(Received: July 10, 2019)

We investigate the semileptonic decay of the scalar tetraquark $T_{bs,cd}^-$ to final state $T_{cs,md}^0$. For these purposes, we calculate the spectroscopic parameters of the final-state scalar tetraquark $T_{cs,md}^0$. In calculations we use the QCD sum rule method by taking into account the quark, gluon, and mixed condensates up to dimension 10. The mass of the $T_{cs,md}^0$ obtained in the present work $(2878 \pm 128)$ MeV indicates that it is unstable against the strong interactions and decays to the mesons $D^0 K^0$ and $D^+ K^-$. Partial widths of these $S$-wave modes as well as the full width of the tetraquark $T_{cs,md}^0$ are found by means of the QCD light-cone sum rule method and technical tools of the soft-meson approximation. The partial widths of the main semileptonic processes $T_{bs,cd}^- \to T_{cs,md}^0 l \bar{\nu}$, $l = e, \mu$, and $\tau$ are computed by employing the weak form factors $G_1(q^2)$ and $G_2(q^2)$, which are extracted from the QCD three-point sum rules. We also trace back the weak transformations of the stable tetraquark $T_{bs,cd}^-$ to conventional mesons. The obtained results for the full width $\Gamma_{\text{full}} = (3.28 \pm 0.48) \times 10^{-10}$ MeV and mean lifetime $2.01^{+0.34}_{-0.26}$ ps of $T_{bs,cd}^-$ as well as predictions for decay channels of the tetraquark $T_{bs,cd}^-$ can be used in experimental studies of these exotic states.

I. INTRODUCTION

Investigation of exotic mesons composed of four valence quarks, i.e., tetraquarks is one of the interesting and intriguing problems on agenda of high energy physics. Experimental data collected by various collaborations and achievements in their theoretical explanations made these states an important part of hadron spectroscopy. But the nonstandard mesons discovered till now and considered as candidates to exotics are wide resonances which decay strongly to conventional mesons. These circumstances obscure their four-quark bound-state nature and inspire appearance of alternative dynamical models to account for observed effects. Therefore, theoretical and experimental studies of 4-quark states, which are stable against the strong interactions can be decisive for distinguishing dynamical effects and genuine multiquark states from each another.

The problems of stability of 4-quark mesons were already addressed in the original papers. The main conclusion made in these works was that, if a mass ratio $m_Q/m_q$ is large, then the heavy $Q$ and light $q$ quarks may constitute stable $QQ\bar{q}\bar{q}$ compounds. The stable nature of the axial-vector tetraquark $T_{bc,cd}^-$ was predicted in Ref. and confirmed by recent investigations. The similar conclusions about the strong-interaction stability of the tetraquarks $T_{bc,cd}^-$ and $T_{bc,cd}^0$ were drawn in Ref. as well. The spectroscopic parameters and semileptonic decays of the axial-vector tetraquark $T_{bc,cd}^-$ were analyzed in our work. Our result for the mass of the $T_{bc,cd}^-$ state $(10035 \pm 260)$ MeV is below the $B^-B^0$ and $B^-B^0$ thresholds, respectively, which means that it is strong- and electromagnetic-interaction stable particle and can decay only weakly. We evaluated the full width and mean lifetime of $T_{bc,cd}^0$ using its semileptonic decay channel $T_{bc,cd}^- \to Z_{bc}^0 l \bar{\nu}$ (for simplicity, $Z_{bc}^0 = Z_{bc,cd}^0$). The predictions $\Gamma = (7.17 \pm 1.23) \times 10^{-8}$ MeV and $\tau = 9.18^{+1.90}_{-1.40}$ fs are obtained in Ref. and are useful for further experimental studies of this double-heavy exotic meson.

Because the tetraquark $T_{bc,cd}^-$ decays dominantly to the scalar state $Z_{bc}^0$ in Ref. we calculated also the spectroscopic parameters of $Z_{bc}^0$. The mass of this state $(6660 \pm 150)$ MeV is considerably below $7145$ MeV required for strong decays to heavy mesons $B^-D^+$ and $B^-D^0$. The threshold for electromagnetic decays of $Z_{bc}^0$ exceeds $7600$ MeV, and is also higher than its mass. The semileptonic decays of the tetraquark $Z_{bc}^0$ were explored in Ref. and the dominant weak decay modes of $Z_{bc}^0$ contain at the final state the scalar tetraquark $T_{bc,md}^-$, which has the mass $(5380 \pm 170)$ MeV, and is strong-and electromagnetic-interaction stable particle.

The spectroscopic parameters and width of the axial-vector state $T_{bc}^0$ with the same quark content $bc\bar{c}\bar{d}$ were computed in Ref. The central value of its mass $(7105 \pm 155)$ MeV is lower than corresponding thresholds both for strong and electromagnetic decays. The semileptonic decays of $T_{bc}^0$ create at the final state the scalar tetraquark $T_{cs,md}^0$ which is strong-interactions unstable particle and decays to conventional mesons $D^+D^0$.

The 4-quark compounds $bc\bar{c}\bar{d}$ were subjects of interesting theoretical studies. Thus, an analysis performed in Ref. showed that $Z_{bc}^0$ lies below
the threshold for $S$-wave decays to conventional heavy mesons, whereas the authors of Ref. [12] predicted the masses of the scalar and axial-vector $bc\bar{d}d$ states above the $B^-D^+ + \bar{B}^0 D^0$ and $B^- D$ thresholds, respectively. Nevertheless, explorations conducted using the Bethe-Salpeter method [17], and recent lattice simulations proved the strong-interaction stability of the axial-vector exotic meson $T_{bc}$ [18]. An independent analysis of Ref. [19] also confirmed the stability of the tetraquarks $bc\bar{d}d$; it was demonstrated there, that both the scalar and axial-vector states $bc\bar{d}d$ are stable against the strong interactions.

Summing up one sees, that $T_{bc\bar{d}d}^-$ transforms due to a chain of the decays $T_{bc\bar{d}d}^- \rightarrow Z_{bc}^0 u\bar{l} \rightarrow T_{bs\bar{d}d}^- u\bar{l} T_{\nu l}$, where the last state $T_{bs\bar{d}d}^-$ should also decay through semileptonic processes. At the next stage $T_{bs\bar{d}d}^-$ creates a new tetraquark, which may be unstable or stable against the strong interactions. Therefore, semileptonic decays of $T_{bs\bar{d}d}^-$ to ordinary mesons through intermediate 4-quark state are important for throughout analysis of the tetraquark $T_{bs\bar{d}d}^-$.

In the present work we consider namely the processes $T_{bs\bar{d}d}^- \rightarrow T_{cs\bar{d}d}^0 l\bar{l}$, with $l = e, \mu, \tau$ (in what follows we denote $T_{bs\bar{d}d}^- \rightarrow T_{cs\bar{d}d}^0$ and $T_{cs\bar{d}d}^0 \rightarrow T_{cs\bar{d}d}^0$, respectively), and calculate their partial widths. To this end, we first explore the properties of the scalar 4-quark state $T_{cs}^0$ and calculate its mass and coupling. Our prediction for the mass of this state $m_T = (2878 \pm 128)$ MeV demonstrates that $T_{cs}^0$ can decay strongly to the conventional mesons $D^0 \bar{K}^0$ and $D^+ K^-$, partial widths of which are computed as well. Using information about parameters of $T_{cs}^0$, we study its semileptonic decays and find branching ratios of the processes $T_{bs}^- \rightarrow D^0 \bar{K}^0 l\bar{l}$ and $T_{bs}^- \rightarrow D^+ K^- l\bar{l}$. Results of the present work allow us also to analyze decays of the tetraquark $T_{bs\bar{d}d}^-$ and trace back its transformations to ordinary mesons.

This paper is organized in the following manner. In Sec. II we calculate the spectroscopic parameters of the scalar 4-quark state $T_{cs}^0$. Its strong decays are also analyzed in this section. The section III is devoted to semileptonic decays, where we calculate the partial widths of the processes $T_{bs}^- \rightarrow T_{cs}^0 l\bar{l}$. In Sec. IV we sum up information on $T_{bs}^-$, and analyze transformations of $T_{bc\bar{d}d}^-$ to conventional mesons.

II. SPECTROSCOPIC PARAMETERS AND STRONG DECAYS OF THE TETRAQUARK $T_{cs}^0$

It has been emphasized above that transformation of the $T_{bs}^-$ to meson pairs $D^0 \bar{K}^0$ and $D^+ K^-$ runs through creating and decaying of the intermediate scalar 4-quark state $T_{bs}^0$. Hence, parameters of this tetraquark are essential for our following analysis. In this section we calculate the mass and coupling of the tetraquark $T_{cs}^0$ by means of the QCD two-point sum rule method, which is an effective and powerful nonperturbative approach to investigate parameters of hadrons [20, 21]. It can be used to determine masses, couplings, and decay widths not only of the conventional hadrons, but also of exotic states [22]. In calculations, we take into account effects of the vacuum condensates up to dimension 10.

Here, we also analyze decays of this exotic state to conventional mesons via strong interactions. For these purposes, we use the parameters of the tetraquark $T_{cs}^0$ and calculate the strong couplings $g_{T_{cs}^0 D^0 \bar{K}^0}$ and $g_{T_{cs}^0 D^+ K^-}$ corresponding to the vertices $T_{cs}^0 D^0 \bar{K}^0$ and $T_{cs}^0 D^+ K^-$, respectively. These couplings are necessary to find the widths of the $S$-wave decays $T_{cs}^0 \rightarrow D^0 \bar{K}^0$ and $T_{cs}^0 \rightarrow D^+ K^-$, and can be calculated by means the QCD light-cone sum rule (LCSR) approach [23]. Because the aforementioned vertices contain a tetraquark the LCSR method should be supplemented by a technique of the soft-meson approximation [24]. For investigation of the diquark-antidiquark states the soft-meson approximation was adjusted in Ref. [26], and successfully applied later to explore their strong decays (see, for example, Refs. [27–29]).

A. Mass and coupling of the $T_{cs}^0$

The mass and coupling of the tetraquark $T_{cs}^0$ can be obtained from the QCD two-point sum rules. To this end, we start from the analysis of the two-point correlation function

$$\Pi(p) = i \int d^4xe^{ipx} \langle 0 | T\{J^T(x)J^{T\dagger}(0)\} | 0 \rangle,$$

(1)

where

$$J^T(x) = \bar{e}e[\gamma_5(x)C\gamma_5 s_c(x)][\bar{u}d(x)C\gamma_5 C\gamma_5 T(x)]$$

(2)

is the interpolating current for the tetraquark $T_{cs}^0$. Here, $\bar{e}e = e^{abc}[\gamma^5 C\gamma_5 s_c]$ in the color antitriplet and flavor antisymmetric state, and the antidiquark $e^{abc}[\bar{u}d]C\gamma_5 C\gamma_5 T$ in the color triplet state. Because these diquark configurations are most attractive ones [23], the current (2) corresponds to the ground-state scalar particle $T_{cs}^0$ with lowest mass.

To find the phenomenological side of the sum rule $\Pi^{\text{phys}}(p)$, we use the “ground-state+continuum” scheme. Then, $\Pi^{\text{phys}}(p)$ contains a contribution of the ground-state particle which below is written down explicitly, and effects of higher resonances and continuum states denoted by dots

$$\Pi^{\text{phys}}(p) = \frac{\langle 0 | J^T_{T_{cs}^0}(p) J^{T\dagger}_{T_{cs}^0}(p) | J \rangle | 0 \rangle}{m_T^2 - p^2} + \ldots$$

(3)
The QCD side of the sum rules is determined by the same correlation function $\Pi^{\text{OPE}}(p)$ found using the perturbative QCD and expressed in terms of the quark propagators. The obtained formulas, and manipulations with $\Pi^{\text{Phys}}(p)$ and $\Pi^{\text{OPE}}(p)$ to derive the required sum rules for the mass $m_T$ and coupling $f_T$ of the tetraquark $T_{bs}^0$ are similar to ones presented in Ref. [14], therefore we do not repeat them here; necessary theoretical results can be obtained from corresponding expressions for the $T_{bs}^-$ by a simple $b \rightarrow c$ replacement.

The sum rules for $m_T$ and $f_T$ contain the quark, gluon and mixed vacuum condensates, values of which are collected in Table I. This table contains also the masses of the $b, c,$ and $s$ quarks, as well as spectroscopic parameters of the mesons $D$ and $K$, which will be utilized in the next subsection.

The sum rules also depend on two auxiliary parameters. First of them is $M^2$, which appears in expressions after applying the Borel transformation to sum rules to suppress contributions of the higher resonances and continuum states. The dependence on the continuum threshold parameter $s_0$ is an output of the continuum subtraction procedure. A choice of these parameters is controlled by convergence of the operator product expansion (OPE), dominance of the pole contribution (PC), and by a minimum sensitivity of the extracted quantities on $M^2$ and $s_0$. Thus, the maximum allowed $M^2$ should be fixed to obey the restriction imposed on the pole contribution; as usual, for tetraquarks $PC > 0.2$. The lower bound of the window for the Borel parameter is determined from convergence of the OPE. A stability of extracted quantities is among important requirements of the sum rule calculations. In real computations these quantities, i.e., $m_T$ and $f_T$ is the case under consideration, demonstrate a residual dependence on $M^2$ and $s_0$. It is worth noting that a dependence of the parameters $M^2$ and $s_0$ is a main source of unavoidable theoretical errors in the sum rule calculations, which however can be systematically taken into account.

Performed analysis allows us to determine the working regions

$$M^2 \in [1.8, 2.8] \text{ GeV}^2, \ s_0 \in [11, 12] \text{ GeV}^2$$

that obey the constraints imposed on the Borel and continuum threshold parameters. In fact, at $M^2 = 1.8$ GeV$^2$ the convergence of the OPE is fulfilled, because a contribution of the last three terms to the Borel transformed and subtracted invariant amplitude $\Pi^{\text{OPE}}(M^2, s_0)$ does not exceed 0.7% of its value. At $M^2 = 1.8$ GeV$^2$ the pole contribution reaches its maximum and forms 61% of $\Pi^{\text{OPE}}(M^2, s_0)$. At $M^2 = 2.8$ GeV$^2$ the pole contribution is larger than 22% of the whole result.

![Fig. 1](image1.png)

**FIG. 1:** The mass $m_T$ of the tetraquark $T_{bs}^0$ as a function of the Borel and continuum threshold parameters.

![Fig. 2](image2.png)

**FIG. 2:** The same as in Fig. 1, but for the coupling $f_T$.

The predictions for the mass $m_T$ and $f_T$ are plotted in Figs. 1 and 2 where one can note their mild dependence on the parameters $M^2$ and $s_0$. The results for the spectroscopic parameters of the tetraquark $T_{bs}^0$

$$m_T = (2878 \pm 128) \text{ MeV},$$

$$f_T = (0.45 \pm 0.08) \times 10^{-2} \text{ GeV}^4$$

will be used below to study its strong decays.
B. Strong decays $T_{cs}^0 \to D^0 K^\mp$ and $T_{cs}^0 \to D^+ K^-$

The spectroscopic parameters of the tetraquark $T_{cs}^0$ obtained in the previous subsection provide an information necessary to answer a question about its stability against the strong interactions. It is not difficult to see, that the mass $m_T$ makes kinematically allowed the strong decays $T_{cs}^0 \to D^0 K^\mp$ and $T_{cs}^0 \to D^+ K^-$. There are other strong decay modes of $T_{cs}^0$, but these two channels are $S$-wave processes. Here, we are going to consider in a detailed form the channel $T_{cs}^0 \to D^0 K^0$, and give final results for the second one.

The width of the decay $T_{cs}^0 \to D^0 K^0$, apart from other parameters, is determined by the strong coupling $g_{TD^0 K^0}$ corresponding to the vertex $T_{cs}^0 D^0 K^0$. Our aim is to calculate the coupling $g_{TD^0 K^0}$ which quantitatively describes strong interactions between the tetraquark and two conventional mesons. To this end, we use the LCSR method and begin from analysis of the correlation function

$$\Pi(p, q) = i \int d^4x e^{ipx} \langle K^0(q)|T\{J^{D^0}(x)J^{T^1}(0)\}|0\rangle,$$

where $J^{D^0}(x)$ is the interpolating current of the meson $D^0$; it has following form

$$J^{D^0}(x) = \overline{u}(x)\gamma_5 c(x).$$

(7)

Standard recipes require to write $\Pi(p, q)$ in terms of physical parameters of the particles $T_{cs}^0, D^0$, and $K^0$

$$\Pi^{\text{Phys}}(p, q) = \frac{(0|J^{D^0}|D^0(p))}{p^2 - m^2_D} \langle D^0(p) K^0(q)|T_{cs}^0(p')\rangle \times \frac{\langle T_{cs}^0(p')|J^{T^1}|0\rangle}{p'^2 - m^2_T} + \ldots,$$

(8)

where $p'$ and $p$ are 4-momenta of the initial and final particles, respectively. In the expression above by dots we note contributions of excited resonances and continuum states. The correlation function $\Pi^{\text{Phys}}(p, q)$ can be simplified by introducing the matrix elements

$$\langle 0|J^{D^0}|D^0(p)\rangle = \frac{f_{TM} m^2_D}{m_c + m_u},$$

$$\langle D^0(p) K^0(q)|T_{cs}^0(p')\rangle = g_{TD^0 K^0} (p \cdot p').$$

(9)

The matrix element $\langle 0|J^{D^0}|D^0(p)\rangle$ is expressed in terms of $D^0$ meson’s mass and its decay constant $f_D$, whereas $\langle D^0(p) K^0(q)|T_{cs}^0(p')\rangle$ is written down using the strong coupling $g_{TD^0 K^0}$. In the soft-meson limit $q \to 0$ we get $p' = p + \mathbf{q}$, and must carry out the Borel transformation of $\Pi^{\text{Phys}}(p, q = 0)$ over the variable $p^2$, which gives

$$B\Pi^{\text{Phys}}(p^2) = g_{TD^0 K^0} \frac{f_{TM} m^2_T f_{TMT} m^2_c e^{-\tilde{m}^2_c/M^2}}{m_c + m_u} \frac{1}{M^2} \ldots,$$

(10)

where

$$\tilde{m}^2 = \frac{m_T^2 + m_D^2}{2}.$$
should be recast to forms suitable for expressing them as standard matrix elements of $K^0$. For these purposes, we employ the expansion

$$
\xi_\alpha T^{d_\beta} \rightarrow \frac{1}{12} \Gamma^{\beta}_{\alpha d} \delta^{e\epsilon} (\phi^{\epsilon \gamma} d),
$$

(15)

where $\Gamma^{\beta}_{\alpha d}$ is the full set of Dirac matrices

$$
\Gamma^{\beta}_{\alpha d} = 1, \gamma_5, \gamma_\lambda, i\gamma_5\gamma_\lambda, \sigma_\lambda\rho/\sqrt{2},
$$

(16)

Then operators $\Phi^{\epsilon \gamma} d$ and ones appeared due to $G$ insertions from propagators $S$ and $T$, give rise to local matrix elements of the $K^0$ meson. Substituting Eq. (15) into the correlation function and performing the color summation in accordance with prescriptions described in Ref. [26], we fix local matrix elements of $K^0$ that contribute to $\Pi^{OPE}(p)$. It turns out, that only the twist-3 matrix element

$$
(0|d(0)i\gamma_5s(0)|\overline{K}^0) = \frac{f_{K^0}\alpha^2}{m_s + m_d}
$$

(17)

contributes to the correlation function.

The function $\Pi^{OPE}(p)$ contains the trivial Lorentz structure which is proportional to $I$. The Borel transformed and subtracted expression of the corresponding invariant amplitude $\Pi^{OPE}(p^2)$ reads

$$
\Pi^{OPE}(M^2, s_0) = \int_{(m_s + m_d)^2}^{s_0} ds \rho^{pert.}(s) e^{-s/M^2}
$$

$$
+ \frac{\mu_{K^0}}{6} e^{-m^2_{K^0} + \frac{m^2_{K^0}}{M^2}} \left[ m(c_{\bar{q}q}) + \frac{1}{8} \left( \frac{\alpha_s G^2}{\pi} \right) \left[ 1 + \frac{m^2_c}{6M^2} \right] \right]
$$

$$
- \frac{m_0^2}{4M^2} \left( g_0 \sigma G \right) \left[ \frac{2m^2_c + \frac{1}{18} \alpha_s G^2}{\pi} \left( \frac{\bar{q}q}{M^2} \left( m^2_c - 3M^2 \right) \right) \right],
$$

(18)

where

$$
\rho^{pert.}(s) = \frac{\mu_{K^0}}{24\pi^2} (3m_c^2 - s),
$$

(19)

and $\mu_{K^0} = f_{K^0}\alpha^2/(m_s + m_d)$. Let us note that calculations of $\Pi^{OPE}(M^2, s_0)$ are carried out by taking into account nonperturbative terms up to seventh dimension. Then, the sum rule for the strong coupling $g_{TD^0K^0}$ takes the form

$$
g_{TD^0K^0} = \frac{m_c + m_s}{f_D m_D f_M M^2} \mathcal{P}(M^2, \tilde{m}^2) \Pi^{OPE}(M^2, s_0).
$$

(20)

The width of the decay $T^{0}_{cs} \rightarrow D^0 K^0$ is given by the formula

$$
\Gamma[T^{0}_{cs} \rightarrow D^0 K^0] = \frac{g^2_{TD^0K^0}}{8\pi} \lambda \left( 1 + \frac{\lambda^2}{m_D^2} \right),
$$

(21)

where

$$
\lambda = \lambda(m_T^2, m_D^2, m_{K^0}^2) = \frac{1}{2m_T} \left[ m_T^4 + m_D^4 + m_{K^0}^4 - 2(m_T^2 m_D^2 + m_T^2 m_{K^0}^2 + m_{K^0}^2 m_D^2) \right]^{1/2}.
$$

(22)

Numerical computations of the strong coupling $g_{TD^0K^0}$ yield

$$
|g_{TD^0K^0}| = (0.37 \pm 0.05) \text{ GeV}^{-1},
$$

(23)

which allows us to evaluate the partial width of the decay $T^{0}_{cs} \rightarrow D^0 K^0$:

$$
\Gamma \left( T^{0}_{cs} \rightarrow D^0 K^0 \right) = (15.35 \pm 3.24) \text{ MeV}.
$$

(24)

Let us note that in the sum rule computations the Borel and continuum subtraction parameters are chosen as in Eq. (4).

The decay $T^{0}_{cs} \rightarrow D^+ K^-$ can be analyzed by the same manner. The difference is connected with quark contents of the mesons $D^+$ and $K^-$ that generate small modifications, for example, $\Pi^{OPE}(p)$ takes the form

$$
\Pi^{OPE}(p) = i \int d^4xe^{i\pi x} \left[ \gamma_5 \tilde{\phi} \left( x \right) \gamma_5 \phi \left( -x \right) \right] \alpha_\beta \times \left( \phi^{\epsilon \gamma} d \right) (0) \langle 0 | | 0 \rangle.
$$

(25)

Therefore, we write down the final results for the strong coupling $g_{TD^+K^-}$ and corresponding decay width

$$
|g_{TD^+K^-}| = (0.38 \pm 0.06) \text{ GeV}^{-1},
$$

$$
\Gamma \left( T^{0}_{cs} \rightarrow D^+ K^- \right) = (15.40 \pm 3.35) \text{ MeV}.
$$

(26)

These dominant decay channels allow us to estimate the full width of the tetraquark $T^{0}_{cs}$

$$
\Gamma_{T^{0}_{cs}} = (30.8 \pm 4.7) \text{ MeV},
$$

that can be classified as a relatively narrow state.

### III. SEMILEPTONIC DECAY $T^{0}_{bs} \rightarrow T^{0}_{cs} \ell\nu$.

The semileptonic decay $T^{0}_{bs} \rightarrow T^{0}_{cs} \ell\nu$ runs through the transitions $b \rightarrow W^- c$ and $W^- \rightarrow \ell\nu$. It is not difficult to see that decays with all lepton species $\ell = e, \mu$ and $\tau$ are kinematically allowed processes.

The transition $b \rightarrow c$ at the tree-level can be described using the effective Hamiltonian

$$
\mathcal{H}^{\text{eff}} = \frac{G_F}{\sqrt{2}} V_{bc} \gamma_\mu(1 - \gamma_5) \bar{\nu}_\ell \gamma_\mu(1 - \gamma_5) u_t,
$$

(27)

where $G_F$ is the Fermi coupling constant, and $V_{bc}$ is the relevant Cabibbo-Kobayashi-Maskawa (CKM) matrix element. After placing the effective Hamiltonian $\mathcal{H}^{\text{eff}}$ between the initial and final tetraquarks and factoring out the lepton fields one gets the matrix element of the current

$$
J^W = \bar{\nu}_\ell(1 - \gamma_5) b.
$$

(28)

The matrix element $\langle T^{0}_{cs}(p') | J^W | T^{0}_{bs}(p) \rangle$ can be expressed in terms of the form factors $G_i(q^2)$ that parameterize the
long-distance dynamics of the weak transition. In the case of scalar tetraquarks it has the rather simple form

$$
\langle T^i_{cs}(p')|J^W_\mu|T^i_{bs}(p)\rangle = G_1(q^2)P_\mu + G_2(q^2)q_\mu, \tag{29}
$$

where $p$ and $p'$ are the momenta of the tetraquarks $T^i_{cs}$ and $T^0_{bs}$, respectively. Here, we use the shorthand notations $P_\mu = p'_\mu + p_\mu$ and $q_\mu = p_\mu - p'_\mu$. The $q_\mu$ is the momentum transferred to the leptons, and $q^2$ changes within the limits $m_t^2 \leq q^2 \leq (m - m_T)^2$, where $m_t$ is the mass of a lepton $i$.

The sum rules for the form factors $G_i(q^2), i = 1, 2$ can be derived from the three-point correlation function

$$
\Pi_\mu(p, p') = i^2 \int dt \, d^4y \, e^{-i(p'y - px)}
\times \langle 0|T\{J^T(y)J^W_\mu(0), J^I(x)\}|0\rangle, \tag{30}
$$

where $J^T(y)$ and $J(x)$ are the interpolating currents for the states $T^i_{cs}$ and $T^0_{bs}$, respectively. The current $J^T(y)$ is given by Eq. (2), whereas for $J(x)$ we use the expression

$$
J(x) = e\bar{c}b^T(x)C\gamma_5 s(x)\{\bar{\pi}_d(x)\gamma_5 C\bar{d}^T(x)\}. \tag{31}
$$

First, we express the correlation function $\Pi_\mu(p, p')$ in terms of the spectroscopic parameters of the tetraquark and mesons, and fix the physical side of the sum rule, i.e., find the function $\Pi_\mu^{phys}(p, p')$. It can be easily written down in the form

$$
\Pi_\mu^{phys}(p, p') = \langle 0|J^T|T^0_{cs}(p')\rangle \langle T^0_{cs}(p')|J^W_\mu|T^0_{bs}(p)\rangle
\times (T^0_{bs}(p)|J^I|0) + \ldots, \tag{32}
$$

where we take explicitly into account a contribution of the ground-state particles, and denote by dots effects due to excited and continuum states.

Using the tetraquarks' matrix elements and expressing the vertex $\langle T(p')|J^W_\mu|T^0_{bs}(p)\rangle$ in terms of the weak transition form factors $G_i(q^2)$ it is not difficult to find that

$$
\Pi_\mu^{phys}(p, p') = \frac{f_T m_T m_f}{(p^2 - m^2)(p'^2 - m_T^2)}
\times \left( G_1(q^2)P_\mu + G_2(q^2)q_\mu \right), \tag{33}
$$

where the matrix element of the state $T^0_{bs}$ is defined by

$$
\langle T^0_{bs}(p)|J^I|0\rangle = f_m. \tag{34}
$$

To calculate $\Pi_\mu(p, p')$, we employ the interpolating currents and quark propagators, and find

$$
\Pi_\mu^{off}(p, p') = i^2 \int dt \, d^4y \, e^{-i(p'y - px)}e\bar{c}b^T(x - y)
\times Tr\left[\gamma_5 \tilde{S}_d^c(x - y)\gamma_5 S_u d(x - y)\right] Tr\left[\gamma_\mu(1 - \gamma_5)\right]
\times S_b^d(-x)\gamma_5 \tilde{S}_u^c(y - x)\gamma_5 S_b^c(y). \tag{35}
$$

Then, the sum rules for the form factors $G_i(q^2)$ can be derived by equating the invariant amplitudes corresponding to the same Lorentz structures in $\Pi_\mu^{phys}(p, p')$ and $\Pi_\mu^{off}(p, p')$. Afterwards, we carry out the double Borel transformation over $p^2$ and $p'^2$ which is required to suppress contributions of the higher excited and continuum states, and perform the continuum subtraction. These operations lead to the sum rules

$$
G_i(M^2, s_0, q^2) = \frac{1}{f_T m_T m_f} \int_{(m_{bs} + s)^2}^{s_0} ds \rho_i(s, s', q^2)e^{(m_0^2 - s)/M^2 e^{-s'/M^2}}. \tag{36}
$$

where $\rho_i(s, s', q^2)$ are the spectral densities calculated as the imaginary parts of the correlation function $\Pi_\mu^{off}(p, p')$ with dimension-five accuracy. In Eq. (36) $M^2$ and $s_0$ is a couple of the Borel and continuum threshold parameters, respectively; the set $(M^2, s_0)$ corresponds to the initial state $T^0_{bs}$, and the second set $(m^2, s_0)$ describes the tetraquark $T^0_{cs}$.

Parameters for numerical computations of $G_i(M^2, s_0, q^2)$ are listed in Table I. The mass and coupling of the tetraquark $T^0_{cs}$

$$
m = (5380 \pm 170) \text{ MeV}, \tag{37}
$$

and working windows for the parameters $(M^2, s_0)$

$$
M^2 \in [3.4, 4.8] \text{ GeV}^2, \quad s_0 \in [35, 37] \text{ GeV}^2 \tag{38}
$$

are borrowed from Ref. [14]. The regions for $(M^2, s_0)$ and spectroscopic parameters of $T^0_{cs}$ are given by Eqs. (4) and (5), respectively. In numerical computations we also use the Fermi coupling constant $G_F = 1.16637 \times 10^{-5} \text{ GeV}^{-2}$ and CKM matrix element $|V_{bc}| = (41.2 \pm 1.01) \times 10^{-3}$.

To obtain the width of the decay $T^0_{bs} \rightarrow T^0_{cs} \pi^0$, one must integrate the differential decay rate $d\Gamma/dq^2$ (see, explanation below) of this process in the kinematical limits $m_t^2 \leq q^2 \leq (m - m_T)^2$. But, QCD sum rules for the form factors $G_i(q^2)$ lead to reliable predictions only in the interval $m_t^2 \leq q^2 \leq 5 \text{ GeV}^2$, which do not cover the whole integration region $m_t^2 \leq q^2 \leq 6.26 \text{ GeV}^2$. Therefore, the weak form factors $G_i(q^2)$ should be replaced by the fit functions $G_i(q^2)$, which at $q^2$ accessible for the sum rule computations coincide with $G_i(q^2)$, but can be easily extrapolated to the full integration region.

For the fit functions we choose the analytic expressions

$$
G_i(q^2) = G_i^0 \exp\left[\frac{g_i^2 q^2}{m^2} + g_i^3 \left(\frac{q^2}{m^2}\right)^2\right]. \tag{39}
$$

Here, $G_i^0$, $g_i^1$, and $g_i^2$ are parameters

$$
G_i^0 = 1.022, \quad g_i^1 = 1.383, \quad g_i^2 = 0.756, \quad G_2^0 = -0.886, \quad g_2^1 = 1.440, \quad g_2^2 = 0.813. \tag{40}
$$
Branching ratios of the processes \( T_{bs} \) tonic decays have computed partial widths of its dominant semileptonic decays. To this end, we present the following predictions of the tetraquark and weak form factors. Calculations yield the form factor \( G_2(q^2) \) as well.

The differential decay rate \( d\Gamma/dq^2 \) of the process \( T_{bs} \rightarrow T_{cs}^0 \bar{\nu}_l \) can be calculated using the expression derived in Ref. [14], where one needs to replace parameters of the tetraquarks and weak form factors. Calculations yield the following predictions

\[
\begin{align*}
\Gamma(T_{bs}^0 \rightarrow T_{cs}^0 e^- \bar{\nu}_e) &= (1.55 \pm 0.34) \times 10^{-10} \text{ MeV}, \\
\Gamma(T_{bs}^0 \rightarrow T_{cs}^0 \mu^- \bar{\nu}_\mu) &= (1.54 \pm 0.33) \times 10^{-10} \text{ MeV}, \\
\Gamma(T_{bs}^0 \rightarrow T_{cs}^0 \tau^- \bar{\nu}_\tau) &= (1.91 \pm 0.42) \times 10^{-11} \text{ MeV}.
\end{align*}
\]

Then, for the full width and mean lifetime of the tetraquark \( T_{bs}^0 \) we find

\[
\begin{align*}
\Gamma_{\text{full}} &= (3.28 \pm 0.48) \times 10^{-10} \text{ MeV}, \\
\tau &= 2.01^{+0.34}_{-0.26} \times 10^{-12} \text{ s}.
\end{align*}
\]

Branching ratios of the processes \( T_{bs}^0 \rightarrow D^0 K^0 \bar{\nu}_l \) and \( T_{bs}^0 \rightarrow D^+ K^- \bar{\nu}_l \) can be found using \( \text{BR} \left( T_{bs}^0 \rightarrow T_{cs}^0 \bar{\nu}_l \right) \) and \( \text{BR} \left( T_{bs}^0 \rightarrow D^0 K^0 \right) \approx \text{BR} \left( T_{cs}^0 \rightarrow D^+ K^- \right) \approx 0.5 \). Results of these computations are collected in Table II.

TABLE II: The decay channels of the tetraquark \( T_{bs}^0 \) and their branching ratios.

and decays to conventional mesons \( D^0 K^0 \) and \( D^+ K^- \). We have also evaluated the spectroscopic parameters of \( T_{cs}^0 \) and computed the partial widths of its strong decays, which allowed us to find the branching ratios of the processes \( T_{bs}^0 \rightarrow D^0 K^0 \bar{\nu}_l \) and \( T_{bs}^0 \rightarrow D^+ K^- \bar{\nu}_l \). Predictions for the mass of \( T_{bs}^0 \) obtained in our previous work [14], and results for the full widths and mean lifetimes of the tetraquarks \( T_{bs}^0 \) and \( T_{cs}^0 \) provide a basis for their experimental investigations.

But, information gained in the present article is important also to trace back transformations of the state \( T_{bb,cs} \).

Stable nature of the \( T_{bb,cs}^0 \) was explored and confirmed by different methods and authors. This state transforms in accordance with the chain of decays \( T_{bb,cs}^0 \rightarrow Z_0^0 l^0 \bar{\nu}_l \rightarrow T_{bs}^0 l^0 \bar{\nu}_l l^0 \nu_l \rightarrow l^0 \nu_l l^0 \nu_l \). Now with information on decays of the tetraquark \( T_{bs}^0 \) at hands, we can fix decay channels of \( T_{bb,cs}^0 \) to conventional mesons. It is not difficult to see, that \( T_{bb,cs}^0 \rightarrow D^0 K^0 l^0 \bar{\nu}_l l^0 \nu_l \) and \( T_{bb,cs}^0 \rightarrow D^+ K^- l^0 \bar{\nu}_l l^0 \nu_l \) are main modes of such transformations, branching ratios of which can be found using results of Refs. [13, 14] and information obtained in the present work. In Fig. 4 as an example, we depict one of such channels. For these decay modes relevant computations yield

\[
\begin{align*}
\text{BR} \left( T_{bb,cs}^0 \rightarrow D^0 K^0 L \right) &= \text{BR} \left( T_{bs}^{-} \rightarrow T_{bs}^{-} e^- e^+ \right) \\
&= 4.4 \times 10^{-2},
\end{align*}
\]

For simplicity, above we have denoted \( L = e^- e^+ e^- \) and omitted final-state neutrinos. The branching ratio for the second channel is also given by Eq. [15]. Other decays can be analyzed by the same manner.

The results for the width and lifetime of the tetraquark \( T_{bs}^0 \), and predictions for branching ratios of \( T_{bs}^0 \) and \( T_{bb,cs}^0 \) have been obtained using their dominant semileptonic decays. During our analysis we have neglected their numerous subdominant weak decay modes. At earlier levels of this cascade some of these modes might create unstable 4-quarks that dissociate to other than \( D \) and \( K \) mesons. Such processes are connected, first of all, with weak decays of heavy quarks that are suppressed due to CKM matrix elements, and were ignored in our studies. In the

FIG. 3: Dependence of the weak form factor \( G_1(q^2) \) on \( q^2 \): QCD sum rule predictions and the fit function \( G_1(q^2) \).
present work the exotic meson $T_{bs}^-$ has been treated as a scalar particle. But in the decay $Z_{bc}^0 \rightarrow T_{bs}^- \nu \bar{\nu}$ the final-state tetraquark may bear also other quantum numbers. By including into analysis these options one may reveal new decay modes of $Z_{bc}^0$, and, hence of $T_{bs}^-$.

Various strong decays of $T_{cs}^0$ trigger alternative channels as well. Thus, here we have analyzed only $S$-wave decays of $T_{cs}^0$, but its $P$-wave and other decays create various ordinary mesons at the final stages and also lead to different decays. Finally, intermediate $W^\pm$ bosons can couple to a quark-antiquark $W^\pm \rightarrow q\bar{q}'$, and transform to a pair of ordinary mesons. Creating of two mesons from $q\bar{q}'$, requires, naturally, additional quarks $q''\bar{q}''$ which appear due to a gluon emitted from one of $q$ or $\bar{q}$ quarks. As a result, multimeson processes $T_{bs}^- \rightarrow T_{cs}^0 M_1(q\bar{q}') M_2(q''\bar{q}'')$ are suppressed relative to the semileptonic decays by the additional factor $\alpha_s^2 |V_{qq'}|^2$, but they form a part of the whole picture. Investigation of these alternative decays can add a valuable new information on features of the exotic mesons $T_{bs}^-$ and $T_{bs}^-$.

FIG. 4: One of the decay modes of the tetraquark $T_{bs}^-$. Here, we use the notation $L = e^- e^+ e^-$.
