DYNAMICAL LOW-RANK INTEGRATOR FOR THE LINEAR BOLTZMANN EQUATION

ZHIIYAN DING*, LUKAS EINKEMMER†, AND QIN LI‡

Abstract. Dynamical low-rank algorithms are a class of numerical methods that compute low-rank approximations of dynamical systems. This is accomplished by projecting the dynamics onto a low-dimensional manifold and writing the solution directly in terms of the low-rank factors. The approach has been successfully applied to many types of differential equations. Recently, efficient dynamical low-rank algorithms have been applied in [11, 15] to treat kinetic equations, including the Vlasov–Poisson and the Boltzmann equation, where it was demonstrated that the methods are able to capture the low rank structure of the solution and significantly reduce numerical cost, while often maintaining high accuracy. However, no numerical analysis is currently available.

In this paper, we investigate the error analysis for a dynamical low-rank algorithm applied to the multi-scale linear Boltzmann equation (a classical model in kinetic theory) to showcase the validity of the application of dynamical low-rank algorithms to kinetic theory. The equation, in its parabolic regime is known to be rank one theoretically, and we will prove that the scheme can dynamically and automatically capture this low-rank structure. This work thus serves as the first mathematical error analysis for a dynamical low rank approximation applied to a kinetic problem.

Key words. Dynamical low-rank approximation, multiscale analysis, linear Boltzmann equation, low-rank structure

1. Introduction. Kinetic equations are a class of model equations used to describe the statistical behavior of a large number of particles that follow the same physics laws. They have been widely used in many aspects of physics and engineering. These equations, despite having different terms for various specific kinds of particles, share a similar structure: The dynamics is described in phase space and the solution is thus a distribution function $u(t, x, v)$ that counts the density of particles at a particular time $t$, location $x$, and velocity $v$. One main challenge for the computation of kinetic equation comes from the fact that the equation is supported on the phase space instead of the physical space, and thus the dimensionality of the problem typically doubles.

During the past decade, numerous methods have been proposed to numerically solve kinetic equations and many of them succeed in reducing computational cost without sacrificing accuracy. The main body of work concentrates on developing fast solvers for the collision operators and overcoming the stability requirement via relaxing the time-discretization [24, 22], through either finding fast methods to treat the transport term [17, 47, 5, 12], or implementing the resulting discrete system efficiently [18, 13]. However, reducing the complexity due to the high dimensionality is largely left unaddressed. The difficulty here is rather clear. To compute PDEs, one needs to sample a certain amount of discrete points per dimension, and for kinetic equations that have high dimensionality, the degrees of freedom is large, driving up the numerical cost.

The viewpoint of degrees of freedom merely depending on the dimensionality of
the problem was challenged in recent years, see [45] and references therein. In these works, the traditional approach is abandoned and one explores the structure of the intrinsic low-dimensional manifold where the PDE solution lives on. The method is designed to follow the flow of the dynamics and to identify the important features in the evolution. Since the equation is projected onto a solution manifold of lower dimensionality, only the core information is preserved and redundant information is neglected. The numerical cost thus depends mainly on the intrinsic dimensionality of the dynamics, rather than the total number of discrete points. The method was first utilized to deal with coupled ODE systems [39] and then was applied to a range of problems for which the accuracy has been demonstrated.

The success in dealing with ODE systems inspired the generalization to PDEs. More recently, a class of efficient numerical schemes were proposed for computing kinetic equations, including the Vlasov–Poisson system [28, 15], the Vlasov-Maxwell system [16] and the classical Boltzmann equation [11] in both collisionless and strong-collisional regimes. In these experiments, it was observed that both the sophisticated Landau damping phenomenon for the VP system [48, 44], and the incompressible Navier-Stokes limit for the Boltzmann equation are captured rather accurately at very low cost. Different equations may require slightly modified dynamical low-rank algorithms to suit the specific structures of the equation, but the general approach is quite similar. The main features in the evolution are preserved by following the flow of the equation projected onto the low dimensional solution manifold.

However, despite the strong intuition and the many promising numerical experiments, rigorous mathematical analysis is largely absent, especially in the PDE setting. There are two major difficulties, one from the theoretical level, and one is numerical. First, we often do not have results to show that the true solution is indeed approximately of low-rank. This point is more subtle than one might think. In fact, a Fourier expansion is also a low-rank approximation. But, a Fourier expansion uses a fixed set of basis functions, and the prediction of the rank is higher than the intrinsic rank of the solution. In addition, showing the low rank structure by performing a Fourier decomposition relies on assuming smoothness of the solution, which for kinetic equations is certainly problematic. It should be noted, however, that for elliptic equations some results can be obtained [6].

The second difficulty is numerical: How to show the method can capture the low-rank structure of the solution? For the ODE case an analysis has been performed in [26] and related works, but this analysis only applies to the non-stiff case and is thus not applicable to PDEs. The only mathematical analysis of a dynamical low-rank scheme in the PDE setting we are aware of is found in [46]. This paper considers a special situation where the stiffness originates only from the linear differential operator whose corresponding flow is exactly computable within the low-rank formulation. This separation suggests a splitting procedure that decouples the stiff and non-stiff dynamics, which permits a convergence analysis of the resulting method. This is not the situation for kinetic equations, and thus the analysis does not apply.

In this paper, we will consider a multi-scale linear Boltzmann equation. The equation is equipped with a parameter called the Knudsen number, and when it is small, the equation has strong collision operator, and is in the diffusive scaling. It is a well known result that when this happens, the solution reduces to a rank 1 function, namely the solution can be written as a multiplication of two functions, one for $x$ and one for $v$ respectively. The first challenge mentioned above therefore turns out to be trivial in this case. In this particular paper, we aim at solving the second challenge, which is to prove the dynamical low-rank algorithm can indeed capture this
low rank structure. More specifically, we will rigorously show, through utilizing the Hilbert expansion, that in the small Knudsen number limit, the method automatically captures the rank 1 behavior of the solution. These results imply that compared to the traditional approaches that require discretization of the full phase space, the essential degrees of freedom only scale as the number of grid points in the physical space.

We should mention that the results shown here only address the low-rank dynamics of the linear Boltzmann equation. It is a showcase for the validity of the algorithm on kinetic equations, and serves as a stepping stone for future studies on more complicated kinetic equations. We also stress that although the linear Boltzmann equation itself is linear, the studied dynamical low-rank algorithm is nonlinear and involved, making the proof highly non-trivial. We report the analytical result showing the performance of different time-integrators, discussing both advantages and disadvantages in the asymptotic regimes.

1.1. Multi-scale linear Boltzmann equation. We first give a quick overview of the equation. In $d > 1$ dimension, let $(t,x,v) \in \mathbb{R}^+ \times \Omega_x \times S^{d-1}$, the equation writes:

$$\partial_t u(t,x,v) = \mathcal{L} u = -\frac{v}{\epsilon} \cdot \nabla_x u(t,x,v) + \frac{\sigma(x)}{\epsilon^2} (\rho(x) - u(t,x,v)),$$

where $\sigma(x)$ is the scattering cross-section, $\Omega_x \subset \mathbb{R}^d$, $\epsilon$ is called the Knudsen number, which represents the ratio between the mean free path and the typical domain length, and $v$ is the angular variable. $S^{d-1}$, the unit sphere in $d$ dimensional space showing that all $v$ have the same amplitude. The density $\rho$ is defined as follows

$$\rho(x) = \langle u(t,x,v) \rangle_v = \frac{1}{|S^{d-1}|} \int_{S^{d-1}} u(t,x,v) \, dv,$$

where $|S^{d-1}|$ is the volume of $S^{d-1}$, and $\langle \cdot \rangle_v$ denotes the average with respect to $v \in S^{d-1}$. For the convenience of the notation we also shorten it to

$$d\mu_v = \frac{1}{|S^{d-1}|} \, dv,$$

the normalized measure in $v \in S^{d-1}$. The equation is written in diffusion scaling, meaning the transport term $v \cdot \nabla_x u$ and the collision term $\rho - u$ are enlarged by $\frac{1}{\epsilon}$ and $\frac{1}{\epsilon^2}$, respectively.

It is a well-known result that when $\epsilon \to 0$, the solution $u$ of (1.1) will asymptotically approach $\rho$ and thus becomes $v$ independent. Furthermore, $\rho$ solves the heat equation, with $C_d$ being a constant that depends on $d$ only:

$$\partial_t \rho = \nabla_x \cdot \left( \frac{1}{C_d \sigma(x)} \nabla_x \rho \right), \quad (t,x) \in \mathbb{R}^+ \times \Omega_x.$$

For this reason, the regime is termed parabolic regime, and the limit is called the diffusion limit. For this paper, this limit is particularly interesting because it essentially shows that $u(t,x,v) \sim \rho(t,x)$ is approximately of rank 1.

There are two difficulties in computing this equation. First, when the Knudsen number $\epsilon$ is small, both the transport term and the collision operator are stiff. A traditional numerical method would require small time stepsize that resolves the stiffness. Second, equation (1.1) is posed in an $2d - 1$ dimensional phase space. Suppose the equation has $N_x$ grid points per spatial direction and $N_v$ grid points per velocity.
direction, then $N_x^d N_v^{d-1}$ floating point numbers are needed. The large increase in the degrees of freedom is usually referred to as the *curse of dimensionality* in the literature.

There are indeed techniques developed to enlarge the stability region to overcome the stiffness problem as mentioned in the first challenge. In the kinetic framework, it is usually referred to as asymptotic preserving [21, 8, 30, 3, 9, 33, 7, 29]. Also see reviews [20, 23, 10]. However, the investigation into the second problem is mostly open. The belief that numerical cost mostly depends on the number of grid points and thus the degrees of freedom has been so firm, and essentially has not been challenged in the literature till the proposal of the dynamical low rank approximation.

1.2. Dynamical low rank approximation. Dynamical low rank approximation is a systematic approach to tackle the curse of dimensionality for time-dependent problems. Believing that the number of grid points usually over-represent the necessary numerical information, the main aim of the approximation is to explore the rank structure of the solution manifold. Instead of seeking for the solution on a fixed set of grid points, the method evolves the low rank representation, and characterizes flow of the solution on a low dimensional manifold.

There are many ways to decompose the solution into its low rank presentation. For kinetic equations in particular, it is rather straightforward to separate the physical space and the velocity space:

\[
(1.4) \quad u(t, x, v) = \sum_{i,j=1}^r S_{ij} X_i(t, x) V_j(t, v),
\]

so that the low rank factors $X_i$ and $V_j$ depend only on either $x$ or $v$ respectively. In the formula, $r$ is the rank, and is typically significantly smaller than $\min(N_x, N_v)$. For this presentation, the degrees of freedom is $O(r(N_x^d + N_v^{d-1}))$.

Historically, dynamical low-rank approximations have been considered extensively in high dimensional problems arising in quantum mechanics. Finding a low rank approximation there makes the computation tractable, see [43, 42] and [36, 37, 4] for a mathematical treatment. The application of the method in a general setting is studied in [26, 27, 40, 1], where both the matrix and the general tensor formats are investigated. In the initial development, one significant disadvantage was observed: the methods are not robust with respect to over-approximation. Several strategies were proposed to address the issue, including both regularization, and the project splitting operator approach. The latter is viewed as a major improvement [39] in enhancing the robustness with respect to small singular values [25]. This approach was later extended to various tensor formats [37, 38, 19, 41], and is the approach to be utilized in this paper.

The application of dynamical low-rank approximation for kinetic equations is relatively recent. Numerical experiments have been performed on the Vlasov–Poisson [15, 14], the Vlasov–Maxwell [16], and the Boltzmann equation [11], and the numerical evidence are very promising. However, theoretical justification has been in lack.

To resonate the statement above, we need to answer two questions

1. When do the solutions have low-rank structures?
2. Why do dynamical low-rank approximation can capture the structure?

The first question, in the kinetic framework, would be addressed by utilizing the fluid limit justification, as shown in (1.1) and (1.3). Since one can show that as $\epsilon \to 0$ we get $u(t, x, v) = \rho(t, x)$, the velocity direction completely degenerates, and the rank of
the representation in equation (1.4) is simply 1. It is then reasonable to expect that for small ε the solution is only slightly different from its rank-1 approximation.

To address the second question relies on proper algorithm-designing. As mentioned above, we will use the projector-splitting approach. This leads to a set of three evolution equations for $S$, $X$, and $V$, respectively, and all three will be advanced in every single time step in a proper order. It turns out that the specific time integrator for each equation plays a crucial role. More specifically, we will show that the implicit Euler method, due to the lack of the symmetry, requires fine time discretization for capturing the rank structure, while the Crank–Nicolson will converge for mild time stepsize but does require well-prepared initial data. In the end, we propose to use implicit Euler at the initial step for a very small time stepsize, to reveal the numerical structure of the PDE solution, and then switch to Crank–Nicolson to preserve such a structure.

The rest of the paper is organized as follows. In Section 2 we present the application of the dynamical low-rank splitting projection method on the linear Boltzmann equation. Both the semi-discrete splitting scheme and the fully-discrete methods are presented, in Section 2.1 and 2.2 respectively. In Section 3 we state and prove the main results. In Section 3.1 we study the numerical cost saving and error analysis intuition is presented in Section 3.2. Section 3.3 and 3.4 are dedicated to the error analysis with the implicit Euler and Crank–Nicolson time integrator respectively, and we summarize the analysis with a final proposal of an algorithm in Section 3.5. Some parts of the proof in Section 3 are rather tedious, and we leave them to Appendix. Numerical evidences are presented in Section 4.

2. Numerical scheme. We present the application of the dynamical low rank approximation method on the linear Boltzmann equation in this section. We follow the framework and notations in [15]. Throughout the paper we use the standard $L^2$ vector space in both the spatial and the velocity domain. That is, we have

$$\langle f, g \rangle_x = \int f(x)g(x)\,dx, \quad \langle f, g \rangle_v = \int f(v)g(v)\,d\mu_v.$$  

We call a function $f(x, v)$ a rank-$r$ function if it can be expanded by a set of $r$ orthonormal basis functions in $x$ and $v$. All these functions are collected to the set $\mathcal{M}$:

**Definition 2.1 (Rank-$r$ function in $L_2(\Omega \times \mathbb{S}^{d-1})$).** The collection of all rank-$r$ functions is denoted by

$$\mathcal{M} = \{ f(x, v) \in L^2(\Omega \times \mathbb{S}^{d-1}) : f(x, v) \text{ is rank-$r$} \},$$

where $f(x, v)$ is rank-$r$, meaning: $f(x, v) = \sum_{i,j=1}^r s_{i,j} X_i(x)V_j(v)$ where $X_i$ and $V_i$ being orthonormal in physical and velocity space respectively:

$$\langle X_i, X_j \rangle_x = \int_{\Omega_x} X_i X_j \,dx = \delta_{ij}, \quad \langle V_i, V_j \rangle_v = \int_{\mathbb{S}^{d-1}} V_i V_j \,d\mu_v = \delta_{ij}.$$  

We note that in this definition, only the rank, $r$, is fixed. The basis functions $X_i$ and $V_j$ can be arbitrary, as long as the orthogonality condition is satisfied. We further emphasize that $\mathcal{M}$ is not a function space; it is easily seen that the summation of two rank-$r$ functions may not be rank-$r$.

It is unlikely that the solution is of rank-$r$, i.e. in $\mathcal{M}$, for all time. However, numerically one can argue that the solution is approximately of low rank. Thus for
the numerical solution we seek a rank-$r$ approximation in $\mathcal{M}$ at every time step. The algorithm is consequently looking for a trajectory on the manifold $\mathcal{M}$ that resembles the evolution guided by the equation. In some sense, we need to project the equation in $L^2(\Omega \times S^{d-1})$ to the manifold and find the equation that governs the dynamics of this trajectory in $\mathcal{M}$.

Denote $u(t, x, v)$ the analytic solution and $u_r(t, x, v)$ the numerical rank-$r$ approximation, then with the argument above, the governing equation for $u_r$ is

$$\partial_t u_r = \mathcal{P}_{u_r}(\mathcal{L} u_r) = \mathcal{P}_{u_r} \left( \frac{\sigma(x)}{\epsilon^2} (\rho - u_r) - \frac{v}{\epsilon} \cdot \nabla_x u_r \right),$$

where $\mathcal{P}_f$ stands for the projection of $f$ onto the tangential plane of $\mathcal{M}$ at $u$. Denoting $\mathcal{T}_u, \mathcal{M}$ the tangential plane of $\mathcal{M}$ at $u_r$, this projection operator ensures

$$\hat{u}_r \in \mathcal{T}_u \mathcal{M},$$

guaranteeing that $u_r$ lies in the manifold $\mathcal{M}$ for all time.

We now look for explicitly expression of the tangential plane and the projection operator. For a nonlinear manifold $\mathcal{M}$, such expressions necessarily depend on the point where tangent is looked for. Denote

$$f = \sum_{ij} S_{ij} X_i V_j \in \text{Span}\{X_i\}_{i=1}^r \otimes \text{Span}\{V_j\}_{j=1}^r,$$

then the tangential plane is given by

$$\mathcal{T}_f \mathcal{M} = \left\{ g \in L^2(dx \, dv) : g = \sum_{i,j=1}^r X_i(x) \hat{S}_{ij} V_j(v) + \hat{X}_i(x) S_{ij} V_j(v) + X_i(x) S_{ij} \hat{V}_j(v) \right\},$$

with $\hat{S} \in \mathbb{R}^{r \times r}$, $\hat{X}_i \in L^2(\Omega_x)$, $\hat{V}_j \in L^2(S^{d-1})$, and $\langle \hat{X}_i, \hat{V}_j \rangle_x = \langle V_i, V_j \rangle_v = 0$.

This set collects all functions whose infinitesimal, when added to $f$, still yields a rank-$r$ function. In this definition, we notice that we are allowed to choose arbitrarily an $r \times r$ matrix $\hat{S}$, a function list $\hat{X}_i$ and a function list $\hat{V}_j$, as long as the gauge conditions, $\langle X_i, \hat{X}_j \rangle_x = \langle V_i, \hat{V}_j \rangle_v = 0$, are satisfied. We note that the gauge conditions are imposed to guarantee the uniqueness of the low-rank factors. Interested readers are referred to [39] for details.

With this definition, one has:

$$\mathcal{P}_f g = \mathcal{P}_{X} g + \mathcal{P}_V g - \mathcal{P}_V \mathcal{P}_{X} g, \quad \forall g \in L^2(\Omega_x \times S^{d-1}),$$

where the spatial and velocity projection are

$$\mathcal{P}_X g = \sum_{i=1}^r (X_i, g)_{x} X_i, \quad \mathcal{P}_V g = \sum_{i=1}^r (V_i, g)_v V_i, \quad \mathcal{P}_V \mathcal{P}_X g = \sum_{i,j=1}^r X_i (X_j V_j, g)_{x,v} V_j.$$

Inserting (2.2) into (2.1) gives us the governing equation for $u_r$:

$$\partial_t u_r = \mathcal{P}_{u_r}(\mathcal{L} u_r) = \left( \mathcal{P}_{X u_r} + \mathcal{P}_{V u_r} - \mathcal{P}_{V u_r} \mathcal{P}_{X u_r} \right) (\mathcal{L} u_r).$$

The numerical method will then be developed upon this formulation. We discuss the semi-discrete (in time) and the fully-discrete schemes (both implicit Euler and Crank-Nicolson) in details in the following subsections.
Remark 1. We finish this discussion with a comment on rank-r approximations. In fact, all numerical methods to solve PDEs are rank-r approximations. Let us suppose we have a numerical method with \(N\) grid points in both \(x\) and \(v\). Then

\[
u(x_m, v_n) \approx \sum_{i,j=1}^{N} u_{ij}\Phi_i(x_m)\Phi_j(v_n),
\]

where \(\Phi_i\) are basis functions we use to approximate the solution. For example, in a finite difference method we set \(\Phi_i(x_m) = \delta_i(x_m) = \delta_{im}\) as the Kronecker delta function or hat functions that peak at \(x_i\) and \(u_{ij}\) is the numerical solution evaluated at \((x_i, v_j)\). These \(\Phi\) serve as \(X_i\) and \(V_j\) and are predetermined, while \(u_{ij}\) play the role of \(S_{ij}\). When we consider a low-rank approximation, as in this paper, we always assume that \(r \ll N\). To achieve this, the functions \(X_i\) and \(V_j\) are expected to evolve in time accordingly to capture the dynamics of the equation.

2.1. Semi-discrete low rank splitting method. In this section, we develop a projector-splitting method to solve equation (2.3). In order to be concise, we simply denote the low rank solution \(u_r\) by \(u\) and we decompose the solution using its low-rank representation:

\[
u(t, x, v) = \sum_{i,j=1}^{r} X_i(t, x)S_{i,j}(t)V_j(t, v)
= X(t, x)S(t)V^\top(t, v) = X(t, x)L(t, v) = K(t, x)V^\top(t, v)
\]

where \(X\) and \(V\) collects the basis functions

\[
\begin{align*}
X(t, x) &= [X_1(t, x), X_2(t, x), \ldots, X_r(t, x)] , \\
V(t, v) &= [V_1(t, v), V_2(t, v), \ldots, V_r(t, v)] .
\end{align*}
\]

We will also be using quantities \(K\) and \(L\):

\[
\begin{align*}
L(t, v) &= S(t)V^\top(t, v) = [L_1(t, v), L_2(t, v), \ldots, L_r(t, v)]^\top , \\
K(t, x) &= X(t, x)S(t) = [K_1(t, x), K_2(t, x), \ldots, K_r(t, x)] .
\end{align*}
\]

Computing (2.3) at discrete times \(t_n\) amounts to finding the governing equations that provide the updates of

\[
X^n, \quad V^n, \quad \text{and} \quad S^n,
\]

respectively, for all \(t_n\) with \(n \geq 1\).

To specify the initial data, we project the initial condition onto \(\mathcal{M}\) using the singular value decomposition (SVD), namely:

\[
u(t = 0, x, v) \approx \sum_{i,j=1}^{r} X_i(t = 0, x)S_{i,j}(t = 0)V_j(t = 0, v) = X^0(x)S^0V^0(v).
\]

For updating \(X, V, S\), the Lie-Trotter splitting is used. From time step \(t_n\) to \(t_{n+1} = t_n + \Delta t\), we split the three operators on the right hand side of (2.3) into three
sub-steps:

\[
\frac{\partial u}{\partial t} = \mathcal{P}_X \left( \frac{\sigma(x)}{c^2} \left( \rho - u \right) - \frac{v}{\epsilon} \cdot \nabla_x u \right),
\]

\[
\frac{\partial u}{\partial t} = -\mathcal{P}_V \mathcal{P}_X \left( \frac{\sigma(x)}{c^2} \left( \rho - u \right) - \frac{v}{\epsilon} \cdot \nabla_x u \right),
\]

\[
\frac{\partial u}{\partial t} = \mathcal{P}_V \left( \frac{\sigma(x)}{c^2} \left( \rho - u \right) - \frac{v}{\epsilon} \cdot \nabla_x u \right).
\]

This splitting (2.8)-(2.10) takes place for each time step. That is, given the numerical solution at time \( t_n \) we update the solution to \( t_{n+1} \) by solving the three equations one after another. All equations are advanced for a full time step \( \Delta t \). Different from directly solving (2.3), each sub-step only changes one part of the decomposition. In particular, the first splitting step (2.8) preserves \( X \), the last (2.10) preserves \( V \), and the middle step (2.9) merely updates \( S \). This allows us to update the three components separately. Below we detail the evolution of each sub-step:

- Updating (2.8):

  Starting with \( u^n(x,v) = X^n(x)S^n(V^n(v))^\top \), we run (2.8) for a full time step \( \Delta t \), and we denote the result by \( u^{n+1/3}(x,v) \). The step preserves \( X \) and thus:

  \[ X^{n+1/3}(x) = X^n(x). \]

  To update \( S^{n+1/3} \) and \( V^{n+1/3} \), we plug the low rank formulation (2.4) into (2.8) and obtain, for \( 1 \leq i \leq r \):

  \[
  \frac{\partial}{\partial t} L_i = -\frac{1}{\epsilon} \sum_{j=1}^r \langle X^n_i, v \cdot \nabla X^n_j \rangle_L_j + \frac{1}{\epsilon^2} \sum_{j=1}^r \langle X^n_i, \sigma X^n_j \rangle ((L_j)_v - L_j),
  \]

  By using equation (2.5) we can simplify it to:

  \[
  \frac{\partial}{\partial t} L(t,v) = -\frac{1}{\epsilon} \sum_{k=1}^d v_k \Lambda^n_{\partial k} L(t,v) + \frac{1}{\epsilon^2} \Lambda^n_{\sigma} ((L(t,\cdot))_v - L(t,v)),
  \]

  where \( v = [v_1, \cdots, v_d] \), and \( \Lambda^n_{\partial k} \) and \( \Lambda^n_{\sigma} \), both in \( \mathbb{R}^{r \times r} \), are matrix versions of the differential operator and the scattering operator respectively:

  \[
  [\Lambda^n_{\partial k}]_{i,j} = \langle X^n_i, \partial_k X^n_j \rangle_L, \quad (1 \leq k \leq d),
  \]

  \[
  [\Lambda^n_{\sigma}]_{i,j} = \langle X^n_i, \sigma X^n_j \rangle_L.
  \]

  We denote the solution to (2.11) by \( L^{n+1/3}(v) \), and \( S^{n+1/3} \) and \( V^{n+1/3}(v) \) are obtained through the Gram-Schmidt process (QR factorization) which ensures the orthogonality of \( V^{n+1/3}(v) \):

  \[
  L^{n+1/3}(v) = S^{n+1/3} \left( V^{n+1/3}(v) \right)^\top.
  \]

  Finally:

  \[ u^{n+1/3} = (XSV^\top)^{n+1/3}. \]
- Updating (2.9): In this step, equation (2.9) is ran for $\Delta t$ with initial condition $u^{n+1/3}$. Since the step only changes $S$, we immediately obtain

$$X^{n+2/3} = X^{n+1/3}, \quad \text{and} \quad V^{n+2/3} = V^{n+1/3}.$$ 

Plugging the low rank representation (2.4) into (2.9), we obtain, in matrix form:

$$\partial_t S(t) = \frac{1}{\epsilon} \sum_{k=1}^{d} A_k^\alpha S(t) \Xi^{n+2/3}_{v_k} - \frac{1}{\epsilon^2} A_k^\alpha S(t) \Gamma^{n+2/3},$$  

where $\Xi_{v_k}$ and $\Gamma$, both $\in \mathbb{R}^{r \times r}$, are the matrix versions of the multiplication operator associated to $v_k$ ($1 \leq k \leq d$) and the density term, respectively:

$$[\Xi_{v_k}]_{i,j} = \langle V_i(\cdot) v_k V_j(\cdot) \rangle_v, \quad \text{and} \quad [\Gamma]_{i,j} = \langle \nabla_i(\cdot) \nabla_j(\cdot) \rangle_v."
2.2. Fully-discrete low rank splitting method. We discretize the aforementioned splitting method in time and phase space. We denote

\begin{equation}
\mathcal{X} = \{x_1, x_2, \ldots, x_{N_x}\}, \quad \mathcal{V} = \{v_1, v_2, \ldots, v_{N_v}\}
\end{equation}

the sets of discrete points in $\Omega_x$ and $\mathcal{S}^{d-1}$. The discrete solution can then be represented as follows

$$\mathbb{R}^{N_x \times N_v} \ni u^n = X^n S^n (V^n)^\top,$$

where $S^n = S^n$ and we abuse the notation by calling

\begin{equation}
X^n = [X_1^n, X_2^n, \ldots, X_r^n] \in \mathbb{R}^{N_x \times r}, \quad \text{and} \quad V^n = [V_1^n, V_2^n, \ldots, V_r^n] \in \mathbb{R}^{N_v \times r},
\end{equation}

with $X_i^n$ and $V_i^n$ denoting the $i$-th mode evaluated at grid points.

Implicit time integration of the three equations (2.11), (2.13), and (2.15) to overcome the stability issue introduced by the stiffness.

- For updating (2.11), $X^{n+1/3} = X^n$. Apply the implicit Euler scheme gives

\begin{equation}
\left\{
\frac{L^{n+1/3} - L^n}{\Delta t} + \frac{1}{\epsilon} \sum_{k=1}^d A_{\partial k}^n L^{n+1/3} \Pi_{\sigma_k} = \frac{A^n}{\epsilon^2} L^{n+1/3} C,
\right.
\end{equation}

QR decomposition: $L^{n+1/3} = S^{n+1/3} (V^{n+1})^\top$.

or apply the Crank–Nicolson method, the scheme reads

\begin{equation}
\left\{
\frac{L^{n+1/3} - L^n}{\Delta t} + \frac{1}{\epsilon} \sum_{k=1}^d A_{\partial k}^n \left( \frac{L^{n+1/3} + L^n}{2} \right) \Pi_{\sigma_k} = \frac{A^n}{\epsilon^2} \left( \frac{L^{n+1/3} + L^n}{2} \right) C,
\right.
\end{equation}

QR decomposition: $L^{n+1/3} = S^{n+1/3} (V^{n+1/3})^\top$.

In the equation we have used

\begin{equation}
A_{\partial k}^n = (X^n)^\top D_k X^n, \quad A_{\sigma k}^n = X^\top \Sigma X,
\end{equation}

$$\Pi_{\sigma_k} = \text{diag} (V_k), \quad C = \frac{1}{N_v} ee^\top - I_{N_v},$$

with $e = (1, 1, \ldots, 1)^\top$, $\Sigma = \text{diag}(\sigma(\mathcal{X}))$ is an $N_x \times N_x$ matrix with evaluations of $\sigma$ at the grid points in $\mathcal{X}$ assigned as diagonal entries and $D_k$ is the discrete approximation of $\partial_x$. The specific form of $D_k$ depends on the spatial discretization. We have used the simple rectangle rule for the integration in $\mu_v$. This determines the form of $C$. Other numerical integral rules could also be applied and the specific form of $C$ will change accordingly. Obviously $A_{\partial k}^n$ and $A_{\sigma k}^n$ are the discrete versions of (2.12).

- For updating (2.13), we note that $X$ and $V$ are preserved:

$$X^{n+2/3} = X^{n+1/3}, \quad \text{and} \quad V^{n+2/3} = V^{n+1/3}.$$

The direct application of the implicit Euler scheme gives

\begin{equation}
\frac{S^{n+2/3} - S^{n+1/3}}{\Delta t} - \frac{1}{\epsilon} \sum_{k=1}^d A_{\partial k}^n S^{n+2/3} \Xi_{\mu_k} = \frac{A^n}{\epsilon^2} S^{n+2/3} \Gamma^{n+2/3}.
\end{equation}
Similarly, if Crank–Nicolson is used, the scheme reads

\[
\frac{S_{n+2/3} - S_{n+1/3}}{\Delta t} - \frac{1}{\epsilon} \sum_{k=1}^{d} A^n_{\partial_k} \frac{S_{n+2/3} + S_{n+1/3}}{2} \Xi_{n+2/3} = -\frac{A^n}{\epsilon^2} \frac{S_{n+2/3} + S_{n+1/3}}{2} \Gamma_{n+2/3}.
\]

Here \( \Xi_{n+2/3} \) and \( \Gamma_{n+2/3} \), both \( r \times r \), are discrete versions of (2.14):

\[
\Xi_{n+2/3} = (V^{n+2/3})^\top \Pi_{\partial_k} V^{n+2/3}, \quad \Gamma_{n+2/3} = (V^{n+2/3})^\top CV^{n+2/3}.
\]

– Finally for updating (2.11), we note

\[
V^{n+1} = V^{n+2/3}, \quad \Gamma^{n+1} = \Gamma^{n+2/3}, \quad \Xi^{n+1} = \Xi^{n+2/3}.
\]

Defining:

\[
K^{n+2/3} = X^{n+2/3} S^{n+2/3},
\]

we apply the implicit Euler method for

\[
\begin{align*}
\frac{K^{n+1} - K^{n+2/3}}{\Delta t} + \frac{1}{\epsilon} \sum_{k=1}^{d} D_k K^{n+1} \Xi_{n+1} = \frac{\Sigma}{\epsilon^2} K^{n+1} \Gamma^{n+1},
\end{align*}
\]

QR decomposition: \( X^{n+1} S^{n+1} = K^{n+1} \).

Crank–Nicolson method will not be used in the last step and thus we do not specify it.

We finalize the update for

\[
u^{n+1} = X^{n+1} S^{n+1} (V^{n+1})^\top.
\]

We summarize the one-time step integrators

**Algorithm 2.1 One-timestep implicit Euler integrator**

**Input:**
1. time step \( \Delta t \);
2. Input data: \( X^n, S^n \) and \( V^n \).

**Run:**
- Construct \( A^n_{\partial_k}, A^n_{\sigma} \) by (2.20); Compute \( L^n = S^n (V^n)^\top \);
  - Update \( L^{n+1/3} \) by solving (2.18) with \( \Delta t \);
- Perform QR decomposition to obtain \( S^{n+1/3}, V^{n+1} \) from (2.18); Construct \( \Xi^{n+1} \) and \( \Gamma^{n+1} \) by (2.23);
  - Update \( S^{n+2/3} \) with \( \Delta t \) by solving (2.21);
- Construct \( K^{n+2/3} = X^n S^{n+2/3} \) by (2.24);
  - Update \( K^{n+1} \) with \( \Delta t \) by solving (2.25);
- Perform QR decomposition to obtain \( X^{n+1}, S^{n+1} \) from (2.25);

**Output:** Numerical solution \( X^{n+1}, S^{n+1}, V^{n+1} \);

3. **Properties of the numerical scheme.** We investigate the properties of the numerical method in this section. In particular we will discuss the computational complexity and prove the method captures the rank-1 structure in the parabolic regime.
Algorithm 2.2 One-timestep Crank–Nicolson integrator

**Input:**
1. time step \( \Delta t \);
2. Input data: \( X^n, S^n \) and \( V^n \).

**Run:**
- Construct \( A_{\partial_{\bar{x}}}^0, A_{\sigma}^0 \) by (2.20); Compute \( L^n = S^n(V^n)^T \);
- Update \( L^{n+1/3} \) by solving (2.19) with \( \Delta t \);
- Perform QR decomposition to obtain \( S^{n+1/3}, V^{n+1} \) from (2.19); Construct \( \Xi_{v_{k+1}^n}^+ \) and \( \Gamma_{v_{k+1}^n}^{+1} \) by (2.23);
- Update \( S^{n+2/3} \) with \( \Delta t \) by solving (2.22);
- Construct \( K^{n+2/3} = X^n S^{n+2/3} \) by (2.24);
- Update \( K^{n+1} \) with \( \Delta t \) by solving (2.25);
- Perform QR decomposition to obtain \( X^{n+1}, S^{n+1} \) from (2.25);

**Output:** Numerical solution \( X^{n+1}, S^{n+1}, V^{n+1} \);

### 3.1. Computational complexity.
To analyze the computational complexity is rather straightforward. Denote \( r \) the rank, \( N_x \) and \( N_v \) the cardinality of \( X \) and \( V \) respectively. The matrices in the updating formula, \( X^n, S^n, V^n \) are computed by solving (2.18), (2.21), (2.25). The cost is summarized in Table 1:

</table>

Table 1: Floating point operation required for the dynamical low-rank algorithm.

Because \( r = O(1) \ll \min\{N_x, N_v\} \), in conclusion, we need \( O(N_x^3 + N_v^3) \) flops per time step, instead of the \( O(N_x^3 N_v^3) \) as required by the traditional solvers.

### 3.2. Intuition of the error analysis.
Before describing and proving our results in detail, in this section we first give a relatively vague justification on why the method works. As described in the introduction, there are two points we need to make:
• Why the true solution has an approximate low rank structure? This question is a rather fundamental, and is independent of the method chosen: the rank structure of the solution purely depends on the governing PDE we are studying here.

• Why the method keeps track of the low rank structure? This question concerns the behavior of the specific method (dynamic low-rank approximation) we choose to use here.

To answer the first question, we merely cite the following result.

**Theorem 3.1 (Theorem 2 of [2]).** Denote \( u' \) the solution to the linear Boltzmann equation, for \((t, x, v) \in \mathbb{R}^+ \times \Omega_x \times S^{d-1}:\)

\[
\frac{\partial_t u'}{\epsilon} = \mathcal{L} u' = \frac{\sigma}{\epsilon^2} \mathcal{L}_0 u' + \frac{1}{\epsilon} \mathcal{L}_1 u',
\]

where \( \mathcal{L}_0 u = \rho - u \) and \( \mathcal{L}_1 u = -v \cdot \nabla_x u. \) Then in the zero limit of \( \epsilon, \) the solution converges to the solution of the diffusion equation:

\[
\frac{\partial \rho}{\partial t} = \nabla_x \cdot \left( \frac{1}{d\sigma} \nabla_x \rho \right), \quad (t, x) \in \mathbb{R}^+ \times \Omega_x,
\]

in the sense that

\[
\|u'(t, x, v) - \rho(t, x)\|_{L^2(dx d\mu)} \leq C\epsilon,
\]

Here \( C \) depends only on \( t \) and \( u_0. \)

We note that periodic boundary conditions are imposed in the original theorem to avoid complications that may come from the boundary layers. Essentially this theorem states that in the zero limit of \( \epsilon, u(t, x, v) \) loses its velocity dependence, and the dynamics will purely be reflected in the physical space. In some sense:

\[
u(t, x, v) = \rho(x) + \mathcal{O}(\epsilon),
\]

can be seen as the rank-1 approximation with the threshold set at any value bigger than \( \epsilon. \)

The proof for the theorem follows the Hilbert expansion. Formally, one writes \( u = u_0 + \epsilon u_1 + \epsilon^2 u_2 + \cdots \) and perform asymptotic analysis. Showing Theorem 3.1 rigorously then amounts to bounding \( u_2 \) uniformly in \( \epsilon \), and we omit it from here.

To answer the second question amounts to proving that the dynamical low-rank approximation method captures the rank structure of the solution. This is not at all straightforward. In fact, the direct calculation would suggest otherwise: recall the dynamic low-rank approximation solution is governed by the following equation

\[
\frac{\partial_t u_r}{\epsilon} = \mathcal{P}_{u_r} \mathcal{L} u_r = \mathcal{P}_{u_r} \left[ \frac{1}{\epsilon^2} \mathcal{L}_0 u_r + \frac{1}{\epsilon} \mathcal{L}_1 u_r \right].
\]

Compare it with the original one (3.1), it is rather easy to see that one essentially need to show that

\[
(I - \mathcal{P}_{u_r}) \mathcal{L} u = (I - \mathcal{P}_X)(I - \mathcal{P}_V) \mathcal{L} u \ll \mathcal{O}(1)
\]

in some norm, where \( X \) and \( V \) are basis functions of \( u_r. \) Concerning that \( \mathcal{L} u \) contains stiff terms such as \( \frac{\sigma}{\epsilon^2} u'', \) a brute-force calculation would suggest that the error is of order \( 1/\epsilon \gg \mathcal{O}(1). \)
This straightforward approach, however, overlooks the information hidden in the equation. As will be presented in further details in Section 3, the proof largely relies on the separation of scales and one needs to perform the order by order matching of the scales to derive a clearer view of the solution structure. For that we perform the asymptotic analysis on the discrete level by setting \( u_r = u_{r,0} + \epsilon u_{r,1} + \cdots \). Plugging it back into equation (3.2), one has, in the leading order:

\[
O \left( \frac{1}{\epsilon^2} \right) : \quad \mathcal{P}_u \mathcal{L}_0 u_{r,0} = 0.
\]

With the definition of \( \mathcal{L}_0 \), calling \( u_r \in \text{Span}\{X_i\} \otimes \text{Span}\{V_j\} \), then

\[
\mathcal{L}_0 u_r = \rho - u_r = \langle u_r \rangle_v - u_r \in \text{Span}\{X_i\} \otimes \text{Span}\{V_j\},
\]

thus

\[
\mathcal{P}_u \mathcal{L}_0 u_{r,0} = \mathcal{L}_0 u_{r,0} = 0,
\]

which further suggests that the leading order of the numerical solution

\[
u_{r,0} \in \text{Null} \mathcal{L}_0.
\]

making \( u_r \) approximately rank-1. To show that \( u_{r,0} \) follows the right equilibrium flow requires more delicate derivations in the higher order expansions, and we show details in the following section.

### 3.3. Asymptotic analysis of the implicit Euler method.###

To unify the notation, throughout this section, we denote \( u^n \) a matrix of size \( N_x \times N_v \) with \( u^n_{ij} \) being the numerical solution at \( t_n, x_i, v_j \). Denote \( e = [1, \cdots, 1]^\top \) a column vector of length \( N_v \), \( \epsilon_n = \epsilon / \sqrt{N_v} \) the normalized version, then \( \rho^n = u^n e \) is a vector of length \( N_x \) representing the discrete version of \( \rho \) at time \( t_n \) for spatial grid points \( X \). The hope is to show that density \( \rho^n \) solves equation (1.3) in the limit \( \epsilon \to 0 \).

Our first result concerns the behavior of the implicit Euler method in the asymptotic regime. The corresponding result, stated in Theorem 3.2, is shown under the following technical assumption.

**Assumption 1.** For all \( n \), there exists an orthogonal matrix \( Q^n \in \mathbb{R}^{r \times r} \) such that

\[
V^n = V^n Q^n = (e_n, V_{1,n} + e a_1, V_{2,n} + e a_2, \ldots, V_{d,n} + e a_d, V^*_d+2, \ldots, V^*_r) = O(\epsilon^2),
\]

where the components satisfy (for all \( 1 \leq k \leq d \) and \( i \geq d+2 \))

\[
e_n^\top a_k = O(\epsilon), \quad (V_{k,n})^\top V^{n+1,*}_i = O(\epsilon), \quad e_n^\top V^{n+1,*}_i = O(\epsilon^2).
\]

Here \( V_i \) is the \( i \)-th index of the coordinate set \( V \) and \( V_{i,n} = \frac{\sqrt{2}}{\sqrt{N_v}} V_i \) is the normalized version.

There are direct consequences of this assumption is. Define \( \alpha^n = (V^n)^\top e_n \) and \( \alpha^{n,*} = (V^{n,*})^\top e_n \), then

\[
\alpha^n = Q^n \alpha^{n,*}, \quad \alpha^{n,*} = (V^{n,*})^\top e_n = (1 + O(\epsilon^2), O(\epsilon^2), \ldots, O(\epsilon^2))^\top.
\]

Similarly, let

\[
\Xi^{n,*}_{ik} = (V^{n,*})^\top \Pi_{ik} V^n = Q^T \Xi^{n,*}_{ik} Q, \quad \text{and} \quad \Gamma^{n,*} = (V^{n,*})^\top C V^n = Q^T \Gamma^{n,*} Q.
\]
we have for all $j \leq N$

\[(\Xi_{v_k})_{1,j} = (\Xi_{v_k})_{j,1} = \frac{1}{\sqrt{d}}\delta_{k+1,j} + O(\epsilon),\]

and some straightforward calculation gives:

\[(\alpha^n)\top \Xi_n \Xi_m \alpha^n = (\alpha^{n,*})\top \Xi_m^{n+1,*} \Xi_{v_k}^{n+1,*} \alpha^{n,*} = \frac{1}{d}\delta_{m,n} + O(\epsilon^2),\]

\[(\alpha^n)\top \alpha^n = (\alpha^{n,*})\top \alpha^{n,*} = 1 + O(\epsilon^4),\]

\[V^n \alpha^n = V^{n,*} \alpha^{n,*} = e_n + O(\epsilon^2),\]

\[(\alpha^n)\top \Gamma^n = (\alpha^{n,*})\top \Gamma^{n,*} Q = O(\epsilon^2).\]

This assumption essentially says there are components in $V_{n+1}$ that can represent $e_n$ and all $V_{k,n}$. It is a rather mild condition. Indeed, assuming the initial data has this form, then with small time stepsize, the condition holds true at all later times, as explained in detail in Appendix B.

**Theorem 3.2.** We employ the implicit Euler method to compute $u^{n+1}$ from $u^n$, using equations (2.18), (2.21) and (2.25), then, under Assumption 1, there is a constant $C$ independent of $\epsilon$ so that:

\[\|u^{n+1} - \rho_0^{n+1} e\top\|_2 \leq C\epsilon,\]

where $\rho_0^{n+1}$ solves

\[\frac{\rho_0^{n+1} - \rho_0 + 2/3}{\Delta t} = \frac{1}{d} \sum_{k=1}^d D_k \left( (\Sigma^{-1} \Sigma_{k}) \rho_0^{n+1} \right).\]

and $\|\rho_0 + 2/3 - \rho_0\|_2 = O \left( \frac{(\Delta t)^2}{(\Delta x)^2} \right)$. This means in the $\epsilon \to 0$ limit, the numerical solution is approximately rank 1, with the density solving the diffusion equation according to the implicit Euler method.

**Remark 3. The bad.** We note that the implicit low-rank integrator based on the implicit Euler scheme has a strong requirement on $\Delta t$. It needs to be extremely small due to the $O \left( \frac{(\Delta t)^2}{(\Delta x)^2} \right)$ error term. For example, even if we choose $\Delta t \propto (\Delta x)^4$ the error is only $O(\Delta t)$ and we end up with a global error of order $O(1)$. This renders this numerical method impractical for time integration.

**Remark 4. The good.** The method is able to capture the correct low-rank structure. For $\epsilon \to 0$ we have $u^{n+1} = \rho_0^{n+1} e\top$ approximately, meaning the solution has rank 1 and is a constant in $v$. This is precisely the analytic result derived for the diffusion limit, shown in Theorem 3.1.

**Remark 5. On the rigor of the proof** The proof we provide below for the theorem is formal in the sense that we use the Hilbert expansion without tracing the constant $C$’s dependence on $\epsilon$. This proof, however, can be made rigorous with $C$’s dependence on $\epsilon$ explicitly removed. Essentially one follows the flow of the current structure of the proof, and gives a bound at the second order expansion, as is done in the continuous setting [2]. It is significantly more tedious but provides little intuition, so we leave it out from the current paper.
Proof. Throughout the proof, all quantities of interests will be expanded using the following ansatz, with the subindex standing for the level in the asymptotic expansion.

\[
p = p_0 + \epsilon p_1 + \epsilon^2 p_2 + \cdots.
\]

We now proceed by performing the three steps in the low-rank projector splitting following ansatz, with the subindex standing for the level in the asymptotic expansion.

**Step 1:** This step preserves \(X\) and updates \(L\). Thus, we plug the asymptotic expansion of \(L\) into equation (2.18) and obtain

\[
\begin{cases}
O(1/\epsilon^2) : & A^n_\sigma L^{n+1/3}_0 C = 0, \\
O(1/\epsilon) : & \sum_{k=1}^d A^n_\partial_k L^{n+1/3}_0 \Pi \nu_k = A^n_\sigma L^{n+1/3}_1 C, \\
O(1) : & \frac{L^{n+1/3}_0 - L^{n+1/3}_1}{\Delta t} + \sum_{k=1}^d A^n_\partial_k L^{n+1/3}_1 \Pi \nu_k = A^n_\sigma L^{n+1/3}_2 C.
\end{cases}
\]

(3.13)

Since \(A^n_\sigma\) is invertible, the equation for the leading order implies that \(L^{n+1/3}_0\) lies in the null space of \(C^\top\). According to equation (2.20) \(C\) is symmetric with null space \(\text{span}(e_n)\). Immediately:

\[
L^{n+1/3}_0 = t^{n+1/3}_0 e_n^\top,
\]

(3.14)

where the \(r \times 1\) vector \(t^{n+1/3}_0\) is yet to be determined. Solving the \(O(1/\epsilon)\) level equation for \(L^{n+1/3}_1\) we have:

\[
L^{n+1/3}_1 = -\sum_{k=1}^d (A^n_\sigma)^{-1} A^n_\partial_k t^{n+1/3}_0 e_n^\top \Pi \nu_k + t^{n+1/3}_1 e_n^\top.
\]

(3.15)

where the term \(t^{n+1/3}_1 e_n^\top\) is an undetermined component lying in the null space of \(C\). To close the system we consider the \(O(1)\) equation, and multiply \(e_n\) on both sides:

\[
\frac{L^{n+1/3}_0 - L^n_0 e_n}{\Delta t} + \sum_{k=1}^d A^n_\partial_k L^{n+1/3}_1 \Pi \nu_k e_n = 0.
\]

Plugging (3.15) into this equation and using

\[
e_n^\top \Pi \nu_k \Pi \nu_k e_n = \frac{1}{d} \delta_{k_1,k_2}, \quad e_n^\top \Pi \nu_k e_n = 0,
\]

we obtain

\[
\frac{L^{n+1/3}_0 - L^n_0 e_n}{\Delta t} - \frac{1}{d} \sum_{k=1}^d A^n_\partial_k (A^n_\sigma)^{-1} A^n_\partial_k t^{n+1/3}_0 = 0.
\]

Considering \(u^{n+1/3}_0 = X^n L^{n+1/3}_0 = X^n t^{n+1/3}_0 e_n^\top\) and \(\rho^{n+1/3}_0 = u^{n+1/3}_0 e_n / \sqrt{\nu_{\text{e}}} = X^n t^{n+1/3}_0 / \sqrt{\nu_{\text{e}}},\) we obtain (using \(X^\top X = 1\)):

\[
\frac{\rho^{n+1/3}_0 - \rho^n_0}{\Delta t} - \frac{1}{d} \sum_{k=1}^d X^n A^n_\partial_k (A^n_\sigma)^{-1} A^n_\partial_k (X^n)^\top \rho^{n+1/3}_0 = 0.
\]

(3.16)
Perform the QR decomposition of $L^{n+1/3}$ to obtain $V^{n+1/3}$ and $S^{n+1/3}$, and since $V$ will not change in later steps, we have, also according to (2.23):

\[ V^{n+1} = V^{n+2/3} = V^{n+1/3}, \]
\[ \Gamma^{n+1} = \Gamma^{n+2/3} = \Gamma^{n+1/3} = (V^T CV)^{n+1/3}, \]
\[ \Xi^{n+1} = \Xi^{n+2/3} = \Xi^{n+1/3} = (V^T \Pi_v V)^{n+1/3}. \]

For convenience, we use the superscript $(\cdot)^{n+1}$ uniformly for $V, \Gamma, \Xi$ in the following discussion. According to Assumption 1, there is $Q \in \mathbb{R}^{r \times r}$ such that (3.3) holds true for $V^{n+1, *} = VQ$, then (3.7) holds true at the new time step. Without loss of generality, in the following part of the proof, we ignore high order terms of $\epsilon$.

**Step 2:** This step preserves $X$ and $V$ and updates $S$. We plug the asymptotic expansion of $S$ into equation (2.21) to obtain

\[
\begin{align*}
O(1/\ell^2): & \quad A^n_\sigma S_0^{n+2/3} \Xi^{n+1} = 0, \\
O(1/\ell): & \quad -\sum_{k=1}^d A^n_{\partial_k} S_0^{n+2/3} \Xi^{n+1} = -A^n_0 S_1^{n+2/3} \Gamma^{n+1}, \\
O(1): & \quad \frac{S_0^{n+2/3} - S_0^{n+1/3} \alpha^{-1}}{\Delta t} - \sum_{k=1}^d A^n_{\partial_k} S_1^{n+2/3} \Xi^{n+1} = -A^n_0 S_2^{n+2/3} \Gamma^{n+1}.
\end{align*}
\]

Since $A^n_\sigma$ is invertible, the leading order equation implies that $S_0^{n+2/3}$ lies in the null space of $\Gamma^{n+1}$. Thus, we have

\[
S_0^{n+2/3} = S_0^{n+2/3} (\alpha^{n+1})^T,
\]

where $S_0^{n+2/3} \in \mathbb{R}^{r \times 1}$ is yet to be determined.

We now follow the same strategy as in step 1. That is, we plug the expression for $S_0^{n+2/3}$ into the equation of order $O(1)$ and then project out the null space of $\Gamma^{n+1}$.

\[
S_1^{n+2/3} = -\sum_{k=1}^d (A^n_\sigma)^{-1} A^n_{\partial_k} S_0^{n+2/3} \Xi^{n+1} + S_1^{n+2/3} (\alpha^{n+1})^T.
\]

Then we close the system by plugging the result for $S_1^{n+2/3}$ into the equation of order $O(\ell)$ of $S_0^{n+2/3}$ into the equation of order $O(\ell)$. To do so, we first multiply $\alpha^{n+1}$ on both sides of the equation and use (3.10) for

\[
\frac{S_0^{n+2/3} \alpha^{n+1} - S_0^{n+1/3} \alpha^{n+1}}{\Delta t} - \sum_{k=1}^d A^n_{\partial_k} S_1^{n+2/3} \Xi^{n+1} \alpha^{n+1} = 0.
\]

Noticing (3.18) and (3.7) we obtain

\[
\frac{S_0^{n+2/3} \alpha^{n+1} - S_0^{n+1/3} \alpha^{n+1}}{\Delta t} + \frac{1}{d} \sum_{k=1}^d A^n_{\partial_k} (A^n_\sigma)^{-1} A^n_{\partial_k} S_0^{n+2/3} \alpha^{n+1} = 0.
\]

Use (3.8), we obtain

\[
\frac{S_0^{n+2/3} \alpha^{n+1} - S_0^{n+1/3} \alpha^{n+1}}{\Delta t} + \frac{1}{d} \sum_{k=1}^d A^n_{\partial_k} (A^n_\sigma)^{-1} A^n_{\partial_k} S_0^{n+2/3} \alpha^{n+1} = 0.
\]

Since we further have $V^{n+1} \alpha^{n+1} = \varepsilon_n$ by (3.9), similar to (3.16), we finally obtain

\[
\frac{\rho_0^{n+2/3} - \rho_0^{n+1/3}}{\Delta t} + \frac{1}{d} \sum_{k=1}^d X^n A^n_{\partial_k} (A^n_\sigma)^{-1} A^n_{\partial_k} (X^n) \top \rho_0^{n+2/3} = 0.
\]
where \( \rho_0^{n+2/3} = X_0^n S_0^{n+2/3} (V^{n+1})^\top e_n / \sqrt{N_v} \). We then update the leading order of \( K \) according to

\[
K_0^{n+2/3} = X^n S_0^{n+2/3} = X^n S_0^{n+2/3} (a^{n+1})^\top. \tag{3.21}
\]

**Step 3:** This step preserves \( V \) and updates \( K \). Thus, we plug the asymptotic expansion of \( K \) into equation (2.25) and obtain

\[
\begin{align*}
O(1/\epsilon^2) & : \quad \Sigma K_0^{n+1} \Gamma^{n+1} = 0, \\
O(1/\epsilon) & : \quad \sum_{k=1}^d D_k K_0^{n+1} \Xi_k^{n+1} = \Sigma K_0^{n+1} \Gamma^{n+1}, \\
O(1) & : \quad \frac{K_0^{n+1} \Xi_k^{n+1}}{\Delta t} + \sum_{k=1}^d D_k K_0^{n+1} \Xi_k^{n+1} = \Sigma K_0^{n+1} \Gamma^{n+1}.
\end{align*}
\tag{3.22}
\]

Since \( \Sigma \) is invertible, the leading order equation implies that \( K_0^{n+1} \) lies in the null space of \( \Gamma^{n+1} \). Thus, we have

\[
K_0^{n+1} = k_0^{n+1} (a^{n+1})^\top, \tag{3.23}
\]

where \( k_0^{n+1} \in \mathbb{R}^{N \times 1} \) is yet to be determined. We now follow the same strategy as in step 1 and 2. That is to plug the expression for \( K_0^{n+1} \) into the equation of order \( O(1) \) and then project out the null space of \( \Gamma^{n+1} \). Then we close the system by plugging the result for \( K_0^{n+2/3} \) into the equation of order \( O(\epsilon) \). This yields, once again using (3.7),(3.8), and (3.10):

\[
\frac{K_0^{n+1} a^{n+1} - K_0^{n+2/3} a^{n+1}}{\Delta t} - \frac{1}{d} \sum_{k=1}^d D_k \Sigma^{-1} D_k K_0^{n+1} a^{n+1} = 0.
\tag{3.24}
\]

Now, since \( \rho_0^{n+1} = u_0^{n+1} e_n / \sqrt{N_v} \) and \( u_0^{n+1} = K_0^{n+1} (V^{n+1})^\top = k_0^{n+1} a^\top (V^{n+1})^\top \), we obtain, by using equation (3.9),

\[
\frac{\rho_0^{n+1} - \rho_0^{n+2/3}}{\Delta t} - \frac{1}{d} \sum_{k=1}^d D_k (\Sigma^{-1} D_k \rho_0^{n+1}) = 0,
\tag{3.25}
\]

which concludes the proof for (3.11). To show \( \| \rho_0^{n+2/3} - \rho_0^n \|_2 = O \left( \frac{(\Delta t)^2}{(\Delta x)^2} \right) \), we denote \( \mathcal{L} = \sum_{k=1}^d X^n A_{0_k} (A_{0_k}^n)^{-1} A_{0_k}^n (X^n)^\top \), then equation (3.16) and (3.20) can be written as

\[
\rho_0^{n+2/3} = \left( 1 + \frac{\Delta t}{d} \mathcal{L} \right)^{-1} \left( \mathcal{L} - \frac{\Delta t}{d} \mathcal{L} \right)^{-1} \rho_0^n = \left( 1 - \frac{(\Delta t)^2}{d^2} \mathcal{L} \right)^{-1} \rho_0^n. \tag{3.26}
\]

By using \( (X^n)^\top X^n = I \) we can bound \( \mathcal{L} \) as follows

\[
\| \mathcal{L} \|_2 \leq \frac{C_d}{(\Delta x)^2 \min(\sigma(x))},
\]

with \( C_d \) being a constant depending on \( d \) only. Therefore,

\[
\| \rho_0^{n+2/3} - \rho_0^n \|_2 = O \left( \frac{(\Delta t)^2}{(\Delta x)^2} \right) \Rightarrow \| \rho_0^{n+2/3} - \rho_0^n \|_2 = O \left( \frac{(\Delta t)^2}{(\Delta x)^4} \right) + O(\epsilon).
\]

Finally, since

\[
u_0^{n+1} = k_0^{n+1} a^\top (V^{n+1})^\top = k_0^{n+1} (e_n^\top V^{n+1}) (V_0^{n+1})^\top,
\]

we follow that \( e_n \) lies in the span of \( L_0^{n+1/3} \) and thus in the span of \( V_0^{n+1} = V_0^{n+1/3} \). We thus have \( u_0^{n+1} = k_0^{n+1} e_n^\top \), as desired.
3.4. Asymptotic analysis of the Crank–Nicolson scheme. As observed in the previous section, the implicit Euler has a strong requirement on $\Delta t$ for the low-rank algorithm to preserve the rank structure. In Theorem 3.3 below, we will show that the symmetry in the Crank–Nicolson will bring advantage: the method can preserve the rank structure independent of the time step size $\Delta t$. However, we do assume well-prepared initial data.

**Theorem 3.3.** Apply the Crank–Nicolson method to compute $u^{n+1}$ from $u^n$, using equation (2.19), (2.22) and (2.25). Assuming that $u^n = \rho^n_0 e^\top + \mathcal{O}(\epsilon)$, and under Assumption 1, there is a constant $C$ independent of $\epsilon$ so that

\[
\|u^{n+1} - \rho^{n+1}_0 e^\top\|_2 \leq C\epsilon,
\]

where

\[
\frac{\rho^{n+1}_0 - \rho^n_0}{\Delta t} - \frac{1}{d} \sum_{k=1}^d D_k (\Sigma^{-1} D_k \rho^{n+1}_0) = 0.
\]

This means with well-prepared initial data, the limiting scheme is the implicit Euler applied on the diffusion equation (1.3).

**Remark 6.** The good. It is immediate that Theorem 3.3 differs from Theorem 3.2 in that we preserve $\rho$ in the limit $\epsilon \to 0$ independent of the time step size. Note that both methods share the last step, which is responsible for propagating the diffusion equation.

**Remark 7.** The bad. The Crank–Nicolson based low-rank algorithm used here only “preserves” the asymptotic limit, but is not able to drive the solution to the low-rank space. As stated in Theorem 3.3 we add the assumption that the initial value already has the corresponding structure of rank 1, up to an error of $\mathcal{O}(\epsilon)$, to ensure the initial data is well-prepared at each time step.

**Remark 8.** The choice of $D_k$. We note that $D_k(\Sigma^{-1} D_k)$ may not be self-adjoint operator in general if $D_k$ is not chosen properly. In fact, if $D_k$ is chosen as upwind type, the discretization is a shifted diffusion by one grid point in space. If $D_k$ is chosen as central-scheme type, the self-adjoint property can be preserved, at the sacrifice of staggered behavior in the numerical solution. This type of problem is rather typical. A common way in the literature to overcome it by introducing the even-odd decomposition, the even part goes to the limit and the odd part diminishes. The two components are evolved with different type of fluxes [34]. Here numerically we simply balance the two types with a correctly chosen weight so that central scheme plays the major role in the diffusion limit. We leave the possible extension of introducing even-odd decomposition to future research.

**Proof.** Most of the proof is very similar to the case of the implicit Euler scheme detailed in Theorem 3.2. Thus, we will only highlight the main differences here and refer the reader to the appendix for a more thorough exposition.

The asymptotic expansion for the first step is given by

\[
\begin{cases}
O(1/\epsilon) : & A^\sigma_n \left( L_0^{n+1/3} - L_0^n \right) C = 0, \\
O(1) : & \sum_{k=1}^d A^n_{\partial_k} \left( L_0^{n+1/3} - L_0^n \right) \Pi_{\partial_k} = A^\sigma_n \left( L_1^{n+1/3} - L_1^n \right) C, \\
O(\epsilon) : & \frac{L_1^{n+1/3} - L_1^n}{\Delta t} + \sum_{k=1}^d A^n_{\partial_k} \left( L_1^{n+1/3} - L_1^n \right) \Pi_{\partial_k} = A^\sigma_n \left( L_2^{n+1/3} - L_2^n \right) C.
\end{cases}
\]
From the equation of order $O(1/\epsilon)$ we follow that

$$L_0^{n+1/3} = L_0^n + l_0^{n+1/3} e_n^T.$$ 

Thus, we only know that the difference $L_0^{n+1/3} - L_0^n$ lies in the null space of $C^T$; we can not make a similar claim for $L_0^{n+1/3}$. However, from the assumption $u^n = \rho_0^n e^T + O(\epsilon)$ and from $u^n = X^n L^n$ we immediately obtain $L_0^n = l_0^n e_n^T$. This is an important ingredient in the remainder of the proof. It is also the first major difference between the present proof for the Crank–Nicolson method and the proof of Theorem 3.2, where this condition is automatically satisfied independent of the chosen initial value. Using similar arguments as in the proof of Theorem 3.2 we can then show (see Lemma A.1 in the appendix for details):

- $L^n$ in (2.19) has the same form as (3.14).
- $S^{n+1/3}$ in (2.22) has the same form as (3.18).
- The equations for computing $u_{n+1/3}$ and $u_{n+2/3}$ (equations (A.10) and (A.11) in the appendix).

With further details in Appendix A, we obtain

$$\rho_0^{n+1/3} = \left(1 - \frac{(\Delta t)}{2d} \mathcal{L}^n\right)^{-1} \left(1 + \frac{(\Delta t)}{2d} \mathcal{L}^n\right) \rho_0^n,$$

$$\rho_0^{n+2/3} = \left(1 + \frac{(\Delta t)}{2d} \mathcal{L}^n\right)^{-1} \left(1 - \frac{(\Delta t)}{2d} \mathcal{L}^n\right) \rho_0^{n+1/3},$$

where as before $\mathcal{L} = \sum_{k=1}^d X^n A_k^\sigma (A_k^\sigma)^{-1} A_k^\sigma (X^n)^T$. Combining these two equations we get $\rho_0^{n+2/3} = \rho_0^n$ for all $n > 0$, which is the desired result.

### 3.5. Summary

Viewing Theorem 3.2 and Theorem 3.3, it is clear that the implicit Euler method is able to capture the low-rank structure of the diffusion limit from arbitrary data at the cost of requiring very small time step size, while the Crank–Nicolson preserves the rank structure from the well-prepared initial data with relative relaxed time step size.

When we design algorithms, we should make use of the benefit of both. To do so, one can simply run the implicit Euler with $\Delta t_1$ that small enough such that the error term $O((\Delta t_1)^2/(\Delta x)^4)$ is controlled by the desired accuracy. This time integrator, however, gets applied only once, and then in all subsequent time steps, i.e. all steps from time $t_1$ to time $t_{\text{max}}$, we apply the Crank–Nicolson time integrator. Theorem 3.2 suggests that with the first step taken, all the prerequisites of Theorem 3.3 are already guaranteed, so the rank structure will be preserved along the propagation, as Theorem 3.3 suggests. In conclusion, for $\epsilon \to 0$, the numerical solution is rank 1 and homogeneous in velocity, with the density $\rho$ satisfying the implicit Euler discretization of the diffusion equation (1.3).

We summarize the final method in Algorithm 3.1.

### 4. Numerical experiments

In this section we present some numerical evidence to showcase the property of the proposed dynamical low-rank integrator. Strictly speaking the linear Boltzmann equation is only defined for $d \geq 2$. However, in the quasi-2D case, assuming the data is homogeneous in $y$-direction, the equation degenerates to a problem with 1D in space. In this case the diffusion limit becomes:

$$\partial_t u = \frac{1}{3} \partial_x \left(\sigma^{-1}(x) \partial_x u\right), \quad (t, x) \in \mathbb{R}^+ \times \Omega_x.$$
Algorithm 3.1 (Dynamical low rank splitting method for the linear Boltzmann equation).

**Preparation:**
1. Initial data: \( u(t = 0, x, v) \).
2. Input data: final time: \( t_{\text{max}} \); rank number: \( r \); time step: \( \Delta t_1 \leq \Delta t_2 \).
3. Discretization points: \( X = \{ x_1, x_2, \ldots, x_{N_x} \} \), \( V = \{ v_1, v_2, \ldots, v_{N_v} \} \).
4. Initialization: use SVD to construct initial \( u^0 \) such that \( (2.7): u^0 = X^0 S^0 (V^0)^\top \approx u(t = 0, x, v) \).
5. Construct \( \Pi_{v,k}, C \) by \( (2.20) \).

**Run:**
- set \( n = 0 \);
- call **One-timestep implicit Euler integrator** using \( \Delta t_1 \) to update \( X^1, S^1, V^1 \), using Algorithm 2.1
- While \( t < t_{\text{max}} \): \( n \rightarrow n + 1 \);
- call **One-timestep Crank–Nicolson integrator** using \( \Delta t_2 \) to obtain \( X^{n+1}, S^{n+1}, V^{n+1} \) using Algorithm 2.2.
- end

**Output:** Numerical solution \( X^n, S^n \) and \( V^n \) for \( t_n \leq t_{\text{max}} \).

To measure the error we define:
\[
\mathcal{P}_{x,l}^{\text{error}} = \| u - X_l(X_l)^\top u \|_F \quad \text{and} \quad \mathcal{P}_{v,l}^{\text{error}} = \| u - uV_l(V_l)^\top \|_F ,
\]
where \( u \) is the reference solution and \( X \) and \( V \) are the numerical solution computed using the dynamic low rank integrator. The error is measured in the Frobenius norm for the matrix, which is equivalent to \( L_2(dx\,d\mu_v) \) in the continuous version.

4.1. Projection error and singular value test. Before testing the dynamic low rank numerical integrator, we first numerically justify that the solution is indeed of low rank. Setting the initial data to
\[
f(0, x, v) = \begin{cases} 2, & 0.8 < x < 1.2 \\ 0, & \text{otherwise} \end{cases}
\]
with the equation equipped with isotropic scattering and a varying cross sections (see (4.6) and (4.7) below) at \( \epsilon = 1 \), we compute the equation with fine grids \( (N_x = 200 \text{ and } N_v = 100) \) till \( t_{\text{max}} = 1 \). We plot the singular values of the solution in log-scale in Figure 1. It is clear that the singular values decay exponentially fast for both cases. This gives us the foundation to believe that the dynamical low rank approximation would work.

4.2. Example I. We consider a toy problem with the scattering cross section a constant
\[
\sigma(x) = 2, \quad x \in [0, 2].
\]
and the initial condition set as:
\[
f(0, x, v) = ((x - 1)^2 + 1) (v^2 + 1) .
\]
In running Algorithm 3.1, the dynamical low rank approximation, we combines central difference and upwind (CCP) flux for \( D \), namely:
\[
(Du^n)_{i,j} = \begin{cases} \frac{u^n_{i+1} - u^n_{i-1}}{\Delta x} + (1 - \epsilon) \frac{u^n_{i+1} - u^n_{i-1}}{2\Delta x}, v_j > 0 , \\
\epsilon \frac{u^n_{i+1} - u^n_{i-1}}{\Delta x} + (1 - \epsilon) \frac{u^n_{i+1} - u^n_{i-1}}{2\Delta x}, v_j \leq 0 .
\end{cases}
\]
The combination factor is determined by the Knudsen number $\epsilon$. This means in the kinetic regime when $\epsilon$ is close to 1 the flux becomes purely upwind but in the diffusion regime when $\epsilon \to 0$, the scheme is of central type. In the kinetic regime for $\epsilon = 1$, we set $N_x = 200$ and $N_v = 100$ for computing the reference solution, and we compare the low rank integrator solution with $r = 20$ and the same $(N_x, N_v)$ to this reference solution. In the diffusion regime, for $\epsilon = 10^{-3}$, the reference solution is given by the numerical solution to the diffusion equation directly. Both cases are shown in Figure 2 (for $t_{\text{max}} = 1$ and $t_{\text{max}} = 0.1$ respectively) where we clearly see that the numerical solution matches the reference.

We realize the upwind flux typically brings high artificial diffusion, and this diffusion would be magnified in the diffusion equation when the flux term becomes stiff. To justify the choice of flux $D$ defined above, here we compute the solution using dynamic low rank approximation with $D$ simply set as the upwind type. The results are shown in Figure 3. For relatively big Knudsen number ($\epsilon = 1$), the low rank integrator solution still agrees with the reference solution well, but the behavior significantly deteriorates in the diffusion regime when $\epsilon \to 0$. This is expected as stated in Remark 8 that the stencil for the upwind scheme is not symmetric, leading to the fact that $D(\Sigma^{-1}D)$ is not a self-adjoint operator as it should be for the $\epsilon \to 0$ limit.

4.3. Example II. We consider the following initial condition:

\begin{equation}
    f(0, x, v) = \begin{cases} 
        2, & 0.8 < x < 1.2 \\
        0, & \text{otherwise},
    \end{cases}
\end{equation}

and isotropic scattering with a cross section

\begin{equation}
    \sigma(x) = 100(x - 1)^4.
\end{equation}

The cross section thus become critical at $x = 1$. Comparing the dynamical low rank solution using $r = 20$ to the reference solution (fine discretization for $\epsilon = 1$ and diffusion limit for $\epsilon = 10^{-3}$), we see good agreement, as shown in Figure 4. To be quantitative, we also plot the error, defined in (4.2), in Figure 5. It is clear that the error decays exponentially fast. We also test the dynamic low rank integrator with
Fig. 2: Example I. We set \( N_x = 200, N_v = 100, r = 20 \). Left: \( \epsilon = 1 \), we compare the density \( \rho \) from the dynamical low-rank algorithm with a reference solution at \( t_{\text{max}} = 1 \). Right: \( \epsilon = 10^{-3} \), we compare the density \( \rho \) from the dynamical low rank algorithm with diffusion limit at \( t_{\text{max}} = 0.1 \).

Fig. 3: Example I. Here \( N_x = 200, N_v = 100, r = 20 \). Left: \( \epsilon = 1 \), we compare the reference solution and the dynamic low rank integrator solution with upwinding type of flux at \( t_{\text{max}} = 1 \). Right: \( \epsilon = 10^{-3} \), we compare the solution to the diffusion equation with the dynamic low rank integrator solution with upwinding type of flux at \( t_{\text{max}} = 0.1 \). The \( D(\Sigma^{-1}D) \) term loses its symmetry, and the reference solution is not captured.

\( D \) set to be of central scheme type. In this case, however, the method provides lots of artificial oscillation, as shown in Figure 6. These artificial oscillations do seem to capture the reference solution weakly (with oscillations centered around the true solution).

4.4. Example III. In the third example, we use the same initial condition as in Example II, but modify the cross section:

\[
\sigma(x) = \begin{cases} 
0.02, & x \in [0.35, 0.65] \cup [1.35, 1.65], \\
1, & x \in [0, 0.35) \cup (0.65, 1.35) \cup (1.65, 2].
\end{cases}
\]
Fig. 4: Example II. Here $N_x = 200, N_v = 100$. Left: $\epsilon = 1$ and $r = 10, 20$, we compare the density $\rho$ from the low-rank algorithm using CCP for $D_k$ with the implicit Euler/upwind solver at $t_{\text{max}} = 1$. Right: $\epsilon = 10^{-3}$ and $r = 10, 20$, we compare the density $\rho$ from the low-rank algorithm using CCP with the diffusion limit at $t_{\text{max}} = 0.1$. In the plots, LR stands for dynamic low rank solution.

Fig. 5: Example II. Here we use $N_x = 200, N_v = 100, r = 20$. The numerical solution $u$ is computed using the implicit Euler/upwind solver and $X, V$ is computed using the low-rank algorithm. Left: log$(\frac{\text{error}_{x,l}}{\|u\|_F})$ as a function of $l$. Right: log$(\frac{\text{error}_{v,l}}{\|u\|_F})$ as a function of $l$.

This cross section is of high contrast and has a discontinuity, and thus the equation quickly achieves equilibrium in the optical thick region ($\sigma \sim 1$), while still staying in the kinetic regime in the optical thin region ($\sigma \sim 0.02$). The dynamic low rank integrator uses $r = 20$. To obtain the reference solutions, we either compute the equation with fine grid when $\epsilon = 1$, or compute the diffusion equation directly with $\epsilon = 10^{-3}$. We also compute the error: it decays exponentially fast, as plotted in Figure 8.

5. Conclusion. We have applied a projector splitting based dynamical low-rank approximation to a multi-scale linear Boltzmann equation in diffusive scaling. Theoretically the equation has a low rank structure in this regime, and this paper
Fig. 6: Example II. Here $N_x = 200, N_v = 100$. Left: $\epsilon = 1$ and $r = 10, 20$, we compare the density $\rho$ from the low-rank algorithm using upwind and central differences for $D_k$ with the implicit Euler/upwind solver at $t_{\text{max}} = 1$. Right: $\epsilon = 10^{-3}$ and $r = 20$, we compare the density $\rho$ from the low-rank algorithm using central differences with the diffusion limit at $t_{\text{max}} = 0.1$. In the plots, LR stands for dynamic low rank solution, and CS stands for central scheme, while UP stands for upwinding.

Fig. 7: Example III. Here $N_x = 200, N_v = 100$. Left: $\epsilon = 1$ and $r = 10, 20$, we compare the density $\rho$ from the low-rank algorithm using CCP for $D_k$ with the implicit Euler/upwind solver at $t_{\text{max}} = 1$. Right: $\epsilon = 10^{-3}$ and $r = 10, 20$, we compare the density $\rho$ from the low-rank algorithm using CCP with the diffusion limit at $t_{\text{max}} = 0.1$.

studies if the dynamical low-rank numerical method, a highly nonlinear numerical method, can capture such structure.

The result crucially depends on the employed time integrator. As shown above, if implicit Euler is employed, the time stepsize needs to be small. However, the Crank–Nicolson method, due to its embedded symmetry, can preserve the low rank structure automatically for mild time stepsize requirement, if the initial data is well-prepared. Combining these conclusions, we propose to run the Euler method for a very small time stepsize for merely one step to enforce the low rank structure, and then switch to Crank–Nicolson to preserve the rank structure. Numerical evidences are shown to
Fig. 8: Example III. Here we use $N_x = 200, N_v = 100, r = 20$. The numerical solution $u$ is computed using the implicit Euler/upwind solver and $X, V$ is computed using the low-rank algorithm. Left: $\log \left( \frac{P_{\text{error}}}{\|u\|_F} \right)$ as a function of $l$. Right: $\log \left( \frac{P_{\text{error}}}{\|u\|_F} \right)$ as a function of $l$.

agree with the theoretical results obtained.

To our knowledge, it is the first analytical result on showing that the project-splitting dynamical low-rank approximation method truly preserves the rank structure in the kinetic framework.

Appendix A. Details for the proof of Theorem 3.3.

**Lemma A.1.** If Assumption 1 holds true, then for all $n > 0$, $L^n_0$ and $S^n_{1/3}$ can be written as follows

\begin{align}
L^n_0 &= \ell^n_0 e_n^\top, \\
S^n_{1/3} &= s^n_{1/3} (\alpha^{n+1})^\top,
\end{align}

with some $\ell^n_0 \in \mathbb{R}^{r \times 1}$ and $s^n_{1/3} \in \mathbb{R}^{r \times 1}$.

**Remark 9.** Using Assumption 1 and Lemma A.1, we can further prove that in each step, $L^{n+1/3}_0$ can be written as

\begin{equation}
L^{n+1/3}_0 = \hat{\ell}^{n+1/3}_0 e_n^\top - \epsilon \sum_{k=1}^d (A^n_n)^{-1} A^n_0 \hat{\eta}^{n+1/3}_n e_n^\top \prod_{v_k} + O(\epsilon^2),
\end{equation}

where $\hat{\ell}^{n+1/3}_0 = \ell^{n+1/3}_0 + \epsilon \ell^{n+1/3}_1$.

**Proof.** The proof proceeds by induction. First, for $n = 1$, by (3.23), after doing QR decomposition, we obtain

\begin{equation}
S^1_0 = s^1 e_1, r(\alpha^1)^\top, \; e_1 = (1, 0, \ldots, 0)^\top \in \mathbb{R}^{r \times 1},
\end{equation}

where $s^1 \in \mathbb{R}$ and $\alpha^1 = (V^1)^\top e_n$. Using Assumption 1, we then get

\begin{equation}
L^1_0 = s^1 e_1, r(\alpha^1)^\top (V^1)^\top + O(\epsilon) = s^1 e_1, r(\alpha^{1, *})^\top (V^{1, *})^\top + O(\epsilon) = s^1 e_1, r e_n^\top + O(\epsilon)
\end{equation}

Let $l^0_1 = s^1 e_1, r$, if we consider terms of order $O(1/\epsilon)$ in the asymptotic expansion of equation (2.19), we obtain

\begin{align}
L^{4/3}_0 + L^1_0 &= l^{4/3}_0 e_n^\top + l^1_0 e_n^\top.
\end{align}

After performing the QR decomposition we have

\begin{equation}
S^{4/3}_0 = L^{n+1/3}_0 \sqrt{2} + O(\epsilon) = l^{4/3}_0 e_n^\top \sqrt{2} + O(\epsilon) = l^{4/3}_0 (\alpha^2)^\top + O(\epsilon).
\end{equation}

This shows that equation (A.1) holds true for $n = 1$.

Now if for $n = k - 1$ equation (A.1) holds true, then we can show that

\begin{equation}
L^k_0 = l^k_0 e_n^\top,
\end{equation}

which implies

\begin{equation}
L^{k+1/3}_0 + L^k_0 = l^{k+1/3}_0 e_n^\top + l^k_0 e_n^\top.
\end{equation}

Then we perform a QR decomposition and obtain

\begin{equation}
S^{k+1/3}_0 = s^{k+1/3}_0 (\alpha^{n+1})^\top,
\end{equation}

where $s^{k+1/3}_0 = l^{k+1/3}_0$.

We now consider the proof of Theorem 3.3 in more detail.
Proof. Step 1-2: Instead of (3.16) and (3.20). We can obtain

\begin{equation}
\frac{u_0^{n+1/3} - u_0^n}{\Delta t} - \frac{1}{d} \sum_{k=1}^{d} X^n A_{\alpha_k}^n (A_e^n)^{-1} A_{\alpha_k}^n (X^n)^T u_0^{n+1/3} e + \frac{u_0^n}{2} e = 0,
\end{equation}

\begin{equation}
\frac{u_0^{n+2/3} - u_0^n}{\Delta t} + \frac{1}{d} \sum_{k=1}^{d} X^n A_{\alpha_k}^n (A_e^n)^{-1} A_{\alpha_k}^n (X^n)^T u_0^{n+2/3} e + \frac{u_0^n}{2} e = 0
\end{equation}

This gives us

\begin{align}
\rho_0^{n+1/3} &= \left( I - \frac{(\Delta t)}{2d} \mathcal{L}^n \right)^{-1} \left( I + \frac{(\Delta t)}{2d} \mathcal{L}^n \right) \rho_0^n, \\
\rho_0^{n+2/3} &= \left( I + \frac{(\Delta t)}{2d} \mathcal{L}^n \right)^{-1} \left( I - \frac{(\Delta t)}{2d} \mathcal{L}^n \right) \rho_0^{n+1/3}
\end{align}

\begin{equation}
\Rightarrow \rho_0^{n+2/3} = \rho_0^n.
\end{equation}

Now, we obtain

\begin{equation}
\rho_0^{n+2/3} = \rho_0^n, \quad \text{for } n > 0.
\end{equation}

in the first two splitting step with Crank–Nicolson scheme.

Step 3: Using equation (A.1) we have

\begin{equation}
S_0^{n+1/3} = s_0^{n+1/3} (\alpha^{n+1})^T.
\end{equation}

From the terms of order \(O(1/\epsilon)\) we then obtain

\begin{equation}
S_0^{n+2/3} = s_0^{n+2/3} (\alpha^{n+1})^T \Rightarrow k_0^{n+2/3} = k_0^{n+2/3} (\alpha^{n+1})^T.
\end{equation}

Repeating the procedure used to derive equations (3.24)-(3.25), we still recover the diffusion limit in the last splitting step as

\begin{equation}
\frac{\rho_0^{n+1} - \rho_0^{n+2/3}}{\Delta t} - \frac{1}{d} \sum_{k=1}^{d} D_k (\Sigma^{-1} D_k \rho_0^{n+1}) = 0.
\end{equation}

Appendix B. Discussion on the technical assumption.

We first note that conditions (3.4),(3.5) in Assumption 1 guarantee the orthonormality of \(V^{1,*}\). Now, using equation (3.5) and denoting \(\alpha^{n+1,*} = Q^T \alpha^{n+1}\) we have

\begin{equation}
\alpha^{n+1,*} (\alpha^{n+1,*})^T = Q^T \alpha^{n+1} (\alpha^{n+1})^T Q; \quad (\alpha^{n+1,*})^T \alpha^{n+1,*} = (\alpha^{n+1})^T \alpha^{n+1} = 1 + O(\epsilon^4).
\end{equation}

For each \(1 \leq k \leq d\), we define

\begin{equation}
\Xi^{n+1,*}_{v_k} = (V^{n+1,*})^T \text{diag}(V_k) V^{n+1,*},
\end{equation}

then we get

\begin{equation}
\Xi^{n+1,*}_{v_k} = Q^T \Xi^{n+1}_{v_k} Q; \quad (\Xi^{n+1,*}_{v_k})_{1,j} = (\Xi^{n+1}_{v_k})_{j,1} = \frac{1}{\sqrt{d}} \delta_{k+1,j} + O(\epsilon), \quad 1 \leq j \leq N_v,
\end{equation}

This manuscript is for review purposes only.
where the second equality can be shown by using equation (3.5).

By considering equations (3.15) and (A.2), it suffices to show that the space spanned by the rows of $l_{n+1/3}^\top e_n - \epsilon \sum_{i=1}^d (A_{n}^\top)^{-1} A_{n_i} t_{n+1/3}^\top \Pi_{v_i}$ can contain $e_n, V_1, \ldots, V_d$. This, in turn, is equivalent to show that the following $R^r \times (d+1)$ matrix has at least rank $d + 1$

$$R = \left( A_{n}^\top l_{0}^{n+1/3}, A_{n_0}^\top l_{0}^{n+1/3}, \ldots, A_{n_d}^\top l_{0}^{n+1/3} \right).$$

For convenience, we only consider $\sigma(x) = 1$ and $D_2$ is skew-symmetric.

First, we define the operator $H : \mathbb{R}^{N_x \times 1} \rightarrow \mathbb{R}^{d \times d}$ as follows

$$(B.4) \quad (H(k))^i,j = (D_i k)^\top (D_j k), \quad k \in \mathbb{R}^{N_x \times 1}.$$

**Lemma B.1.** Assume Assumption 1 is true for the numerical solution at time $t_n$, and $\epsilon$ are small enough, if

$$det(H(k^n)) \neq 0,$$

where $k^n$ is defined in equation (3.23), then Assumption 1 is true for the numerical solution at time $t_{n+1}$.

**Remark 10.** By Lemma B.1, we only need to check condition (B.5). Since $k^n$ is a discrete approximation to $\rho(x, t^n)$, assume numerical error is small and the solution satisfies

$$D(\rho)(t) = det \left( \int_{\Omega_x} \nabla \rho(x, t) (\nabla \rho(x, t))^\top dx \right) \neq 0, \quad \forall 0 \leq t \leq T,$$

then we have $H(k^n) \approx D(\rho)(t^n)$ and (B.5).

**Proof.** If Assumption 1 is true at time $t_{n-1}$, we have

$$K^n = k^n (\alpha^n)^\top - \epsilon \sum_{i=1}^d D_i k^n (\alpha^n)^\top \Xi_{v_i} + O(\epsilon^2).$$

and there exists an orthogonal matrix $Q$ such that

$$(B.6) \quad K^n Q = k^n (\alpha^{n,*})^\top - \epsilon \sum_{i=1}^d D_i k^n (\alpha^{n,*})^\top \Xi_{v_i}^{n,*} + O(\epsilon^2),$$

where $\alpha^{n,*}, \Xi_{v_i}^{n,*}$ satisfy (B.1) and (B.2).

Use (B.1) and (B.2), we can rewrite (B.6) as

$$(B.7) \quad K^n Q = \left( k^n, -\frac{\epsilon}{\sqrt{d}} D_1 k^n, \ldots, -\frac{\epsilon}{\sqrt{d}} D_d k^n, \ldots \right) + O(\epsilon^2).$$

We notice that $X^n$ comes from QR decomposition of $K^{n-1}$. Therefore, use (B.7), there exists an invertible matrix $P \in \mathbb{R}^{r \times r}$ such that

$$(B.8) \quad X^n = X^n P^{-1} = \left( k^n, -D_1 k^n, \ldots, -D_d k^n, \ldots \right) + O(\epsilon).$$

This manuscript is for review purposes only.
For any $1 \leq i \leq d$, we further define

(B.9) \[ A^*_{0i} = (X^*)^T D_i X^*, \] then $A^*_{0i} = P^T A^*_{0i} P$

and

(B.10) \[ A^*_i = (X^*)^T \Sigma X^*, \] then $A^*_i = P^T A^*_i P$.

Plug equations (B.9),(B.10) into (B.3) and define $l^* = P_l^{n+1/3}$, it suffices to show that $\mathcal{R}^*(A^*_0 l^*, A^*_1 l^*, \ldots, A^*_d l^*)$

has rank $d + 1$. Now we divide the following proof into two steps:

**First step:** $(l^*)_1 \gg 0$. Similar to equation (A.7), we have

\[ S^n (V^n)^T = L^n = l_0^n e_n^T + O(\epsilon). \]

Using (3.3),(3.23),(B.1), we get

\[ X^* P S^n (V^n)^T = K^n (V^n)^T = k^n (\alpha^n)^T (V^n)^T = k^n (\alpha^n e_n^T) (V^n e_n^T) = k^n e_n^T + O(\epsilon^2), \]

which implies

\[ X^* P l_0^n e_n = k^n e_n^T. \]

Because $X^*$ is an invertible matrix and the first column of $X^*$ is $k^n$, we must have

(B.11) \[ (P_l)_1^n = 1 + O(\epsilon). \]

Recall that

(B.12) \[ (l^*)_1 = \left( P_l^{n+1/3} \right)_1, \]

similar to asymptotic analysis performed to obtain (3.16), we have

\[ \frac{l_0^n e_n}{\Delta t} - L_0^n e_n - \sum_{i=1}^d A^*_0 (A^n_0)^{-1} A^n_0 \frac{l_0^n + 1}{2} e_n^T P_l^n e_n = 0, \]

\[ \Rightarrow \frac{l_0^n + 1}{\Delta t} - \frac{l_0^n}{\Delta t} + \frac{1}{d} \sum_{i=1}^d A^*_0 (A^n_0)^{-1} A^n_0 \frac{l_0^n + 1}{2} + \frac{l_0^n}{2} = 0, \]

which implies

(B.13) \[ \|l_0^n + 1/\Delta t - l_0^n\|_2 = O\left( \frac{\Delta t}{(\Delta x)^2} \right). \]

Combining (B.11),(B.12) with (B.13), we finally obtain

\[ \left( P \left( l_0^n + 1/\Delta t - l_0^n \right) \right)_1 = O\left( \frac{\Delta t}{(\Delta x)^2} \right) + O(\epsilon) \Rightarrow (l^*)_1 > 1 - O\left( \frac{\Delta t}{(\Delta x)^2} \right) + O(\epsilon) \gg 0, \]

where $\frac{\Delta t}{(\Delta x)^2}$, $\epsilon$ have to be very small.

**Second step:** $\Gamma^*$ is invertible. Now we can prove (B.5) by contradiction. If we assume there exists $\gamma \in \mathbb{R}^{(d+1) \times 1}$ with $\|\gamma\|_2 = 1$ such that

(B.14) \[ \mathcal{R}^* \gamma = 0 \Rightarrow \left( A^*_0 \gamma_1 + \sum_{i=1}^d A^*_i \gamma_{i+1} \right) l^* = 0. \]
Because $D_i$ is skew-symmetric, $A_{0i}^*$ is skew-symmetric for each $i$. From equation (B.14), we deduce

$$(l^*)^\top \left( A_{0i}^* \gamma_1 + \sum_{i=i}^{d} A_{0i}^* \gamma_{i+1} \right) l^* = 0 \Rightarrow \gamma_1 (l^*)^\top A_{0i}^* l^* = 0 \Rightarrow \gamma_1 = 0 \Rightarrow \sum_{i=i}^{d} A_{0i}^* l^* \gamma_{i+1} = 0,$$

where we use $(l^*)^\top A_{0i}^* l^* = 0$.

Plug equation (B.8) into equation (B.9), we obtain

$$(A_{0m}^*)_{i,j} = \begin{cases} O(\epsilon), & 2 \leq i, j \leq d + 1 \\ 0, & i = j \\ -(D_{i-1}k^n)^\top (D_mk^n) + O(\epsilon), & 2 \leq i \leq d + 1, j = 1 \end{cases}$$

for any $1 \leq m \leq d$. Consider the first column of $A_{0i}^*$ from equation (B.15). Since $(l^*)_1 \gg 0$, equation (B.14) implies

$$\mathcal{H}(k^n) \gamma_{(2:d+1)} = 0,$$

where $\mathcal{H}$ is defined in equation (B.4) and $\gamma_{(2:d+1)} \in \mathbb{R}^{d \times 1}$ is the cutoff vector to $\gamma$ defined as

$$(\gamma_{(2:d+1)})_i = \gamma_{i+1}, \quad 1 \leq i \leq d.$$  

Since $\mathcal{H}(k^n)$ is an invertible matrix, this finally shows that $\gamma_{(2:d+1)}$ has to be zero, which contradicts to $\|\gamma\|_2 = 1$.  

□
