ldots,t, m=1,\ldots,r}$ defining $\mathcal{Q}^{*}_{[t],Y}$ in $\mathcal{Q}^{*}_{[t]}$ is generated by the entries of $\mathbf{P}_{[t]}^*$ that only involve the last variables $w_{1,1},\ldots,w_{t,1}$. The multiplication of a matrix $D$ by $\mathbf{P}_{[t]}$ gives a matrix whose column $i$ is the column $i+1$ of $D$, for every $i = 1,\ldots,d-1$; hence the first column of $\mathbf{P}_{[t]}$ coincides with the last one in $\mathbf{P}_{[t]}$. Therefore the ideal $I_{\mathbf{P}_{[t]}^*}$ contains (hence coincides with) the ideal generated by $w_{1,1},\ldots,w_{t,1}$, so that $\mathcal{Q}^{*}_{[t],Y}$ is isomorphic to $\mathbb{A}^{t(r-1)}$.

In order to prove that $\mathcal{Q}^{*}_{[t],Y}$ is irreducible, it is sufficient to observe that, for every pair of $k$-points of $\mathcal{Q}^{*}_{[t],Y}$, we may perform a sufficiently general change of the basis $e_1,\ldots,e_r$ such that both of them belong to $\mathcal{Q}^{*}_{[t],Y}$, which is irreducible, as we have just proved.

Now we prove that $\text{Quot}_Y^{t}_{\mathcal{F}_Y/Y/k}$ has embedded components; by what we have just proved they must be supported on $\text{Quot}_Y^{t}_{\mathcal{F}_Y/Y/k} \setminus \mathcal{Q}^{*}_{[t]}$. To this aim we consider the open subscheme $\mathcal{Q}^{*}_{[t],Y}$ of $\text{Quot}_Y^{t}_{\mathcal{F}_Y/Y/k}$ and consider it as a closed subscheme of $\mathcal{Q}^{*}_{[t-1],Y}$.

Following the description given in Proposition 3.4, $\mathcal{Q}^{*}_{[t-1],Y}$ is isomorphic to $\mathbb{A}^{t(r)}$, the matrix $\mathbf{P}_{[t-1]}$ is as follows

$$
\mathbf{P}_{[t-1]} = \begin{bmatrix}
0 & 0 & \ldots & 0 & w_{1,1} & w_{1,2} \\
1 & 0 & \ldots & 0 & w_{2,1} & w_{2,2} \\
0 & 1 & \ldots & 0 & w_{3,1} & w_{3,2} \\
\vdots & \vdots & \ddots & \vdots & \vdots & \vdots \\
0 & 0 & \ldots & 1 & w_{t-1,1} & w_{t-1,2} \\
0 & 0 & \ldots & 0 & w_{1,1} & w_{1,2}
\end{bmatrix}
$$

and the ideal $J$ defining $\mathcal{Q}^{*}_{[t-1],Y}$ as a subscheme of $\mathcal{Q}^{*}_{[t-1],Y}$ is generated by the entries of $\mathbf{P}_{[t-1]}^*$. Note that $\mathbf{P}_{[t-1]}^* = 0$ gives constraints only involving the variables $w_{i,j}$ with $j = 1,2$.

We observe that the matrix $P(M)$ associated to any $k$-point of $\mathcal{Q}^{*}_{[t-1],Y}$ is given by setting $w_{i,j} = c_{i,j} \in k$ for every $i = 1,\ldots,t$, $j = 1,2$ in $\mathbf{P}_{[t-1]}$. $P(M)$ has characteristic polynomial $T^t$. 

so that in particular it must have a null trace, namely \(c_{1,t-1} + c_{2,t} = 0\), so that the polynomial \(w_{t-1,1} + w_{t,2}\) vanishes on the support of \(Q_{[t-1,1],Y}\), namely \(w_{t-1,1} + w_{t,2} \in \sqrt{J}\).

An easy check shows that in \(P^2_{[t-1,1]}\) (and then in any following power of \(P_{[t-1,1]}\)) the variable \(w_{t,2}\) appears only in monomials of degree larger than 1, so that \(w_{t-1,1} + w_{t,2} \notin \sqrt{J}\). Therefore, \(Q_{[t-1,1],Y}\) is not included in those considered in the proof of the previous result.

Observe that \(Q_{[r-1,1],Y}\) intersects properly \(Q_{[r],Y}\): consider for instance the quotient module of \(F_Y\) given by the relations \(x^te_2 = (x^t + y^t)e_1\) and \(e_j = 0\), for \(j \geq 3\). This means that the non-reduced structure is only given by embedded components.

The above arguments also prove that \(\sqrt{J}\) is generated by the non-leading coefficients of the characteristic polynomial of \(P_{[t-1,1]}\) and it is a prime ideal.

We can then conclude that \(Q_{[t-1,1],Y}\), being irreducible, non reduced, and generically smooth, has (at least) one embedded component.

Finally, we prove that the support of \(Q_{[t-1,1],Y}\) is singular. Let \(M\) be any \(k\) point of the support of \(Q_{[t-1,1],Y}\) corresponding to setting \(w_{i,j} = 0\) for every \(j = 1, 2\) (and freely choosing values in \(k\) for the remaining \((r-1)t\) variables). Now we compute the Zariski tangent space at \(M\) to the support of \(Q_{[t-1,1],Y}\) in \(\mathbb{A}^{tr}\) taking the linear component of the non-leading coefficients of the characteristic polynomial of \(P_{[t-1,1]}\). The linear part of the coefficient of \(T^i\) is \(w_{i,1}\) for \(i = 1, \ldots, t-1\), while for \(i = 0\) the coefficient is the determinant \(w_{t-1,1}w_{t,2} - w_{t,1}w_{t-1,2}\), which is homogeneous of degree 2. Therefore, the Zariski tangent space at \(M\) has codimension \(t - 1\), while the codimension of \(Q_{[t-1,1],Y}\) in \(\mathbb{A}^{tr}\) is \(t\).

We can now prove the main result of the paper.

**Proof of Theorem 1.1.** It is sufficient to sum up the results of Proposition 5.9 and Theorem 6.4. \(\Box\)

We conclude the paper with two examples.

The following example concerns the case \(r \geq t \geq 2\) and describes singular points for \(\text{Quot}^t_{F_Y/Y/k}\) which is not included in those considered in the proof of the previous result.

**Example 6.5.** Let \(r \geq t \geq 2\) and let \(Y = tR\); assume that \(R\) is the point of \(P^1\) given by \(y = 0\).

If (and only if) this condition on \(t, r\) is fulfilled, we can find in \(\text{Quot}^t_{F_Y/Y/k}\) points corresponding to modules \(M\) whose schematic support is \(R\). They are the points of \(Q_{[1,\ldots,1],Y}\) such that \(P(M) = 0\) (while all the points in \(Q_{[1,\ldots,1],Y}(A)\) with \(i_1 > 1\) it holds \(P(M)^{i_1-1} \neq 0\), hence \(P(M) \neq 0\)). In this example we describe these points and prove that they are all singular in \(\text{Quot}^t_{F_Y/Y/k}\).

Making reference to Corollary 4.3 (and also to Example 4.2), a module \(M\) in \(Q_{[1,\ldots,1]}(A)\) is determined by the second columns of the blocks \(B_1, \ldots, B_t\) and the first columns of the following blocks of \(C(M)\). The matrix \(P_{[1,\ldots,1]} = P\) has the following form

\[
P = \begin{bmatrix}
w_{1,1} & w_{1,2} & \cdots & w_{1,t} \\
w_{2,1} & w_{2,2} & \cdots & w_{2,t} \\
w_{3,1} & w_{3,2} & \cdots & w_{3,t} \\
\vdots & \vdots & \ddots & \vdots \\
w_{t,1} & w_{t,2} & \cdots & w_{t,t}
\end{bmatrix}
\] (6.3)

Furthermore, the affine scheme \(Q_{[1,\ldots,1],Y}\) is defined by the ideal generated by the entries of the matrix \(P^t\) in the polynomial ring \(k[w_{i,j}]\). In \(\mathbb{A}^t\), the entries of \(P^t\) define the so-called null cone. The arguments used in the proof of Theorem 6.4 prove that it is irreducible and not reduced of dimension \(t(t-1)\). Hence, \(Q_{[1,\ldots,1],Y}\) is the product of this null cone with an affine space of dimension \(t(r-1)\).

Observe that \(Q_{[1,\ldots,1],Y}(A)\) properly intersects \(Q_{[t],Y}(A)\); consider for instance the module \(M\) given by the quotient of \(F_Y\) with the relations \(x^te_i - (x^t + x^{t+i+1}y^{-1})e_1\), for \(i = 2, \ldots, t\), and \(e_i = 0\) for \(i \geq t + 1\). This means that the non-reduced structure is only given by embedded components.
The locus in $\mathbb{Q}_{[1,...,1],Y}$ we are now focusing on is defined by $P = 0$, hence it is isomorphic to $\mathbb{A}^{t(r-t)}$. All the points in this locus are singular points of $\text{Quot}^{t}_{F_Y/Y/k}$. Indeed, considering the embedding $\mathbb{Q}_{[1,...,1],Y} \hookrightarrow \mathbb{Q}_{[2]} \simeq \mathbb{A}^{tr}$, the Zariski tangent space at each such point has codimension $t^2$, while the codimension of $\mathbb{Q}_{[1,...,1],Y}$ is $t$.

**Example 6.6.** For $r = t = 2$ and $Y = 2R$, $\text{Quot}^{2}_{F_Y/Y/k}$ has a unique singular point, the vertex of the cone described in Example 6.3. Note that for $t = 2$, $\mathbb{Q}_{[1,1],Y} = \mathbb{Q}_{[t-1,1],Y}$, namely Example 6.3 is both a special case of Example 6.5 and of the case $\mathbb{Q}_{[t-1,1],Y}$ in the proof of Theorem 6.4. Indeed, the vertex of the cone is actually the unique point in $\text{Quot}^{2}_{F_Y/Y/k} \setminus \mathbb{Q}_{[2],Y}$, and it is not only singular for the support of $\text{Quot}^{2}_{F_Y/Y/k}$, but at this point is supported the only embedded component $\text{Quot}^{2}_{F_Y/Y/k}$.

**Acknowledgements**

The authors are grateful to Roy Skjelnes for several discussions and his insight on the topic of the present paper. The authors also thank Federica Galluzzi for discussions on the Hilbert-Chow morphism, that inspired the definition of the map $\xi$ of the present paper, and Qiaochu Yuan for useful suggestions on the null-cone of nilpotent matrices.
