Modified golden ratio algorithms for solving equilibrium problems

Dang Van Hieu · Jean Jacques Strodiot · Le Dung Muu

Abstract In this paper an explicit algorithm is proposed for solving an equilibrium problem whose associated bifunction is pseudomonotone and satisfies a Lipschitz-type condition. Contrary to many algorithms, our algorithm is done without using explicitly the Lipschitz constants of bifunction although its convergence is obtained under such that condition. The introduced method is a form of proximal-like method whose steplengths are explicitly generated at each iteration without using any linesearch procedure. First we prove the convergence of the algorithm, and after we establish its $R$-linear rate of convergence under the assumption of strong pseudomonotonicity of the bifunction. Afterwards several numerical results are displayed to illustrate and to compare the behavior of the new algorithm with other ones.

1 Introduction

This paper concerns an iterative method for approximating a solution of an equilibrium problem (shortly, EP) in the sense of Blum, Muu and Oettli in [6, 20, 21]. This problem is also called the Ky Fan inequality [16] due to his early contribution in this field. Problem (EP) can be considered a general mathematical model because it unifies in a simple form numerous models as optimization problems, variational inequalities, fixed point problems and many...
This can be the reason why in recent years problem (EP) has received a lot of attention by some authors both theoretically and algorithmically. The most well-known algorithms for solving problem (EP) are the proximal point method [19, 13], the proximal-like method (extragradient method) [9, 23], the descent method [4, 15], the linesearch extragradient method [23], the projected subgradient method [25], the golden ratio algorithm [27] and others [1, 3, 9, 10, 11, 12, 17, 26].

The proximal point method is based on the so-called resolvent of bifunction. At each iteration, this method consists in solving a regularized equilibrium subproblem depending on a parameter. The solutions of these subproblems can converge finitely or asymptotically to some solution of the original problem. In this paper, we are interested in another well-known kind of methods using optimization subprograms. It is the extragradient method as developed in [9, 10, 23], where two optimization programs are solved at each iteration. This can be expensive in the cases where the bifunction and/or the feasible set have complicated structures. Very recently, a nice and elegant algorithm, named the golden ratio algorithm, has been proposed by Malitsky [18] for solving (pseudo) monotone variational inequalities in finite dimensional spaces. Unlike extragradient-like algorithms, the golden ratio algorithm [18] only requires to compute one projection on feasible set and one value of operator at the current approximation. This algorithm is done in both cases with and without previously knowing the Lipschitz constant of operator.

Recently, motivated by the results of Malitsky [18], Vinh has introduced an algorithm which only uses one optimization program per iteration to construct solution approximations for problem (EP), see [27, Algorithm 3.1] for more details. At this stage, it is emphasized that the algorithms in [9, 10, 23, 27] are applied to pseudomonotone (EP) under a Lipschitz-type condition, and that these algorithms explicitly use a stepsize depending on the Lipschitz-type constants of the bifunction. In particular, this means that the Lipschitz-type constants must be the input parameters of the algorithms although these constants are often unknown or difficult to estimate. In his paper Vinh has presented another algorithm [27, Algorithm 4.1] where the Lipschitz-type constants associated with the bifunction are not supposed to be a priori known. The stepsizes are defined explicitly at each iteration in such a way that their sequence is decreasing and not summable. Under these new rules, Vinh has established the strong convergence of the iterative sequence generated by his algorithm without its rate of convergence.

In this paper, motivated and inspired by the aforementioned results, we introduce an iterative algorithm for solving an equilibrium problem involving a pseudomonotone and Lipschitz-type bifunction in a finite dimensional space. The algorithm is explicit in the sense that it is done without previously knowing the Lipschitz-type constants. The algorithm uses variable stepsizes which are generated at each iteration and are based on some previous iterates. No linesearch procedure is required and the convergence of the resulting algorithm is obtained under the assumption of pseudomonotonicity of the bifunction. These results improve the ones obtained by Vinh in [27]. Furthermore, in the case when the bifunction is strongly pseudomonotone, we can establish the \(R\)-linear rate of convergence of the algorithm. Numerical results are reported to demonstrate the behavior of the new algorithm and also to compare it with some other algorithms.

The remainder of this paper is organized as follows: In Sect. 2, we collect some definitions and preliminary results used in the paper. Sect. 3 deals with the description of the new algo-
rithm and its convergence. Finally, in Sect. 4 several numerical experiments are reported to illustrate the behavior of the new algorithm.

2 Preliminaries

Let $C$ be a nonempty closed convex subset in $\mathbb{R}^n$ and $f : C \times C \to \mathbb{R}$ be a bifunction with $f(x, x) = 0$ for all $x \in C$. The equilibrium problem (shortly, EP) for the bifunction $f$ on $C$ can be stated as follows:

$$\text{Find } x^* \in C \text{ such that } f(x^*, y) \geq 0 \text{ for all } y \in C.$$  \hfill (EP)

For solving this problem, we need to recall some concepts of monotonicity of a bifunction, see [1,2,1] for more details. A bifunction $f : C \times C \to \mathbb{R}$ is said to be:

(a) **strongly monotone** on $C$ if there exists a constant $\gamma > 0$ such that

$$f(x, y) + f(y, x) \leq -\gamma \|x - y\|^2 \text{ for all } x, y \in C;$$

(b) **monotone** on $C$ if

$$f(x, y) + f(y, x) \leq 0 \text{ for all } x, y \in C;$$

(c) **pseudomonotone** on $C$ if

$$f(x, y) \geq 0 \implies f(y, x) \leq 0 \text{ for all } x, y \in C;$$

(d) **strongly pseudomonotone** on $C$ if there exists a constant $\gamma > 0$ such that

$$f(x, y) \geq 0 \implies f(y, x) \leq -\gamma \|x - y\|^2 \text{ for all } x, y \in C.$$

From the above definitions, it is easy to see that the following implications hold:

$$(a) \implies (b) \implies (c) \text{ and } (a) \implies (d) \implies (c).$$

We say that the bifunction $f$ satisfies a Lipschitz-type condition if there exist $c_1 > 0, c_2 > 0$ such that

$$f(x, y) + f(y, z) \geq f(x, z) - c_1 \|x - y\|^2 - c_2 \|y - z\|^2 \text{ for all } x, y, z \in C.$$

Let $g : C \to \mathbb{R}$ be a proper, lower semicontinuous, convex function and let $\lambda > 0$. The proximal operator $\text{prox}_{\lambda g}$ associated with $g$ and $\lambda > 0$ is defined by

$$\text{prox}_{\lambda g}(z) = \arg \min \left\{ \lambda g(x) + \frac{1}{2} \|x - z\|^2 : x \in C \right\}, \quad z \in \mathbb{R}^n.$$

The following lemma gives an important property of the proximal mapping (see [1] for more details)

**Lemma 2.1** Let $z \in \mathbb{R}^n$. Then $\bar{x} = \text{prox}_{\lambda g}(z) \iff (\bar{x} - z, x - \bar{x}) \geq \lambda (g(\bar{x}) - g(x))$, $\forall x \in C$.

**Remark 2.1** From Lemma 2.1 it is easy to show that if $x = \text{prox}_{\lambda g}(x)$ then

$$x \in \arg \min \left\{ g(y) : y \in C \right\} = \left\{ x \in C : g(x) = \min_{y \in C} g(y) \right\}.$$ 

The next result is also valid in any Hilbert space, see, e.g., in [1] Corollary 2.14.

**Lemma 2.2** For all $x, y \in \mathbb{R}^n$ and $\alpha \in \mathbb{R}$, the following equality always holds

$$\|\alpha x + (1 - \alpha) y\|^2 = \alpha \|x\|^2 + (1 - \alpha) \|y\|^2 - \alpha(1 - \alpha) \|x - y\|^2.$$
3 Explicit Golden Ratio Algorithm

In this section, we introduce an explicit golden ratio algorithm (EGRA) for solving the pseudomonotone equilibrium problem (EP) under a Lipschitz-type condition. Although, for the convergence of the algorithm, we assume that the bifunction \( f \) satisfies Lipschitz-type condition, but the prior knowledge or even an estimate of Lipschitz-type constants is not necessary to be required. This is particularly interesting when these constants are unknown or difficult to approximate.

For displaying the new algorithm and for the sake of simplicity, we use the notation \( [t]_+ = \max \{0, t\} \) and adopt the convention \( \bar{0} = +\infty \). Now our algorithm can be displayed in details as follows:

\[
\text{Algorithm 3.1 (EGRA for Equilibrium Problem).}
\]

\textbf{Initialization:} Set \( \phi = \frac{1}{2}(\sqrt{5} + 1) \). Choose \( \bar{x}_{-1} \in \mathbb{R}^m, x_0 \in C, \lambda_0 > 0 \) and \( \mu \in (0, \frac{1}{2}\phi) \).

\textbf{Iterative Steps:} Assume that \( \bar{x}_{n-1} \in \mathbb{R}^m, x_{n-1}, x_n \in C \) and \( \lambda_n \) are known and calculate \( x_{n+1} \) and \( \lambda_{n+1} \) as follows:

\[
\begin{aligned}
\bar{x}_n &= \frac{(\phi - 1)x_{n-1} + x_{n-1}}{\phi}, \\
\lambda_{n+1} &= \text{prox}_{\lambda_n f}(\bar{x}_n), \\
\lambda_{n+1} &= \min \left\{ \lambda_n, \frac{\mu((\|x_{n-1} - x_n\|^2 + \|x_{n-1} - x_{n+1}\|^2))}{f(\bar{x}_{n-1}, x_{n+1}) - f(\bar{x}_{n-1}, x_{n}) - f(x_n, x_{n+1})} \right\}.
\end{aligned}
\]

\textbf{Remark 3.2} For Algorithm [3.1] we can use the following stopping criterion:

if \( x_{n+1} = x_n = \bar{x}_n \) then stop: the iterate \( x_n \) is a solution of problem (EP).

In fact, this criterion comes from the definition of \( x_{n+1} \) and from the Remark [2.1].

\textbf{Remark 3.3} Contrary to the algorithm in [27, Algorithm 3.1] Algorithm 3.1 does not require to know the values (even, the estimates) of the two Lipschitz-type constants associated to \( f \) and is also without any linesearch procedure. The sequence of the stepsizes \( \lambda_n \) can be suitably updated at each iteration by some cheap computations.

As Remark [3.4] below, the sequence of stepsizes \( \{\lambda_n\} \) generated by Algorithm [3.1] is separated from 0. Then, our algorithm can be more attractive than an algorithm with diminishing stepsizes or with a linesearch procedure which requires many computations over iteration with some stopping criterion, and of course this is time-consuming.

3.1 The convergence of EGRA

In this part, we establish the convergence of algorithm EGRA. For that purpose, we consider the following standard assumptions imposed on the bifunction \( f \):

- (A1) \( f(x, x) = 0 \) for all \( x \in C \) and \( f \) is pseudomonotone on \( C \);
- (A2) \( f \) satisfies the Lipschitz-type condition on \( C \);
- (A3) \( f(., y) \) is upper semicontinuous for each \( y \in C \);
- (A4) \( f(x, .) \) is convex and subdifferentiable on \( C \) for each \( x \in C \).
Remark 3.4 Let $n$ be fixed. Since $f$ satisfies the Lipschitz-type condition, we obtain for all $n$
\[
    f(x_{n-1}, x_{n+1}) - f(x_{n-1}, x_n) - f(x_n, x_{n+1}) \leq c_1\|x_n - x_{n+1}\|^2 + c_2\|x_n - x_{n+1}\|^2
    \leq \max \{c_1, c_2\} \left[\|x_{n-1} - x_n\|^2 + \|x_n - x_{n+1}\|^2\right].
\]
Hence, when $f(x_{n-1}, x_{n+1}) - f(x_{n-1}, x_n) - f(x_n, x_{n+1}) > 0$, we can deduce that
\[
    \min \left\{\lambda_n, \frac{\mu}{2 \max \{c_1, c_2\}}\right\} \leq \lambda_{n+1} \leq \lambda_n.
\]
Since, by convention, $\lambda_{n+1} = \bar{\lambda}$ when $f(x_{n-1}, x_{n+1}) - f(x_{n-1}, x_n) - f(x_n, x_{n+1}) \leq 0$, we obtain that the sequence $\{\lambda_n\}$ is nonincreasing and bounded below by $\min \left\{\lambda_0, \frac{\mu}{2 \max \{c_1, c_2\}}\right\}$. Hence $\lambda_n \to \bar{\lambda} > 0$.

Remark 3.5 A characteristic of the constant $\varphi = \frac{1}{2} (\sqrt{5} + 1)$ in Algorithm 3.1 is that
\[
    1 + \frac{1}{\varphi} = \varphi \quad \text{or} \quad \varphi^2 - \varphi - 1 = 0.
\]

This is technically used in our analysis.

We have the following convergence result.

Theorem 3.1 Under assumptions (A1)-(A4), the sequence $\{x_n\}$ generated by Algorithm 3.1 converges to some solution of problem (EP).

Proof Lemma 2.1 and the definition of $x_{n+1}$ ensure that
\[
    \langle x_{n+1} - x_n, x - x_{n+1} \rangle \leq \lambda_n (f(x_{n+1}, x) - f(x_n, x_{n+1})), \quad \forall x \in C
\]
which, by multiplying both sides by 2, follows that
\[
    2 \langle x_{n+1} - x_n, x - x_{n+1} \rangle \leq 2 \lambda_n (f(x_n, x) - f(x_n, x_{n+1})).
\]
Using the equality $2 \langle a, b \rangle = \|a\|^2 + \|b\|^2 - \|a - b\|^2$ for $a = x_{n+1} - x_n$ and $b = x - x_{n+1}$, we obtain from the relation (2) that
\[
    \|x_n - x_{n+1}\|^2 + \|x_{n+1} - x\|^2 - \|x_n - x\|^2 \leq 2 \lambda_n (f(x_n, x) - f(x_n, x_{n+1})), \quad \forall x \in C.
\]
Similarly, it follows from relation (1) with $n := n - 1$ that
\[
    \langle x_{n+1} - x_n, x - x_{n+1} \rangle \leq \lambda_{n-1} (f(x_n - 1, x) - f(x_n, x_n)), \quad \forall x \in C,
\]
and, with $x = x_{n+1}$, that
\[
    \langle x_{n+1} - x_n, x_{n+1} - x_n \rangle \leq \lambda_{n-1} (f(x_{n+1}, x_{n+1}) - f(x_{n+1}, x_n)).
\]
Since, by definition of $x_n$, we have $x_{n+1} - x_n = \varphi (x_{n+1} - x_n)$, relation (5) implies that
\[
    \varphi \langle x_{n+1} - x_n, x_{n+1} - x_n \rangle \leq \lambda_{n-1} (f(x_{n+1}, x_{n+1}) - f(x_{n+1}, x_n))
\]
Now, multiplying both sides of the last inequality by $\frac{\lambda_n}{\lambda_{n-1}} > 0$, we obtain
\[
    \frac{\varphi \lambda_n}{\lambda_{n-1}} 2 \langle x_{n+1} - x_n, x_{n+1} - x_n \rangle \leq 2 \lambda_{n-1} (f(x_{n+1}, x_{n+1}) - f(x_{n+1}, x_n)).
\]
Thus, from relation (6) and the equality
\[ 2 \langle \bar{x}_n - x_n, x_{n+1} - x_n \rangle = \| x_n - x_n \|^2 + \| x_{n+1} - x_n \|^2 - \| x_{n+1} - \bar{x}_n \|^2, \]
we deduce the following inequality,
\[
\frac{\varphi \lambda_n}{\lambda_{n-1}} \left[ \| x_n - x_n \|^2 + \| x_{n+1} - x_n \|^2 - \| x_{n+1} - \bar{x}_n \|^2 \right] \leq 2 \lambda_n \left( f(x_{n-1}, x_{n+1}) - f(x_{n-1}, x_n) \right). 
\]

(7)

Summing up both sides of relations (3) and (7) and using the definition of \( \lambda_{n+1} \), we obtain
\[
\| x_{n+1} - x \|^2 - \| \bar{x}_n - x \|^2 + (1 - \frac{\varphi \lambda_n}{\lambda_{n-1}}) \| x_{n+1} - \bar{x}_n \|^2 + \frac{\varphi \lambda_n}{\lambda_{n-1}} \| x_n - x_n \|^2 + \frac{\varphi \lambda_n}{\lambda_{n-1}} \| x_{n+1} - x_n \|^2
\leq 2 \lambda_n f(x_n, x) - 2 \lambda_n \left[ f(x_{n-1}, x_n) + f(x_n, x_{n+1}) - f(x_{n-1}, x_{n+1}) \right]
\leq 2 \lambda_n f(x_n, x) + \frac{\mu \lambda_n}{\lambda_{n-1}} \| x_{n-1} - x_n \|^2 + \| x_n - x_{n+1} \|^2,
\]
which can be rewritten as
\[
\| x_{n+1} - x \|^2 - \| \bar{x}_n - x \|^2 + (1 - \frac{\varphi \lambda_n}{\lambda_{n-1}}) \| x_{n+1} - \bar{x}_n \|^2 + \frac{\varphi \lambda_n}{\lambda_{n-1}} \| x_n - x_n \|^2
+ \left( \frac{\varphi \lambda_n}{\lambda_{n-1}} \frac{\mu \lambda_n}{\lambda_{n-1}} \| x_{n+1} - x_n \|^2 \right)
\leq 2 \lambda_n f(x_n, x) + \frac{\mu \lambda_n}{\lambda_{n-1}} \| x_{n-1} - x_n \|^2, \quad \forall x \in C.
\]

(9)

Thus
\[
\| x_{n+1} - x \|^2 + \left( \frac{\varphi \lambda_n}{\lambda_{n-1}} - \frac{\mu \lambda_n}{\lambda_{n-1}} \right) \| x_{n+1} - x_n \|^2 \leq \| \bar{x}_n - x \|^2 + \frac{\lambda_n}{\lambda_{n+1}} \| x_{n+1} - x_n \|^2
- (1 - \frac{\varphi \lambda_n}{\lambda_{n-1}}) \| x_{n+1} - \bar{x}_n \|^2 - \frac{\varphi \lambda_n}{\lambda_{n-1}} \| x_n - x_n \|^2 + 2 \lambda_n f(x_n, x).
\]

(10)

Since \( \bar{x}_{n+1} = \frac{(\phi - 1)x_{n+1} + x_n}{\phi} \), we obtain immediately that
\[
x_{n+1} = \frac{\varphi}{\varphi - 1} \bar{x}_{n+1} - \frac{1}{\varphi - 1} \bar{x}_n = (1 + \frac{1}{\varphi - 1}) \bar{x}_{n+1} - \frac{1}{\varphi - 1} \bar{x}_n.
\]

Applying Lemma (2,2) we come to the following equality,
\[
\| x_{n+1} - x \|^2 = \frac{\varphi}{\varphi - 1} \| \bar{x}_{n+1} - x \|^2 - \frac{1}{\varphi - 1} \| \bar{x}_n - x \|^2 + \frac{\varphi}{(\varphi - 1)^2} \| \bar{x}_{n+1} - \bar{x}_n \|^2
= \frac{\varphi}{\varphi - 1} \| \bar{x}_{n+1} - x \|^2 - \frac{1}{\varphi - 1} \| \bar{x}_n - x \|^2 + \frac{1}{\varphi} \| x_{n+1} - \bar{x}_n \|^2,
\]

(11)

where the last equality follows from the fact
\[
\| \bar{x}_{n+1} - \bar{x}_n \|^2 = \left\| \frac{\varphi - 1}{\varphi} x_{n+1} + \frac{\varphi}{\varphi - 1} x_n - \bar{x}_n \right\|^2 = \frac{(\varphi - 1)^2}{\varphi^2} \| x_{n+1} - \bar{x}_n \|^2.
\]

Combining relations (10) and (11), we obtain
\[
\frac{\varphi}{\varphi - 1} \| \bar{x}_{n+1} - x \|^2 + \left( \frac{\varphi \lambda_n}{\lambda_{n-1}} - \frac{\mu \lambda_n}{\lambda_{n+1}} \right) \| x_{n+1} - x_n \|^2 \leq \frac{\varphi}{\varphi - 1} \| \bar{x}_n - x \|^2 + \frac{\lambda_n}{\lambda_{n-1}} \| x_{n+1} - x_n \|^2
- (1 + \frac{1}{\varphi - 1}) \| x_{n+1} - \bar{x}_n \|^2 - \frac{\varphi \lambda_n}{\lambda_{n-1}} \| \bar{x}_n - x_n \|^2 + 2 \lambda_n f(x_n, x), \quad \forall x \in C.
\]

(12)
Note that \( \{ \lambda_n \} \) is non-increasing, i.e., \( \lambda_n \leq \lambda_{n-1} \) for all \( n \geq 1 \). Then
\[
1 + \frac{1}{\phi} \frac{\phi \lambda_n}{\lambda_{n-1}} \geq 1 + \frac{1}{\phi} \frac{\phi \lambda_{n-1}}{\lambda_{n-1}} = 1 + \frac{1}{\phi} - \phi = 0, \quad \forall n \geq 1. \quad (13)
\]
Moreover, since \( \lambda_n \to \lambda > 0 \) and \( 0 < \mu < \frac{1}{2} \phi \), we obtain
\[
\lim_{n \to \infty} \left( \frac{\phi \lambda_n}{\lambda_{n-1}} - \frac{\mu \lambda_n}{\lambda_{n+1}} - \frac{\mu \lambda_{n+1}}{\lambda_{n+2}} \right) = \phi - 2 \mu > 0.
\]
Hence, there exists \( n_0 \geq 1 \) such that
\[
\frac{\phi \lambda_n}{\lambda_{n-1}} - \frac{\mu \lambda_n}{\lambda_{n+1}} - \frac{\mu \lambda_{n+1}}{\lambda_{n+2}} > 0, \quad \forall n \geq n_0
\]
i.e.,
\[
\frac{\phi \lambda_n}{\lambda_{n-1}} > \frac{\mu \lambda_{n+1}}{\lambda_{n+2}}, \quad \forall n \geq n_0. \quad (14)
\]
Combining the relations (12), (13), we obtain for all \( x \in C \) and \( n \geq n_0 \) that
\[
\frac{\phi}{\phi - 1} ||x_{n+1} - x||^2 + \frac{\mu \lambda_{n+1}}{\lambda_{n+2}} ||x_n - x_{n+1}||^2 \leq \frac{\phi}{\phi - 1} ||x_n - x||^2 + \frac{\mu \lambda_n}{\lambda_{n+1}} ||x_{n-1} - x_n||^2
\]
\[
- \frac{\phi \lambda_n}{\lambda_{n-1}} ||x_n - x||^2 + 2 \lambda_n f(x_n, x).
\]
Note that for each \( x^* \in EP(f, C) \), we have that \( f(x^*, x_n) \geq 0 \) because \( x_n \in C \). Hence, from the pseudomonotonicity of \( f \), we derive \( f(x_n, x^*) \leq 0 \). Now, using relation (15) for \( x = x^* \in C \) and setting
\[
a_n = \frac{\phi}{\phi - 1} ||x_n - x^*||^2 + \frac{\mu \lambda_n}{\lambda_{n+1}} ||x_{n-1} - x_n||^2,
\]
\[b_n = \frac{\phi \lambda_n}{\lambda_{n-1}} ||x_n - x||^2,
\]
we deduce that
\[
a_{n+1} \leq a_n - b_n, \quad \forall n \geq n_0. \quad (16)
\]
Thus, the limit of \( \{ a_n \} \) exists and \( \lim b_n = 0 \). Hence, the sequences \( \{ x_n \} \) and \( \{ \bar{x}_n \} \) are bounded. Moreover, from the definition of \( b_n \) and \( \lambda_n \to \lambda > 0 \), we obtain
\[
\lim_{n \to \infty} ||x_n - x||^2 = 0. \quad (17)
\]
Consequently, since \( \bar{x}_{n-1} - x_n = \phi(\bar{x}_n - x_n) \), we get
\[
\lim_{n \to \infty} ||\bar{x}_{n-1} - x_n||^2 = 0. \quad (18)
\]
From the relations (17) and (18), we have
\[
\lim_{n \to \infty} ||\bar{x}_n - \bar{x}_{n-1}||^2 = 0. \quad (19)
\]
Also, from (18), we have that \( ||\bar{x}_n - x_{n+1}||^2 \to 0 \) which together with (17) implies that
\[
\lim_{n \to \infty} ||x_{n+1} - x_n||^2 = 0. \quad (20)
\]
Now, assume that $p$ is a cluster point of the sequence $\{x_n\}$, i.e., there exists a subsequence of $\{x_n\}$, denoted by $\{x_n\}$, which converges to $p$. We will prove that $p \in EP(f, C)$. Indeed, it follows from relation (15) that

$$f(x_n, x) \geq \frac{\varphi}{2\lambda_n(\varphi - 1)} \left( ||x_{n+1} - x||^2 - ||x_n - x||^2 \right) - \frac{\mu}{2\lambda_{n+1}} ||x_n - x||^2 + \frac{\mu\lambda_{n+1}}{2\lambda_n\lambda_{n+2}} ||x_n - x_{n+1}||^2. \quad (21)$$

Passing to the limit in the last inequality as $n = m \to \infty$ and using the upper semicontinuity of $f(., x)$, the relation (20), and the limit $\lambda_n \to \lambda$, we obtain

$$f(p, x) \geq \limsup_{m \to \infty} f(x_m, x) \geq \frac{\varphi}{2\lambda_n(\varphi - 1)} \lim_{m \to \infty} \left( ||\bar{x}_{m+1} - x||^2 - ||\bar{x}_m - x||^2 \right), \quad \forall x \in C. \quad (22)$$

Note that from the relations (17) and (19), we also obtain that $\bar{x}_m, \bar{x}_{m+1} \to p$ as $m \to \infty$. Thus

$$\lim_{m \to \infty} ||\bar{x}_m - x||^2 - ||\bar{x}_{m+1} - x||^2 = 0, \quad \forall x \in C. \quad (23)$$

Combining the relations (22) and (23), we get $f(p, x) \geq 0$ for all $x \in C$. Thus $p \in EP(f, C)$. To finish the proof, we prove that the whole sequence $\{x_n\}$ converges to $p$ as $n \to \infty$. Indeed, assume that $\{x_l\}$ is another subsequence of $\{x_n\}$ converging to $\bar{p} \neq p$. As mentioned above, we have that $\bar{p} \in EP(f, C)$. The fact $\lim a_n \in \mathbb{R}$ and the relation (20) ensure that $\lim ||\bar{x}_n - x^*||^2 \in \mathbb{R}$, and thus $\lim ||x_n - x^*||^2 \in \mathbb{R}$ for each $x^* \in EP(f, C)$. On the other hand, we have

$$2 \langle x_n - p, \bar{p} \rangle = ||x_n - \bar{p}||^2 - ||x_n - p||^2 + ||p||^2 - ||\bar{p}||^2.$$

Thus, since $\lim ||x_n - p||^2 \in \mathbb{R}$ and $\lim ||x_n - \bar{p}||^2 \in \mathbb{R}$, we obtain that $\lim \langle x_n, p - \bar{p} \rangle \in \mathbb{R}$. Setting

$$\lim_{n \to \infty} \langle x_n, p - \bar{p} \rangle = M \quad (24)$$

and passing to the limit in (24) as $n = k, l \to \infty$, we obtain

$$\langle p, p - \bar{p} \rangle = \lim_{k \to \infty} \langle x_k, p - \bar{p} \rangle = M = \lim_{l \to \infty} \langle x_l, p - \bar{p} \rangle = \langle \bar{p}, p - \bar{p} \rangle.$$

Thus, $||p - \bar{p}||^2 = 0$ and $\bar{p} = p$. This completes the proof.

Remark 3.6 The obtained result in Theorem 3.1 can be extended to an infinite dimensional Hilbert space $H$. In that case, hypothesis (A3) is replaced by the sequentially weakly upper semicontinuity of $f(., x)$ on $C$ for each $y \in C$, and the sequence $\{x_n\}$ generated by Algorithm 3.1 converges weakly to some solution of problem (EP).

3.2 The convergence rate of the Explicit Golden Ratio Algorithm

In this subsection, we study the convergence rate of algorithm EGRA under the assumption that the bifunction $f$ is strongly pseudomonotone (SP) and satisfies the Lipschitz-type condition (LC). Recently, Vinh has proposed in [27] Algorithm 4.1 a strongly convergent algorithm for solving problem (EP) in a Hilbert space under the conditions (SP) and (LC). His algorithm uses a decreasing and non-summable sequence of stepsizes. However, it is easy to see that such an algorithm cannot linearly converge. Contrary to [27], our algorithm
Proof Using the relation \((12)\) with \(\lambda_n\) to establish the \(R\)-linear rate of convergence (at least) of Algorithm 3.1. Furthermore, in addition to the assumptions (SP) and (LC), we will also impose that for each \(y \in C\), the function \(f(\cdot, y)\) is convex, lower semicontinuous and for each \(x \in C\), the function \(f(x, \cdot)\) is hemi-continuous on \(C\). Under these assumptions, problem (EP) has a unique solution denoted by \(x^*\) (see, e.g., [22, Proposition 1]).

Let us recall two fundamental concepts of convergence rate in [24, Chapter 9]. A sequence \(\{x_n\}\) in \(H\) converges in norm to \(x^* \in H\). We say that

(a) \(\{x_n\}\) converges to \(x^*\) with \(R\)-linear convergence rate if

\[
\limsup_{n \to \infty} \|x_n - x^*\|^{1/n} < 1,
\]

(b) \(\{x_n\}\) converges to \(x^*\) with \(Q\)-linear convergence rate if there exists \(\mu \in (0, 1)\) such that

\[
\|x_{n+1} - x^*\| \leq \mu \|x_n - x^*\|,
\]

for all sufficiently large \(n\).

Note that \(Q\)-linear convergence rate implies \(R\)-linear convergence rate, see [24, Section 9.3]. The inverse in general is not true. Algorithm 3.1 has the following rate of convergence.

**Theorem 3.2** Under the assumptions (SP) and (LC), the sequence \(\{x_n\}\) generated by Algorithm 3.1 converges at least \(R\)-linearly to the unique solution \(x^*\) of problem (EP).

Proof Using the relation \((12)\) with \(x = x^* \in C\), we obtain

\[
\frac{\phi - \lambda_n}{\phi - 1} \|\tilde{x}_{n+1} - x^*\|^2 + \left(\frac{\phi \lambda_n}{\lambda_{n+1}} - \frac{\mu \lambda_n}{\lambda_{n+1}}\right) \|x_n - x_{n+1}\|^2 \\
= \frac{\phi - \lambda_n}{\phi - 1} \|\tilde{x}_{n+1} - x^*\|^2 + \frac{\lambda_n}{\lambda_{n+1}} \|x_{n+1} - x_n\|^2 - \frac{\phi \lambda_n}{\lambda_{n+1}} \|\tilde{x}_n - x_n\|^2 + \frac{\mu \lambda_n}{\lambda_{n+1}} \|x_{n+1} - x_n\|^2 - 2\lambda_n f(x_n, x^*), \quad \forall n \geq 1. \tag{25}
\]

Note that \(\lambda_n \leq \lambda_{n-1}\) for all \(n \geq 1\). Thus, \(1 + \frac{\phi \lambda_n}{\lambda_{n+1}} \geq 1 + \frac{\phi}{\phi - 1} = 0\). This together with the relation \((25)\) and the strong pseudomonotonicity of \(f\) implies that

\[
\frac{\phi - \lambda_n}{\phi - 1} \|\tilde{x}_{n+1} - x^*\|^2 + \left(\frac{\phi \lambda_n}{\lambda_{n-1}} - \frac{\mu \lambda_n}{\lambda_{n+1}}\right) \|x_n - x_{n+1}\|^2 \\
\leq \frac{\phi - \lambda_n}{\phi - 1} \|\tilde{x}_n - x^*\|^2 + \frac{\mu \lambda_n}{\lambda_{n+1}} \|x_{n+1} - x_n\|^2 + 2\lambda_n f(x_n, x^*) \\
\leq \frac{\phi - \lambda_n}{\phi - 1} \|\tilde{x}_n - x^*\|^2 + \frac{\mu \lambda_n}{\lambda_{n+1}} \|x_{n+1} - x_n\|^2 - 2\lambda_n \gamma \|x_n - x^*\|^2, \tag{26}
\]

where \(\gamma\) is the modulus of strong pseudomonotonicity of \(f\). Note that from the definition of \(\tilde{x}_n\), we obtain \(x_n = \frac{\phi}{\phi - 1} \tilde{x}_n - \frac{1}{\phi - 1} \tilde{x}_{n-1}\). Thus, it follows from Lemma 2.2 that

\[
\|x_n - x^*\|^2 = \frac{\phi}{\phi - 1} \|\tilde{x}_n - x^*\|^2 - \frac{1}{\phi - 1} \|\tilde{x}_{n-1} - x^*\|^2 + \frac{\phi}{(\phi - 1)^2} \|\tilde{x}_n - \tilde{x}_{n-1}\|^2 \\
\geq \frac{\phi}{\phi - 1} \|\tilde{x}_n - x^*\|^2 - \frac{1}{\phi - 1} \|\tilde{x}_{n-1} - x^*\|^2. \tag{27}
\]
From the relations (26) and (27), we see that
\[
\frac{\varphi}{\varphi - 1} ||\hat{x}_{n+1} - x^\dagger||^2 + \left(\frac{\varphi \lambda_n}{\lambda_{n-1}} - \frac{\mu \lambda_n}{\lambda_{n+1}}\right) ||x_{n+1} - x_{n}||^2 \leq \frac{\varphi}{\varphi - 1} \left(1 - 2\gamma \lambda_n\right)||\tilde{x}_n - x^\dagger||^2
+ 2\gamma \lambda_n \frac{\varphi}{\varphi - 1} ||\hat{x}_{n-1} - x^\dagger||^2 + \frac{\mu \lambda_n}{\lambda_{n+1}} ||x_n - x_{n-1}||^2. \tag{28}
\]

Let \( \rho \) and \( \theta \) be two real numbers such that
\[
1 < \rho < \frac{\varphi}{\mu} - 1 \quad \text{and} \quad 1 < \theta < \varphi. \tag{29}\]

Thus, from the fact \( \lim_{n \to \infty} \lambda_n = \lambda > 0 \), we have
\[
\lim_{n \to \infty} \left(\frac{\varphi \lambda_n}{\lambda_{n-1}} - \frac{\mu \lambda_n}{\lambda_{n+1}}\right) = \varphi - (1 + \rho)\mu > 0,
\lim_{n \to \infty} \frac{2\gamma \lambda_n}{\varphi - 1} = \frac{2\gamma \lambda}{\varphi - 1} < \frac{2\gamma \lambda}{\varphi - 1}.
\]

These limits imply that there exists \( n_0 \geq 1 \) such that
\[
\frac{\varphi \lambda_n}{\lambda_{n-1}} - \frac{\mu \lambda_n}{\lambda_{n+1}} > \frac{\mu \rho \lambda_{n+1}}{\lambda_{n+2}}, \quad \forall n \geq n_0, \tag{30}\]
\[
\frac{2\gamma \lambda_n}{\varphi - 1} < \frac{2\gamma \lambda}{\varphi - 1}, \quad \forall n \geq n_0. \tag{31}\]

Moreover, since \( \{\lambda_n\} \) is non-increasing and \( \lambda_n \to \lambda \), we obtain that \( \lambda_n \geq \lambda_{n+1} \geq \lambda_{n+2} \geq \ldots \geq \lambda_\infty = \lambda \). Thus
\[
1 - 2\gamma \lambda_n \leq 1 - 2\gamma \lambda. \tag{32}\]

Combining the relation (28) with the relations (30) - (32), we obtain
\[
\frac{\varphi}{\varphi - 1} ||\hat{x}_{n+1} - x^\dagger||^2 + \frac{\mu \rho \lambda_{n+1}}{\lambda_{n+2}} ||x_{n+1} - x_{n}||^2 \leq \frac{\varphi}{\varphi - 1} \left(1 - 2\gamma \lambda\right)||\tilde{x}_n - x^\dagger||^2
+ 2\gamma \lambda \frac{\varphi}{\varphi - 1} ||\hat{x}_{n-1} - x^\dagger||^2 + \frac{\mu \lambda_n}{\lambda_{n+1}} ||x_n - x_{n-1}||^2. \tag{33}\]

Setting \( \Gamma_n = \frac{\varphi}{\varphi - 1} ||\tilde{x}_n - x^\dagger||^2 \), \( \Xi_n = \frac{\varphi \lambda_n}{\lambda_{n+1}} ||x_n - x_{n-1}||^2 \) and \( \alpha = 2\lambda \gamma > 0 \), the inequality (33) can be shortly rewritten as
\[
\Gamma_{n+1} + \Xi_{n+1} \leq (1 - \alpha)\Gamma_n + \frac{\alpha \alpha}{\varphi} \Gamma_{n-1} + \frac{\Xi_n}{\rho}. \tag{34}\]

Let \( r_1 > 0 \) and \( r_2 > 0 \). Now, we can rewrite relation (34) in the following form,
\[
\Gamma_{n+1} + r_1 \Gamma_n + \Xi_{n+1} \leq r_2 (\Gamma_n + r_1 \Gamma_{n-1}) + \frac{\Xi_n}{\rho}
+ (1 - \alpha - r_2 + r_1)\Gamma_n + \left(\frac{\alpha \alpha}{\varphi} - r_1 r_2\right)\Gamma_{n-1}. \tag{35}\]
Choosing \( r_1 > 0 \) and \( r_2 > 0 \) such that \( 1 - \alpha - r_2 + r_1 = 0 \) and \( \frac{d\alpha}{\varphi} - r_1 r_2 = 0 \), we obtain, by a straightforward computation

\[
 r_1 = \frac{\alpha - 1 + \sqrt{(\alpha - 1)^2 + \frac{4\alpha}{\varphi}}}{2} \quad \text{and} \quad r_2 = \frac{1 - \alpha + \sqrt{(\alpha - 1)^2 + \frac{4\alpha}{\varphi}}}{2}.
\]

Afterwards we study the behavior of the following function,

\[
h(t) = \frac{1 - t + \sqrt{(t - 1)^2 + \frac{4t}{\varphi}}}{2}, \quad t \in [0, \infty).
\]

whose derivative is given by

\[
h'(t) = -\frac{1}{2} + \frac{t - 1 + \frac{20}{\varphi}}{2\sqrt{(t - 1)^2 + \frac{4t}{\varphi}}} = \frac{\frac{20}{\varphi} (\frac{\theta}{\varphi} - 1)}{2\sqrt{(t - 1)^2 + \frac{4t}{\varphi}} (t - 1 + \frac{20}{\varphi} + \sqrt{(t - 1)^2 + \frac{4t}{\varphi}})} < 0
\]

because \( 1 < \theta < \varphi \) (see, the relation (29)). Thus, \( h(t) \) is non-increasing on \([0, \infty)\), and \( 0 < r_2 = h(\alpha) < h(0) = 1 \). Next, set \( \varepsilon = \max \left\{ \frac{r_2}{\varphi} \right\} \) and note that \( \varepsilon \in (0, 1) \). Then from the relation (35) and the equalities \( 1 - \alpha - r_2 + r_1 = 0 \) and \( \frac{d\alpha}{\varphi} - r_1 r_2 = 0 \), we obtain

\[
\Gamma_{n+1} + r_1 \Gamma_n + \Xi_{n+1} \leq r_2 (\Gamma_n + r_1 \Gamma_{n-1}) + \frac{\Xi_n}{\rho} \leq \varepsilon (\Gamma_n + r_1 \Gamma_{n-1} + \Xi_n), \quad \forall n \geq n_0.
\]  

(36)

From the \( Q \)-convergence rate for the sequence \( \{\Gamma_n + r_1 \Gamma_{n-1} + \Xi_n\} \), we obtain the \( R \)-convergence rate for the sequence \( \{\Xi_n\} \) and thus, from the definition of \( \Xi_n \), for the sequence \( \{\|x_n - x_{n-1}\|\} \) because the sequence \( \left\{\frac{\mu \rho \lambda}{\lambda_{n+1}}\right\} \) is bounded below from 0. This implies immediately that the sequence \( \{x_n\} \) converges \( R \)-linearly. This completes the proof.

4 Numerical Illustrations

In this section, we consider an equilibrium problem which is based on the Nash-Cournot equilibrium model [7,8], and we present some experiments to describe the numerical behavior of Algorithm 5.1 (EGRA) in comparison with two other algorithms, namely the linesearch extragradient method (LEGM) introduced in [23, Algorithm 2a] and the ergodic method (ErgM) proposed in [2]. We choose these algorithms for the comparison because they have the same features: the Lipschitz-type constants are not necessarily known. In order to demonstrate the computational performance of the algorithms, we use the sequence \( D_n = \|x_n - \text{prox}_{\bar{f},\lambda}(x_n)\|^2, \quad n = 0, 1, 2, \ldots \) versus the number of iterations (\# Iterations) or the execution time (Elapsed Time) in seconds. Here \( \lambda > 0 \) and the sequence \( \{x_n\} \) is generated by each algorithm. Finally let us observe that \( D_n = 0 \) if and only if \( x_n \) is a solution of the problem.

In a purpose of legibility, we simplify the model as follows: Assume that there are \( m \) companies that produce a commodity. Let \( x \) denote the vector whose entry \( x_j \) stands for the quantity of the commodity produced by company \( j \). We suppose that the price \( p_j(s) \) is a decreasing affine function of \( s \) with \( s = \sum_{j=1}^{m} x_j \), i.e., \( p_j(s) = \alpha_j - \beta_j s \), where \( \alpha_j > 0, \beta_j > 0 \). Then the profit made by company \( j \) is given by \( f_j(s) = p_j(s) x_j - c_j(s) \), where \( c_j(x_j) \) is the tax and
fee for generating $x_j$. Suppose that $C_j = [x_j^{\text{min}}, x_j^{\text{max}}]$ is the strategy set of company $j$, then the strategy set of the model is $C := C_1 \times C_2 \times \ldots \times C_m$. Actually, each company seeks to maximize its profit by choosing the corresponding production level under the presumption that the production of the other companies is a parametric input. A commonly used approach to this model is based upon the famous Nash equilibrium concept. We recall that a point $x^* \in C = C_1 \times C_2 \times \cdots \times C_m$ is an equilibrium point of the model if

$$f_j(x^*) \geq f_j(x^*[x_j]), \quad \forall x_j \in C_j, \quad \forall j = 1, 2, \ldots, m,$$

where the vector $x^*[x_j]$ stands for the vector obtained from $x^*$ by replacing $x_j^*$ with $x_j$. By taking $f(x,y) := \psi(x,y) - \psi(x,x)$ with $\psi(x,y) := -\sum_{j=1}^m f_j(x[y_j])$, the problem of finding a Nash equilibrium point of the model can be formulated as:

Find $x^* \in C$ such that $f(x^*, x) \geq 0$ for all $x \in C$.

Furthermore, assume that the tax-fee function $c_j(x_j)$ is increasing and affine for every $j$. This assumption means that both tax and fee for producing a unit are increasing as the quantity of the production gets larger. In that case, the bifunction $f$ can be formulated in the form

$$f(x,y) = \langle Px + Qy + q, y - x \rangle,$$

where $q \in \mathbb{R}^m$ and $P, Q$ are two matrices of order $m$ such that $Q$ is symmetric positive semidefinite and $Q - P$ is symmetric negative semidefinite. In this case, the bifunction $f$ is pseudomonotone and satisfies the Lipschitz-type condition.

We perform the numerical computations in $\mathbb{R}^m$ with $m = 100, 200, 300$; the starting point $x_0 = x_{-1} = (1, 1, \ldots, 1)^T \in \mathbb{R}^m$; the feasible set is a polyhedral convex set given by $C = \{x \in \mathbb{R}^m : Ax \leq b\}$, where $A$ is a random matrix of size $l \times m$ ($l = 10$) and $b \in \mathbb{R}^l$ is a random vector such that $x_0 \in C$. The control parameters are $\mu = 0.45p$ (for the EGRA); $\lambda_0 = \frac{1}{2}$ (for the ErgM). The data is generated as follows: All the entries of $q$ are generated randomly and uniformly in the interval $[-2, 2]$ and the two matrices $P, Q$ are also generated randomly such that their conditions hold. All the optimization subproblems are effectively solved by the subroutine quadprog in Matlab 7.0.

The numerical results are shown in Figures 1-6 where we can see that the convergence of the EGRA strictly depends on the starting stepsize $\lambda_0$. These results also illustrate that the EGRA works well and has a competitive advantage over the other algorithms.

5 Conclusions

The paper has presented an explicit golden ratio algorithm for solving an equilibrium problem involving a (strongly) pseudomonotone and Lipschitz-type bifunction in a finite dimensional space. The convergence as well as the $R$-linear rate of convergence of the proposed algorithm are established. Several numerical experiments have been done to illustrate the computational advantages of the new algorithm. The main advantages of the presented algorithm are that it only requires to solve one optimization problem by iteration and that it

1 We randomly choose $\lambda_{1k} \in [-2.0], \lambda_{2k} \in [0.2], k = 1, \ldots, m$. We set $\hat{Q}_1, \hat{Q}_2$ as two diagonal matrices with eigenvalues $\{\lambda_{1k}\}_{k=1}^m$ and $\{\lambda_{2k}\}_{k=1}^m$, respectively. Then, we construct a positive semidefinite matrix $Q$ and a negative definite matrix $T$ by using random orthogonal matrices with $\hat{Q}_2$ and $\hat{Q}_1$, respectively. Finally, we set $P = Q - T$. 

Dang Van Hieu et al.
does not use any information on the value of the Lipschitz-type constant of the bifunction. In addition, the stepsize is generated by the algorithm at each iteration without using any linesearch procedure.
Acknowledgements

We would like to thank Dr. Yura Malitsky and Dr. Nguyen The Vinh for sending us the papers [18, 27]. They have given us many valuable comments and suggestions to write this paper.
