REGULARITY RESULTS FOR SHORTEST BILLIARD TRAJECTORIES IN CONVEX BODIES IN $\mathbb{R}^n$

STEFAN KRUPP AND DANIEL RUDOLF

Abstract. We derive properties of closed billiard trajectories in convex bodies in $\mathbb{R}^n$. Building on techniques introduced by K. and D. Bezdek we establish two regularity results for length minimizing closed billiard trajectories: one for billiard trajectories in general convex bodies, the other for billiard trajectories in the special case of acute convex polytopes. Moreover, we attach particular importance to various examples, also including examples which show the sharpness of the first regularity result. Finally, we show how our results can be used in order to calculate (analytically and by computer) length minimizing closed regular billiard trajectories in convex polytopes.

1. Introduction

In this paper we analyze closed billiard trajectories in convex bodies in $\mathbb{R}^n$. The billiard trajectories are meant to be Euclidean which for bouncing points locally means: The angle of reflection equals the angle of incidence. This local reflection rule can be seen as consequence of the global least action principle. For a planar billiard table boundary this principle means that a billiard trajectory segment $(p_{j-1}, p_j, p_{j+1})$ minimizes the Euclidean length in the space of all paths connecting $p_{j-1}$ and $p_{j+1}$ via a reflection at the billiard table boundary.

From the geometric optics point of view, Euclidean billiards describe the wave propagation in a medium which is not only homogeneous and isotropic but also contains perfectly reflecting mirrors.

There is generally much interest into the study of billiards: Problems in almost every mathematical field can be related to problems in mathematical billiards, see for example [8], [9] and [14] for comprehensive surveys. Euclidean billiard trajectories in the plane have been investigated intensively. Nonetheless, so far not much is known about Euclidean billiard trajectories on higher-dimensional „tables”.

The aim of this paper is to establish two regularity results for length minimizing closed Euclidean billiard trajectories in higher-dimensional convex bodies and to show how these results can be used to calculate (analytically and by computer) these trajectories for certain classes of convex polytopes.

Let us precisely define closed Euclidean billiard trajectories based on the above mentioned least action principle.

Definition 1.1. Let $T \subset \mathbb{R}^n$ be a convex body, i.e. a compact convex set with non-empty interior, which from now on we call the billiard table. We say that a closed polygonal line with in order pairwise distinct vertices $p_1, \ldots, p_m$, $m \geq 2$, on the boundary of $T$ (denoted by $\partial T$), is a closed billiard trajectory in $T$ if for
Figure 1. The billiard reflection rule: $p_j$ minimizes \((1)\) over all $\bar{p}_j \in H_j$ where $H_j$ is a $T$-supporting hyperplane through $p_j$.

Every $j \in \{1, ..., m\}$ there is a $T$-supporting hyperplane $H_j$ through $p_j$ such that $p_j$ minimizes

\[
\|\bar{p}_j - p_{j-1}\| + \|p_{j+1} - \bar{p}_j\|
\]

over all $\bar{p}_j \in H_j$ and if $p_j$ is not contained in the line segment connecting $p_{j-1}$ and $p_{j+1}$. We encode this closed billiard trajectory by $(p_1, ..., p_m)$ and call its vertices bouncing points. Its length is given by

\[
\ell((p_1, ..., p_m)) = \sum_{j=1}^{m} \|p_{j+1} - p_j\|.
\]

We call a boundary point $p \in \partial T$ smooth if there is a unique $T$-supporting hyperplane through $p$. We say that $\partial T$ is smooth if every boundary point is smooth.

We remark that the notion of billiard trajectories is usually used for classical trajectories, i.e., for trajectories with bouncing points in smooth boundary points (billiard table gangs) while they stop in non-smooth boundary points (billiard table holes). Definition 1.1 generalizes this classical billiard reflection rule to non-smooth boundaries. To the author’s knowledge the papers [4], [7] and [5] in order were among the first suggesting a detailed study of these generalized billiard trajectories.

This definition implies the local billiard reflection rule: The angle of reflection equals the angle of incidence. In this generalized version the angle of incidence/reflection is the angle enclosed by the incoming/reflecting billiard trajectory and the hyperplane which appears within the minimization in (1). Since a $T$-supporting hyperplane through non-smooth boundary points of the billiard table $T$ is not unique, the billiard reflection rule may produce different bouncing points following two already known consecutive ones.

In order to state our first regularity result let

\[
N_T(p) := \{ n \in \mathbb{R}^n : \langle n, y - p \rangle \leq 0 \text{ for all } y \in T \}
\]

be the outer normal cone at $T$ in the point $p \in \partial T$. Then the first regularity result reads as follows:

1Whenever we have settled indices $1, ..., m$, then indices in $\mathbb{Z}$ will be considered as indices modulo $m$. 
Theorem 1.2. Let $T \subset \mathbb{R}^n$ be a billiard table and $p = (p_1, \ldots, p_m)$ a length minimizing closed billiard trajectory in $T$. Further, let $V \subset \mathbb{R}^n$ be an affine subspace such that $T \cap V$ is the smallest affine section of $T$ containing $p$. Then, it follows that $\dim V = m - 1$ and
\[ \dim (N_T(p_j) \cap V_0) = 1 \]
for all $j \in \{1, \ldots, m\}$, where $V_0$ is the linear subspace that is parallel to the affine subspace $V$.

From $\dim V \leq n$ it follows that $m \leq n + 1$. Furthermore, $\dim V = m - 1$ implies that $p$ is maximally spanning by what we mean
\[ \dim (\text{conv}\{p_1, \ldots, p_m\}) = m - 1. \]
In fact, (3) is a regularity result: If $m = n + 1$, meaning that $V = \mathbb{R}^n$, then $p$ is regular, i.e. all bouncing points of $p$ are smooth boundary points of $T$; because: $N_T(p_j)$ is one-dimensional for all $j \in \{1, \ldots, m\}$. For $n = 2$ this means that every length minimizing billiard trajectory in $T$ has either two or three bouncing points, while in the latter case all of them are smooth boundary points of $T$.

Some special cases of Theorem 1.2 were already known: In [5] it has been proven for length minimizing closed billiard trajectories that $m$ is bounded from above by $n + 1$. In [2] it was shown the two-dimensional case, while in [1] it has been proven that every length minimizing closed billiard trajectory in $T \subset \mathbb{R}^n$ with $n + 1$ bouncing points is regular.

Theorem 1.2 refutes the presumption, which at first appears to be intuitively correct, that every length-minimizing closed billiard trajectory with more than two bouncing points is regular within the smallest section of $T$ containing this trajectory. We remark that in our upcoming paper [10] we extend Theorem 1.2 from the Euclidean setting to the more general Finsler/Minkowski setting.

For the second regularity result we introduce the following definition: Let $P \subset \mathbb{R}^n$ be a full dimensional convex polytope, i.e. a bounded intersection of finitely many closed half-spaces of $\mathbb{R}^n$ with non-empty interior. Let $F_1, \ldots, F_k$ be the facets, i.e. the $(n-1)$-dimensional faces, of $P$ where we denote by $q_1, \ldots, q_k$ the inward unit normal vectors to them. For $i, j \in \{1, \ldots, k\}$ with $i \neq j$ and $\dim (F_i \cap F_j) = n - 2$ let $\gamma_{ij} \in (0, \pi)$ be the angle enclosed by $q_i$ and $q_j$. Then $\alpha_{ij} = \pi - \gamma_{ij}$ is called the dihedral angle between $F_i$ and $F_j$. The dihedral angle $\alpha_{ij}$ is called acute when $\alpha_{ij} \in (0, \frac{\pi}{2})$. We call $P$ acute if all dihedral angles of $P$ are acute.

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{diagram}
\caption{The dihedral angle $\alpha_{ij}$ is acute if $\alpha_{ij} = \pi - \gamma_{ij} \in (0, \frac{\pi}{2})$.}
\end{figure}
Then the second regularity result is:

**Theorem 1.3.** Let $P \subset \mathbb{R}^n$ be an acute convex polytope that plays the role of the billiard table. Then every length minimizing closed billiard trajectory in $P$ is maximally spanning, regular and has exactly $n+1$ bouncing points.

This second regularity result is an improvement of Theorem 1.1 in [1] for the special case of acute convex polytopes. There it has been proven that every length minimizing closed billiard trajectory in the more general class of acute convex bodies in $\mathbb{R}^n$ is regular and has at most $n+1$ bouncing points.

Since every dihedral acute angled simplex (cf. [11] for a survey on the simplices’ dihedral angles) is an acute convex polytope the same regularity result holds for these simplices (this is already known from Corollary 1.2 in [11]). In order to emphasize the significance of Theorem 1.3, it remains to understand the difference between acute convex polytopes and acute simplices: Is there any acute polytope which is not a simplex? We discuss this question at the end of Section 4.

In this paper we attach particular importance to various examples. These include counter-intuitive conclusions concerning (length minimizing) closed billiard trajectories within sections of the billiard table. Furthermore, we provide some examples showing the sharpness of Theorem 1.2.

More precisely, we provide examples for the following statements:

(i) The length minimality of closed billiard trajectories in $T \subset \mathbb{R}^n$ is not invariant under going to sections of $T$ containing the billiard trajectory (cf. Example A). The length minimality may not even be locally preserved (cf. Example B).

(ii) The length minimality of closed billiard trajectories in $T \subset \mathbb{R}^n$ is not invariant under going to smallest sections of $T$ containing the billiard trajectory (cf. Example C). The length minimality may not even be locally preserved (cf. Example D).

(iii) A length minimizing closed billiard trajectory in $T \subset \mathbb{R}^n$ may not be regular within the smallest section of $T$ containing the billiard trajectory (cf. Example E). This can even appear for the unique length minimizing closed billiard trajectory (cf. Example F).

(iv) A length minimizing closed billiard trajectory in $T \subset \mathbb{R}^n$ can have bouncing points in vertices as well as in more than 0-dimensional faces of $T$ (cf. Examples E and F).

Let us briefly present the structure of this paper. In Section 2, we discuss properties of closed billiard trajectories in convex bodies. In Section 3 and 4 we prove our first and second regularity result, respectively. In Section 5, we provide various examples concerning above listed statements. In Section 6, we show how our results can be used in order to calculate (analytically and by computer) length minimizing closed billiard trajectories in convex polytopes.

2. Properties of closed billiard trajectories

We start by recalling the statements of the following useful Lemma for which for a convex body $T \subset \mathbb{R}^n$ we first define

\[ F(T) := \{ F : F \text{ is a set of points in } \mathbb{R}^n \text{ that cannot be translated into } T \}, \]
where \( \hat{T} \) denotes the interior of \( T \) in \( \mathbb{R}^n \), and write for the sake of simplicity 
\((p_1, \ldots, p_m) \in F(T)\) while we actually mean \( \{p_1, \ldots, p_m\} \in F(T)\).

**Lemma 2.1** (Lemmata 2.1, 2.2 and 2.3 in [5]).
(i) Let \( T \subset \mathbb{R}^n \) be a convex set and \( F \) a finite set of at least \( n+1 \) points in \( \mathbb{R}^n \). Then there is a translate of \( T \) that covers \( F \) if and only if every choice of \( n+1 \) points of \( F \) can be covered by a translate of \( T \).

(ii) Let \( T \subset \mathbb{R}^n \) be a convex body and \( F \) a set of points \( p_1, \ldots, p_m \in \mathbb{R}^n \). Then \( F \in F(T) \) is equivalent to: There is a translate \( T' \) of \( T \) and there are closed half-spaces \( H_1^+, \ldots, H_m^+ \) of \( \mathbb{R}^n \) such that
- \( p_j \in \partial H_j^+ \) for all \( j \in \{1, \ldots, m\} \),
- \( T' \subseteq H_j^+ \) for all \( j \in \{1, \ldots, m\} \),
- \( \bigcap_{j=1}^{m} H_j^+ \) is nearly bounded, i.e. it lies between two parallel hyper-planes.

(iii) Let \( T \subset \mathbb{R}^n \) be a billiard table and \( p = (p_1, \ldots, p_m) \) a closed billiard trajectory in \( T \). Then we have \( p \in F(T) \).

We note that Lemma 2.1(i) can be equivalently (by contra-position applied on \( \hat{T} \)) expressed by: A set \( F \) of at least \( n+1 \) points in \( \mathbb{R}^n \) is in \( F(T) \) if and only if there is a choice of \( n+1 \) points out of \( F \) that is in \( F(T) \).

Furthermore, we recall the following characterisation of length minimizing closed billiard trajectories:

**Theorem 2.2** (Theorem 1.1 and Lemma 2.4 in [5]). Let \( T \subset \mathbb{R}^n \) be a billiard table. Then every length minimizing closed billiard trajectory in \( T \) has at most \( n+1 \) bouncing points. Moreover, every length minimizing closed billiard trajectory in \( T \) is a length minimizing element of \( F(T) \) and, conversely, every length minimizing element of \( F(T) \) can be translated to a length minimizing closed billiard trajectory in \( T \).

We note that Theorem 2.2 is an existence result for closed billiard trajectories in arbitrary billiard tables: Let \( T \subset \mathbb{R}^n \) be any billiard table. Then there is a closed billiard trajectory in \( T \) (with at most \( n+1 \) bouncing points). This can be easily concluded by a compactness argument applied on the set of closed polygonal lines in \( F(T) \) combined with the \( d_{H} \)-continuity, i.e. continuity with respect to the Hausdorff distance \( d_{H} \), of the length functional.

We continue by stating the following property of closed billiard trajectories:

**Proposition 2.3.** Let \( T \subset \mathbb{R}^n \) be a billiard table, \( p = (p_1, \ldots, p_m) \) a closed billiard trajectory in \( T \) and \( V \subset \mathbb{R}^n \) an affine subspace such that \( T \cap V \) is an affine section of \( T \) containing \( p \). Then \( p \) is a closed billiard trajectory in \( T \cap V \).

**Proof.** Since \( p = (p_1, \ldots, p_m) \) is a closed billiard trajectory in \( T \) there are \( T \)-supporting hyperplanes \( H_1, \ldots, H_m \) in \( \mathbb{R}^n \) through \( p_1, \ldots, p_m \) such that \( p_j \) minimizes
\[
\|p_j - p_{j-1}\| + \|p_{j+1} - p_j\|
\]
over all \( p_j \in H_j \) for all \( j \in \{1, \ldots, m\} \). Since \( T \cap V \) contains \( p \) it follows that \( p_j \) minimizes \( \|p_j - p_{j-1}\| + \|p_{j+1} - p_j\| \) over all \( \tilde{p}_j \in H_j \cap V \) for all \( j \in \{1, \ldots, m\} \). This implies that \( p \) is a billiard trajectory in \( T \cap V \).

Clearly, the converse is not true: We can imagine an affine subspace \( V \subset \mathbb{R}^n \) such that the section \( T \cap V \) of \( T \) can be translated into \( \hat{T} \). Then every closed
billiard trajectory \( p \) in \( T \cap V \) can be translated into \( \tilde{T} \). But by Lemma 2.1(iii) then \( p \) cannot be a closed billiard trajectory in \( T \).

In Section 5 (cf. Examples A, B, C and D) we will see that generally the length minimality of a closed billiard trajectory in \( T \) is not invariant under going to (smallest) affine sections of \( T \) containing the closed billiard trajectory.

For what follows it will be useful to reformulate the billiard reflection rule in the sense of the following Proposition 2.4. For that we denote the \( p \)-dimensional unit sphere of \( \mathbb{R}^n \) by \( S^{n-1} \).

**Proposition 2.4.** Let \( T \subset \mathbb{R}^n \) be a billiard table. A closed polygonal line with vertices \( p_1, ..., p_m \) on \( \partial T \) is a closed billiard trajectory in \( T \) if and only if there are vectors \( n_1, ..., n_m \in S^{n-1} \) such that

\[
\begin{align*}
    p_{j+1} - p_j &= \lambda_j n_j, \quad \lambda_j > 0, \\
    n_{j+1} - n_j &= -N_T(p_{j+1})
\end{align*}
\]

is fulfilled for all \( j \in \{1, ..., m\} \).

![Figure 3. The visualization of (5).](image)

**Proof.** Let \( p = (p_1, ..., p_m) \) be a closed polygonal line with vertices on \( \partial T \). Let us assume there are vectors \( n_1, ..., n_m \in S^{n-1} \) which together with \( p \) fulfill (5). Then for all \( j \in \{1, ..., m\} \) there is a unit vector \( n_T(p_{j+1}) \in N_T(p_{j+1}) \) such that

\[
\begin{align*}
    p_{j+1} - p_j &= \lambda_j n_j, \quad \lambda_j > 0, \\
    n_{j+1} - n_j &= -\mu_{j+1} n_T(p_{j+1}), \quad \mu_{j+1} > 0,
\end{align*}
\]

holds. We define \( H_1, ..., H_m \) to be the \( T \)-supporting hyperplanes in \( \mathbb{R}^n \) through \( p_1, ..., p_m \) which are normal to \( n_T(p_1), ..., n_T(p_m) \). Then the following holds for all \( j \in \{1, ..., m\} \):

\[
\nabla_{\bar{p}_j = p_j} (||\bar{p}_j - p_j - 1|| + ||p_{j+1} - \bar{p}_j||) = \frac{p_j - p_{j-1}}{||p_j - p_{j-1}||} - \frac{p_{j+1} - p_j}{||p_{j+1} - p_j||} = \lambda_j - \lambda_j n_j - n_j = \mu_j n_T(p_j).
\]
Therefore, for all $j \in \{1, \ldots, m\}$ $p_j$ extremizes
\begin{equation}
\frac{p_j - p_{j-1}}{||p_j - p_{j-1}||} - \frac{p_{j+1} - p_j}{||p_{j+1} - p_j||} = \mu_j n_T(p_j), \quad \mu_j \in \mathbb{R},
\end{equation}
over all $\tilde{p}_j \in H_j$ near $p_j$. Since for all $j \in \{1, \ldots, m\}$ (6) is a convex function with respect to $\tilde{p}_j$ it follows for all $j \in \{1, \ldots, m\}$ that $p_j$ is a global minimizer of (6) over all $\tilde{p}_j \in H_j$. Therefore the billiard reflection rule is fulfilled in $p_j$ for all $j \in \{1, \ldots, m\}$. Eventually $p$ is a closed billiard trajectory in $T$.

Conversely, let us assume $p = (p_1, \ldots, p_m)$ is a closed billiard trajectory in $T$. Then there are $T$-supporting hyperplanes $H_1, \ldots, H_m$ in $\mathbb{R}^n$ through $p_1, \ldots, p_m$ such that for all $j \in \{1, \ldots, m\}$ $p_j$ minimizes (6) over all $\tilde{p}_j \in H_j$. By Lagrange’s multiplier theorem this means
\begin{equation*}
\frac{p_j - p_{j-1}}{||p_j - p_{j-1}||} - \frac{p_{j+1} - p_j}{||p_{j+1} - p_j||} = \mu_j n_T(p_j), \quad \mu_j \in \mathbb{R},
\end{equation*}
where $n_T(p_j)$ is the outer unit vector normal to $H_j$, for all $j \in \{1, \ldots, m\}$. Scalar multiplication with $n_T(p_j)$ gives $\mu_j > 0$ for all $j \in \{1, \ldots, m\}$. If we define
\begin{equation}
\lambda_j := \frac{p_{j+1} - p_j}{||p_{j+1} - p_j||}, \quad \lambda_j := \frac{p_j - p_{j-1}}{||p_j - p_{j-1}||}, \quad j \in \{1, \ldots, m\},
\end{equation}
and consider $n_T(p_j) \in N_T(p_j)$ for all $j \in \{1, \ldots, m\}$ then (5) is fulfilled for $p$ together with the unit vectors $n_1, \ldots, n_m$ defined in (7).

The proof of Proposition 2.4 shows even more: A closed polygonal line with vertices $p_1, \ldots, p_m$ on $\partial T$ is a closed billiard trajectory in $T$ with $H_1, \ldots, H_m$ the $T$-supporting hyperplanes which are associated to the billiard reflection rule if and only if there are vectors $n_1, \ldots, n_m \in S^{n-1}$ such that
\begin{align*}
\begin{cases}
p_j + 1 - p_j = \lambda_j n_j, & \lambda_j > 0, \\
n_{j+1} - n_j = -\mu_{j+1} n_{H_{j+1}}, & \mu_{j+1} > 0
\end{cases}
\end{align*}
is fulfilled for all $j \in \{1, \ldots, m\}$ where we denoted the outer unit normal vectors at $H_1, \ldots, H_m$ by $n_{H_1}, \ldots, n_{H_m}$.

The following rather obvious Proposition is needed within the proof of Theorem 1.2. It follows immediately from within the proof of Proposition 2.4.

**Proposition 2.5.** Let $T \subset \mathbb{R}^n$ be a billiard table and $p = (p_1, \ldots, p_m)$ a closed billiard trajectory in $T$. Then for every $j \in \{1, \ldots, m\}$ there is only one $T$-supporting hyperplane through $p_j$ for which the billiard reflection rule in $p_j$ is fulfilled.

**Proof.** This claim follows from the fact that the outer unit vector $n_T(p_j)$ normal to $H_j$ is uniquely determined by the condition
\begin{equation*}
\frac{p_j - p_{j-1}}{||p_j - p_{j-1}||} - \frac{p_{j+1} - p_j}{||p_{j+1} - p_j||} = \mu_j n_T(p_j), \quad \mu_j \neq 0,
\end{equation*}
which arises from Lagrange’s multiplier theorem as within the converse implication of the proof of Proposition 2.4.

The next two Propositions make a statement on the positional relationship of the hyperplanes which determine the billiard reflection rule.

**Proposition 2.6.** Let $T \subset \mathbb{R}^n$ be a billiard table, $p = (p_1, \ldots, p_m)$ a closed billiard trajectory in $T$ and $V \subset \mathbb{R}^n$ an affine subspace such that $T \cap V$ is the smallest affine section of $T$ containing $p$. Then the convex cone spanned by the outer unit vectors $n_T(p_1), \ldots, n_T(p_m)$
which are normal to the $T$-supporting hyperplanes $H_1, \ldots, H_m$ through $p_1, \ldots, p_m$ associated to the billiard reflection rule is $V_0$, where $V_0$ is the linear subspace underlyng $V$.

**Proof.** Since $p$ is a closed billiard trajectory in $T$ and $T \cap V$ an affine section of $T$ containing $p$ the vectors

$$(8) \quad p_2 - p_1, \ldots, p_m - p_{m-1}, p_1 - p_m$$

are all in $V_0$. Since $T \cap V$ is the smallest affine section containing $p$ it follows that the convex cone spanned by the vectors in (8) actually is $V_0$.

From the proof of Proposition 2.4 it follows that there are $n_1, \ldots, n_m \in S^{n-1}$ (cf. (7) for the definition) such that

$$\begin{align*}
    p_{j+1} - p_j &= \lambda_j n_j, \quad \lambda_j > 0, \\
    n_{j+1} - n_j &= -\mu_{j+1} n_T(p_{j+1}), \quad \mu_{j+1} > 0,
\end{align*}$$

holds for all $j \in \{1, \ldots, m\}$.

From

$$p_{j+1} - p_j = \lambda_j n_j, \quad \lambda_j > 0,$$

for all $j \in \{1, \ldots, m\}$ it follows that the convex cone spanned by $n_1, \ldots, n_m$ is $V_0$ and the same is true for the convex cone spanned by

$$n_2 - n_1, \ldots, n_m - n_{m-1}, n_1 - n_m.$$

Then

$$n_{j+1} - n_j = -\mu_{j+1} n_T(p_{j+1}), \quad \mu_{j+1} > 0,$$

for all $j \in \{1, \ldots, m\}$ implies that the convex cone spanned by

$$n_T(p_1), \ldots, n_T(p_m)$$

is $V_0$. □

**Proposition 2.7.** Let $T \subset \mathbb{R}^n$ be a billiard table, $p = (p_1, \ldots, p_m)$ a closed billiard trajectory in $T$ and $V \subset \mathbb{R}^n$ an affine subspace such that $T \cap V$ is the smallest affine section of $T$ containing $p$. Let $H_1^+, \ldots, H_m^+$ be the $T$-supporting half-spaces of $\mathbb{R}^n$ which are bounded by the hyperplanes $H_1, \ldots, H_m$ through $p_1, \ldots, p_m$ which are related to the billiard reflection rule. Further, let $W$ be the orthogonal complement to $V$. Then we can write

$$H_j = (H_j \cap V) \oplus W \quad \text{and} \quad H_j^+ = (H_j^+ \cap V) \oplus W$$

for all $j \in \{1, \ldots, m\}$ and have that

$$\bigcap_{j=1}^m (H_j^+ \cap V) \text{ is bounded in } V, \quad \bigcap_{j=1}^m H_j^+ \text{ is nearly bounded in } \mathbb{R}^n.$$

**Proof.** By Proposition 2.6 the convex cone spanned by the outer unit vectors normal to $H_1, \ldots, H_m$ is the linear subspace $V_0$ that underlies the affine subspace $V$. This implies on the one hand that we can write

$$(9) \quad H_j = (H_j \cap V) \oplus W \quad \text{and} \quad H_j^+ = (H_j^+ \cap V) \oplus W$$

for all $j \in \{1, \ldots, m\}$ and on the other hand that

$$(10) \quad \bigcap_{j=1}^m (H_j^+ \cap V)$$
is bounded in $V$. The latter fact implies that there are parallel hyperplanes $H$ and $H + d$, $d \in V_0$, in $V$ such that (10) lies in-between. With (9) this implies that

$$\bigcap_{j=1}^m H_j^+ = \bigcap_{j=1}^m ((H_j^+ \cap V) \oplus W) = \left( \bigcap_{j=1}^m (H_j^+ \cap V) \right) \oplus W$$

lies between the parallel hyperplanes $H \oplus W$ and $(H + d) \oplus W$ in $\mathbb{R}^n$ and therefore $H_1^+ \cap ... \cap H_m^+$ is nearly bounded in $\mathbb{R}^n$. □

Considering Lemma 2.1(ii) we note that with Proposition 2.7 we have subsequently provided a proof of Lemma 2.1(iii).

The following Proposition is a preparation for the proof of Theorem 1.2.

**Proposition 2.8.** Let $T \subset \mathbb{R}^n$ be a billiard table, $p = (p_1, ..., p_m)$ a closed billiard trajectory in $T$ and $V \subset \mathbb{R}^n$ an affine subspace such that $T \cap V$ is the smallest affine section of $T$ containing $p$. Then there is a selection $\{i_1, ..., i_{\dim V + 1}\} \subseteq \{1, ..., m\}$ such that

$$\{p_{i_1}, ..., p_{i_{\dim V + 1}}\} \in F(T).$$

**Proof.** If $\dim V = n$ then the claim follows immediately by Lemma 2.1(i) & (iii). This is also the case when $m = \dim V + 1$.

Let $\dim V \leq \min\{n-1, m-2\}$. Since $p$ is a closed billiard trajectory in $T$ there are $T$-supporting hyperplanes $H_1, ..., H_m$ through $p_1, ..., p_m$ for which the billiard reflection rule is fulfilled. Proposition 2.7 implies on the one hand that we can write

$$H_j = (H_j \cap V) \oplus W \quad \text{and} \quad H_j^+ = (H_j^+ \cap V) \oplus W$$

for all $j \in \{1, ..., m\}$, where $W$ is the orthogonal complement to $V$ and $H_1^+, ..., H_m^+$ are the closed half-spaces defined by $\partial H_j^+ = H_j$ and $T \subset H_j^+$ for all $j \in \{1, ..., m\}$, and on the other hand that

$$\bigcap_{j=1}^m (H_j^+ \cap V)$$

is bounded in $V$. Then there is a selection $\{i_1, ..., i_{\dim V + 1}\} \subseteq \{1, ..., m\}$ such that

$$\bigcap_{j=i_{\dim V + 1}}^{\dim V + 1} (H_{i_j}^+ \cap V)$$

is nearly bounded in $V$.

Indeed, let us assume this is not the case. Then it follows by Lemma 2.1(ii) that for every selection $\{i_1, ..., i_{\dim V + 1}\} \subseteq \{1, ..., m\}$

$$\{p_{i_1}, ..., p_{i_{\dim V + 1}}\}$$

can be translated into the interior of $T \cap V$. By Lemma 2.1(i) this implies that $\{p_1, ..., p_m\}$ can be translated into the interior of $T \cap V$. But again with Lemma 2.1(ii) this is a contradiction to the fact that (12) is bounded in $V$ and the claim is proven.

---

2One also could produce a contradiction by applying Proposition 2.3 and Lemma 2.1(iii).
We conclude that \([13]\) lies between two parallel hyperplanes in \(V\), say \(H\) and \(H + d\) where \(d\) is an element of the linear subspace \(V_0\) that underlies the affine subspace \(V\). By applying \([14]\) it follows that
\[
\bigcap_{j=1}^{\dim V+1} H_j^+ = \bigcap_{j=1}^{\dim V+1} ((H_j^+ \cap V) \oplus W) = \left(\bigcap_{j=1}^{\dim V+1} (H_j^+ \cap V)\right) \oplus W
\]
lies between the two parallel hyperplanes \(H \oplus W\) and \((H + d) \oplus W\) in \(\mathbb{R}^n\), i.e. it is nearly bounded in \(\mathbb{R}^n\). By Lemma \([2.1\text{ii}]\) it follows that
\[
\{p_{i_1}, \ldots, p_{i_{\dim V+1}}\} \in F(T).
\]

We remark that the statement of Proposition \([2.8]\) is not true when requiring \(p\) just to be a closed polygonal line in \(F(T)\) (and not a closed billiard trajectory in \(T\)). To see this we consider the following example in \(\mathbb{R}^5\) which has been communicated to us by A. Abbondandolo:

We start from four convex bodies \(K_1, K_2, K_3, K_4\) in \(\mathbb{R}^3\) with the following two properties:

(a) the intersection of all of them is empty;
(b) the intersection of any three of them has non-empty interior.

One has these examples because Helly’s theorem is sharp. Then we consider the four vertices of a square in \(\mathbb{R}^2\):
\[
v_1 = (0,0), \ v_2 = (1,0), \ v_3 = (1,1), \ v_4 = (0,1).
\]

Now let \(T\) be the convex hull in \(\mathbb{R}^5 = \mathbb{R}^2 \times \mathbb{R}^3\) of the union of the following four sets:
\[
\{v_1\} \times K_1, \ \{v_2\} \times K_2, \ \{v_3\} \times K_3, \ \{v_4\} \times K_4.
\]

\(T\) projects onto the square, but (a) implies that each section of \(T\) that is parallel to \(\mathbb{R}^2 \times \{0\}\) has area smaller than 1.

Indeed, we take any \(w \in \mathbb{R}^3\) and look at the section \(T \cap (\mathbb{R}^2 \times w)\). By the definition of \(T\) the points in this section are of the form \((v,w)\) with
\[
(14) \quad v = \sum_j \lambda_j v_j \quad \text{and} \quad w = \sum_j \lambda_j w_j,
\]
where \(w_j\) is in \(K_j\) and the \(\lambda_j\)’s are positive and add up to one. In particular, this section is contained in \(Q \times w\), where \(Q\) denotes the square with vertices \(v_j\). This section cannot contain all the four points \((v_j,w)\). In fact, assume that it contains the point \((v_1,w)\). Then \([14]\) and the fact that \(v_1\) is an extremal point of \(Q\) imply that \(w\) belongs to \(K_1\), as all the \(\lambda_j\)’s with \(j > 1\) must vanish in \([14]\). Since any given \(w \in \mathbb{R}^3\) belongs to at most three of the \(K_j\)’s, the claim is proven. Being a closed set that is contained in \(Q \times w\) and does not contain \((v_j,w)\) for at least one \(j\), the section \(T \cap (\mathbb{R}^2 \times w)\) has area strictly smaller than 1. Since the area of the intersection of a convex body with \(\mathbb{R}^2 \times w\) is an upper semi-continuous function of \(w\), all the sections of \(T\) by planes parallel to \(\mathbb{R}^2 \times \{0\}\) have area less than \(A\) for some \(A < 1\).

We choose as \(p_1, p_2, p_3, p_4\) the points
\[
p_1 = (1 - t)v_1, \ p_2 = (1 - t)v_2, \ p_3 = (1 - t)v_3, \ p_4 = (1 - t)v_4
\]
for \( t > 0 \) so small that the area of the square with the vertices \( p_1, p_2, p_3, p_4 \) is larger than \( A \) (while smaller than 1). Then
\[
\{p_1, p_2, p_3, p_4\} \in F(T)
\]
because any translation of these points will enclose a square that is too big to be contained in a section of \( T \) parallel to \( \mathbb{R}^2 \times \{0\} \). However, any triplet from \( \{p_1, p_2, p_3, p_4\} \) is not in \( F(T) \): Consider without loss of generality the triplet \( \{p_1, p_2, p_3\} \). By (b), there is a point \( w \) in the interior of \( K_1 \cap K_2 \cap K_3 \). Then the section \( \mathbb{R}^2 \times \{w\} \) contains a translated copy of the triangle with vertices \( v_1, v_2, v_3 \) and \( \{p_1, p_2, p_3\} \) can be translated into the interior of such triangle, and hence into the interior of \( T \). This proofs the claim.

The next two statements, i.e. Lemma 2.9 and Proposition 2.10, give insights on how to translate sets of finitely many points on the boundary of convex polytopes. Lemma 2.9 is the general version while Proposition 2.10 considers the bouncing points of closed billiard trajectories. The latter is the main ingredient for the proof of Theorem 1.3.

**Lemma 2.9.** Let \( P \subset \mathbb{R}^n \) be a convex polytope. Every set of \( m \leq n - 1 \) points on \( \partial P \) can be translated to a position where all the points still are on its original facets but at least one of them is a non-smooth boundary point of \( P \).

**Proof.** To illustrate the argument we start with the case \( n = 3 \). The facets of \( P \) are two-dimensional and we assume to have two points \( p_1, p_2 \) in the interiors of two of the facets. There are two cases: either the \( P \)-supporting hyperplanes associated to the two facets have no intersection or their intersection is a one-dimensional straight line. The first case is trivial since we can choose any direction (parallel to the facets) for translating \( \{p_1, p_2\} \) without \( p_1, p_2 \) leaving the facets until at least one of these points is a non-smooth boundary point of \( P \). For the second case there is one uniquely determined direction (up to orientation) given by the already mentioned one-dimensional straight line along which translating \( \{p_1, p_2\} \) is possible without \( p_1, p_2 \) leaving the facets until at least one of these points is a non-smooth boundary point of \( P \).

We generalize this argument to higher dimensions: Let \( p_1, \ldots, p_m, m \leq n - 1 \), be interior points of facets \( F_1, \ldots, F_m \) of \( P \). Let \( H_1, \ldots, H_m \) be the supporting hyperplanes of \( F_1, \ldots, F_m \) and suppose \( c_1, \ldots, c_m \in \mathbb{R}^n \) are chosen such that \( H_1 + c_1, \ldots, H_m + c_m \) are \( (n - 1) \)-dimensional linear subspaces of \( \mathbb{R}^n \). We conclude
\[
\dim \bigcap_{j=1}^m (H_j + c_j) = n - 1 - (m - 1) = n - m \geq 1 > 0.
\]
Now \( \{p_1, \ldots, p_m\} \) can be translated in directions given by vectors in
\[
\bigcap_{j=1}^m (H_j + c_j)
\]
while \( p_1, \ldots, p_m \) are not leaving \( F_1, \ldots, F_m \) until at least one of these points is a non-smooth boundary point of \( P \). \( \square \)

**Proposition 2.10.** Let \( P \subset \mathbb{R}^n \) be a convex polytope. Every regular closed billiard trajectory in \( P \) with \( m \leq n \) bouncing points can be translated into a closed non-regular, i.e. not regular billiard trajectory.
Proof. Let \( p = (p_1, \ldots, p_m) \) be a regular closed billiard trajectory in \( P \) with \( m \leq n \) and let \( V \subset \mathbb{R}^n \) be an affine subspace such that \( P \cap V \) is the smallest affine section of \( P \) containing \( p \).

If \( m \leq n - 1 \) then we apply Lemma 2.9 on the set of bouncing points \( \{p_1, \ldots, p_m\} \). Let \( p + c, c \in \mathbb{R}^n \), be the translated set in the sense of Lemma 2.9, i.e. at least one of the points \( p_1 + c, \ldots, p_m + c \) is a non-smooth boundary point of \( P \). (We argue below that \( p + c \) is a closed billiard trajectory in \( P \).)

Let \( m = n \) and \( p_1, \ldots, p_m \) be interior points of facets \( F_1, \ldots, F_m \) of \( P \). Let \( H_1, \ldots, H_m \) be the supporting hyperplanes of \( F_1, \ldots, F_m \). Applying Proposition 2.6 we can choose \( c_1, \ldots, c_m \in V_0 \) (for instance as positive/negative multiples of the unit vectors normal to \( H_1, \ldots, H_m \)), where \( V_0 \) is the linear subspace of \( \mathbb{R}^n \) that underlies the affine subspace \( V \), such that \( H_1 + c_1, \ldots, H_m + c_m \) are \((n-1)\)-dimensional linear subspaces of \( \mathbb{R}^n \). Based on the fact that \( (p_1, \ldots, p_m) \) is a closed billiard trajectory in \( P \) we claim that

\[
\dim \bigcap_{j=1}^{m} (H_j + c_j) > 0.
\]

Then, analogously to the proof of Lemma 2.9 \( \{p_1, \ldots, p_m\} \) can be translated in directions given by vectors in

\[
\bigcap_{j=1}^{m} (H_j + c_j)
\]

while \( p_1, \ldots, p_m \) are not leaving \( F_1, \ldots, F_m \) until at least one of these points is a non-smooth boundary point of \( P \). Let \( p + c \) with \( c \in \mathbb{R}^n \) in (16) be this translate. (We argue below that \( p + c \) is a closed billiard trajectory in \( P \).)

We justify (15): Since \( m = n \) the affine section \( P \cap V \) of \( P \) has dimension less or equal than \( n - 1 \). Since \( p \) is a closed billiard trajectory in \( P \) it follows by Proposition 2.7 that we can write

\[
H_j = (H_j \cap V) \oplus W \text{ and } (H_j \cap V) \perp W
\]

for all \( j \in \{1, \ldots, m\} \), where we denote by \( W \) the \((n - \dim V)\)-dimensional orthogonal complement to \( V \). Using that \( c_1, \ldots, c_m \) where chosen to be vectors in \( V_0 \) we can write

\[
H_j + c_j = (H_j \cap V) \oplus W + c_j = ((H_j \cap V) + c_j) \ominus W = ((H_j + c_j) \cap V) \ominus W
\]

for all \( j \in \{1, \ldots, m\} \) and therefore

\[
\dim \bigcap_{j=1}^{m} (H_j + c_j) = \dim \bigcap_{j=1}^{m} (H_j \cap V) \ominus W + c_j = \dim \bigcap_{j=1}^{m} ((H_j \cap V) + c_j) \ominus W
\]

\[
= \dim \bigcup_{j=1}^{m} ((H_j \cap V) + c_j) + \dim (W) \geq \dim (W) = n - \dim V \geq 1.
\]

By using Proposition 2.4 we argue that \( p + c \) (for \( m \leq n - 1 \) as well as for \( m = n \)) is a closed billiard trajectory in \( P \): Since \( p \) is a closed billiard trajectory in \( P \) there are unit vectors \( n_1, \ldots, n_m \in S^{n-1} \) such that

\[
\begin{align*}
\begin{cases}
      p_{j+1} - p_j = \lambda_j n_j, & \lambda_j > 0 \\
n_{j+1} - n_j \in -N_p(p_{j+1})
\end{cases}
\end{align*}
\]
is fulfilled for all $j \in \{1, \ldots, m\}$, where $N_{P}(p_1), \ldots, N_{P}(p_m)$ are one-dimensional since $p_1, \ldots, p_m$ are smooth boundary points of $P$. Then with

$$N_{P}(p_j) \subseteq N_{P}(p_j + c)$$

for all $j \in \{1, \ldots, m\}$ it follows that $p_1 + c, \ldots, p_m + c$ fulfil

$$\begin{cases} (p_{j+1} + c) - (p_j + c) = p_{j+1} - p_j = \lambda_j n_j \\ n_{j+1} - n_j \in -N_{P}(p_{j+1}) \subseteq -N_{P}(p_j + c) \end{cases}$$

for all $j \in \{1, \ldots, m\}$. Therefore Proposition 2.4 implies that $p + c$ is a closed billiard trajectory in $P$. $\square$

A consequence of Proposition 2.10 is: If there is a length minimizing closed billiard trajectory in a convex polytope $P$ with less than $n + 1$ bouncing points then there always is a non-regular length minimizing closed billiard trajectory.

We briefly note that the opposite is not the case: There are convex polytopes in $\mathbb{R}^n$ with closed inscribed non-regular billiard trajectories with $\leq n$ bouncing points that cannot be translated into a regular one (cf. for instance the length minimizing closed billiard trajectory in Example F discussed in Section 5).

3. Proof of Theorem 1.2

In order to prove Theorem 1.2 it will be useful to formulate the following Lemma:

**Lemma 3.1.** Let $H_1^+, \ldots, H_k^+$ be half-spaces of $\mathbb{R}^{d+2}$ such that

$$H_1^+ \cap \ldots \cap H_k^+$$

is bounded in $\mathbb{R}^d$. Let $n_1, \ldots, n_k$ be the outer (with respect to $H_1^+, \ldots, H_k^+$) unit vectors normal to $H_1, \ldots, H_k$. The following holds for every $j \in \{1, \ldots, k\}$: There is an $\varepsilon_j > 0$ such that

$$H_j^{pert,+} \cap \left( \bigcap_{i=1, i \neq j}^k H_i^+ \right)$$

is bounded in $\mathbb{R}^d$ for all $H_j^{pert,+} := \partial(H_j^{pert,+})$ whose outer unit normal vector is an element of $S^{d-1} \cap B_{\varepsilon_j}(n_j)$, where by $B_{\varepsilon_j}(n_j)$ we denote the $d$-dimensional ball of radius $\varepsilon_j$ fixed in $n_j$.

**Proof.** The statement is equivalent to the following one: Let $n_1, \ldots, n_k \in S^{d-1}$ be unit vectors with 0 in the interior of the convex hull $\text{conv}\{n_1, \ldots, n_k\}$. Then for every $j \in \{1, \ldots, k\}$ there is an $\varepsilon_j > 0$ such that 0 is in the interior of

$$\text{conv}\{n_1, \ldots, n_{j-1}, n_j^{pert}, n_{j+1}, \ldots, n_k\}$$

for every $n_j^{pert} \in S^{d-1} \cap B_{\varepsilon_j}(n_j)$. But this is clear since for every $j \in \{1, \ldots, k\}$ the fact

"0 is in the interior of $\text{conv}\{n_1, \ldots, n_k\}"$

is invariant under small perturbations of $n_j$. $\square$

We come to the proof of Theorem 1.2.
Proof of Theorem 1.2. Let \( p = (p_1, \ldots, p_m) \) be a length minimizing closed billiard trajectory in \( T \) and \( V \subset \mathbb{R}^n \) an affine subspace such that \( T \cap V \) is the smallest affine section containing \( p \), i.e. \( \dim V \leq \min\{n, m - 1\} \).

Then by Proposition 2.8 there is a selection \( \{i_1, \ldots, i_{\dim V + 1}\} \subseteq \{1, \ldots, m\} \) with 
\[
\{p_{i_1}, \ldots, p_{i_{\dim V + 1}}\} \in F(T).
\]
Without loss of generality we can assume \( i_1 < \ldots < i_{\dim V + 1} \) and define the closed polygonal line 
\[
\tilde{p} := (p_{i_1}, \ldots, p_{i_{\dim V + 1}}).
\]
For \( m > \dim V + 1 \) it follows \( \ell(\tilde{p}) < \ell(p) \). But with Theorem 2.2 this is a contradiction to the minimality of \( \tilde{p} \). Therefore it follows \( \dim V = m - 1 \).

Let us denote by \( H_{1}^{+}, \ldots, H_{m}^{+} \) the closed half-spaces defined by \( \partial H_{j}^{+} = H_{j} \) and 
\( T \subseteq H_{j}^{+} \) for all \( j \in \{1, \ldots, m\} \), where by \( H_{1}, \ldots, H_{m} \) we denote the \( T \)-supporting hyperplanes through \( p_1, \ldots, p_m \) which are related to the billiard reflection rule in these points. By Proposition 2.7 we conclude that
\[
H_{j} = (H_{j} \cap V) \oplus W \quad \text{and} \quad H_{j}^{+} = (H_{j}^{+} \cap V) \oplus W, \quad j \in \{1, \ldots, m\},
\]
where \( W \) is the orthogonal complement to \( V \), and
\[
\bigcap_{j=1}^{m} (H_{j}^{+} \cap V) \quad \text{bounded in} \quad V \left( \bigcap_{j=1}^{m} H_{j}^{+} \quad \text{nearly bounded in} \quad \mathbb{R}^n \right).
\]

Let \( n_{1}, \ldots, n_{m} \) be the outer unit vectors normal to \( H_{1}, \ldots, H_{m} \). Then it follows by (17) that 
\[
n_{j} \in N_{T}(p_{j}) \cap V_{0}
\]
and therefore 
\[
\dim (N_{T}(p_{j}) \cap V_{0}) \geq 1
\]
for all \( j \in \{1, \ldots, m\} \).

Let us assume there is an \( i \in \{1, \ldots, m\} \) such that 
\[
\dim (N_{T}(p_{i}) \cap V_{0}) > 1.
\]
Noting 
\[
N_{T}(p_{i}) \cap V_{0} \subseteq N_{T \cap V}(p_{i})
\]
it follows 
\[
\dim (N_{T}(p_{i}) \cap N_{T \cap V}(p_{i})) > 1,
\]
and because of Lemma 3.1 (for \( d = n \) and \( k = m \)) we can find a unit vector 
\[
n_{i}^{\text{pert}} \in N_{T}(p_{i}) \cap N_{T \cap V}(p_{i})
\]
with \( n_{i}^{\text{pert}} \neq n_{i} \) such that 
\[
H_{i,V}^{\text{pert},+} \cap \left( \bigcap_{j=1, j \neq i}^{m} (H_{j}^{+} \cap V) \right)
\]
remains bounded in \( V \) where we denote by \( H_{i,V}^{\text{pert},+} \) the closed half-space of \( V \) that contains \( T \cap V \) and which is bounded by \( H_{i,V}^{\text{pert}} \) which is the hyperplane in \( V \) through \( p_i \) that is normal to \( n_{i}^{\text{pert}} \). Since by Proposition 2.5 the billiard reflection rule in \( p_i \) (as bouncing point of the closed billiard trajectory \( p \)) in \( T \cap V \), cf. Proposition 2.3, is no longer fulfilled with respect to the perturbed hyperplane \( H_{i,V}^{\text{pert}} \), the bouncing
point \( p_i \) can be moved along \( H_{i,V}^{pert} \), say to \( p_i^\ast \), in order to reduce the length of the polygonal line segment \((p_{i-1}, p_i, p_{i+1})\). We define the closed polygonal line
\[
\tilde{p} := (p_1, \ldots, p_i, p_i^\ast, p_{i+1}, \ldots, p_m),
\]
for which with the boundedness of (19) in \( V \) we conclude \( \tilde{p} \in F(T \cap V) \) by Lemma 2.1(ii). Now we argue that \( \tilde{p} \in F(T) \): With the boundedness of (19) in \( V \) it follows with
\[
H_i^{pert} := H_{i,V}^{pert} \oplus W, \quad H_i^{pert, +} := H_{i,V}^{pert, +} \oplus W
\]
and (17) the nearly boundedness of
\[
H_i^{pert, +} \cap \left( \bigcap_{j=1, j \neq i}^{m} H_j^+ \right)
\]
in \( \mathbb{R}^n \).

Indeed, when the intersection in (19) is bounded in \( V \) then there is a hyperplane \( H \) in \( V \) such that the intersection lies between \( H \) and \( H + d \) for an appropriate \( d \in V_0 \). Then it follows with (17) and (20) that
\[
H_i^{pert, +} \cap \left( \bigcap_{j=1, j \neq i}^{m} H_j^+ \right) = (H_{i,V}^{pert, +} \oplus W) \cap \left( \bigcap_{j=1, j \neq i}^{m} ((H_j^+ \cap V) \oplus W) \right)
\]

lies between the hyperplanes \( H \oplus W \) and \( H + d \oplus W \).

Since \( H_i^{pert} \) is a \( T \)-supporting hyperplane through \( p_i \) (what follows from the fact that by (18) its outer unit normal vector \( n_i^{pert} \) is an element of \( N_T(p_i) \)) we conclude that \( T \) is a subset of the intersection in (21). Then it follows from the nearly boundedness (in \( \mathbb{R}^n \)) of the intersection in (21) together with Lemma 2.1(ii) that \( \tilde{p} \in F(T) \). By referring to Theorem 2.2 from \( \ell(p) < \ell(p) \) we derive a contradiction to the minimality of \( p \).

Therefore:
\[
\dim (N_T(p_i) \cap V_0) = 1.
\]

\[\square\]

4. Proof of Theorem 1.3

Before we prove Theorem 1.3 we need the following Lemma whose proof was brought to the authors’ attention by A. Balitskiy:

**Lemma 4.1.** Let \( P \subset \mathbb{R}^n \) be an acute convex polytope. Then for every non-smooth boundary point \( p \) of \( P \) and for every ray \( \rho \subset N_P(p) \) there is a section \( N_P(p) \cap \tau \) by a two-dimensional plane \( \tau \supset \rho \) that contains an angle greater than \( \pi/2 \).

**Proof.** Let \( p \) be a non-smooth boundary point of \( P \). Then \( p \) lies in the relative interior of a \( k \)-face \( F_k \), \( 0 \leq k \leq n-2 \). For a ray \( \rho \subset N_P(p) \) we would like to find a two-dimensional plane \( \tau \supset \rho \) such that \( N_P(p) \cap \tau \) is an obtuse angle. Equivalently, we need to place \( P \) in an acute dihedral angle \( H_1^+ \cap H_2^+ \) (bounded by hyperplanes \( H_1 \) and \( H_2 \)) such that \( p \in H_1 \cap H_2 \) and \( (H_1 \cap H_2) \perp \rho \). Take \( H_1 \) to be the spanning hyperplane of any facet \( \overline{F} \) containing \( F_k \). Let \( \ell \) be the one-dimensional subspace normal to \( \overline{F} \) (and \( H_1 \)). Consider the cylinder \( \overline{F} + \ell \). The acuteness of
dihedral angles of $P$ implies that the cylinder contains $P$. Let $H_2$ be a supporting hyperplane for the cylinder at $p$ such that $(H_1 \cap H_2) \perp p$. Since $c(\mathcal{F} + \ell) \cap P$ is the relative boundary of $\mathcal{F}$ one can tilt $H_2$ slightly with respect to $H_1 \cap H_2$ such that the dihedral angle containing $P$ becomes acute.

\[ \square \]

**Proof of Theorem 1.3.** The proof uses Theorem 1.2, Proposition 2.10 and Lemma 4.1 combined with the proof of Theorem 3.3 in [1] which is based on the fact that for any closed non-regular billiard trajectory $p = (p_1, \ldots, p_m)$ in $P$ there is a closed polygonal line $\tilde{p} = (\tilde{p}_1, \ldots, \tilde{p}_{m+1}) \in F(P)$ with $\ell(\tilde{p}) < \ell(p)$.

![Diagram](image.png)

**Figure 4.** The billiard trajectory segment $(p_{i-1}, p_i, p_{i+1})$ is replaced by the polygonal line segment $(p_{i-1}, p_{i-1}^*, p_{i+1}^*, p_{i+1})$.

We briefly rephrase the argument on which is based the proof of Theorem 3.3. in [1]: Let $p = (p_1, \ldots, p_m)$ be any non-regular closed billiard trajectory in $P$. Then there is a non-smooth boundary point $p_i$ of $P$. The acuteness of $P$ guarantees with Lemma 4.1 the existence of a two-dimensional plane $\tau$ containing the ray emanating from $p_i$ with direction $n_P(p_i) \in N_P(p_i)$ opposite to the bisector of the polygonal segment $(p_{i-1}, p_i, p_{i+1})$ which cuts from $p_i + N_P(p_i)$ an angle greater than $\pi/2$. We denote the vectors of the sides of the angle $\tau \cap (p_i + N_P(p_i))$ by $n_i^l, n_i^r$. Without loss of generality we may assume that for $n = 2$ the plane $n_i^l$ lie on one side with respect to $n_P(p_i)$ and $p_{i+1}$ and $n_i^r$ lie on the other side. We denote by $H_i^l, H_i^r$ the $P$-supporting hyperplanes through $p_i$ normal to $n_i^l, n_i^r$. We reflect $p_{i-1}, p_{i+1}$ at $H_i^l, H_i^r$ respectively and obtain points $p_{i-1}', p_{i+1}'$. We note that the angle of the polygonal segment $(p_{i-1}', p_i, p_{i+1}')$ is less than $\pi$ since $p_{i-1}', p_{i+1}'$ lie in the open half-space bounded by the $P$-supporting hyperplane $H_i$ through $p_i$ which is normal to $n_P(p_i)$. Let $p_{i-1}^*, p_{i+1}^*$ be the points of intersection of the line segment $(p_{i-1}', p_{i+1}')$ and $N_P(p_i)$. This construction is repeated for each segment $(p_i, p_j)$. Eventually we obtain a polygonal line $\tilde{p} = (\tilde{p}_1, \ldots, \tilde{p}_{m+1})$ with $\ell(\tilde{p}) < \ell(p)$. The segments $(\tilde{p}_{i-1}, \tilde{p}_i, \tilde{p}_{i+1})$ are contained in the cylinder and the billiard trajectory $p$ is replaced by the polygonal line $\tilde{p}$.
with \( H^1_i \) and \( H^\ell \). Then it follows by triangle inequality that
\[
\|p_{i-1} - p^*_i - p^*_i\| + \|p^*_i - p^*_i + p^*_i\| + \|p^*_i + p^*_i - p_{i+1}\| \\
< \|p'_{i-1} - p_i\| + \|p_i - p'_{i+1}\| = \|p_{i-1} - p_i\| + \|p_i - p_{i+1}\|.
\]
Thus, if we replace the billiard trajectory segment \((p_{i-1}, p_i, p_{i+1})\) by the polygonal line segment \((p_{i-1}, p^*_i, p^*_i, p_{i+1})\) then we have \( \ell(p') < \ell(p) \). Since \( n_p(p_i) \) is a positive combination of \( n_i \) and \( n'_i \) the normals at the vertices of \( p \) still surround the origin (cf. Lemma 2.1(ii)). This guarantees \( p \in F(T) \).

Let us assume there is a length minimizing closed billiard trajectory \( p = (p_1, ..., p_m) \) in \( P \) with \( m \leq n \). Then with Proposition 2.10 \( p \) can be translated within \( P \) to a non-regular closed billiard trajectory \( p + c, c \in \mathbb{R}^n \).

Together with Theorem 1.2 this implies the stated regularity result.

Theorem 1.3 and geometrical considerations make us formulate the following conjecture:

Conjecture. Every acute convex polytope in \( \mathbb{R}^n \) is a simplex.

The conjecture is true for \( n = 2 \). Indeed, the formula for the sum of the interior angles of any convex polygon \( P \) with \( k \geq 3 \) edges is \((k - 2)\pi\). We conclude
\[
\min_{P \text{ convex polygon with } k \text{ vertices}} \max_{\text{a interior angle of } P} \alpha = \frac{(k - 2)\pi}{k}
\]
\[
= \left(2 - \frac{4}{k}\right) \frac{\pi}{2} < \frac{\pi}{2}, \quad k = 3,
\]
\[
> \frac{\pi}{2}, \quad k > 3.
\]
Therefore every acute convex polygon must have three edges, i.e. a simplex.

It remains an open problem whether this approach can be generalized to higher dimensions (below we will prove the conjecture for \( n = 3 \) using a different argument).

Conversely, a sufficient condition for a counterexample, i.e. an acute convex polytope which is not a simplex, is that the sum of all dihedral angles is greater than \( \binom{n}{2} \pi \). For that we recall that Gaddum proved in [6] that the sum of the \( \binom{n+1}{2} \) dihedral angles of a simplex in \( \mathbb{R}^n \) lies between \([\frac{n^2-1}{4}]\pi\) and \( \binom{n}{2} \pi \) and the sum can take any value in this range.

Another sufficient condition for a counterexample is that the sum of all dihedral angles is greater or equal than \( \frac{k \pi}{2} \), where \( k \) is the number of dihedral angles. Otherwise, if there is an acute simplex with dihedral angle sum greater or equal than \( \frac{k \pi}{2} \), then, using the argument in [22] generalized to higher dimensions, there is at least one angle greater or equal than \( \frac{\pi}{2} \). This is a contradiction to the acuteness. Since \( k \) has to be greater or equal than \( \binom{n+1}{2} \) (simplices are minimizing the number of dihedral angles over all convex polytopes) we get that a sufficient condition for a counterexample is that the sum of the dihedral angles is greater than \( \binom{n+1}{2} \frac{\pi}{2} = \frac{\pi}{4}(n + 1)n \) which for \( n \geq 4 \) is even smaller than \( \binom{3}{2} \pi = \frac{\pi}{2} n(n - 1) \) (and equal for \( n = 3 \)). This implies an improvement of Gaddum’s result for the special case of dihedral acute angled simplices:
Proposition 4.2. Let $\Delta_n \subset \mathbb{R}^n$ be an acute simplex, i.e. dihedral acute angled simplex. Then the sum of the $\binom{n+1}{2}$ dihedral angles lies between $\left[\frac{n^2-1}{4}\right] \pi$ and $\left(\binom{n+1}{2}\right) \frac{\pi}{2}$.

Let us briefly argue that the conjecture is also true for $n = 3$: Let $P$ be any acute convex polytope in $\mathbb{R}^3$. Let $F_1$ be a facet of $P$ and $G_1, ..., G_k$ the facets of $F_1$ (without loss of generality we have $G_j \cap G_{j+1} \neq \emptyset$ for all $j \in \{1, ..., k\}$, where we write $G_{k+1} = G_1$). Assume $F_1$ is not a simplex, then $k \geq 4$. Without loss of generality we assume $F_1 \cap F_2 = G_1, ..., F_1 \cap F_{k+1} = G_k$, where $F_2, ..., F_{k+1}$ are other (pairwise distinct) facets of $P$. All dihedral angles between $F_1$ and $F_2, ..., F_{k+1}$ are acute. If one of the angles enclosed by $G_i$ and $G_{i+1}$ is not acute, then also the dihedral angle between $F_{j+1}$ and $F_{j+2}$ - which is greater or equal than the angle between $G_j$ and $G_{j+1}$ - are not acute (we write $F_{k+2} = F_2$). This would be a contradiction to the fact that $P$ is acute. Therefore, $F_1$ is a simplex, i.e. $k = 3$. Now we argue that $F_1, F_2, F_3, F_4$ are the only facets of $P$: Let us assume there is another facet $F_5$. Then, necessarily $F_5$ has non-empty intersection with $F_2, F_3$ and $F_4$ and since the dihedral angles between $F_1$ and $F_2, F_3, F_4$ are all acute it follows that the orthogonal projection of $F_5$ onto the hyperplane supporting $F_1$ is contained in $F_1$. This implies that at least one of the dihedral angles between $F_5$ and $F_2, F_3, F_4$ is not acute. Again, this would be a contradiction to the fact that $P$ is acute. This implies that $F_1, F_2, F_3$ and $F_4$ are the only facets of $P$ and therefore $P$ is a simplex.

Regardless of the fact that (for general dimension) some technical details need to be clarified, this proof-method also seems promising for proving the conjecture for general dimension.

5. Examples

We begin by noting that in Proposition 2.3 in general the length minimality of a closed billiard trajectory is not invariant under going to affine sections of the billiard table containing this trajectory.

More precisely, let $T \subset \mathbb{R}^n$ be a billiard table and $p = (p_1, ..., p_m)$ a length minimizing closed billiard trajectory in $T$. If $V \subset \mathbb{R}^n$ is an affine subspace such that $T \cap V$ is an affine section of $T$ containing $p$, then $p$ may not be a length minimizing closed billiard trajectory in $T \cap V$.

In the following we denote the $(x_i, x_j)$-plane of $\mathbb{R}^3$ by $X_{i,j}$ (for $i, j \in \{1, 2, 3\}$, $i \neq j$).

Example A: Let $T \subset \mathbb{R}^3$ be the convex hull of the points

$$(-\frac{1}{2}, 0, 0), (\frac{1}{2}, 0, 0), (0, 0, 1), (-\frac{1}{2}, -\frac{1}{2}, 0), (\frac{1}{2}, -\frac{1}{2}, 0), (0, -\frac{1}{2}, 1).$$

One checks that $p = (p_1, p_2)$ with

$$p_1 = (0, 0, \frac{3}{4}) \quad \text{and} \quad p_2 = (0, -\frac{1}{2}, \frac{3}{4})$$

is a length minimizing closed billiard trajectory in $T$ with $\ell(p) = 1$. We define $T \cap V$ to be the affine section of $T$ where

$$V := X_{1,2} + (0, 0, \frac{3}{4}).$$

One checks that $\tilde{p} = (\tilde{p}_1, \tilde{p}_2)$ with

$$\tilde{p}_1 = (-\frac{1}{8}, -\frac{1}{4}, \frac{3}{4}) \quad \text{and} \quad \tilde{p}_2 = (\frac{1}{8}, -\frac{1}{4}, \frac{3}{4})$$

is a length minimizing closed billiard trajectory in $T \cap V$ with $\ell(\tilde{p}) = \frac{1}{2} < \ell(p)$. Therefore $p$ is not a length minimizing closed billiard trajectory in $T \cap V$. \hfill $\square$
REGULARITY RESULTS FOR SHORTEST BILLIARD TRAJECTORIES

\[ \pi_{1,2}(T \cap V) \]

\[ \pi_{1,2}(p_1) \]

\[ \pi_{1,2}(p_2) \]

(a) Example A.

(b) Example B. The picture illustrates \( \pi_{1,2}(T) \).

**Figure 5.** The length minimality of a closed billiard trajectory is not invariant under going to affine sections of the billiard table containing this trajectory.

In the above described situation \( p \) may not even locally minimize the length of closed polygonal lines in \( F(T \cap V) \).

**Example B:** Let \( T \subset \mathbb{R}^3 \) be the convex hull of the points

\[ (0,0,0), (4,0,0), (0,-4,0), \left( \frac{16}{5}, -\frac{12}{5}, 0 \right), (0,0,8), (0,-4,8) . \]

One checks that \( p = (p_1, p_2) \) with

\[ p_1 = (0,0,4) \quad \text{and} \quad p_2 = \left( \frac{8}{5}, -\frac{16}{5}, 4 \right) \]

is a length minimizing closed billiard trajectory in \( T \) with \( \ell(p) = \frac{16}{5\sqrt{5}} \). If we define

\[ V := X_{1,2} + (0,0,4) \]

then \( T \cap V \) is an affine section of \( T \) containing \( p \) and is given by the vertices

\[ (0,0,4), (2,0,4), \left( \frac{8}{5}, -\frac{16}{5}, 4 \right), (0,-4,4) . \]

By slightly moving \( p_2 \) clockwise along \( \partial(T \cap V) \) (we denote this slightly perturbed \( p_2 \) by \( \tilde{p}_2 \)) the closed polygonal line \( \tilde{p} = (p_1, \tilde{p}_2) \) is in \( F(T \cap V) \) but not in \( F(T) \) (since \( \pi_{1,2}(\tilde{p}_2) \) is in the interior of \( \pi_{1,2}(T) \)). Additionally one has \( \ell(\tilde{p}) < \ell(p) \). Therefore \( p \) does not locally minimize the length of closed polygonal lines in \( F(T \cap V) \). □

The same can be shown for the smallest affine sections containing length minimizing closed billiard trajectories: Let \( T \subset \mathbb{R}^n \) be a billiard table and \( p = (p_1, \ldots, p_m) \) a length minimizing closed billiard trajectory in \( T \). Let \( T \cap V \) be the smallest affine section of \( T \) containing \( p \). Then \( p \) may not be a length minimizing closed billiard trajectory in \( T \cap V \).

**Example C:** Let \( T \subset \mathbb{R}^3 \) be the convex hull of the points

\[ (0,0,0), (1,0,0), \left( \frac{1}{2}, 0, \frac{\sqrt{3}}{2} \right), (0,-2,0), (1,-2,0) . \]
One checks that $p = (p_1, p_2, p_3)$ with
$$p_1 = \left(\frac{1}{2}, -1, 0\right), p_2 = \left(\frac{1}{4}, -1, \frac{\sqrt{3}}{4}\right), p_3 = \left(\frac{3}{4}, -1, \frac{\sqrt{3}}{4}\right)$$
is a length minimizing closed billiard trajectory in $T$ (it is the Fagnano triangle of the affine section $T \cap X_{1,3}$ translated by $(0, -1, 0)$). If we define
$$V := X_{1,3} + (0, -1, 0)$$
then $T \cap V$ is the smallest affine section of $T$ containing $p$. One checks that $\tilde{p} = (p_1, \tilde{p}_2)$ with
$$\tilde{p}_2 = \left(\frac{1}{2}, -1, \frac{\sqrt{3}}{4}\right)$$
is a length minimizing closed billiard trajectory in $T \cap V$ (with $\tilde{p} \notin F(T)$) but $\ell(\tilde{p}) < \ell(p)$. Therefore $p$ is not a length minimizing closed billiard trajectory in $T \cap V$.

Again, in the situation described in Example C $p$ may not even locally minimize the length of closed polygonal lines in $F(T \cap V)$.

Example D: We consider $T$, $V$ and $p = (p_1, p_2, p_3)$ from Example C. We slightly move $p_2$ clockwise along $\partial(T \cap V)$. We denote this slightly perturbed $p_2$ by $\tilde{p}_2 = (\frac{1}{4} + \delta, -1, \frac{\sqrt{3}}{4})$, $\delta > 0$ small. The closed polygonal line $\tilde{p}^\delta = (\tilde{p}_1, \tilde{p}_2, \tilde{p}_3)$ with $\tilde{p}_1 = p_1$ and $\tilde{p}_3 = p_3$ fulfills $\tilde{p}^\delta \in F(T \cap V)$, $\tilde{p}^\delta \notin F(T)$, $\ell(\tilde{p}^\delta) < \ell(p)$ (for small $\delta > 0$) and $\tilde{p}^\delta$ converges with respect to the Hausdorff distance to $p$ for $\delta \to 0$.

We conclude this Section by illustrating in which sense the statement of Theorem 1.2 is sharp: We recall from the introduction for what we want to give examples:

(iii) A length minimizing closed billiard trajectory in $T \subset \mathbb{R}^n$ may not be regular within the smallest section of $T$ containing the billiard trajectory. This can even appear for the unique length minimizing closed billiard trajectory.

(iv) A length minimizing closed billiard trajectory in $T \subset \mathbb{R}^n$ can have bouncing points in vertices as well as in the interior of more than 0-dimensional faces of $T$.

For the first statement within (iii) we consider Example E, for the second Example F. Examples E and F are also suitable in order to prove the statements in (iv): for the first we refer to Example E ($p_2^3$ as bouncing point of the length minimizing closed billiard trajectory $p_2$ is a vertex of $T_\varepsilon$), for the second to Example F ($p_3$ as
bouncing point of the unique length minimizing closed billiard trajectory \( p \) is an interior point of an one-dimensional face of \( T \subset \mathbb{R}^3 \).

We remark that Examples E and F both are convex polytopes. Nevertheless, this examples proving the statements in (iii) and (iv) are not restricted to convex polytopes. One can check that both Example E as well as Example F can be made strictly convex without losing the characteristics utilized within the proofs of (iii) and (iv).

**Example E:** Let \( T_\varepsilon \subset \mathbb{R}^3 \), \( \varepsilon > 0 \) small, be the convex polytope given by the vertices

\[
(0, 0, 0), \left( -\frac{1}{2}, 0, \frac{\sqrt{3}}{2} \right), \left( \frac{1}{2}, 0, \frac{\sqrt{3}}{2} \right), (0, -2, 0), \left( 0, -2, \frac{\sqrt{3}}{2} \right), \\
\left( -\frac{1}{2} + \frac{\varepsilon}{\sqrt{3}}, -2, \frac{\sqrt{3}}{2} - \varepsilon \right), \left( \frac{1}{2} - \frac{\varepsilon}{\sqrt{3}}, -2, \frac{\sqrt{3}}{2} - \varepsilon \right).
\]

![Figure 7. Example E.](image)

We claim that for sufficiently small \( \varepsilon > 0 \) the length minimizing closed billiard trajectories in \( T_\varepsilon \) are given by \( p^a = (p_1^a, p_2^a, p_3^a) \) with

\[
p_1^a = \left( -\frac{1}{2} - a, \frac{\sqrt{3}}{2} \right), p_2^a = \left( \frac{1}{2} - a, \frac{\sqrt{3}}{2} \right), p_3^a = \left( 0, -a, \frac{\sqrt{3}}{2} \right)
\]

and \( a \in [0, 2] \). Moreover, we claim that \( p^2 \) is not regular within the smallest affine section of \( T_\varepsilon \) containing \( p^2 \).

Indeed, for all \( a \in [0, 2] \) \( p^a \) is contained in the affine section \( T_\varepsilon \cap V^a \) of \( T_\varepsilon \), where \( V^a := X_{1,3} + (0, -a, 0) \), and is subset of the equilateral triangle \( \Delta_1^a \) given by the vertices

\[
(0, -a, 0), \left( -\frac{1}{2} - a, \frac{\sqrt{3}}{2} \right), \left( \frac{1}{2} - a, \frac{\sqrt{3}}{2} \right).
\]
For all $a \in [0, 2]$ holds the following: It is $\ell(p^a) = \frac{3}{2}$ and $p^a$ is coinciding with the Fagnano triangle of $\Delta^a_1$ which is the unique length minimizing closed billiard trajectory in $\Delta^a_1$. Note that the Fagnano triangle is the only regular closed billiard trajectory in $\Delta^a_1$. The next longer closed billiard trajectories in $\Delta^a_1$ have two bouncing points and length $\sqrt{3}$. By construction $p^a$ is a closed billiard trajectory in $T_\varepsilon$ as well as in $T_\varepsilon \cap V^a$: The hyperplanes in $\mathbb{R}^3$, respectively in $V^a$, related to the billiard reflection rule are the one which are normal to the bisectors of the polygonal line segments $(p^1_1, p^2_1, p^3_1)$, $(p^2_2, p^3_2, p^4_2)$ and $(p^3_3, p^4_3, p^5_3)$. We claim that $p^a$ uniquely minimizes the length over all closed billiard trajectories in $T_\varepsilon$ which are contained in $T_\varepsilon \cap V^a$. For $a=0$ this follows from the aforementioned. This follows from the fact that all bouncing points of closed billiard trajectories in $T_\varepsilon$ which are contained in $T_\varepsilon \cap V^a$ necessarily have to be on $\partial \Delta^a_1$. This is due to Proposition 2.6 and the tilt of the hyperplanes supporting the facets of $T_\varepsilon$ which are determined by the points

$$\left(\frac{1}{2}, 0, \frac{\sqrt{3}}{2}\right), \left(\frac{1}{2} - \frac{\varepsilon}{\sqrt{3}}, -2, \frac{\sqrt{3}}{2} - \varepsilon\right), \left(0, -2, \frac{\sqrt{3}}{2}\right)$$

and

$$\left(-\frac{1}{2}, 0, \frac{\sqrt{3}}{2}\right), \left(-\frac{1}{2} + \frac{\varepsilon}{\sqrt{3}}, -2, \frac{\sqrt{3}}{2} - \varepsilon\right), \left(0, -2, \frac{\sqrt{3}}{2}\right)$$

and from now on called $F_1$ and $F_2$.

We show that all other closed billiard trajectories in $T_\varepsilon$ have a length greater than $\frac{3}{2}$: Whenever we consider a closed billiard trajectory in $T_\varepsilon$ with one bouncing point on the front-facet $T_\varepsilon \cap V^0$ and with another one on the back-facet $T_\varepsilon \cap V^2$ of $T_\varepsilon$, then it has a length greater or equal $\frac{3}{2}$. Every other closed billiard trajectory in $T_\varepsilon$ has two bouncing points, one on $F_1$ or $F_2$ and the other on the front facet. This follows from the fact that whenever we have a closed billiard trajectory with bouncing point on $F_1$ ($F_2$), then at least one of the previous and following bouncing points is on the front- and back-facet (or the other way round), respectively. In the case of a closed billiard trajectory $p'$ with one bouncing point on $F_1$ or on $F_2$ and the other on the front-facet, we have

$$\ell(p') = \min_{x \in G_1, y \in F_1} |x - y| > \frac{3}{2} = \ell(p) \quad (\varepsilon > 0 \text{ small})$$

or

$$\ell(p') = \min_{x \in G_2, y \in F_2} |x - y| > \frac{3}{2} = \ell(p) \quad (\varepsilon > 0 \text{ small})$$

respectively, where we denote by $G_1$ the line segment from $(0, 0, 0)$ to $(-\frac{1}{2}, 0, \frac{\sqrt{3}}{2})$ and by $G_2$ the line segment from $(0, 0, 0)$ to $(\frac{1}{2}, 0, \frac{\sqrt{3}}{2})$.

$p^a$ is regular in $T_\varepsilon \cap V^a$ for all $a \in [0, 2)$. This is due to the fact that $T_\varepsilon \cap V^a$ is the smallest affine section of $T_\varepsilon$ containing $p^a$ and the normal cones $N_{T_\varepsilon \cap V^a}(p^a)$ are one-dimensional for all $j \in \{1, 2, 3\}$ and all $a \in [0, 2)$. In contrast to that, $p^2$ is not regular in $T_\varepsilon \cap V^2$: The normal cone $N_{T_\varepsilon \cap V^2}(p^2)$ is two-dimensional, i.e. $p^2$ is a non-smooth boundary point of $T_\varepsilon \cap V^2$.

We clearly see why the argument used in the proof of Theorem 1.2 does not work: The $T_\varepsilon$-supporting hyperplane $H_3$ through $p^2_3$ for which the billiard reflection rule is fulfilled is

$$H_3 := X_{1,2} + \left(0, 0, \frac{\sqrt{3}}{2}\right).$$

There is no way of perturbing $H_3$ to $H^\text{pert}_3$ as required within the proof of Theorem 1.2 except for $H^\text{pert}_3$ having non-empty intersection with the interior of $T_\varepsilon$. 
Therefore (as already was the consequence of the above reasoning) it is not possible to construct a closed polygonal line $\tilde{p}^2 \in F(T_\varepsilon \cap V^2)$ with $\ell(\tilde{p}^2) < \ell(p^2)$ while guaranteeing $\tilde{p}^2 \in F(T_\varepsilon)$.

**Example F:** Let $T_\varepsilon \subset \mathbb{R}^3$, $\varepsilon > 0$ small, be the convex polytope given by the vertices

\[
(0, 0, 0), \left(-\frac{1}{2} + \frac{\sqrt{3}}{2}, 0, \frac{\sqrt{3}}{2} - \varepsilon\right), \left(-\frac{1}{2} + \frac{\sqrt{3}}{2}, 0, \frac{\sqrt{3}}{2} - \varepsilon\right),
\]

\[
(0, -2, 0), \left(-\frac{1}{2} + \frac{\sqrt{3}}{2}, -2, \frac{\sqrt{3}}{2} - \varepsilon\right), \left(\frac{1}{2} - \frac{\sqrt{3}}{2}, -2, \frac{\sqrt{3}}{2} - \varepsilon\right), \left(\frac{1}{2} - \frac{\sqrt{3}}{2}, -2, \frac{\sqrt{3}}{2} - \varepsilon\right).
\]

![Figure 8. Example F.](image)

We claim that for sufficiently small $\varepsilon > 0$ the unique length minimizing closed billiard trajectory in $T_\varepsilon$ is given by $p = (p_1, p_2, p_3)$ with

\[
p_1 = \left(-\frac{1}{4}, -1, \frac{\sqrt{3}}{4}\right), p_2 = \left(\frac{1}{4}, -1, \frac{\sqrt{3}}{4}\right), p_3 = \left(0, -1, \frac{\sqrt{3}}{2}\right).
\]

Moreover, we claim that $p_3$ is not regular within the smallest affine section of $T_\varepsilon$ containing $p$.

Indeed, $p$ is contained in the affine section $T_\varepsilon \cap V$ with

\[
V := X_{1,3} + (0, -1, 0).
\]
$T_\varepsilon \cap V$ is given by the vertices
\[
(0, -1, 0), \left( -\frac{1}{2} + \frac{\sqrt{3}}{\sqrt{3}}, -1, \frac{\sqrt{3}}{2} - \varepsilon \right), \left( -\frac{1}{2} + \frac{\sqrt{3}}{\sqrt{3}}, -1, \frac{\sqrt{3}}{2} + \varepsilon \right), \left( \frac{1}{2} + \frac{\sqrt{3}}{\sqrt{3}}, -1, \frac{\sqrt{3}}{2} - \varepsilon \right),
\]
and is subset of the equilateral triangle $\Delta_1$ given by the vertices
\[
(0, -1, 0), \left( -\frac{1}{2}, -1, \frac{\sqrt{3}}{2} \right), \left( \frac{1}{2}, -1, \frac{\sqrt{3}}{2} \right).
\]
$p$ is coinciding with the Fagnano triangle of $\Delta_1$ which is the unique length minimizing closed billiard trajectory in $\Delta_1$ (with length $\frac{3}{2}$). By construction $p$ is a closed billiard trajectory in $T_\varepsilon$ as well as in $T_\varepsilon \cap V$: The hyperplanes in $\mathbb{R}^3$, respectively in $V$, related to the billiard reflection rule are the one which are normal to the bisectors of the polygonal line segments $(p_1, p_2, p_3)$, $(p_2, p_3, p_1)$ and $(p_3, p_1, p_2)$. Similar to within Example E we conclude for sufficiently small $\varepsilon > 0$ that $p$ uniquely minimize the length over all closed billiard trajectory in $T_\varepsilon$ which are contained in $T_\varepsilon \cap V$.

We show that all other closed billiard trajectories in $T_\varepsilon$ have a length greater $\frac{3}{2}$: Let $F_1$ be the facet of $T_\varepsilon$ given by the vertices
\[
\left( -\frac{1}{2} + \frac{\sqrt{3}}{\sqrt{3}}, 0, \frac{\sqrt{3}}{2} \right), \left( \frac{1}{2} + \frac{\sqrt{3}}{\sqrt{3}}, 0, \frac{\sqrt{3}}{2} \right), \left( \frac{1}{2} - \frac{\sqrt{3}}{\sqrt{3}}, -2, \frac{\sqrt{3}}{2} \right),
\]
and $F_2$ the facet of $T_\varepsilon$ given by the vertices
\[
\left( -\frac{1}{2} + \frac{\sqrt{3}}{\sqrt{3}}, 0, \frac{\sqrt{3}}{2} \right), \left( \frac{1}{2} - \frac{\sqrt{3}}{\sqrt{3}}, -2, \frac{\sqrt{3}}{2} \right), \left( -\frac{1}{2} + \frac{\sqrt{3}}{\sqrt{3}}, -2, \frac{\sqrt{3}}{2} \right).
\]
Then we begin to argue: Again, as in Example E, we first notice that whenever we consider a closed billiard trajectory in $T_\varepsilon$ with one bouncing point on the front-facet $T_\varepsilon \cap X_{1,3}$ and another one on the back-facet $T_\varepsilon \cap (X_{1,3} + (0, -2, 0))$ of $T_\varepsilon$, then it has a length greater or equal than 4. Every other closed billiard trajectory in $T_\varepsilon$ either has two bouncing points, one on $F_1$ or $F_2$ and the other on the back- or front-facet, respectively, or it has one bouncing point on $F_1$ and another on $F_2$ while it has non-empty intersection either with the front- or with the back-facet. This follows from the fact that whenever we have a closed billiard trajectory with bouncing point on $F_1$ ($F_2$) and no other on $F_2$ ($F_1$), then at least one of the previous and following bouncing points is on the front- and back-facet (or the other way round), respectively. In the case of a closed billiard trajectory $p'$ with two bouncing points, one on $F_1$ or on $F_2$ and the other on the back- or the front-facet, respectively, we have
\[
\ell(p') = \min_{x \in G_1, y \in F_1} |x - y| > \frac{3}{2} = \ell(p) \quad (\varepsilon > 0 \text{ small})
\]
or
\[
\ell(p') = \min_{x \in G_2, y \in F_2} |x - y| > \frac{3}{2} = \ell(p) \quad (\varepsilon > 0 \text{ small})
\]
respectively, where we denote by $G_1$ the line segment from $(0, -2, 0)$ to $\left( -\frac{1}{2} + \frac{\sqrt{3}}{\sqrt{3}}, -2, \frac{\sqrt{3}}{2} \right)$ and by $G_2$ the line segment from $(0, 0, 0)$ to $\left( \frac{1}{2} - \frac{\sqrt{3}}{\sqrt{3}}, 0, \frac{\sqrt{3}}{2} \right)$.

In the case of a closed billiard trajectory $p'$ with one bouncing point on $F_1$ and another on $F_2$ while it has non-empty intersection either with the front- or with the back-facet, we have
\[
\ell(p') \geq \min_{x \in F_1, y \in F_2, z \in G} (|x - z| + |z - y|) > \frac{3}{2} = \ell(p),
\]
where we denote by $G$ the line segment from $(0,0,0)$ to $(0,-2,0)$.

$p$ is not regular in $T_e \cap V$ since the normal cone $N_{T_e \cap V}(p)$ is two-dimensional, i.e. $p_3$ is a non-smooth boundary point of $T_e \cap V$.

Again, we clearly see why the argument used in the proof of Theorem 1.2 does not work. The $T_e$-supporting hyperplane through $p_3$ for which the billiard reflection rule is fulfilled is

$$H_3 := X_{1,2} + \left(0,0,\frac{\sqrt{3}}{2}\right).$$

The only way of perturbing $H_3$ to $H_3^{\text{pert}}$ as required within the proof of Theorem 1.2 is by tilting it around the axis through the points

$$\left(-\frac{1}{2} + \frac{\varepsilon}{\sqrt{3}},0,\frac{\sqrt{3}}{2}\right) \text{ and } \left(\frac{1}{2} - \frac{\varepsilon}{\sqrt{3}},-2,\frac{\sqrt{3}}{2}\right).$$

But in any case

$$H_1^+ \cap H_2^+ \cap H_3^{\text{pert},+}$$

cannot be nearly bounded in $\mathbb{R}^3$ (when $H_1$ and $H_2$ denote the uniquely determined $T_e$-supporting hyperplanes through $p_1$ and $p_2$). Therefore it is not possible to construct a closed polygonal line $\tilde{p} \in F(T_e \cap V)$ with $\ell(\tilde{p}) \leq \ell(p)$ and $\tilde{p} \neq p$ while guaranteeing $\tilde{p} \in F(T_e)$.

6. Constructing closed billiard trajectories

Throughout this section we let $T \subset \mathbb{R}^n$ be a full dimensional polytope which plays the role of the billiard table. The observations in Section 2 motivate an algorithm to find a length minimizing closed regular billiard trajectory in $T$. The following is a sketch of this algorithm.

- For $m \in \{2,\ldots,n+1\}$ do:
  - Choose $m$ pairwise different facets $F_1,\ldots,F_m$ of $T$. For every $j \in \{1,\ldots,m\}$ we let $u_j = n_T(p_{j+1})$ for some point $p_{j+1}$ in the relative interior of $F_{j+1}$. Note that $u_j$ does not depend on the choice of $p_{j+1}$.
  - Find $n_1,\ldots,n_m \in S^{n-1}$ such that $n_{j+1} - n_j = -\mu_j u_j$ with $\mu_j > 0$ holds for every $j \in \{1,\ldots,m\}$.
  - Find $p_j \in F_j$ for $j \in \{1,\ldots,m\}$ such that $p_{j+1} - p_j = \lambda_j n_j$ with $\lambda_j > 0$ holds for every $j \in \{1,\ldots,m\}$.
  - Calculate the length of the closed polygonal line and store it, if it is smaller than any such closed polygonal line found so far.
- Output the stored closed polygonal line and its length.

Proposition 2.4 ensures that any closed polygonal line found by the algorithm is indeed a closed billiard trajectory. More precisely, if $p_1,\ldots,p_m$ are the vertices of the closed polygonal line, then (5) is fulfilled by construction. We will now examine this algorithm in more detail.

We start by letting $F_1,\ldots,F_m$ and $u_1,\ldots,u_m$ be as described above. Let $U$ be the $(n \times m)$-matrix containing $u_1,\ldots,u_m$ as columns. If there are $p_j \in F_j$ smooth boundary points of $T$ and $n_j \in S^{n-1}$ for $1 \leq j \leq m$ such that (5) is fulfilled, then there are $\mu_1,\ldots,\mu_m > 0$ such that $n_{j+1} - n_j = -\mu_j u_j$. Thus, because of

$$0 = \sum_{j=1}^{m} (n_{j+1} - n_j) = -\sum_{j=1}^{m} \mu_j u_j$$

we have that $u_1,\ldots,u_m$ are not linearly independent. Hence, $\text{rk}(U) \leq m - 1$. On the other hand, if we assume that the closed regular billiard trajectory given by
$p_1, \ldots, p_m$ is length minimizing, then by Theorem 1.2 any affine space containing these $m$ bouncing points has dimension at least $m - 1$. By Proposition 2.6 the convex cone spanned by $u_1, \ldots, u_m$ is an $(m - 1)$-dimensional linear space. In particular, there are $(m - 1)$ linearly independent vectors in $\{u_1, \ldots, u_m\}$, so $\text{rk}(U) \geq m - 1$. Together, we have that $\text{rk}(U) = m - 1$ is necessary if we search for a length minimizing closed billiard trajectory. This way some choices of $F_1, \ldots, F_m$ can be discarded immediately. We note that $\text{rk}(U) = m - 1$ also implies that

$$- \sum_{j=1}^{m} \mu_j u_j = 0$$

has up to scaling a unique solution $\mu_1, \ldots, \mu_m$. Consequently, there is (up to scaling) only one closed polygonal line that can be constructed by using negative multiples of $u_1, \ldots, u_m$ in order.

To find suitable $n_1, \ldots, n_m \in S^{n-1}$ we let $\gamma = (\gamma_1, \ldots, \gamma_m)$ be this closed polygonal line, encoded by its $m$ vertices. The task is now to scale (only using a positive scalar factor) and translate $\gamma$ such that the vertices of $\gamma$ lie on $S^{n-1}$. We take $n_1, \ldots, n_m$ as these vertices. Note that in the remainder of the algorithm it is required to form another closed polygonal line using only positive multiples of $n_1, \ldots, n_m$ in order, i.e.:

$$\exists \lambda_1, \ldots, \lambda_m > 0: \sum_{j=1}^{m} \lambda_j n_j = 0.$$  

If this property is true one says that $n_1, \ldots, n_m$ are a totally cyclic vector configuration. Following [15] we can find an equivalent property by using Farkas’ lemma. This property states that for every vector $v \in \mathbb{R}^n$ one of the following conditions hold:

(a) $\langle n_j, v \rangle < 0$, for some $j \in \{1, \ldots, m\}$,

(b) $\langle n_j, v \rangle = 0$, for all $j \in \{1, \ldots, m\}$.

Hence, if $n_1, \ldots, n_m$ are a totally cyclic vector configuration it follows that

$$\forall \ v \in \mathbb{R}^n \exists \ j \in \{1, \ldots, m\} : \langle v, n_j \rangle \leq 0.$$  

This property is less restrictive than (23) but is still sufficient for the upcoming arguments.

While there might be multiple possibilities to scale and translate $\gamma$ such that its vertices lie on $S^{n-1}$, there is at most one possibility such that the vertices are a totally cyclic vector configuration.

**Proposition 6.1.** Let $\gamma = (\gamma_1, \ldots, \gamma_m) \in \mathbb{R}^n \times \ldots \times \mathbb{R}^n$,

$$S_\gamma = \{ (\mu, t) : \mu \in \mathbb{R}_{\geq 0}, t \in \mathbb{R}^n, ||\mu \gamma_j + t|| = 1, j \in \{1, \ldots, m\} \}$$

and $(\mu^*, t^*) \in S_\gamma$. If $n_1, \ldots, n_m \in S^{n-1}$ satisfy (24), where $n_j = \mu^* \gamma_j + t^*$ for every $j$, then $\mu^* = \max\{ \mu : (\mu, t) \in S_\gamma \}$ for some $t \in \mathbb{R}^n$.

**Proof.** We show that the existence of $(\hat{\mu}, \hat{t}) \in S_\gamma$ with $\hat{\mu} > \mu^*$ yields a contradiction. For $j \in \{1, \ldots, m\}$ we have

$$\hat{\mu} n_j + \hat{t} = \frac{\mu^* n_j + t^*}{\mu^*} + \hat{t} = \mu^* n_j + t',$$
where $\mu' = \bar{\mu}/\mu > 1$ and $t' = \bar{t} - (\bar{\mu}/\mu \ast)t^\ast$. Because of $(\mu^\ast, t^\ast)$, $(\bar{\mu}, \bar{t}) \in S_\gamma$ we get
\[
1 = ||\bar{\mu}\gamma_j + \bar{t}||^2 = ||\mu' n_j + t'||^2 = \mu'^2 ||n_j||^2 + 2\mu' \langle n_j, t' \rangle + ||t'||^2
\]
\[
= \mu'^2 + 2\mu' \langle n_j, t' \rangle + ||t'||^2.
\]
Since $n_1, \ldots, n_m$ satisfy (24), there is some $i \in \{1, \ldots, m\}$ such that $\langle -t', n_i \rangle \leq 0$. Note that this is obviously true if $t' = 0$. Therefore,
\[
0 = \mu'^2 + 2\mu' \langle n_i, t' \rangle + ||t'||^2 - 1 \geq \mu'^2 + ||t'||^2 - 1 > ||t'||^2 \geq 0,
\]
which is a contradiction. \hfill \Box

We point out that the maximum in Proposition 6.1 is indeed a maximum because the unit ball is compact and hence $\{\mu: (\mu, t) \in S, \text{ for some } t \in \mathbb{R}^n\}$ is compact as well. Proposition 6.1 implies that if the vertices of $\mu_1 \gamma + t_1$ and $\mu_2 \gamma + t_2$ with $(\mu_1, t_1), (\mu_2, t_2) \in S$, are totally cyclic vector configurations (and hence satisfy (23)) then they are scaled by the same factor, i.e. $\mu_1 = \mu_2$. However, we also need $t_1 = t_2$ to make sure that there is only one suitable way to scale and translate $\gamma$.

The next Proposition shows that this is indeed the case.

**Proposition 6.2.** Let $\gamma = (\gamma_1, \ldots, \gamma_m) \in \mathbb{R}^n \times \cdots \times \mathbb{R}^n$, $S_\gamma$ as in Proposition 6.1 and $(\mu_1, t_1), (\mu_2, t_2) \in S_\gamma$. Further, let $n_1, \ldots, n_m, n'_1, \ldots, n'_m \in S^{n-1}$ defined by
\[
n_j = \mu_1 \gamma_j + t_1, \quad n'_j = \mu_2 \gamma_j + t_2
\]
for every $j \in \{1, \ldots, m\}$. If $n_1, \ldots, n_m$ satisfy (24), then $(\mu_1, t_1) = (\mu_2, t_2)$.

**Proof.** From Proposition 6.1 we have $\mu_1 = \mu_2$ and therefore for every $j \in \{1, \ldots, m\}$:
\[
n'_j = \mu_1 \gamma_j + t_2 = \mu_1 \frac{n_j - t_1}{\mu_1} + t_2 = n_j - t_1 + t_2.
\]

Similar to the calculation in the proof of Proposition 6.1 we get
\[
1 = ||n'_j|| = ||n_j - t_1 + t_2|| = 1 + 2 \langle n_j, t_2 - t_1 \rangle + ||t_2 - t_1||^2.
\]

Hence, the term $\langle n_j, t_2 - t_1 \rangle$ does not depend on $j$. Because of (24), one can find $i, j \in \{1, \ldots, m\}$ such that
\[
\langle n_i, t_1 - t_2 \rangle \leq 0 \quad \text{and} \quad \langle n_j, t_1 - t_2 \rangle \geq 0.
\]
Since these terms don’t depend on the index of $n$, we get $\langle n_j, t_1 - t_2 \rangle = 0$ for every $j \in \{1, \ldots, m\}$. Further, we get
\[
1 = 1 + ||t_2 - t_1||^2,
\]
and so $t_2 = t_1$. \hfill \Box

Assume we find some $n_1, \ldots, n_m \in S^{n-1}$ by scaling and translating the polygonal line $\gamma$ as described above. Remember that by construction of $\gamma$ we have $n_{j+1} - n_j = -\mu_j u_j$ for some $\mu_j > 0$ for every $j \in \{1, \ldots, m\}$. This implies:
\[
1 = ||n_{j+1}||^2 = ||n_j - \mu_j u_j||^2 = ||n_j||^2 - 2\mu_j \langle n_j, u_j \rangle + \mu_j^2 ||u_j||^2
\]
\[
= 1 - 2\mu_j \langle n_j, u_j \rangle + \mu_j^2
\]
\[
\implies 0 = \mu_j (\mu_j - 2 \langle n_j, u_j \rangle).
\]
Because $\mu_j$ is positive, we have $\mu_j = 2 \langle n_j, u_j \rangle$ and
\[
n_{j+1} = n_j - \mu_j u_j = n_j - 2 \langle n_j, u_j \rangle u_j
\]
for every $j \in \{1, \ldots, m\}$. Therefore, if any of the vectors $n_1, \ldots, n_m$ is known, the remaining ones can be calculated easily. In the following we choose to search for $n_1$. This search can be carried out by a second-order cone program (SOCP). An SOCP is a convex optimization problem, where one is looking for an element of the second-order cone $L^{n+1} = \{(x,t) \in \mathbb{R}^n \times \mathbb{R} : \|x\| \leq t\}$ such that some linear constraints are fulfilled and a linear objective function is optimized. An SOCP in standard form looks like this:

$$\begin{align*}
\text{maximize} & \quad c^T x + st \\
\text{s.t.} & \quad (x,t) \in L^{n+1} \\
& \quad a_i^T x + r_i t = b_i, \quad \text{for } i \in I,
\end{align*}$$

where $c, a_i \in \mathbb{R}^n$, $s, r_i, b_i \in \mathbb{R}$ and $I$ is some index set. It is well known that SOCPs can be solved efficiently (see [3]).

Before we state the SOCP we need the following identity:

$$n_j = n_{j-1} - 2 \langle n_{j-1}, u_{j-1} \rangle u_{j-1} = (I - 2u_{j-1}u_{j-1}^T)n_{j-1} = (I - 2u_{j-1}u_{j-1}^T)(I - 2u_{j-2}u_{j-2}^T)n_{j-2} = \cdots = \left(\prod_{i=1}^{j-1} I - 2u_iu_i^T\right)n_1,$$

where $I$ is the $n \times n$ identity matrix. This identity holds for $1 \leq j \leq m$. Two types of constraints are necessary for the SOCP. First we need to make sure that $n_1 = n_{m+1}$ with $n_{m+1} := n_m - 2 \langle n_m, u_m \rangle u_m$ is satisfied:

$$n_1 = n_m - 2 \langle n_m, u_m \rangle u_m = (I - 2u_mu_m^T)n_m = \left(\prod_{i=1}^{m} I - 2u_iu_i^T\right)n_1.$$

Second, we require

$$0 < \mu_j = 2 \langle n_j, u_j \rangle = 2u_j^T \left(\prod_{i=1}^{j-1} I - 2u_iu_i^T\right)n_1$$

for every $j \in \{1, \ldots, m\}$. Here we can replace the strict inequality by $\leq$. The reason for this is the observation made earlier, that the polygonal line $\gamma$ is unique up to scaling. So, if any solution of the SOCP yields $\mu_i = 0$ for some $i$, then every solution yields $\mu_i = 0$ and no closed regular billiard trajectory $p = (p_1, \ldots, p_m)$ with $p_j \in F_j$ for $j \in \{1, \ldots, m\}$ exists.

For the objective of the SOCP we note that

$$\sum_{j=1}^{m} \mu_j = \sum_{j=1}^{m} 2 \langle n_j, u_j \rangle = \sum_{j=1}^{m} 2u_j^T \left(\prod_{i=1}^{j-1} I - 2u_iu_i^T\right)n_1. \quad (25)$$

The vectors $n_1, \ldots, n_m$ are required to be vertices of $\mu \gamma + t$ for some $(\mu, t) \in S_\gamma$. Proposition 6.1 states that the only possible way for $n_1, \ldots, n_m$ to be a totally cyclic vector configuration is if $\mu$ is maximal. Hence we would like to choose $n_1$
such that (25) is as big as possible. Thus, we obtain the following SOCP:

\[
\begin{align*}
\text{maximize} & \quad \sum_{j=1}^{m} 2u_j^T \left( \prod_{i=1}^{j-1} I - 2u_iu_i^T \right) x \\
\text{s.t.} & \quad x \in \mathbb{R}^n, \quad ||x|| \leq 1 \\
& \quad 2u_j^T \left( \prod_{i=1}^{j-1} I - 2u_iu_i^T \right) x \geq 0, \quad \forall \ j \in \{1, \ldots, m\} \\
& \quad \left( \prod_{i=1}^{m} I - 2u_iu_i^T \right) - I \ x = 0.
\end{align*}
\]

If this SOCP has an optimal solution \( x^* \), we pick \( n_1 = x^* \). It is easy to see that this way \( n_1 \) lies on \( S^{n-1} \). If we assume \( ||x^*|| = ||n_1|| < 1 \) then \( x^*/||x^*|| \) would be feasible as well but would have a greater objective value (unless the optimal value is 0 in which case \( \mu_j = 0 \) for every \( j \). But then there is no closed regular billiard trajectory for the given choice of facets). This contradicts the optimality of \( x^* \).

We now have a way to find \( n_1 \) and hence also \( n_2, \ldots, n_m \). These vectors are unique by Proposition 6.2. We proceed in a similar fashion as before in order to find the bouncing points \( p_1, \ldots, p_m \) of a closed regular billiard trajectory. (5) states that \( p_{j+1} - p_j = \lambda_j n_j \) needs to hold for every \( j \in \{1, \ldots, m\} \), where \( \lambda_j > 0 \). Thus, just like \( u_1, \ldots, u_m \), we have that \( n_1, \ldots, n_m \) are not linearly independent:

\[
0 = \sum_{j=1}^{m} (p_{j+1} - p_j) = \sum_{j=1}^{m} \lambda_j n_j.
\]

We would like to have that the \((n \times m)\)-matrix \( (n_1, \ldots, n_m) \) has rank \( m - 1 \). Then, the closed polygonal line which can be constructed by positive multiples of \( n_1, \ldots, n_m \) is unique up to scaling. Indeed it can be shown that this is the case. We clearly have

\[
\text{rk}(n_1, \ldots, n_m) \leq m - 1
\]

because \( n_1, \ldots, n_m \) are not linearly independent. Since we are interested in a length minimizing closed billiard trajectory, we can assume that the bouncing points \( p_1, \ldots, p_m \), which we are going to find in the remainder, belong to a minimizer. According to Theorem 1.2 the smallest affine section containing \( p_1, \ldots, p_m \) has dimension \( m - 1 \). In other words

\[
p_1 - p_m, \ p_2 - p_m, \ldots, \ p_{m-1} - p_m
\]
are linearly independent. Recall that $\text{rk}(AB) = \text{rk}(A)$ for $A \in \mathbb{R}^{n \times m}$ and $B \in \text{Gl}_m(\mathbb{R})$.

$$m - 1 = \text{rk} \begin{pmatrix} p_1 - p_m & p_2 - p_m & \ldots & p_{m-1} - p_m \end{pmatrix}$$

$$= \text{rk} \begin{pmatrix} p_1 - p_m & p_2 - p_m & \ldots & p_{m-1} - p_m \end{pmatrix} \cdot \begin{pmatrix} 1 & -1 & 0 \\ \vdots & \ddots & \vdots \\ 0 & \ldots & -1 \end{pmatrix}$$

$$= \text{rk} \begin{pmatrix} p_1 - p_m & p_2 - p_m & \ldots & p_{m-1} - p_m \end{pmatrix} \cdot \begin{pmatrix} \lambda_m n_m & \lambda_1 n_1 & \lambda_2 n_2 & \ldots & \lambda_{m-2} n_{m-2} \end{pmatrix}$$

$$= \text{rk} \begin{pmatrix} n_m & n_1 & n_2 & \ldots & n_{m-2} \end{pmatrix}$$

$$\leq \text{rk} \begin{pmatrix} n_1 & n_2 & \ldots & n_m \end{pmatrix}$$

The second to last line of the equation holds since $\lambda_m, \lambda_1, \ldots, \lambda_{m-2} > 0$.

In the following we let $\xi = (\xi_1, \ldots, \xi_m)$ be such a closed polygonal line, i.e. $\xi_{j+1} - \xi_j = \lambda_j n_j$ with $\lambda_j > 0$ for $j \in \{1, \ldots, m\}$. The task is now to find $\lambda > 0$ and $s \in \mathbb{R}^n$ such that $\lambda \xi_j + s \in F_j$ for every $j$. This can be done via a linear program (LP).

Just like an SOCP, an LP is a convex optimization with a linear objective function and linear constraints. As opposed to an SOCP where the goal is to find an optimal member of $\mathcal{L}_{n+1}$, an LP asks for an optimal member of the non-negative orthant $\mathbb{R}^n_{\geq 0}$. An LP in standard form looks as follows:

$$\text{maximize } c^T x$$

$$\text{s.t. } x \in \mathbb{R}^n_{\geq 0}$$

$$Ax = b,$$

where $c \in \mathbb{R}^n, b \in \mathbb{R}^r, A \in \mathbb{R}^{r \times n}$. Here, $r$ is the number of linear constraints. Linear programming is a special case of second-order cone programming. In particular, it is not surprising that LPs can be solved efficiently as well (see [13]).

For $j \in \{1, \ldots, m\}$ let

$$H_j = \{ x \in \mathbb{R}^n : \langle u_j, x \rangle = b_j \}$$

be the unique supporting hyperplane of $T$ which contains $F_j$. Then we require

$$\lambda \xi_j + s \in F_j \iff \lambda \xi_j + s \in T \cap H_j$$

$$\iff \langle \lambda \xi_j + s, u_j \rangle = b_j, \langle \lambda \xi_j + s, u_i \rangle \leq b_i, \forall i \neq j$$

$$\iff \begin{pmatrix} \xi_j^T u_j & u_j^T \end{pmatrix} \begin{pmatrix} \lambda \\ s \end{pmatrix} = b_j, \begin{pmatrix} \xi_i^T u_j & u_i^T \end{pmatrix} \begin{pmatrix} \lambda \\ s \end{pmatrix} \leq b_i, \forall i \neq j.$$
maximize $\rho$

s.t. $\rho, \lambda \in R_{\geq 0}$, $s \in R^n$

$$(\xi_j^T u_j \ u_j^T) \left( \begin{array}{c} \lambda \\ s \end{array} \right) = b_j, \ \forall \ j \in \{1, \ldots, m\}$$

$$\rho \leq b_i - (\xi_j^T u_i \ u_i^T) \left( \begin{array}{c} \lambda \\ s \end{array} \right), \ \forall i, j \in \{1, \ldots, m\}, i \neq j.$$

Note that any solution of the LP satisfies $\lambda > 0$. If otherwise $\lambda = 0$ then the equality constraints state that $s \in H_j$. This means all supporting hyperplanes which contain a face of $T$ intersect at a common point. This is not possible. If a solution exists, we let $p_j = \lambda \xi_j + s$ for $j \in \{1, \ldots, m\}$. If the optimal solution fulfils $\rho > 0$ then $p = (p_1, \ldots, p_m)$ is a closed regular billiard trajectory which is potentially length minimizing (meaning it fulfils the condition in Theorem 1.2). To ensure that we don’t miss any potentially length minimizing closed regular billiard trajectories, we are going to prove that it suffices to find one such closed billiard trajectory per choice of $F_1, \ldots, F_m$.

**Proposition 6.3.** Let $F_1, \ldots, F_m$ be facets of some full dimensional polytope $T$ and let $p_j, p_j' \in F_j$ for every $j$. Assume $p = (p_1, \ldots, p_m)$ and $p' = (p_1', \ldots, p_m')$ are closed regular billiard trajectories in $T$, which satisfy the condition in Theorem 1.2. Then $\ell(p) = \ell(p')$.

**Proof.** According to Proposition 2.4 there are $n_1, \ldots, n_m, n_1', \ldots, n_m'$ such that:

$$ \begin{align*}
\{ p_{j+1} - p_j = \lambda_j n_j, \ \lambda_j > 0, \\
n_{j+1} - n_j \in -NT(p_{j+1}) \end{align*} $$

and

$$ \begin{align*}
\{ p'_{j+1} - p'_j = \lambda'_j n'_j, \ \lambda'_j > 0, \\
n'_{j+1} - n'_j \in -NT(p'_{j+1}) \end{align*} $$

As has been discussed earlier in this section $n_1, \ldots, n_m$ are unique and only depend on $n_T(p_1), \ldots, n_T(p_m)$. Therefore, we have $n'_j = n_j$ for $j \in \{1, \ldots, m\}$. Furthermore, we can use the fact that $||n_j|| = 1$ to get:

$$ \ell(p) = \sum_{j=1}^m \| p_{j+1} - p_j \| = \sum_{j=1}^m |\lambda_j n_j| = \sum_{j=1}^m \lambda_j ||n_j|| = \sum_{j=1}^m \lambda_j \langle n_j, n_j \rangle$$

$$ = \sum_{j=1}^m \langle \lambda_j n_j, n_j \rangle = \sum_{j=1}^m \langle p_{j+1} - p_j, n_j \rangle.$$ 

Similarly, we get:

$$ \ell(p') = \sum_{j} \langle p'_{j+1} - p'_j, n_j \rangle.$$
This implies:
\[
\ell(p) - \ell(p') = \sum_{j=1}^{m} \langle p_{j+1} - p_j, n_j \rangle - \langle p'_{j+1} - p'_j, n_j \rangle \\
= \sum_{j=1}^{m} \langle p_{j+1} - p'_{j+1}, n_j \rangle + \langle p'_j - p_j, n_j \rangle \\
= \sum_{j=1}^{m} \langle p_{j+1} - p'_{j+1}, n_j \rangle + \sum_{j=1}^{m} \langle p'_{j+1} - p_{j+1}, n_{j+1} \rangle \\
= \sum_{j=1}^{m} \langle p_{j+1} - p_j, n_{j+1} - n_j \rangle.
\]

As before, we let
\[
H_{j+1} = \{ x \in \mathbb{R}^n : \langle n_T(p_{j+1}), x \rangle = b_{j+1} \}
\]
be the supporting hyperplane of \( T \) which contains \( F_{j+1} \). On the one hand we have
\[
\langle n_T(p_{j+1}), p'_{j+1} - p_{j+1} \rangle = \langle n_T(p_{j+1}), p'_{j+1} \rangle - \langle n_T(p_{j+1}), p_{j+1} \rangle = b_{j+1} - b_{j+1} = 0.
\]
On the other hand \( n_{j+1} - n_j \) is a multiple of \( n_T(p_{j+1}) \). This yields \( \ell(p) - \ell(p') = 0 \).

For each choice of \( F_1, \ldots, F_m \) the algorithm needs to solve the following tasks: Calculate the rank of an \((n \times m)\)-matrix, solve an SOCP with \( n + m + 1 \) constraints and \( n + 1 \) variables, solve an \((n + 1) \times m\) system of linear equations, solve an LP with \( mf \) constraints and \( n + 2 \) variables, where \( f \) is the number of facets of \( T \). All these tasks are solvable in polynomial time (with respect to the dimension \( n \) and the number of facets of \( T \)), see for instance [12]. However, there are \( \sum_{j=2}^{n+1} \binom{j}{2} j! \) possibilities to choose at least 2 but at most \( n + 1 \) facets, respecting their order. We can slightly improve this number since a cyclic shift of the chosen facets \( F_1, \ldots, F_m \) will yield a similar (but shifted) result. This leaves us with \( \sum_{j=2}^{n+1} \binom{j}{2} (j - 1)! \) possibilities. The calculations for each of these possibilities are independent of each other. Therefore, we utilize parallel computing to accelerate the algorithm.

In Table 1 the running time of the algorithm can be seen. Each time the billiard table is a polytope \( T \) with dimension 2, 3 or 4 which we generated in the following way. First we chose some normally distributed random vectors. We scaled each of these vectors by some scalar between 1 and 3 (we decreased the length of this range if the amount of random vectors became too large). Afterwards, we received \( T \) as the convex hull of these vectors. Instead of a total running time the table shows the time needed to compute a length minimizing closed regular billiard trajectory with 2, 3, 4 and 5 bouncing points respectively. The table suggests that the calculations for \( m \) bouncing points with \( m < d + 1 \) terminate very quickly. The reason for this is that many iterations are cancelled early when the rank of \( (u_1, \ldots, u_m) \) is checked. All calculations have been done on a Dell Latitude E6530 laptop with Intel Core i7-3520M processor, 2.9 GHz (capable of running four threads). The algorithm has been implemented in Python and mainly utilizes the NumPy library. The LPs and SOCPs are solved via the software Mosek. The algorithm is available upon personal request.
### Table 1.

Running times of the algorithm outlined above. The billiard table $T$ is a polytope. The first two columns contain the number of facets and dimension of $T$. The last four columns contain the running time for 2, 3, 4 and 5 bouncing points in seconds.
