A note about scalar curvature on the total space of a vector bundle

Jialong Deng

Abstract

We construct complete Riemannian metrics to show that the total space of tangent bundles of orientable closed surfaces (except torus) admits complete uniformly PSC-metrics. It gives a partial positive answer to one of Gromov’s question.

The scalar curvature of a Riemannian metric on closed manifolds has been deeply studied (see [RS94], [Ros07], [Sch14] and references therein) for the reason of geometry and general relativity. In this paper, we consider the scalar curvature of a Riemannian metric on the total space of tangent bundle of the orientable closed surfaces. It is a classic result that any noncompact Riemannian surface admits complete Riemannian metrics with constant negative scalar curvature. Bland and Kalka [BK89] generalized it to manifolds of any dimension: any noncompact manifold of dimensions at least three admits complete Riemannian metrics with constant negative scalar curvature. In contrast to the negative scalar curvature, it exists obstructions to admit a complete Riemannian metric with positive scalar curvature (PSC-metric) on open manifold. If one does not require completeness, then the curvature will not restrict the topology of open manifold according to Gromov’s Theorem [Gro69].

For instance, closed Riemannian manifolds with nonpositive sectional curvature are enlargeable manifolds. There is a widely open conjecture: for closed manifold $M^n$, $M^n \times \mathbb{R}$ admits no complete PSC-metric. Here $X$ is a closed enlargeable manifold ([GL83], Definition 5.5). For instance, closed Riemannian manifolds with nonpositive sectional curvature are enlargeable manifolds. In contrast to the negative scalar curvature, it exists obstructions to admit a complete Riemannian metric with positive scalar curvature (PSC-metric) on open manifold. If one does not require completeness, then the curvature will not restrict the topology of open manifold according to Gromov’s Theorem [Gro69].

Gromov and Lawson ([GL83], Corollary 6.13) proved that $X \times \mathbb{R}$ carries no complete PSC-metric. Here $X$ is a closed enlargeable manifold ([GL83], Definition 5.5). For instance, closed Riemannian manifolds with nonpositive sectional curvature are enlargeable manifolds. There is a widely open conjecture: for closed manifold $M^n$, $M^n \times \mathbb{R}$ admits a complete PSC-metric if and only if $M^n$ admits PSC-metrics. Gromov and Lawson also showed in [GL83] that hyperbolic manifold times $\mathbb{R}^2$ does not admit complete uniformly PSC-metric. However, if the fiber is the vector space $\mathbb{R}^n (n \geq 3)$, the total space of vector bundles (trivial or nontrivial) will admit complete uniformly PSC-metric, as $\mathbb{R}^n$ admits $O(n)$-invariant complete uniformly PSC-metrics.

Rosenberg and Stolz ([RS94], proposition 7.2) described a proof that $M^n \times \mathbb{R}^2$ admits complete PSC-metrics, where $M^n$ is a closed manifold. Moreover, Gromov proved the following theorem in [Gro18], section 4:

Iso-enlargeable $[\leq \frac{\pi^2}{4}]$-Decay Theorem. Let a manifold $X$ admit a proper map of non-zero degree to $Y \times \mathbb{R}^2$, where $Y$ is a compact iso-enlargeable manifold, then the scalar curvature of all complete Riemannian metric $g$ in $X$ restricted to concentric balls $B(R) = B_{x_0}(R) \subset X$ satisfy

$$\min_{B(R)} \text{Sc}(X) \leq \frac{\pi^2}{4(R - R_0)}$$

for some $R_0 = R_0(X, g, x_0)$ and all $R \geq R_0$.

Riemannian manifolds with non-positive sectional curvature are examples of iso-enlargeable manifolds and the definition of the iso-enlargeable manifold can be found in [Gro18], section 4, p.658. Gromov posted a question in [Gro18], section 6:

Do all products manifold $Y \times \mathbb{R}^2$, and, more generally, the total spaces of all $\mathbb{R}^2$-bundles admit complete metric $g$ with $\text{Sc}(g) \geq 0$, i.e. scalar curvature $\geq 0$? Do, for example, such metrics $g$ exist for compact manifold $Y$ which admit metrics with strictly negative sectional curvature?

Gromov also pointed out in the paper that the best candidates of this kind of manifolds with no complete PSC-metric on them are non-trivial $\mathbb{R}^2$-bundles over surfaces of genus at least 2. However, it may has a positive answer.

Theorem (Rosenberg-Stolz). If $Y$ is a smooth manifold without boundary (compact or non-compact), then $Y \times \mathbb{R}^2$ admits complete PSC-metrics.

Remark 1. Though Rosenberg and Stolz ([RS94], proposition 7.2, p.263) only deal with the case of closed manifold times $\mathbb{R}^2$, their argument can be used to here. Since the open manifold can be endowed with a complete Riemannian metric with constant negative scalar curvature by the theorem of Bland and Kalka [BK89]. Thus the theorem is attributed to Rosenberg and Stolz.
Theorem. The total space of tangent bundle of orientable closed surface (except torus) admits complete uniformly PSC-metrics.

Proof. The total space of tangent bundle of $S^2$ admits complete metrics of positive Ricci curvature and the Cheeger-Gromoll metric on it is a complete uniformly PSC-metric [GK90, Theorem 1.1, property 3.3]. The trivialization of the tangent bundle $T^2$ makes it carry no complete uniformly PSC-metric as $T^2$ is enlargeable [GLS93, Theorem 7.3]. But it admits complete PSC-metrics.

Let $\Sigma$ be the orientable surface with genus at least 2 which is endowed a hyperbolic metric $g$. Then the Levi-Civita connection $\nabla$ on $\Sigma$ induces a natural splitting of the tangent space $T_{(p, U)} \Sigma$ into

$$T_{(p, U)} \Sigma = V_{(p, U)} \Sigma \oplus H_{(p, U)} \Sigma$$

Where $(p, U) \in T \Sigma$, $V_{(p, U)} \Sigma$ is the vertical space, i.e. $\text{Ker} \pi_{(p, U)}$, $\pi : T \Sigma \to \Sigma$ and $H_{(p, U)} \Sigma$ is the horizontal space at $(p, U)$ obtained by using $\nabla$. A horizontal curve in $T \Sigma$ corresponds to a vector field on $\Sigma$ which is parallel with respect to connection $\nabla$ on $(\Sigma, g)$. A vector on $T \Sigma$ is horizontal if it is tangent to a horizontal curve and vertical if it is tangent to a fiber. There exists the horizontal (resp. vertical) distribution $HT \Sigma$ (resp.$VT \Sigma$) and the direct sum decomposition: $T \Sigma = HT \Sigma \oplus VT \Sigma$. This rises to the horizontal and vertical lifts $X^h$, $X^v$ of a vector field $X$ on $\Sigma$. The metric $g^{a,b}$ on $T \Sigma$ is constructed by:

$$\begin{cases} g^{a,b}_{(p, U)}(X^h, Y^h) = g_p(X, Y), & g^{a,b}_{(p, U)}(X^h, Y^v) = 0 \\ g^{a,b}_{(p, U)}(X^v, Y^v) = 0.01g_p(X, Y) + [1 + \frac{1}{2}g_p(U, U)]g_p(X, U)g_p(Y, U) \end{cases}$$

The metric induced by $100 \times g^{a,b}$ is no less than the metric induced by Cheeger-Gromoll metric [CG72] which is complete. Thus, it implies the completeness of $g^{a,b}$. Let $t = \frac{1}{2}g_p(U, U)$, then the metric $g^{a,b}$ is a special example of the general metric on $T \Sigma$:

$$\begin{cases} \tilde{g}^{a,b}_{(p, U)}(X^h, Y^h) = g_p(X, Y), & \tilde{g}^{a,b}_{(p, U)}(X^h, Y^v) = 0 \\ \tilde{g}^{a,b}_{(p, U)}(X^v, Y^v) = a(t)g_p(X, Y) + b(t)g_p(U, U)g_p(Y, U) \end{cases}$$

The general metric was firstly defined in [Ana99] and Munteanu computed its scalar curvature [Mun08, Corollary 2.16]: Let $(M^n, g)$ be a space form, then

$$Sc(g) = (n-1) \left\{ nC + t[2-3a(t)]C^2 - \frac{nF_2 + 4tF_3}{a(t)} \right\}$$

where $n$ is the dimension of $M$, $C$ is the constant of sectional curvature of $(M^n, g)$,

$$F_2 = L - M(1 + 2tL), \quad F_3 = N - (M' + M^2 + 2tMN)$$

$$L = \frac{a'(t)}{2a(t)}, \quad M = \frac{2b(t) - a'(t)}{2[a(t) + 2b(t)]}, \quad N = \frac{a(t)b(t) - 2a'(t)b(t)}{2a(t)[a(t) + 2b(t)]}.$$  

In putting the data $n = 2$, $C = -1$, $a = 0.01$, $b = 1 + t$ to the formulas, one gets

$$L = 0, \quad M = \frac{1 + t}{0.01 + 2t(1 + t)}, \quad N = \frac{1}{2[0.01 + 2t(1 + t)]}, \quad M' = \frac{0.01 - 2(1 + t)^2}{2(0.01 + 2t(1 + t))^2}, \quad F_2 = \frac{-1(1 + t)}{0.01 + 2t(1 + t)}, \quad F_3 = \frac{(1 + t)^2 - 0.005}{2(0.01 + 2t(1 + t))^2}.$$  

Then the scalar curvature of $g^{a,b}$ at $(p, U)$ is

$$Sc(g^{a,b})(p, U) = -2 + 1.97t + \frac{2 + 4t}{0.01 + 2t(1 + t)^2}$$

$$= 7.88t^5 + 7.76t^4 - 8.0412t^3 - 8.0012t^2 + 3.920197t + 1.9998$$

Since $g(t) > 1$ for $t \geq 0$ and $g(t)$ increases faster than $h(t)$ when $t$ goes to positive infinity, $Sc(g^{a,b})(p, U) \geq C_1 > 0$ for all $(p, U) \in T \Sigma$. Thus, $g^{a,b}$ is a complete uniformly PSC-metric. ∎
