Abstract. The advantages offered by the presence of a schema are numerous. However, many XML documents in practice are not accompanied by a (valid) schema, making schema inference an attractive research problem. The fundamental task in XML schema learning is inferring restricted subclasses of regular expressions. Most previous work either lacks support for interleaving or only has limited support for interleaving. In this paper, we first propose a new subclass \textit{Single Occurrence Regular Expressions with Interleaving} (SOIRE), which has unrestricted support for interleaving. Then, based on single occurrence automaton and maximum independent set, we propose an algorithm \textit{iSOIRE} to infer SOIREs. Finally, we further conduct a series of experiments on real datasets to evaluate the effectiveness of our work, comparing with both ongoing learning algorithms in academia and industrial tools in real-world. The results reveal the practicability of SOIRE and the effectiveness of \textit{iSOIRE}, showing the high preciseness and conciseness of our work.

Keywords: XML, schema inference, learning expressions, interleaving

1 Introduction

XML schemas have always played a crucial role in XML management. The presence of a schema for XML documents has many advantages, such as for query processing and optimization, development of database applications, data integration and exchange \cite{15, 22, 34, 18}. However, many XML documents in practice are not accompanied by a (valid) schema \cite{3, 37, 36, 6, 41, 25}, making schema inference an attractive research problem \cite{2, 5, 7, 17, 22, 43, 13, 30, 32}. Studying schema inference also has several practical motivations. Schema inference techniques may be extended to schema repairing techniques \cite{25}. Besides, schema inference is also useful in situations where a schema is already available, such as in schema cleaning and dealing with noise \cite{7}.
The content models of XML schemas are defined by regular expressions, and previous research has shown that the essential task in schema learning is inferring regular expressions from a set of given samples [9, 2, 5, 7, 17, 22, 43, 13, 30, 32]. In fact, in some cases these learned regular expressions can directly be used as parts of the schema, and in other cases the inference of regular expressions is the most important component of the schema inference. Therefore, research on schema learning has focused on inferring regular expressions from a set of given samples.

We focus on learning regular expressions with interleaving (shuffle), denoted by \( \text{RE}(\&) \). Since \( \text{RE}(\&) \) are widely used in various areas of computer science [4], including XML database systems [19, 43], complex event processing [33], system verification [10, 21, 23], plan recognition [26] and natural language processing [27, 39].

Inference of regular expressions from a set of given samples belongs to the problem of language learning. Gold proposed a classical language learning model (learning in the limit or explanatory learning) and pointed out that the class of regular expressions could not be identifiable from positive samples only [24]. This means that no matter how many positive samples from the target language (i.e., the language to be learned) are provided, no algorithm can infer every target regular expression. Hence, researchers have turned to study subclasses of regular expressions [38, 9, 25, 11, 24, 13, 30, 32].

Most existing subclasses of regular expressions for XML are defined on standard regular expressions, e.g., [5, 7, 6, 16, 35] which were analyzed together in [31, 28]. For single occurrence regular expressions (SOREs), in which each symbol occurs at most once and its subclass chain regular expressions (CHAREs), Bex et al. proposed two inference algorithms \( \text{RWR} \) and \( \text{CRX} \) [7, 8]. Freydenberger and K"otzing [17] proposed more efficient algorithms \( \text{Soa2Sore} \) and \( \text{Soa2Chare} \) for the above mentioned SOREs and CHAREs. Bex et al. [5] also studied learning algorithms, based on the Hidden Markov Model, for the subclass of regular expressions \( (k\text{-OREs}) \) in which each alphabet symbol occurs at most \( k \) times.

Notice that none of the above subclasses support an important feature in XML, i.e., the interleaving.

There may be no order constraint among siblings in data-centric applications [11]. In such cases the interleaving is necessary. Here we list the more recent efforts on \( \text{RE}(\&) \) inference (see [13, 40, 43, 30, 32]). The aim of these approaches is to infer restricted subclasses of single occurrence \( \text{RE}(\&) \), in which each symbol occurs at most once, starting from a positive set of words. Ciucanu and Staworko proposed two subclasses disjunctive multiplicity expression (DME) and disjunction-free multiplicity expression (ME) [11, 13] which support unordered concatenation, a weaker form of interleaving. The concatenation operator is disallowed in both formalisms and ME even uses no disjunction operator. For example, \( r_1 = (a|b^+)^\&c \) is a DME and \( r_2 = a^*b^*c^* \) is an ME. But \( r_3 = (a^+b^*)^\&c^* \) and \( r_4 = a^*((b^*|c^*)d^*) \) do not satisfy both formalisms. The inference algorithm based on maximum clique for DME was given in [13]. Li et al. provided an algorithm to learn DMEs from both positive and negative examples based on genetic algorithms and simplified candidate regions (SCRs) [29]. When there is no order
constraint among siblings, the relative orders within siblings are still important. Peng and Chen [40] proposed a subclass SIRE using the grammar: 
\[ S ::= T \& S | T \] 
But it does not support the union operator. For example, \( r_2 \) and \( r_3 \) are SIREs but \( r_1 \) and \( r_4 \) are not. Besides, they presented an approximate algorithm to infer SIREs [40]. Li et al. [30] proposed a subclass ICRE using the grammar:
\[ E ::= F_1^{p_1} \cdots F_n^{p_n}, \quad (n \geq 0, p_i \in \{?, 1\}), \]
\[ F_i ::= D_1 \& \cdots \& D_k, \quad (i \in \{1, \ldots, n\}, k \geq 1), \]
\[ D_j ::= a_{mul_1}^{a_{o_1}} \cdots a_{mul_m}^{a_{o_m}}, \quad (j \in \{1, \ldots, k\}, m \geq 1), \]
where \( mul_o \in \{?, *, +\} \) and \( a_o \in \Sigma \) for \( o \in \{1, m\} \). For example, \( r_1, r_2 \) and \( r_4 \) are ICREs but \( r_3 \) is not. Besides, they presented an approximate algorithm to infer ICREs [30]. Zhang et al. [43] proposed a subclass called ICHARE considering interleaving. The inference algorithm is based on SOA and maximum independent set (MIS). However, components of interleaving are restricted to the extended strings (ES) defined in [43]. For example, \( r_2 \) and \( r_3 \) are ICHAREs but \( r_1, r_4 \) and \( r_5 = a^4(b^2|c)d^4|e|f^2) \) are not. Li et al. [32] proposed a practical subclass called ESIRE and designed an inference algorithm GenESIRE to infer ESIREs. For example, \( r_1, r_2, r_3, r_4 \) and \( r_5 \) are ESIREs, but \( r_6 = a^4b^2|f|m^2|c^2|d|e(n|k)^2|g|h^2|j^2|k^2 \) is not. All of the above subclasses are restricted subclasses of single occurrence RE(&). As shown above, the support for interleaving in existing work is very limited.

In this paper, based on the analysis of large-scale real data, we propose a new subclass of RE(&), i.e., single occurrence RE(&), called SOIRE. The relationships among ME, DME, SIRE, ICRE, ICHARE, ESIRE, SOIRE and RE(&) are shown in Figure 1. Among them, ME \( \subset \) DME \( \subset \) ICRE, ME \( \subset \) SIRE \( \subset \) ICHARE, DME \( \cap \) SIRE = ME, ICRE \( \subset \) ESIRE \( \subset \) SOIRE \( \subset \) RE(&) and ICHARE \( \subset \) ESIRE \( \subset \) SOIRE \( \subset \) RE(&). For example, all of \( r_1, r_2, r_3, r_4 \) and \( r_5 \) are SOIREs. It reveals that SOIRE is more powerful than the above subclasses since the latter are all subclasses of SOIRE, and especially SOIRE has unrestricted support for interleaving, which was never achieved by existing work. Then, we develop the corresponding learning algorithm, \( iSOIRE \), to carry out SOIREs inference automatically. The massive experimental results demonstrate the practicality of the proposed subclass as well as the preciseness and conciseness of \( iSOIRE \).

The main contributions of this paper are listed as follows.

- We propose a new subclass SOIRE of RE(&). SOIRE is more powerful than the existing subclasses and especially has unrestricted support for interleaving.
- Correspondingly, we design an inference algorithm \( iSOIRE \) which can learn SOIREs effectively based on single occurrence automaton (SOA) and maximum independent set (MIS).
- We conduct a series of experiments, comparing the performance of our algorithm with both ongoing learning algorithms in academia and industrial
Fig. 1: Relationships among ME, DME, SIRE, ICRE, ICHARE, ESIRE, SOIRE and RE(κ).
tools in real-world. The results reveal the practicability of SOIRE and the
effectiveness of iSOIRE, showing the high preciseness and conciseness of our
work.

The rest of this paper is organized as follows. Preliminaries are presented in
Section 2. Section 3 provides the learning algorithm. Then a series of experiments
is presented in Section 4. Finally we conclude this work in Section 5.

2 Preliminaries

2.1 Definitions

Let $\Sigma$ be a finite alphabet of symbols. The set of all words over $\Sigma$ is denoted by
$\Sigma^*$. The empty word is denoted by $\varepsilon$.

**Definition 1. Regular Expression with Interleaving.** A regular expression
with interleaving over $\Sigma$ is defined inductively as follows: $\varepsilon$ or $a \in \Sigma$ is a regular
expression, for regular expressions $r_1$ and $r_2$, the disjunction $r_1 \cup r_2$, the conca-
nation $r_1 \cdot r_2$, the interleaving $r_1 \& r_2$, or the Kleene-Star $r_1^*$ is also a regular
expression. $r^2$ and $r^+$ are abbreviations of $r|\varepsilon$ and $r \cdot r^*$, respectively. They are
denoted as $\text{RE}(\Sigma)$.

The size of a regular expression $r$, denoted by $|r|$, is the total number of sym-

bols and operators occurred in $r$. The language $L(r)$ of a regular expression
$r$ is defined as follows: $L(\phi) = \emptyset$; $L(\varepsilon) = \{\varepsilon\}$; $L(a) = \{a\}$; $L(r_1 \cup r_2) = L(r_1) \cup L(r_2)$; $L(r_1 \cdot r_2) = L(r_1) \cdot L(r_2)$; $L(r_1 \& r_2) = L(r_1) \& L(r_2)$. Let $u = au'$ and $v = bv'$ where $a, b \in \Sigma$ and $u', v' \in \Sigma^*$, then $u \& v = \varepsilon \lor u = \{u\}$ and
$u \lor v = a(u' \lor v) \cup b(u \lor v')$. For example, $L(ab\&c) = \{cab, acb, abc\}$.

**Definition 2. Single Occurrence Regular Expressions with Interleaving (SOIRE).** A regular expression with interleaving is SOIRE, in which each symbol occurs at most once.

For instance, $r_1 = a^2(b^3cd^*e(f)^2)$ is an SOIRE, but $r_2 = a^+b\&c^+b$ is not
because $b$ appears twice.

**Definition 3. Single Occurrence Automaton (SOA) [7,17]** Let $\Sigma$ be a fi-
nite alphabet. src and snk are distinct symbols that do not occur in $\Sigma$. A single
occurrence automaton (short: SOA) over $\Sigma$ is a finite directed graph $A = (V, E)$
such that

1. $\text{src}, \text{snk} \in V$, and $V \subseteq \Sigma \cup \{\text{src}, \text{snk}\}$;
2. src has only outgoing edges, snk has only incoming edges and every node
   $v \in V$ lies on a path from src to snk.

For example, the SOA $A$ for $r = a(bc)^3d^+$ is shown in Figure 2. A general-
ized single occurrence automaton (generalized SOA) over $\Sigma$ is defined as
a directed graph in which each node $v \in V \setminus \{\text{src}, \text{snk}\}$ is an SOIRE and all
nodes are pairwise alphabet-disjoint SOIREs.
3 Learning Algorithm

In this section, we give the learning algorithm $i$SOIRE, which efficiently infers an SORE from a set of positive samples $S$. We show the major technical details of our algorithm in this section. The input and output of the algorithm $i$SOIRE is a set of given samples and an SOIRE respectively. The algorithm $i$SOIRE consists of two steps, constructing an SOA from samples, and converting the SOA into an SOIRE. Constructing an SOA from samples is introduced in Section 3.1. Converting the SOA into an SOIRE is given in Section 3.2.

Algorithm 1: $i$SOIRE

<table>
<thead>
<tr>
<th>Input: a set of positive sample $S$</th>
</tr>
</thead>
<tbody>
<tr>
<td>Output: an SOIRE</td>

<tr>
<td>1. Construct SOA $A$ for $S$ using method 2T-INF \cite{20};</td>
</tr>
<tr>
<td>2. return Soa2Soire($S$, $A$)</td>
</tr>
</tbody>
</table>

3.1 Constructing an SOA from Samples

We use method 2T-INF \cite{20} to construct SOA $A$ for $S$. The algorithm 2T-INF \cite{20} used in the algorithm is proved to construct a minimal-inclusion generalization of $S$. Here minimal-inclusion means that there is no other SOA $A$ such that $S \subseteq L(A) \subset L(SOA(S))$.

Here we give an example to show the execution process. Let $S = \{begk, aabengk, abegjj, beg, hk, behgj, behy, bhec, bfcmd, bfdm, afmed, adf\}$. Using method 2T-INF, we construct the graph $SOA(S)$ shown in Figure 3.

3.2 Converting the SOA into an SOIRE

We use dot-notation to denote the application of subroutines. For a given SOA $A$, we let $A.src$ and $A.snk$ denote the source and the sink of $A$, respectively. We let $V$ be the set of vertices and $E$ the set of edges in $A$, respectively.

- For any vertex $v \in V$, we let $A.pred(v)$ denote the set of all predecessors of $v$ in $A$; similarly, $A.succ(v)$ denotes the set of all successors of $v$ in $A$. 

Fig. 2: Example SOA $A$ for $r = a(bc)^*d^+$. 

\begin{figure}[h]
    \centering
    \includegraphics[width=0.3\textwidth]{example_soa.png}
    \caption{Example SOA $A$ for $r = a(bc)^*d^+$.}
\end{figure}
Fig. 3: Constructing SOA $\mathcal{A}$ for $S$.

- For any vertex $v \in V$, we let $\mathcal{A}.\text{reach}(v)$ be the set of all vertices reachable from $v$.
- “first” returns all vertices $v$ such that the only predecessor of $v$ is the source in $\mathcal{A}$.
- “contract” on SOA $\mathcal{A}$ takes a subset $U$ of vertices of $\mathcal{A}$ and a label $\delta$. The procedure modifies $\mathcal{A}$ such that all vertices of $U$ are contracted to a single vertex and labeled $\delta$ (edges are moved accordingly).
- “extract” on SOA $\mathcal{A}$ takes as argument a set of vertices $U$ of $\mathcal{A}$; it does not modify $\mathcal{A}$, but returns a new SOA with copies of all vertices of $U$ as well as two new vertices for source and sink; all edges between vertices of $U$ are copied, all vertices in $U$ having an incoming edge in $\mathcal{A}$ from outside of $U$ have now an incoming edge from the new source, and all vertices in $U$ having an outgoing edge in $\mathcal{A}$ to outside of $U$ have now an outgoing edge to the new sink.
- “addEpsilon” on SOA $\mathcal{A}$ adds a new vertex labeled $\varepsilon$; all outgoing edges from the source to vertices that have more than one predecessor (vertices, that are not in the first-set) are redirected via this new vertex.
- “exclusive” on SOA $\mathcal{A}$ on argument $v$ (a vertex of $\mathcal{A}$) returns the set of all vertices $u$ such that, on any path from the source to the sink that visits $u$, $v$ is necessarily visited previously. Intuitively, the exclusive set of a vertex $v$ is the set of all vertices exclusively reachable from $v$, not from any other vertex incomparable to $v$. 
Furthermore, we use the following eight subroutines or algorithms.

- “plus” on label $\delta$ returns $\delta^+$.
- “or” on labels $\delta$ and $\delta'$ returns $\delta \lor \delta'$.
- “concatenate” on labels $\delta$ and $\delta'$ returns $\delta \cdot \delta'$.
- “filter” on a subset $U$ of vertices and a set of given sample $S$ returns a new subset $S'$. For string $s \in S$ each symbol of which is computed as follows:
  $\pi_s(U, s_i) = s_i$ if $s_i \in U$; $\pi_s(U, s_i) = \epsilon$ otherwise. And the result is reduced by $x\epsilon = \epsilon x = x$. For example, let $U = \{b, c, r\}$ and $S = \{abgr, ebbf\epsilon c\}$, $S' = \text{filter}(U, S) = \{br, bbc\}$.
- “Merge” on a set of positive samples $S$ returns an expression $\zeta$ with interleaving.
- For a set of positive sample $S$, we let $\text{por}(S)$ denote the set of all partial order relations of each string in $S$ and $\text{cs}(S)$ denote the constraint set. The $\text{cs}(S)$ is defined as follows. $\text{cs}(S) = \{(x, y) | (x, y) \in \text{por}(S) \text{ and } (y, x) \in \text{por}(S)\}$.
- “combine” on a subset $U$ of vertices returns a new vertex, which combines all vertices in $U$ with interleaving operator. For example, let $U = \{a^*, b^+\}$, $\text{combine}(U)$ is $a^* \& b^+$.
- “clique-removal” on an undirected graph $G$ returns a maximum independent set (MIS). Finding an MIS of a graph $G$ is a NP-hard problem. Hence we use the method $\text{clique-removal()}$ [12] to find an approximate result.

The algorithm Soa2Soire is given in Algorithm 2. The main procedures are as follows.

1. We first deal with all strongly connected looped components, replace each with a new vertex.
2. After the SOA is a directed acyclic graph (DAG), focus on the set $F$ of all vertices which can be reached from the source directly, but not via other vertices; make sure that there are no vertices which can be reached directly and via other vertices (if necessary, add an auxiliary node labeled $\epsilon$).
3. Recurse on the sets of vertices exclusively reachable from a vertex in $F$ and contract these sets to vertices labeled with the result of the recursion.
4. Combine vertices in $F$ with “or”, recurse again on what is exclusively reachable from this new vertex.
5. Once only one item is left in $F$, split it off and recurse on the remainder.

Note that the algorithm introduces “?” by way of constructing “or $\epsilon$”. This can be cleaned up by postprocessing the resulting SOIRE.

The algorithm Merge is given in Algorithm 3. The main procedures are as follows.

1. The first step (line 1): We first compute the constraint set $\text{constraint}_I$ using the function $\text{cs}(S)$.
2. The second step (line 4): We construct an undirected graph $G$ using element in $\text{constraint}_I$ as edges.
3. The third step (lines 5-8): We select a maximum independent set (MIS) of $G$, add it to list $\text{all\_mis}$ and delete the MIS and their related edges from $G$. The process is repeated until there exists no nodes in $G$. 

Algorithm 2: Soa2Soire

Input: a set of positive sample $S$; an SOA $A = (V,E)$
Output: an SOIRE

1. if $|E| = 0$ then return $\emptyset$;
2. ;
3. else if $|V| = 2$ then return $\epsilon$;
4. ;
5. else if $A$ has a cycle then
6. Let $U$ be a strongly connected component of $A$;
7. if $|U| = 1$ then
8. Let $v$ be the only vertex of $U$;
9. $A$.contract($U$,plus($v$.label()));
10. else $A$.contract($U$.Merge(filter($U$, $S$))); ;
11. else if $A$.succ($A$.src) $\neq A$.first() then
12. $A$.addEpsilon();
13. else if $|A$.first()| = 1 then
14. Let $v$ be the only successor of src;
15. $\delta \leftarrow v$.label();
16. $A$.contract({$A$.src,$v$},src);
17. $\delta' \leftarrow$ Soa2Soire($S$,$A$);
18. return concatenate($\delta$,$\delta'$);
19. else if $\exists v \in A$.first(), $A$.exclusive($v$) $\neq \{v\}$ then
20. Let $v$ be such that $A$.exclusive($v$) $\neq \{v\}$;
21. $U \leftarrow A$.exclusive($v$);
22. $A$.contract($U$,Soa2Soire($S$,$A$.extract($U$)));
23. else
24. Let $u,v \in A$.first() with $u \neq v$ s.t. $A$.reach($u$) $\cap A$.reach($v$) is $\subseteq$-maximal;
25. $A$.contract({$u$,$v$},or($u$.label(),v.label()));
26. return Soa2Soire($S$,$A$);

4. The fourth step (lines 9-13): We get the sample set $S'$ using the function filter($mis$, $S$) for each MIS, and construct SOAs for sample sets by calling the algorithm 2T-INF [20]. Then convert SOAs into SOIREs using algorithm Soa2Soire.
5. The last step (line 14): We call the function combine to generate an expression $\xi$ with interleaving operator.

Following the example in section 3.1 there are four strongly connected components $U_1 = \{a\}$, $U_2 = \{j\}$, $U_3 = \{f,d,m,c\}$ and $U_4 = \{l,g,h,e,n\}$ shown in Figure 4. For strongly connected component (SCC) $U_1 = \{a\}$, because $|U_1| = 1$, we use $A$.contract($U_1$,plus($j$)) to modify $A$ such that vertex $a$ is contracted to a new vertex $a^+$ and the self-loop is removed. Similarly, we use $A$.contract($U_2$,plus($j$)) to modify $A$ such that vertex $j$ is contracted to a new vertex $j^+$ and the self-loop is removed (Figure 5). For SCC $U_3$, because $|U_3| > 1$, so we should call $A$.contract($U_3$.Merge(filter($U_3$, $S$))). In this sub-process, we first compute the
Algorithm 3: Merge

Input: a set of positive sample $S$
Output: an expression $\zeta$

1. $\text{constraint}_\mathcal{L} \leftarrow \text{cs}(S)$;
2. $U \leftarrow \emptyset$;
3. $G \leftarrow \text{Graph}(\text{constraint}_\mathcal{L})$;
4. $\text{all}_\mathcal{mis} \leftarrow \emptyset$;
5. while $|G.| > 0$ do
   6. $W \leftarrow \text{clique-removal}(G)$ [12];
   7. $G \leftarrow G \setminus W$;
   8. $\text{all}_\mathcal{mis}.\text{append}(G)$
   9. foreach $\text{mis} \in \text{all}_\mathcal{mis}$ do
      10. $S' \leftarrow \text{filter}(\text{mis}, S)$
      11. Construct SOA $\mathcal{A}$ for $S'$ using method 2T-INF [20];
      12. $\delta \leftarrow \text{Soa2Soire}(S', \mathcal{A})$
      13. $U.\text{append}(\delta)$
14. return $\zeta \leftarrow \text{combine}(U)$

New sample set $S_1 = \{fmcd, fcmd, df, fdm\}$ using function filter($U_3, S$). Then we get $\text{cs}(S_1) = \{(f, d), (d, f), (m, d), (d, m), (c, m), (c, e)\}$ in the algorithm Merge. Next, we constructing undirected graph $G_1$ based on $\text{cs}(S_1)$ shown in Figure 6. We compute the set of all maximum independent sets ($\text{all}_\mathcal{mis} = \{(f, m), (c, d)\}$) for Figure 6. We construct two SOAs using filter($\{f, m\}, S_1$) and filter($\{c, d\}, S_1$), respectively. They are shown in Figure 7 and Figure 8. We convert two SOAs into $fm^?c?d^?$ and $c?d^?$, respectively. Then we get the new label $\zeta = fm^?c?d^?$ using combine($fm^?c?d^?$). We use $\mathcal{A}.\text{contract}(U_3, \delta)$ to modify $\mathcal{A}$ such that all vertices of $U_3$ are contracted to a single vertex and labeled $\zeta$ (edges are moved accordingly) shown in Figure 9. Similarly, we also call $\mathcal{A}.\text{contract}(U, \text{Merge(filter}(U_4, S)))$. We first compute the new sample set $S_2 = \{egh, eng, eg, elhg, ehg, heg\}$ using filter($U_4, S$). Then we get $\text{cs}(S_2) = \{(g, h), (h, g), (h, e), (e, h)\}$ in the algorithm Merge. Next, we constructing undirected graph $G_2$ based on $\text{cs}(S_2)$ shown in Figure 10. We compute the set of all maximum independent sets ($\{l, g, e, n\}, \{h\}$) for Figure 10. We construct two SOAs using filter($\{l, g, e, n\}, S_2$) and filter($\{h\}, S_2$), respectively. They are shown in Figure 11 and Figure 12. We convert two SOAs into $e(n|l)^\gamma g$ and $h^\gamma$, respectively. Then we get the new label $\delta = e(n|l)^\gamma g \& h^\gamma$ using combine($e(n|l)^\gamma g \& h^\gamma$). We use $\mathcal{A}.\text{contract}(U_4, \delta)$ to modify $\mathcal{A}$ such that all vertices of $U_4$ are contracted to a single vertex and labeled $\delta$ (edges are moved accordingly) shown in Figure 13. Continue to execute the remaining processes of the algorithm $iSOIRE$ and we get the final inferred result $r = a^*b^*(fm^?c?d^?)(e(n|l)^\gamma g \& h^\gamma)(j^?|k)^?$.

4 Experiments

In this section, we conduct a series of experiments to analyze the practicability of SOIRE, and compare algorithm iSOIRE with not only the learning algorithms from ongoing researches but also the industrial-level tools used in real world. In terms of preciseness and conciseness, our work has achieved satisfying results compared with existing methods, reaching higher preciseness with less description length. Specifically, indicators Language Size (|\(L(r)|\)) [5] and datacost (DC) [5] are used to measure preciseness, while Len [30] and Nesting Depth (ND) [31] for conciseness. Similar as the discussion of |\(L(r)|\) and Len above, we have that larger the value of DC (ND) is, more precise (concise) the regular expression will be. Language Size [5], denoted by |\(L(r)|\), is defined as:

\[|L(r)| = \sum_{\ell=1}^{\ell_{max}} |L^{\ell}(r)|,\]

where |\(L^{\ell}(r)|\) is the size of subset containing words with length \(\ell\) in \(L(r)\). Generally, \(L(r)\) is an infinite language with infinitely large value of \(\ell\), it is of course impossible to take all words into account. Hence, we only consider the word length \(\ell\) up to a maximum value: \(\ell_{max} = 2m + 1\) where \(m\) is the length of \(r\) excluding \(\varepsilon\), \(\emptyset\) and regular expression operators. Language Size (|\(L(r)|\)) can well measure the preciseness of a regular expression. Smaller the value of |\(L(r)|\) is, more precise the regular expression will be. datacost (DC) [5], is defined as:

\[\text{datacost}(r, S) = \sum_{\ell=1}^{\ell_{max}} \left( 2 \times \log_2 \ell + \log_2 \left( \frac{|L^{\ell}(r)|}{|S^{\ell}|} \right) \right),\]

where \(\ell_{max} = 2m + 1\) and |\(L^{\ell}(r)|\) as before, |\(S^{\ell}|\) is the number of words in \(S\) that have length \(\ell\). Smaller the value of DC is, more precise the regular expression.
will be. $Len$ \[[30]\] is defined as:

$$Len = n \times \lceil \log_2(|\Sigma| + |\mathcal{M}|) \rceil,$$

where $|\Sigma|$ is the number of distinct symbols occurring in regular expression $r$, $\mathcal{M}$ is the set of metacharacters \{[,\cdot,\&,?,\*,+,(,\})\} and $n$ is the length of $r$ including symbols and metacharacters. An expression with a smaller value of $Len$ is more concise. Nesting Depth (ND) \[[31]\] is defined as:

- $ND(r) = 0$, if $r = \varepsilon$, $\emptyset$ or $a$ for $a \in \Sigma$.
- $ND(r) = ND(r_1) + 1$, if $r = r_1^*$, $r = r_1^?$ or $r = r_1^+$, where $r_1$ is a regular expression over $\Sigma$.
- $ND(r) = \max\{ND(r_1), ND(r_2)\}$, if $r = r_1|r_2$, $r = r_1 \cdot r_2$ or $r = r_1\&r_2$, where $r_1$ and $r_2$ are regular expressions over $\Sigma$.

The learning algorithms compared in experiments are Soa2Sore \[17\] and Soa2Chare \[17\], GenEchare \[16\], learner$^+$DME \[13\], conMiner \[40\], GenICHARE \[32\] and GenESIRE \[32\]. The industrial tools which are capable of supporting inference of XML schemas used in this section include IntelliJ IDEA\[4\], Liquid Studio\[5\], Trang\[6\], and InstanceToSchema\[7\].

For the massive comparative experiments, we conduct the experiments based on two kinds of datasets: small dataset (i.e., mastersthesis) and large dataset (i.e., www) of XML documents, which are both extracted from DBLP. DBLP is a data-centered database of information on major computer science journals and proceedings. We download the file of version dblp-2015-03-02.xml.gz\[8\]. mastersthesis and www are two elements chosen from DBLP with 5 (small) and 2,000,226 (large) samples, respectively.

All of our experiments are conducted on a machine with 16 cores Intel Xeon CPU E5620 @ 2.40GHz with 12M Cache, 24G RAM, OS: Windows 10.

### 4.1 Usage of SOIRE in Practice

Though interleaving is indispensable in data-centric applications, the lack of research on it is still a concern. In Figure 14, we visualized the coverage rates of regular expressions covered by different subclasses on Relax NG. We can see that the initial subclass, DME, only covers 50.62%. Then the proportions show an upward trend, reaching more than 85.55% (ICRE, ICHARE, ESIRE). Compared with their coverage, SOIRE covers 93.24%, which is 5.68% more than the second largest proportion. Therefore, the experimental result reveals the high practicality of SOIRE, and its strong support for interleaving.

4.2 Analysis of Inference Results

To better illustrate the performance of our work, we first compare the inferred results of our work with that of existing learning algorithms and industrial tools in real world. To save space, we use the short names of words and the list of abbreviations is shown in Table 1. The experimental results are shown in Table 2-5.

Table 1: The list of abbreviations for words in DBLP.

We can see from Table 3 that for dataset masterthesis, the first six algorithms/tools (Liquid Studio, Soa2Sore, Soa2Chare, GenEchare, IntelliJ IDEA and Trang) reach high conciseness at enormous cost of $|\mathcal{L}(r)|$, from unaffordable $1.57 \times 10^{10}$ to $1.64 \times 10^{4}$. Algorithms/tools InstanceToSchema, learner$^{*}_{DME}$ and conMiner have highest conciseness, with 52 for Len, yet their preciseness is not the highest among these algorithms. Finally, the last three algorithms including iSOIRE reach the performance at the same level, with highest preciseness and
the equal magnitude of conciseness. From the table we can draw a conclusion that though interleaving could improve the preciseness, the former one sacrifices the conciseness to some degree.

Table 2: Expressions of inference using different learning algorithms/inference tools on mastersthesis.

For the second dataset (Table 5), the advantage of our work is more outstanding. Without supporting the usage of interleaving, the previous eleven algorithms/tools have huge $|\mathcal{L}(r)|$ and DC, from $1.11 \times 10^{21}$ to $4.39 \times 10^{11}$ and from 15158.773 to 8479.873, respectively. Among them, Liquid Studio, Soa2Chare and IntelliJ IDEA have the shortest $Len$, which are 120, while learner_{DME} and ESIRe have the longest, which are 175. Soa2Sore has the deepest ND [31], with 3, followed by Liquid Studio, GenEchare, GenICHARE and GenESIRE, with 2 nestings. On the other hand, the algorithms/tools which support interleaving have smaller values on average. Especially for the indicator $|\mathcal{L}(r)|$, the magnitudes are much smaller than that of the first group of methods. It is noteworthy that our work reaches almost the same conciseness with much less values of $|\mathcal{L}(r)| (1.84 \times 10^{11})$ and DC(7599.996).

It is clear from the above analysis, our work outperforms other state-of-the-art learning algorithms and published tools, achieving the highest preciseness and the equal level of conciseness. Furthermore, through the comparison, the performance of our method indicates that the involvement of interleaving could contribute to both preciseness and conciseness.
Table 3: Results of inference using different learning algorithms/inference tools on masterthesis.

| Method           | |L(r)|| DC   | Len | ND |
|------------------|-----------------|-----------------|-----|-----|-----|

5 Conclusion and Future Work

Based on large-scale real data, we proposed a new subclass SOIRE of regular expressions with interleaving. SOIRE is more powerful than the existing subclasses and has unrestricted support for interleaving. Correspondingly, we design an inference algorithm iSOIRE which can learn SOIREs effectively based on single occurrence automaton (SOA) and maximum independent set (MIS). We conduct a series of experiments, comparing the performance of our algorithm with both ongoing learning algorithms in academia and industrial tools in real-world. The results reveal the practicability of SOIRE and the effectiveness of iSOIRE, showing the high preciseness and conciseness of our work.

We will study another subclass of regular expressions: $k$-occurrence regular expressions with interleaving ($k$-OIREs) in our future work. Its inference algorithm will also be considered.
