The motto of this work is to generate a general formalism of \(f(\bar{R}, L(X))\)-gravity in the context of dark energy under the framework of the K-essence emergent geometry with the Dirac-Born-Infeld (DBI) variety of action, where \(\bar{R}\) is the familiar Ricci scalar, \(L(X)\) is the DBI type non-canonical Lagrangian with \(X = \frac{1}{2} g^{\mu \nu} \nabla_\mu \phi \nabla_\nu \phi\) and \(\phi\) is the scalar field of the K-essence geometry. The emergent gravity metric \(g_{\mu \nu}\) and the well known gravitational metric \(g_{\mu \nu}\) are not conformally equivalent. We have constructed a modified field equation using the metric formalism in \(f(\bar{R}, L(X))\)-gravity incorporating the corresponding Friedmann equations in the framework of the background gravitational metric which is of Friedmann-Lemaître-Robertson-Walker (FLRW) type. The solution of modified Friedmann equations have been deduced for the specific choice of \(f(\bar{R}, L(X))\), which is of Starobinsky type, using power law expansion method. The consistency of the model with the accelerating phase of the Universe has been shown, when we restrict ourselves to consider the value of the dark energy density, as \(\Omega = 0.888 < 1\), which indicates that the present Universe is dark energy dominated. Graphical plots for the energy density \(\rho\), pressure \(p\) and equation of state parameter \(\omega\) w.r.t. time \(t\) based on parametric values are interestingly consistent with the dark energy domination and hence accelerating features. We also put some light on the corresponding energy conditions and constraints of the \(f(\bar{R}, L(X))\) theory with one basic example.

I. INTRODUCTION

Einstein’s gravitational theory, General relativity (GR), was reshaped by Weyl in 1919 [1] and Eddington in 1923 [2] through incorporating higher-order invariants in its action. We are bound to quantize GR by the non-renormalizability of the theory in a conventional way. Utiyama and De Witt [3] in 1962 showed that, renormalization at one loop is possible if, the Einstein-Hilbert action is supplemented by higher-order curvature terms and made renormalizable. In addition, when quantum corrections or string theory entered in the scenario, the effective low energy gravitational action admits higher-order curvature invariants [4]. Being inspired by this argument, scientists have been tried to modify the Einstein-Hilbert action in applied higher order theories of gravity.

Therefore, it was evident that higher-order curvature invariants, concerning Ricci scalar, should be taken into consideration. We should keep it in mind that, the corrected theories of GR are considered to be important only at scales which are close to the Planck scale, i.e., in the early universe or near the black hole singularities, such as curvature-driven inflation scenario [5]. Sotiriou and Fiecle [6, 7] made a significant contribution by introducing the well-known “\(f(R)\) theory of gravity”. This \(f(R)\) gravity was reconstructed by Dunsby et al. [8] from the background Friedmann-Lemaître-Robertson-Walker (FLRW) expansion history. To be particular, they have found that the only real-valued Lagrangian for which \(f(R)\) can generate an exact \(\Lambda CDM\) expansion history for a universe which is filled with dust-like matter and is equivalent to the Einstein-Hilbert Lagrangian with positive cosmological constant. A general formalism was proposed by Mukherjee and Banerjee [9] to observe the late time dynamics of the universe for any analytic \(f(R)\) gravity model, along with a cold dark matter. The fruits of energy conditions using the Raychaudhuri equations in expanding universe was also studied in [10–17].
Harko et al. [18] generalized the $f(R)$ gravity taking the gravitational Lagrangian as an arbitrary function of the Ricci scalar ($R$) along with the matter Lagrangian ($L_m$). They have obtained the gravitational field equations of $f(R, L_m)$ gravity, using the metric formalism, as well as the equations of motion for test particles. Also, later on, the general energy conditions of the $f(R, L_m)$ gravity was developed by Wang et al. [19]. In [20–22], the authors have described the power-law cosmic expansion in higher derivative gravity.

On the basis of the Dirac-Born-Infeld (DBI) model [23–25], Manna et al. [26–28] have developed the simplest form of the K-essence emergent gravity metric $G_{\mu \nu}$, which is obviously different from the usual gravitational metric $g_{\mu \nu}$. The K-essence model [29–35] is a scalar field model where the kinetic energy of the field dominates over the potential energy of the field. The K-essence field Lagrangian is non-canonical in nature and it confirms the non-dependency of the Lagrangian on the field explicitly. The K-essence theory with non-canonical kinetic terms and the relativistic field theories with canonical kinetic terms are different in the non-trivial dynamical solutions of the K-essence equation of motion. Besides spontaneously breaking Lorentz invariance it also changes the metric for the perturbations around these solutions. Thus, the perturbations propagate in the so-called emergent or analogue curved space-time with the metric. The general form of the Lagrangian for K-essence model is $L = -V(\phi)F(X)$ where $\phi$ is the K-essence scalar field and $X = \frac{1}{2}g^{\mu \nu}\nabla_\mu \phi \nabla_\nu \phi$.

A modified version of $f(R)$ gravity was also studied by Nojiri et al. [36], in which they consider the higher order kinetic terms of a scalar field, added in the action of vacuum $f(R)$ gravity. Actually, in the form of action, they added a general class of the K-essence Lagrangian $G(X)$ with the vacuum $f(R)$ gravity Lagrangian. In the context of slow-roll approximation they have investigated the inflationary aspects of their theory. Odintsov et al. [37] have studied the consequences of K-essence terms in the late-time phenomenology of $f(R)$ gravity in the presence of cold dark matter and radiation. Perfect fluids with the similar model was considered in [36]. Several cosmological quantities of cosmological interest, such as the dark energy equation of state parameter, the dark energy density parameter, and some state finder quantities were also some of their findings. Recently, Oikonomou et al. [38] have discussed the phase space of a simple K-essence $f(R)$ gravity theory. They have worked with both canonical and phantom scalar fields and found that the canonical scalar K-essence theory is structurally more fascinating in comparison with the phantom theory.

At this juncture, let us discuss the importance of the K-essence theory with specific choice of DBI type Lagrangian: It is now unavoidable to accept the accelerating universe after analysing the observations of Large-Scale Structure, searches of type Ia Supernovae and measurements of Cosmic Microwave Background anisotropy [39]. It has also been acknowledged that our universe is now dominated by a component named dark energy which poses negative pressure. Scientists proposed cosmological constant or vacuum density to be the candidate for such an exotic component of the universe. But the barrier of cosmological coincidence problem created hurdles for us and raised the question that why does the strange dark energy component possesses a tiny energy density $(O(meV^4))$ compared to the simple expectation based on quantum field theory. Additionally, the occurrence of the acceleration at such a late stage of evolution continuously poked cosmologists for better theories. The problem with most of the dark energy models (take cosmological constant as example) are that they require extraordinary fine tuning of the initial energy density which is of the orders of 100 or more smaller than the initial matter-energy density.

Here comes the new class of scalar field model with amazing dynamic properties that avoids the fine-tuning problem, known as K-essence theory [40]. The most promising feature of this model is that it brings the negative pressure from its nonlinear kinetic energy of the scalar field. It has already been investigated that for a wide class of theories, there exist attractor solution [41, 42] in which the scalar field changes its speed of evolution to give the required equation of state of the K-essence theory of different epoch on the basis of the changing equation of state of the background. While the universe was going through the radiation dominated epoch, K-essence theory was driven to be sub-dominant and imitated the equation of state (EOS) of the radiation so that the ratio of K-essence theory to radiation density remains constant. When the universe stepped into the dust dominated epoch K-essence theory failed to mimic the dust-like EOS for dynamical reasons but it deceased its energy value quickly by several orders of magnitude and settled upon at a constant value. Afterwards the field outgrew the matter density and took the universe into cosmic acceleration at a time, roughly corresponding to the current age of the universe. At last, the EOS of K-essence theory slowly reclines to an value between the range 0 and –1.

The well-known Quintessence Trackers models [43–49] almost give the same result as given by the K-essence theory but with one problem. It is good that it can mimic the equation of state of matter and radiation of background EOS, but it requires an adjustable parameter which need to be finely tuned to achieve the energy density for which the pressure becomes negative at present age.

The unique characteristics of K-essence theory is that it tracks the background energy density only in the radiation epoch. The sharp transition of positive pressure to negative pressure at the matter-radiation equality occurs automatically with the help of its dynamics only. K-essence theory was unable to dominate before matter-radiation equality as it was busy to track the radiation background. Since its energy density inevitably drops several orders of magnitude at the transition to dust domination, it was also impossible to dominate immediately just after the dust
domination. On the other hand, as the matter density decreases more rapidly than the energy density with expanding universe, K-essence theory took the dominating role at the age roughly around the current epoch. Thus, the whole problem of Cosmic Coincidence Problem (i.e., why we live in the particular era during which the dark matter and dark energy densities are roughly equal) vanishes to the fact that we came to observe the universe at the right time after matter-radiation equality.

There is another interesting characteristic of K-essence model that it can produce a dark energy component where the sound speed \( c_s \) does not exceed the speed of light. These models are observationally distinguished from standard scalar field quintessence models with a canonical kinetic term (for which \( c_s = 1 \)), and may provide a mechanism to reduce cosmic microwave background (CMB) fluctuations on large angular scales [50–52]. Some cosmological behaviours and the stability of the K-essence model in FLRW spacetime has been studied by Yang et al. [53].

Historically, a theory with a non-canonical kinetic term was first proposed by Born and Infeld [23] in order to get rid of the infinite self-energy of the electron. Similar type of theories was also studied in the literature [24, 25]. The literature [54–62] of string theory, brane cosmology, D-branes, etc. have also used the DBI type non-canonical Lagrangian.

Motivated by the above said importance of the K-essence theory which is a theoretical model to investigate the effects of the presence of dark energy in cosmological scenarios, in this paper we study the \( f(R) \)-gravity in the context of K-essence emergent gravity, i.e., dark energy in a general manner. We have made the generalization of the \( f(\bar{R}, L(X)) \) theory by using the metric formalism where \( \bar{R} \) is the Ricci scalar of the K-essence geometry and \( L(X) \) is the DBI type non-canonical Lagrangian. Also, we have calculated the energy conditions and modified Friedman equations in \( f(\bar{R}, L(X)) \) gravity, where we have considered the flat FLRW type metric as the background gravitational metric. The modified field equation, Friedmann equations and energy conditions for the new \( f(\bar{R}, L(X)) \) gravity theory are different from the usual \( f(\bar{R}, L_m) \) [18] and \( f(R) \) [6] gravity theories. Also, we have solved the modified Friedmann equations using power law cosmic expansion method.

The paper is organized as follows: In Sec. II, we have briefly discussed about the K-essence emergent geometry with the help of the following works [26–33]. In Sec. III, we have formulated the \( f(\bar{R}, L(X)) \) gravity in the context of the K-essence emergent geometry. We also have derived the modified field equations and the condition of the requirement of the conservation of the energy-momentum tensor in the \( f(\bar{R}, L(X)) \) gravity. The modified Friedmann equations were brought into limelight in Sec. IV, considering the background gravitational metric as flat FLRW and the K-essence scalar field as a function of time only. The solution of Friedmann equations have been solved for specific choice of \( f(\bar{R}, L(X)) \) using power law method in Sec. V, whereas in Sec. VI we develop the energy conditions and constraints of the \( f(\bar{R}, L(X)) \) gravity with example. The last section Sec. VI contains some general discussion and crucial conclusion of our work. Also, we have briefly discussed the \( f(R) \)-gravity and \( f(R, L_m) \)-gravity and corresponding energy conditions [10–14, 19, 73] in Sec. VIII (Appendix).

II. K-ESSENCE THEORY: A GLIMPSE OF BACKGROUND AND DEVELOPMENT

In this section, we will discuss about the development of the effective metric for the emergent spacetime corresponding to a general background geometry and a very general K-essence scalar field vector. The K-essence scalar field \( \phi \), minimally coupled with the background space-time metric \( g_{\mu\nu} \) has action [29–33]

\[
S_k[\phi, g_{\mu\nu}] = \int d^4x \sqrt{-g} L(X, \phi),
\]

where \( X = \frac{1}{2} g^{\mu\nu} \nabla_\mu \phi \nabla_\nu \phi \) is the canonical kinetic term.

The energy-momentum tensor is

\[
T_{\mu\nu} = \frac{-2}{\sqrt{-g}} \frac{\delta S_k}{\delta g^{\mu\nu}} = -2 \frac{\partial L}{\partial g^{\mu\nu}} + g_{\mu\nu} L = -L_X \nabla_\mu \phi \nabla_\nu \phi + g_{\mu\nu} L,
\]

with \( L_X = \frac{dL}{dX} \), \( L_{XX} = \frac{d^2L}{dX^2} \), \( L_\phi = \frac{dL}{d\phi} \) and \( \nabla_\mu \) is the covariant derivative defined with respect to the gravitational metric \( g_{\mu\nu} \).

The equation of motion of the scalar field is

\[
- \frac{1}{\sqrt{-g}} \frac{\delta S_k}{\delta \phi} = G^{\mu\nu} \nabla_\mu \phi = 2XL_{XX} \phi - L_\phi = 0,
\]

where

\[
G^{\mu\nu} = \frac{c_s}{L_X} [L_X g^{\mu\nu} + L_{XX} \nabla^\mu \phi \nabla_\nu \phi],
\]
with $1 + \frac{2X}{L_X} > 0$ and $c_s^2(X, \phi) \equiv (1 + 2X/L_X)^{-1}$.

The inverse metric of $G^{\mu\nu}$ takes the form

$$G_{\mu\nu} = \frac{L_X}{c_s^2}[g_{\mu\nu} - c_s^2 L_{XX} \nabla_\mu \phi \nabla_\nu \phi].$$

(5)

A further conformal transformation [26, 27] $\bar{G}_{\mu\nu} = \frac{T}{L_X} G_{\mu\nu}$ gives

$$\bar{G}_{\mu\nu} = g_{\mu\nu} - \frac{L_{XX}}{L_X + 2XL_{XX}} \nabla_\mu \phi \nabla_\nu \phi.$$  

(6)

Using Eq. (2), the effective emergent metrics (6) can be written as [31, 32]

$$\bar{G}_{\mu\nu} = \left(1 - \frac{LL_{XX}}{L_X(L_X + 2XL_{XX})}\right) g_{\mu\nu} + \frac{L_{XX}}{L_X(L_X + 2XL_{XX})} T_{\mu\nu}.$$  

(7)

Here one must always have $L_X \neq 0$ for $c_s^2$ to be positive definite and only then Eqs. (1) – (4) will be physically meaningful.

It is clear that for non-trivial space-time configurations of $\phi$, the emergent metric $\bar{G}_{\mu\nu}$ is in general, not conformally equivalent to $g_{\mu\nu}$. So $\phi$ has different properties as of the canonical scalar fields with the local causal structure. It is distinct from those defined with $g_{\mu\nu}$. Further, if $L$ is not an explicit function of $\phi$, the equation of motion (3) reduces to

$$-\frac{1}{\sqrt{-g}} \delta S_k \delta \phi = \bar{G}^{\mu\nu} \nabla_\mu \nabla_\nu \phi = 0.$$  

(8)

We shall take the Dirac-Born-Infeld (DBI) type non-canonical Lagrangian [23–25, 32, 33] as

$$L(X, \phi) = 1 - \sqrt{1 - 2X}.$$  

(9)

It should be noted that here we ignore any type of potential part of the Lagrangian, since in the $K$-essence theory, the kinetic energy dominates over the potential energy of the $K$-essence scalar field. Then $c_s^2(X, \phi) = 1 - 2X$ and thus the effective emergent metric (6) becomes

$$\bar{G}_{\mu\nu} = g_{\mu\nu} - \nabla_\mu \phi \nabla_\nu \phi \equiv g_{\mu\nu} - \partial_\mu \phi \partial_\nu \phi,$$  

(10)

since $\phi$ is a scalar.

Using Eq. (2), this can also be written in terms of $T_{\mu\nu}$ and $\nabla_\mu \phi$, (10) as

$$\bar{G}_{\mu\nu} L = L_X \nabla_\mu \phi \nabla_\nu \phi + T_{\mu\nu} - L \nabla_\mu \phi \nabla_\nu \phi.$$  

(11)

Following [26, 63] the new Christoffel symbols can be related to the old ones by

$$\bar{\Gamma}^\alpha_{\mu\nu} = \Gamma^\alpha_{\mu\nu} + (1 - 2X)^{-1/2} \bar{G}^{\alpha\gamma}[\bar{G}_{\mu\gamma} \partial_\nu (1 - 2X)^{1/2} + \bar{G}_{\nu\gamma} \partial_\mu (1 - 2X)^{1/2} - \bar{G}_{\mu\nu} \partial_\gamma (1 - 2X)^{1/2}]
+ \frac{1}{2(1 - 2X)} [\delta_\nu^\alpha \partial_\mu X + \delta_\mu^\alpha \partial_\nu X].$$  

(12)

The geodesic equation for the $K$-essence theory in terms of the new Christoffel connections $\bar{\Gamma}$ now becomes

$$\frac{d^2x^\alpha}{d\lambda^2} + \bar{\Gamma}^\alpha_{\mu\nu} \frac{dx^\mu}{d\lambda} \frac{dx^\nu}{d\lambda} = 0,$$  

(13)

where $\lambda$ is an affine parameter.

Now we introduce the covariant derivative $D_{\mu}$ [31, 32], associated with the emergent metric $\bar{G}_{\mu\nu}$ ($D_{\alpha} \bar{G}^{\alpha\beta} = 0$) as

$$D_{\mu} A_{\nu} = \partial_{\mu} A_{\nu} - \bar{\Gamma}^{\lambda}_{\mu\nu} A_{\lambda},$$  

(14)

and the inverse emergent metric is $\bar{G}^{\mu\nu}$ such that $\bar{G}_{\mu\alpha} \bar{G}^{\lambda\nu} = \delta^\nu_\mu$.

Therefore, the “emergent” Einstein’s equation is

$$\bar{E}_{\mu\nu} = \bar{R}_{\mu\nu} - \frac{1}{2} \bar{G}_{\mu\nu} \bar{R} = \kappa T_{\mu\nu},$$  

(15)

where $\kappa = 8\pi G$ is constant, $\bar{R}_{\mu\nu}$ is Ricci tensor and $\bar{R} (= \bar{R}_{\mu\nu} \bar{G}^{\mu\nu})$ is the Ricci scalar of the emergent space-time.
III. $f(R, L(X))$ Gravity in the Context of K-Essence Emergent Space-Time

We are now considering the action of the modified gravity in the context of the K-essence emergent space-time, which takes the following form ($\kappa = 1$)

$$S = \int d^{4}x \sqrt{-G} f(\bar{R}, L(X)),$$

where $f(\bar{R}, L(X))$ is an arbitrary function of the Ricci scalar $\bar{R}$ and the non-canonical Lagrangian density $L(X)$ corresponding to the K-essence theory, and

$$\sqrt{-G} = \sqrt{\text{det}(G_{\mu\nu})}.$$  

Based on [18], varying the action $S$ with respect to the K-essence emergent gravity metric $\bar{G}^{\mu\nu}$ we obtain

$$\delta S = \int \left[ f_{R}(\bar{R}, L)\delta \bar{R} + f_{L}(\bar{R}, L) \frac{\delta L}{\delta G_{\mu\nu}} \delta \bar{G}^{\mu\nu} - \frac{1}{2} \bar{G}^{\mu\nu} f(\bar{R}, L) \delta \bar{G}^{\mu\nu} \right] \times \sqrt{-G} d^{4}x,$$

where we have denoted $f_{R}(\bar{R}, L) = \frac{\partial f(\bar{R}, L)}{\partial \bar{R}}$ and $f_{L}(\bar{R}, L) = \frac{\partial f(\bar{R}, L)}{\partial L}$.

Now we obtain the variation of the Ricci scalar for the K-essence emergent gravity metric

$$\delta \bar{R} = \delta(\bar{R}_{\mu\nu}\bar{G}^{\mu\nu}) = \delta \bar{R}_{\mu\nu}\bar{G}^{\mu\nu} + \bar{R}_{\mu\nu}\delta \bar{G}^{\mu\nu} = \bar{R}_{\mu\nu}\delta \bar{G}^{\mu\nu} + \bar{G}^{\mu\nu}(D_{\lambda}\delta \bar{\Gamma}_{\mu\nu}^{\lambda} - D_{\nu}\delta \bar{\Gamma}_{\mu\lambda}^{\lambda}),$$

where

$$\bar{R}_{\mu\nu} = \partial_{\mu}\bar{\Gamma}_{\alpha\nu}^{\alpha} - \partial_{\nu}\bar{\Gamma}_{\mu\alpha}^{\alpha} + \bar{\Gamma}_{\beta\mu}^{\alpha}\bar{\Gamma}_{\alpha\nu}^{\beta} - \bar{\Gamma}_{\alpha\beta}\bar{\Gamma}_{\mu\nu}^{\alpha},$$

and the variation of $\delta \bar{\Gamma}_{\mu\nu}^{\lambda}$ is

$$\delta \bar{\Gamma}_{\mu\nu}^{\lambda} = \frac{1}{2} \bar{G}^{\lambda\alpha}[D_{\mu}\delta \bar{G}_{\nu\alpha} + D_{\nu}\delta \bar{G}_{\mu\alpha} - D_{\alpha}\delta \bar{G}_{\mu\nu}].$$

Thus, the expression for the variation of Ricci scalar $\delta \bar{R}$ is

$$\delta \bar{R} = \bar{R}_{\mu\nu}\delta \bar{G}^{\mu\nu} + \bar{G}_{\mu\nu}D_{\alpha}D^{\alpha}\delta \bar{G}^{\mu\nu} - D_{\mu}D_{\nu}\delta \bar{G}^{\mu\nu}.$$  

Therefore, variation of the action (17) is

$$\delta S = \int \left[ f_{R}(\bar{R}, L)\bar{R}_{\mu\nu}\delta \bar{G}^{\mu\nu} + f_{R}(\bar{R}, L)\bar{G}_{\mu\nu}D_{\alpha}D^{\alpha}\delta \bar{G}^{\mu\nu} - f_{R}(\bar{R}, L)D_{\mu}D_{\nu}\delta \bar{G}^{\mu\nu} \right] \sqrt{-G} d^{4}x.$$  

After partially integrating second and third terms of the above Eq. (23), we get

$$\delta S = \int \left[ f_{R}(\bar{R}, L)\bar{R}_{\mu\nu} + \bar{G}_{\mu\nu}D_{\alpha}D^{\alpha}f_{R}(\bar{R}, L) - D_{\mu}D_{\nu}f_{R}(\bar{R}, L) \right] \delta \bar{G}^{\mu\nu} \sqrt{-G} d^{4}x.$$  

Therefore, using principle of least action, i.e. $\delta S = 0$, we have the modified field equation for $f(\bar{R}, L(X))$ theory

$$f_{R}(\bar{R}, L)\bar{R}_{\mu\nu} + \bar{G}_{\mu\nu}D_{\alpha}D^{\alpha}f_{R}(\bar{R}, L) - D_{\mu}D_{\nu}f_{R}(\bar{R}, L) - \frac{1}{2} \bar{G}_{\mu\nu}f(\bar{R}, L) + f_{L}(\bar{R}, L) \frac{\delta L}{\delta G_{\mu\nu}} = 0.$$  

(25)
Now, we evaluate the term $\frac{\delta L}{\delta G_{\mu\nu}}$ as

$$\frac{\delta L}{\delta G_{\mu\nu}} = \frac{\delta L}{\delta X} \frac{\delta g^{\mu\nu}}{\delta G_{\mu\nu}} = \frac{1}{2} L_X D_\mu \phi D_\nu \phi (1 + D_\alpha \phi D^\alpha \phi), \tag{26}$$

since for the scalar field $\nabla_\mu \phi \equiv \partial_\mu \phi \equiv D_\mu \phi$.

Using Eqs. (11), (25) and (26), we obtain the expression for modified field equation for the $f(R, L(X))$ theory in terms of $T_{\mu \nu}$ as

$$f_R(\bar{R}, L)R_{\mu \nu} + (\bar{G}_{\mu\nu} \Box - D_\mu D_\nu) f_R(\bar{R}, L) - \frac{1}{2} \left[ f(\bar{R}, L) - L f_L(\bar{R}, L)(1 + D_\alpha \phi D^\alpha \phi) \right] \bar{G}_{\mu\nu}$$

$$+ \frac{1}{2} L f_L(\bar{R}, L) D_\mu \phi D_\nu \phi [1 + D_\alpha \phi D^\alpha \phi] = \frac{1}{2} f_L(\bar{R}, L) T_{\mu \nu} \left[ 1 + D_\alpha \phi D^\alpha \phi \right] = \frac{1}{2} f_L(\bar{R}, L) T_{\mu \nu},$$

(27)

where $\Box = D_\mu D^\mu$ and $\bar{T}_{\mu \nu} = T_{\mu \nu} [1 + D_\alpha \phi D^\alpha \phi]$.

The above Eq. (27) is different from the usual Eq. (A6) of $f(R, L_m)$ theory in the presence of the K-essence scalar field (vide Appendix). If we consider the emergent gravity metric $\bar{G}_{\mu\nu}$ is conformally equivalent to the gravitational metric $g_{\mu\nu}$ and $L$ can be matter Lagrangian then we get back to the usual $f(R, L_m)$ theory in the absence of the K-essence scalar field. Also, if we consider $f(\bar{R}, L(X)) \equiv f(\bar{R}, L_m) \equiv \frac{2}{3} \bar{R} + L_m$, i.e., the Hilbert-Einstein Lagrangian form, then from (27), we lead to the Standard Einstein field equation $\bar{R}_{\mu\nu} - \frac{1}{2} g_{\mu\nu} \bar{R} = T_{\mu\nu}$.

Contracting the above field equation (27) with $\bar{G}^{\mu\nu}$, we have the modified trace equation for the $f(\bar{R}, L(X))$ theory is

$$f_R(\bar{R}, L)\bar{R} + 3\Box f_R(\bar{R}, L) - 2 \left[ f(\bar{R}, L) - L f_L(\bar{R}, L)(1 + D_\alpha \phi D^\alpha \phi) \right]$$

$$+ \frac{1}{2} L f_L(\bar{R}, L) D_\mu \phi D_\nu \phi [1 + D_\alpha \phi D^\alpha \phi] = \frac{1}{2} f_L(\bar{R}, L) (\bar{T}_{\mu \nu} - \frac{1}{3} \bar{G}_{\mu \nu} \bar{T}) + D_\mu D_\nu f_R(\bar{R}, L),$$

(28)

where $\bar{T} = \bar{T}_{\mu \nu}$ is trace of the energy-momentum tensor.

On subtracting Eq. (28) $\times \bar{G}_{\mu\nu}$ from Eq. (27) $\times 3$, we get

$$f_R(\bar{R}, L) R_{\mu \nu} - \frac{1}{3} \bar{G}_{\mu\nu} \bar{R} + \frac{1}{6} \bar{G}_{\mu\nu} [f(\bar{R}, L) - L f_L(\bar{R}, L)(1 + D_\alpha \phi D^\alpha \phi)]$$

$$+ \frac{1}{3} L f_L(\bar{R}, L) D_\mu \phi D_\nu \phi [1 + D_\alpha \phi D^\alpha \phi] = \frac{1}{2} f_L(\bar{R}, L) (\bar{T}_{\mu \nu} - \frac{1}{3} \bar{G}_{\mu \nu} \bar{T}) + D_\mu D_\nu f_R(\bar{R}, L),$$

(29)

which is another form of the modified field equation in the presence of K-essence scalar field $\phi$.

By taking covariant divergence with respect to $D^\mu$ of Eq. (27), we have

$$D^\mu [f_R(\bar{R}, L) \bar{R}_{\mu \nu} - (\Box D_\nu - D_\nu \Box) f_R(\bar{R}, L) + f_R(\bar{R}, L) D^\mu (R_{\mu \nu} - \frac{1}{2} \bar{G}_{\mu\nu} \bar{R})$$

$$+ \frac{1}{2} \bar{G}_{\mu\nu} f_R(\bar{R}, L) D^\mu (\bar{R}) - \frac{1}{2} D^\mu [f(\bar{R}, L)] \bar{G}_{\mu\nu} + \frac{1}{2} D^\mu [L f_L(\bar{R}, L)(1 + D_\alpha \phi D^\alpha \phi)] \bar{G}_{\mu\nu}$$

$$+ \frac{1}{2} D^\mu [L f_L(\bar{R}, L) D_\mu \phi D_\nu \phi (1 + D_\alpha \phi D^\alpha \phi)] = \frac{1}{2} D^\mu [f_L(\bar{R}, L) \bar{T}_{\mu \nu}].$$

(30)

Using the identities on purely geometrical grounds [64–66] $D^\mu (R_{\mu \nu} - \frac{4}{3} \bar{G}_{\mu\nu} \bar{R}) = D^\mu \bar{E}_{\mu\nu} = 0$, $D^\mu [f_R(\bar{R}, L) \bar{R}_{\mu \nu} = (\Box D_\nu - D_\nu \Box) f_R(\bar{R}, L)$ and also using Eqs. (11) and (26), the above Eq. (30) becomes

$$D^\mu [f_L(\bar{R}, L) \bar{T}_{\mu \nu}] = - f_L(\bar{R}, L) D^\mu (\bar{G}_{\mu\nu} \bar{L}) + D^\mu [L f_L(\bar{R}, L)(1 + D_\alpha \phi D^\alpha \phi)] (\bar{G}_{\mu\nu} + D_\mu \phi D_\nu \phi)$$

$$\Rightarrow D^\mu \bar{T}_{\mu \nu} = D^\mu \ln[f_L(\bar{R}, L)] \left[ L_X D_\mu \phi D_\nu \phi (1 + D_\alpha \phi D^\alpha \phi) \right]$$

$$+ D^\mu \left[ L D_\mu \phi D_\nu \phi (1 + D_\alpha \phi D^\alpha \phi) + L \bar{G}_{\mu\nu} D_\alpha \phi D^\alpha \phi \right]$$

$$\Rightarrow D^\mu \bar{T}_{\mu \nu} = 2D^\mu \ln[f_L(\bar{R}, L)] \frac{\delta L}{\delta G_{\mu\nu}} + D^\mu \left[ L D_\mu \phi D_\nu \phi (1 + D_\alpha \phi D^\alpha \phi) + L \bar{G}_{\mu\nu} D_\alpha \phi D^\alpha \phi \right].$$

(31)

Thus, the requirement of the conservation of the energy-momentum tensor ($D^\mu \bar{T}_{\mu \nu} = 0$) for the K-essence Lagrangian, gives an effective functional relation as

$$2D^\mu \ln[f_L(\bar{R}, L)] \frac{\delta L}{\delta G_{\mu\nu}} + D^\mu \left[ L D_\mu \phi D_\nu \phi (1 + D_\alpha \phi D^\alpha \phi) + L \bar{G}_{\mu\nu} D_\alpha \phi D^\alpha \phi \right] = 0.$$  

(32)
IV. MODIFICATION OF THE FRIEDMANN EQUATIONS

We consider the gravitational metric \( g_{\mu\nu} \) to be a flat Friedmann-Lemaître-Robertson-Walker (FLRW) metric and the line element for this is,

\[
 ds^2 = dt^2 - a^2(t) \sum_{i=1}^3 (dx^i)^2 ,
\]

with \( a(t) \) being the scale factor as usual.

From Eq. (10), we have the components of the emergent gravity metric as

\[
 \bar{G}_{00} = (1 - \dot{\phi}^2) ; \quad \bar{G}_{0i} = - (a^2(t) + (\phi')^2) ; \quad \bar{G}_{0i} = - \dot{\phi} \phi' = \bar{G}_{i0},
\]

where we consider \( \phi \equiv \phi(t, x^i) \), \( \dot{\phi} = \frac{\partial \phi}{\partial t} \) and \( \phi' = \frac{\partial \phi}{\partial x^i} \).

Therefore \( \dot{\phi} \) parameter and the time derivatives of the \( K \) leads to non-applicability of the \( \bar{G}_{0i} \).

So the line element of the FLRW emergent gravity metric is

\[
 dS^2 = (1 - \dot{\phi}^2) dt^2 - (a^2(t) + (\phi')^2) \sum_{i=1}^3 (dx^i)^2 - 2 \dot{\phi} \phi' dt dx^i .
\]

Now from the emergent gravity equation of motion (8) we have

\[
 \bar{G}^{00}(\partial_0 \partial_0 \phi - \Gamma^0_0 \partial_0 \phi - \Gamma^0_i \partial_i \phi) + \bar{G}^{i0}(\partial_0 \partial_i \phi - \Gamma^0_i \partial_0 \phi - \Gamma^0_0 \partial_i \phi) + \bar{G}^{i0}(\partial_0 \partial_0 \phi - \Gamma^0_0 \partial_0 \phi - \Gamma^0_0 \partial_i \phi) = 0.
\]

For simplification, we consider the homogeneous \( K \)-essence scalar field \( \phi \), i.e., \( \phi(t, x^i) \equiv \phi(t) \) then \( \bar{G}_{00} = (1 - \dot{\phi}^2) \), \( \bar{G}_{0i} = \bar{G}_{i0} = 0 = \partial_i \phi, \bar{G}_{ii} = -a^2(t) \) and \( X = \frac{1}{2} \bar{G}_{\mu
u} \nabla_\mu \phi \nabla_\nu \phi = \frac{1}{2} \dot{\phi}^2 \). This consideration is possible in this case since, the dynamical solutions of the \( K \)-essence scalar fields spontaneously break Lorentz symmetry. Therefore, the flat FLRW emergent gravity line element (35) and the equation of motion (36) become

\[
 dS^2 = (1 - \dot{\phi}^2) dt^2 - a^2(t) \sum_{i=1}^3 (dx^i)^2,
\]

and

\[
 \frac{\ddot{a}}{a} = H(t) = - \frac{\ddot{\phi}}{\phi(1 - \dot{\phi}^2)},
\]

where \( H(t) = \frac{\ddot{a}}{a} \) is the usual Hubble parameter (always \( \ddot{a} \neq 0 \)). The Eq. (38) gives the relation between Hubble parameter and the time derivatives of the \( K \)-essence scalar field. Note that, in the above space-time (37) always \( \dot{\phi}^2 < 1 \). If \( \dot{\phi}^2 > 1 \), the signature of this space-time will be ill-defined. Also, \( \dot{\phi}^2 \neq 0 \) condition holds good instead of \( \dot{\phi}^2 = 0 \), which leads to non-applicability of the \( K \)-essence theory. Also, \( \ddot{\phi} \neq 1 \) because \( \Omega_{\text{matter}} + \Omega_{\text{radiation}} + \Omega_{\text{darkenergy}} = 1 \) and we can measured \( \ddot{\phi} \) as dark energy density in units of the critical density, i.e., it is nothing but \( \Omega_{\text{darkenergy}} \). Therefore \( \ddot{\phi} \) takes the value in between 0 and 1.

The Ricci tensors and Ricci scalar of the emergent gravity space-time are

\[
 \bar{R}_{ii} = - \frac{a^2}{1 - \dot{\phi}^2} \left[ \frac{\ddot{a}}{a} + 2 \left( \frac{\dot{a}}{a} \right)^2 + \frac{\ddot{\phi}}{a} \right] = - \frac{a^2}{1 - \dot{\phi}^2} \left[ \frac{\ddot{a}}{a} + \left( \frac{\dot{a}}{a} \right)^2 (2 - \dot{\phi}^2) \right] = - \frac{a^2}{1 - \dot{\phi}^2} \left[ \ddot{H} + H^2(3 - \dot{\phi}^2) \right],
\]

\[
 \bar{R}_{00} = 3 \frac{\ddot{a}}{a} + 3 \frac{\dot{a} \ddot{\phi}}{a} = 3 \ddot{a} + 3 \left( \frac{\dot{a}}{a} \right)^2 \ddot{\phi}^2 = 3 \left[ \ddot{H} + H^2(1 - \dot{\phi}^2) \right],
\]

and

\[
 \bar{R} = \frac{6}{1 - \dot{\phi}^2} \left[ \frac{\ddot{a}}{a} + \left( \frac{\dot{a}}{a} \right)^2 + \frac{\ddot{\phi}}{a} \right] = \frac{6}{1 - \dot{\phi}^2} \left[ \frac{\ddot{a}}{a} + \left( \frac{\dot{a}}{a} \right)^2 (1 - \dot{\phi}^2) \right] = \frac{6}{1 - \dot{\phi}^2} \left[ \ddot{H} + H^2(2 - \dot{\phi}^2) \right].
\]
where we have used the relation (38) and \( \dot{H} = \frac{\partial F}{\partial t} = \frac{\dot{a}^2 - \dot{a}^2}{a^3} \).

Combining Eqs. (39) and (40) with (41) we get

\[
\dot{R}_{00} = \frac{1}{2}(1 - \dot{\phi}^2)\ddot{R} - 3H^2, \tag{42}
\]

\[
\dot{R}_{ii} = -\frac{a^2}{(1 - \dot{\phi}^2)} \left[ \frac{1}{6} \ddot{R}(1 - \dot{\phi}^2) + H^2 \right]. \tag{43}
\]

We assume that the energy-momentum tensor is an ideal fluid type which is

\[
T^\nu_{\mu} = \text{diag}(\rho, -p, -p, -p) = (\rho + p) u_\mu u^\nu - \delta^\nu_\mu p
\]

\[
T_{\mu\nu} = \bar{G}_{\mu\alpha} T^\alpha_{\nu}, \tag{44}
\]

where \( p \) is pressure and \( \rho \) is the matter density of the cosmic fluid. In the co-moving frame we have \( u^0 = 1 \) and \( u^\alpha = 0 \); \( \alpha = 1, 2, 3 \) in the \( K \)-essence emergent gravity space-time.

Now the question is whether this type of energy-momentum tensor is valid or not in case of a perfect fluid model when the kinetic energy (\( \dot{\phi}^2 \)) of the \( K \)-essence scalar field is present. The answer is yes since our Lagrangian is \( L(X) = 1 - \sqrt{1 - 2X} \). This class of models is equivalent to perfect fluid models with zero vorticity and the pressure (Lagrangian) can be expressed through the energy density only [32, 67].

Now we evaluate the \( ii \) and 00 components of the modified field equation (27) using (44) and considering \( \phi \equiv \phi(t) \) only:

\[
FR_{ii} + (\bar{G}_{ii} \square - D_i D_i) F - \frac{1}{2} [f - Lf_L(1 + \dot{\phi}^2)] \bar{G}_{ii}, = \frac{1}{2} f_L a^2(t) \ddot{\rho} \tag{45}
\]

and

\[
FR_{00} + (\bar{G}_{00} \square - D_0 D_0) F - \frac{1}{2} [f - Lf_L(1 + \dot{\phi}^2)] \bar{G}_{00} + \frac{1}{2} Lf_L \dot{\phi}^2 (1 + \dot{\phi}^2) = \frac{1}{2} f_L (1 - \dot{\phi}^2) \ddot{\rho}, \tag{46}
\]

with \( F = f_R(\bar{R}, L) = \frac{\partial f(\bar{R}, L)}{\partial \bar{R}}, \ddot{\rho} = p(1 + \dot{\phi}^2) \) and \( \bar{\rho}(1 + \dot{\phi}^2) \).

Now, we calculate the terms \( \bar{G}_{00} \square F \) and \( \bar{G}_{ii} \square F \), using the determinant of the flat FLRW emergent gravity metric \( \sqrt{-G} = a^3 \sqrt{1 - \dot{\phi}^2} \) and the relation (38):

\[
\bar{G}_{00} \square F = \bar{F} + F \frac{\phi \ddot{\phi}}{(1 - \dot{\phi}^2)} = \bar{F} + H \bar{F}(3 - \dot{\phi}^2), \quad \tag{47}
\]

and

\[
\bar{G}_{ii} \square F = D_i D_i F - \frac{a^2}{(1 - \dot{\phi}^2)} \left[ \bar{F} + 2H \bar{F}(1 - \dot{\phi}^2) \right], \tag{48}
\]

where we have used, \( (\partial_i t)^2 = \frac{a^2}{1 - \dot{\phi}^2} \) for flat FLRW emergent gravity metric.

Now we substitute Eqs. (42) and (47) in the above Eq. (46), so that we have the first modified Friedmann equation as

\[
3H^2 = \frac{1}{F} [ -\frac{1}{2} \dot{f}_L(1 - \dot{\phi}^2) + 3 \bar{H} \bar{F} + (1 - \dot{\phi}^2) \frac{1}{2} (\bar{F} \dot{R} - f) + \frac{1}{2} Lf_L (1 + \dot{\phi}^2) ]
\]

\[
= \frac{1}{F} [ -\frac{1}{2} \dot{f}_L(1 - \dot{\phi}^2) + 3 \bar{H} \bar{F} + 3 Hf_L \dot{X} + (1 - \dot{\phi}^2) \frac{1}{2} (\bar{F} \dot{R} - f) + \frac{1}{2} Lf_L (1 + \dot{\phi}^2) ]. \quad \tag{49}
\]

We also substitute Eqs. (39), (41) and (48) in the \( ii \)-components of Eq. (45) and thereafter rearranging, we get the second modified Friedmann equation for the flat FLRW \( K \)-essence emergent gravity space-time under \( f(\bar{R}, L(X)) \).
theory. Hence

\[
2\dot{H} + H^2(3 - 2\dot{\phi}^2) = \frac{1}{F}\left[\dot{\phi}f_L(1 - \dot{\phi}^2) + \ddot{\phi}F + 2H\dot{\phi}(1 - \dot{\phi}^2) - \frac{1}{2}(1 - \dot{\phi}^2)(f - RF)\right]
\]

\[
+ \frac{1}{L}f_L(1 - \dot{\phi}^2)(1 + \dot{\phi}^2)\right]
\]

\[
= \frac{1}{F}\left[\dot{\phi}f_L(1 - \dot{\phi}^2) + \ddot{\phi}F + (\ddot{R})F_R + 2H\dot{R}F_R(1 - \dot{\phi}^2) - \frac{1}{2}(1 - \dot{\phi}^2)(f - RF)\right]
\]

\[
+ \frac{1}{L}f_L(1 - \dot{\phi}^2)(1 + \dot{\phi}^2)\right] + \frac{1}{F}\left[2H(1 - \dot{\phi}^2)f_L L_X \dot{X} + f_{LL}(L_X \dot{X})^2 + f_L L_{XX}(\dot{X})^2 + f_L L_X \ddot{X}\right].
\]

(50)

Since the Lagrangian \( L \) of the \( K \)-essence theory is function of \( X = \frac{1}{2}g^{\mu\nu}\nabla_\mu\phi\nabla_\nu\phi \), therefore we can write

\[
\ddot{F} = F_R \ddot{R} + f_L L_X \dot{X} \text{ and } \dot{F} = F_R \dot{R} + (\ddot{R})^2 F_R + f_{LL}(L_X \dot{X})^2 + f_L L_{XX}(\dot{X})^2 + f_L L_X \ddot{X}.
\]

(51)

The above Friedmann equations in the presence of the kinetic energy of the \( K \)-essence scalar field are different from the usual \( f(R) \) gravity model. Note that, if we consider \( f(R, L(X)) = f(R) \) and \( G_{\mu\nu} = g_{\mu\nu} \) then, the above modified Friedmann equations (49) and (50) reduces to the usual Friedmann equations of \( f(R) \) gravity, with \( \kappa = 1 \) and \( T_{\mu\nu} \) replaced by \( \frac{1}{2}T_{\mu\nu} \) [6, 7] as

\[
3H^2 = \frac{1}{F}\left[\dot{\rho} - \frac{p}{2} + \frac{RF - f}{2}\right] - 3H\dot{RF}_R,
\]

(52)

and

\[
2\dot{H} + 3H^2 = \frac{1}{F}\left[\dot{\rho} - \frac{p}{2} + (\ddot{R})^2 F_R + 2H\dot{R}F_R + \dot{R}F_R - \frac{f - RF}{2}\right].
\]

(53)

### V. Solution to the Friedmann Equation Using Power Law

We choose Starobinsky type model [5, 6] to investigate our theory and evaluate some cosmological values of the universe. This model has achieved popularity as, the inflationary predictions produced by this theory seems very much consistent with the observational data. The coefficient of \( R^2 \) curvature term single-handedly obtains the slow-roll inflation with tremendous success, without the introduction of outside inflation field by hand. Other reasons for Staroinksky model to be treated as an important model has been discussed in [81]. Now we write \( f(R, L) \) as

\[
f(R, L) = \dot{R} + \alpha R^2 + L,
\]

(54)

and \( L \) can be written for homogeneous \( K \)-essence scalar field as

\[
L = 1 - \sqrt{1 - 2\dot{X} = 1 - \sqrt{1 - \dot{\phi}^2}}.
\]

(55)

Therefore, we get

\[
f_L = \frac{\partial f}{\partial L} = 1, \quad F = \frac{\partial f}{\partial R} = 1 + 2\alpha \dot{R}, \quad F_R = 2\alpha, \quad F_L = 0.
\]

(56)

Using these values and after some algebraic calculations we can write Friedmann equation (49) as

\[
(1 + 2\alpha \dot{R})3H^2 = \frac{1}{2}\dot{\rho}(1 - \dot{\phi}^2) + \frac{1}{2}(1 - \dot{\phi}^2)\alpha \dot{R}^2 + 6\alpha H\dot{R} + \dot{\phi}^2(1 - \sqrt{1 - \dot{\phi}^2}).
\]

(57)

Analogous to [20–22], let us now assume, there exists an exact power–law solution to the field equations, i.e., the scale factor behaves as

\[
a(t) = a_0 t^m,
\]

(58)

where \( m(> 0) \) is a fixed real number.

The definition of \( H \) gives us

\[
H = \frac{\dot{a}}{a} = \frac{m}{t}, \quad \ddot{H} = \frac{m}{t^2}, \quad \dot{\dot{H}} = \frac{2m}{t^3}, \quad \dot{H} = -\frac{6m}{t^4}.
\]

(59)
Now, taking Eq. (41) into consideration we can evaluate the value of Ricci scalar as
\[
\dot{R} = \frac{6}{(1 - \phi^2)} t^2 \left[ -m + m^2 (2 - \phi^2) \right],
\]
and then using Eq. (38) we get
\[
\ddot{R} = \frac{6}{1 - \phi^2} \left[ \ddot{H} + 4H \dot{H} (1 - \phi^2) - 2H^2 \phi^2 \right] = \frac{12}{t^3 (1 - \phi^2)} \left[ m - m^3 \phi^2 - 2m^2 (1 - \phi^2) \right].
\]
Now putting the values of Eqs. (58) – (61) in (57), we simply get
\[
\frac{1}{2} \ddot{\rho} (1 - \phi^2) = \frac{90a \rho^2}{t^4 (1 - \phi^2)} - \frac{180a \rho^3}{t^4 (1 - \phi^2)} + \frac{180a \rho^3}{t^4 (1 - \phi^2)}
- \frac{108a \rho^4 \phi^2}{t^4 (1 - \phi^2)} + \frac{18a \rho^4 \phi^4}{t^4 (1 - \phi^2)} - \frac{3m^2}{t^2} + \phi^2 (1 - \sqrt{1 - \phi^2}).
\]
Now from the second Friedmann equation (50), we have
\[
(1 + 2a \dot{\rho}) \left[ 2\dot{H} + H^2 (3 - 2\phi^2) \right] = \frac{1}{2} \ddot{\rho} (1 - \phi^2) + 2a \ddot{R}
+ 4aH \dot{R} (1 - \phi^2) + \frac{1}{2} a \dot{R}^2 (1 - \phi^2) + \phi^2 (1 - \sqrt{1 - \phi^2})
\]
or
\[
\frac{1}{2} \ddot{\rho} (1 - \phi^2) = \frac{2m}{t^2} + \frac{3m^2}{t^2} + \frac{3m \phi^2}{t^2} - \frac{5m \phi^2}{t^2} - \frac{186a \rho^2}{t^4 (1 - \phi^2)} + \frac{240a \rho^3 \phi^2}{t^4 (1 - \phi^2)}
+ \frac{84a \rho^3}{t^4 (1 - \phi^2)} - \frac{252a \rho^3}{t^4 (1 - \phi^2)} + \frac{12a \rho^4 \phi^2}{t^4 (1 - \phi^2)} + \frac{72a}{t^4 (1 - \phi^2)} - \frac{42a \rho^4 \phi^4}{t^4 (1 - \phi^2)}
+ \frac{96a \rho^4 \phi^4}{t^4 (1 - \phi^2)} - \frac{1}{2} \phi^2 (1 - \sqrt{1 - \phi^2}) + \frac{1}{2} \phi^4 (1 - \sqrt{1 - \phi^2}).
\]
For our case, the energy-momentum conservation relation is
\[
D^\mu \tilde{T}_{\mu \nu} = 0,
\]
with \(\tilde{T}_{\mu \nu} = T_{\mu \nu} [1 + D_\alpha \phi D^\alpha \phi] \).
Now, using Eqs. (44) and (65), we have the conserving equation as
\[
\dot{\rho} = 3 \frac{\dot{a}}{a} (\rho + \bar{p}),
\]
where \(\rho\) and \(\bar{p}\) already have been defined. It is essential to mention here that, \(\bar{\rho}\) and \(\bar{p}\) are not same as the normal \(\rho\) and \(p\).
Now considering the power law, we get from Eq. (66)
\[
\bar{\rho} = \rho (1 + \dot{\phi}^2) = \rho_0 t^{-3m (1 + \omega)},
\]
where \(\omega = \frac{\dot{\rho}}{\rho} = \frac{\dot{\bar{p}}}{\bar{p}}\).
Now, putting the value of \(\bar{\rho}\) in Friedmann equation (62) we have
\[
\frac{1}{2} \rho_0 t^{-3m (1 + \omega)} = \frac{90a \rho^2}{t^4 (1 - \phi^2)^2} - \frac{180a \rho^3}{t^4 (1 - \phi^2)^2} + \frac{180a \rho^3}{t^4 (1 - \phi^2)^2} - \frac{108a \rho^4 \phi^2}{t^4 (1 - \phi^2)^2}
+ \frac{18a \rho^4 \phi^4}{t^4 (1 - \phi^2)^2} - \frac{3m^2}{t^2} + \frac{\dot{\phi}^2}{(1 - \phi^2)} (1 - \sqrt{1 - \phi^2}).
\]
On the other hand, to maintain the energy-momentum conservation, the relation (32) must be satisfied. So, the effective functional relation (32) for homogeneous K-essence scalar field reduces to
\[
3\dot{\phi}^2 - 2 = 2 \sqrt{1 - \phi^2},
\]
where we have used Eqs. (55) and (56).

Solving the above Eq. (69) we have either, $\dot{\phi}^2 = 0$, which is not acceptable for our case or

$$\dot{\phi}^2 = \frac{8}{9} \approx 0.888 = \text{constant}. \quad (70)$$

It should be noted that, the exact solution of field equations (Eq. no. 2 in [22]) are already obtained by the assumption of power law form of the scale factor using Starobinsky Model in [22]. The results of that case is

$$\rho_0 = \frac{3n^2}{t^2} - \frac{\rho_0}{t^{3n(1+\omega)}} + \frac{54\alpha n^2(2n-1)}{t^4}, \quad (71)$$

and

$$p_\phi = \frac{n(2-3n)}{t^2} + \frac{18\alpha n(2n-1)(4-3n)}{t^4} - \frac{\omega \rho_0}{t^{3n(1+\omega)}}, \quad (72)$$

where $\rho_\phi$ and $p_\phi$ is the energy density and pressure of the scalar field and $n$ is synonymous to $m$ for our case.

Rearranging Eq. (71) we get

$$\rho_0 t^{-3n(1+\omega)} = \frac{3n^2}{t^2} + \frac{108\alpha n^3}{t^4} - \frac{54\alpha n^2}{t^4} - \frac{1}{2} \dot{\phi}^2 - V(\phi), \quad (73)$$

where they have defined, $\rho_\phi = \frac{1}{2} \dot{\phi}^2 + V(\phi)$, $p_\phi = \frac{1}{2} \dot{\phi}^2 - V(\phi)$, $V(\phi)$ is the scalar potential.

Singh et al. [22] in their paper have used canonical Lagrangian and usual field equations of $f(R)$-gravity but, in our case we have used non-canonical Lagrangian and corresponding field equations (27). This is the basic difference between these two articles. Also, it should be clearly mentioned that, the scalar field of them is not identical with the K-essence scalar field.

Now let us concentrate upon the deceleration parameter using the expression

$$q = -\frac{1}{H^2} \frac{\ddot{a}}{a} = \frac{1}{m} - 1, \quad (74)$$

where we have used Eq. (58). From the above expression, it is obvious that for our present epoch the deceleration parameter should have a negative value to support the acceleration of the universe. Therefore, we can conclude from Eq. (74) that the $m$ takes the value greater than 1. Negative value of $m$ can not be considered, since observations show the universe is expanding.

As we know that, the value of $\dot{\phi}^2$ is less than 1, so neglecting the higher order terms $O(\dot{\phi}^4)$ in Eq. (62) and (64), and using Eq. (70), we get the equation of state (EOS) parameter of this scenario as:

$$\omega = \frac{-(2+13m)t^2 + \alpha(648 + 246m - 1260m^2 - 96m^3)}{-3mt^2 + \alpha m(810 - 180m - 864m^2)}. \quad (75)$$

The variation of $\rho$ and $p$ (using Eqs. (62) and (64) and omitting $O(\dot{\phi}^4)$ terms) with time ($t$) has been plotted in Fig. 1 for different choices of the positive power law parameter ($m = 1.5, 2$) and the positive coefficient of $R^2$ in Starobinsky model ($\alpha = 1, 3, 5, 7, 9$). Fig. 2 shows the variation of EOS parameter $\omega$ with $t$ for the aforementioned values of $m$ and $\alpha$. As we know that, the values of $\rho$ and $p$ should differ in signature for dark energy dominated era and simultaneously the value of EOS parameter ($\omega$) should approach a value close to $-1$, therefore, the above two figures concludes that the choice of positive $m$ and positive $\alpha$ is ruled out for our model to produce dark energy conditions.

The negative values of $\alpha$ has already been considered in [83] for $f(R,T)$ gravity. So, let’s check the results of our model for positive value of $m(=2,3)$ and negative values of $\alpha(= -0.9, -0.7, -0.5, -0.3, -0.1)$. Fig. 3 depicts the variation of $\rho$ and $p$ with time ($t$) for above values of the parameters. Fig. 4 shows the variation of EOS parameter ($\omega$) with time ($t$). From Fig. 3, it is evident that the value of $\rho$ and $p$ have the expected nature at a particular region of time. Simultaneously, Fig. 4 produces the anticipated value of $\omega$ which is $-1$ for dark energy epoch. We discuss the results more elaborately obtained in Figs. 3 and 4 in the following subsection.
A. Observational Verification of the Model

Before entering into this section we would like to discuss two significant works, one has been done by Tripathi et al. [82] and the other one is done by Moraes et al. [83]. In [82] they have constrained the dark energy models for low redshifts and compared the data with the observations of Supernova Type Ia data, Baryon Acoustic Oscillation data and Hubble parameter measurements. On the other hand, in [83] the authors have studied various cosmological aspects with the help of Starobinsky model in the framework of $f(R,T)$ gravity. They have found the nature of material content of the universe, i.e. $\rho$ and $p$ in both decelerated and accelerated regime of the universe.

TABLE I. Table for Observational Verification of the Model.

The variation of $\rho$ and $p$ with time obtained in Fig. 3 is quite similar with the variation obtained in [83], though our models differ from each other. Fig. 3 shows that at early time ($t \to 0$) the pressure was positive. But after a certain value of time it takes negative value which may be correlated with the effect of the negative pressure fluid, responsible for the accelerating universe. We have shown a table which depicts that for different choices of the positive $m$ and the negative $\alpha$, we get a range of $t$ (from Fig. 4) where the value of $\omega$ satisfies with the observational data of Supernova Type Ia data, Baryon Acoustic Oscillation data and Hubble parameter measurements (Observational data are taken from [82]). Furthermore, if we concentrate on the range of $t$ that has been shown in Table 1 and match those values...
with Fig. 3, then can be observed that at those particular region of time, the value of \( p \) takes the negative sign whereas the \( \rho \) is positive.

VI. ENERGY CONDITIONS IN \( f(\bar{R}, L(X)) \)-GRAVITY

With the help of the modified field equation (27) for \( f(\bar{R}, L(X)) \) theory, the emergent Einstein’s equation (15) can be written as \( (\kappa = 1) \)

\[
\bar{R}_{\mu\nu} - \frac{1}{2} \bar{G}_{\mu\nu} \bar{R} = T^\text{eff}_{\mu\nu},
\]

(76)

where

\[
T^\text{eff}_{\mu\nu} = \frac{1}{F} [ \frac{1}{2} f_L \bar{T}_{\mu\nu} - \frac{1}{2} RF \bar{G}_{\mu\nu} - (\bar{G}_{\mu\nu} \Box - D_\mu D_\nu) F + \frac{1}{2} \bar{G}_{\mu\nu} (f - L f_L (1 + D_\alpha \phi D^\alpha \phi))
- \frac{1}{2} L f_L D_\mu \phi D_\nu \phi (1 + D_\alpha \phi D^\alpha \phi)]
- \frac{1}{F} \frac{1}{2} f_L \bar{T}_{\mu\nu} + \frac{1}{2} \bar{G}_{\mu\nu} (f - F \bar{R}) - (\bar{G}_{\mu\nu} \Box - D_\mu D_\nu) F - \frac{1}{2} L f_L \bar{G}_{\mu\nu} (1 + D_\mu \phi D^\mu \phi)^2],
\]

(77)

with \( F = f_R = \frac{\partial f(\bar{R}, L(X))}{\partial \bar{R}} \).

The trace of the effective energy momentum tensor (77) is

\[
T^\text{eff} = \frac{1}{F} [ \frac{1}{2} f_L \bar{T} + 2 (f - F \bar{R}) - 3 \Box F - 2 L f_L (1 + D_\mu \phi D^\mu \phi)^2].
\]

(78)

Now from Eq. (76), we have the emergent Ricci tensor in terms of the effective energy momentum tensor as

\[
\bar{R}_{\mu\nu} = T^\text{eff}_{\mu\nu} - \frac{1}{2} \bar{G}_{\mu\nu} T^\text{eff}.
\]

(79)

Let \( \bar{u}^\mu \) be the tangent vector field to a congruence of time-like geodesics in the \( \mathbf{K} \)-essence emergent space-time manifold endowed with the metric \( \bar{G}_{\mu\nu} \) \( (\bar{G}_{\mu\nu} \bar{u}^\mu \bar{u}^\nu = 1) \), then the strong energy condition (SEC) (A9) in \( f(\bar{R}, L(X)) \) modified gravity can be expressed as

\[
\bar{R}_{\mu\nu} \bar{u}^\mu \bar{u}^\nu = (T^\text{eff}_{\mu\nu} \bar{u}^\mu \bar{u}^\nu - \frac{1}{2} T^\text{eff}) \geq 0.
\]

(80)
On the other hand, if we consider \( \bar{k}^\mu \) be the tangent vector along the null geodesic congruence \( (\bar{G}_{\mu\nu}\bar{k}^\mu\bar{k}^\nu = 0) \), then the null energy condition (NEC) (A11) in \( f(\bar{R}, L(X)) \) gravity is

\[
\bar{R}_{\mu\nu}\bar{k}^\mu\bar{k}^\nu = T_{\mu\nu}^{\text{eff}}\bar{k}^\mu\bar{k}^\nu \geq 0.
\] (81)

So, considering an additional condition \[ 19] \( \frac{f_{L(R,L)}}{f_R(R,L)} > 0 \), and the K-essence scalar field to be homogeneous, i.e., \( \phi(x^i, t) \equiv \phi(t) \) and using the perfect fluid energy momentum tensor (44), we have the SEC and NEC in the \( f(\bar{R}, L(X)) \)
gravity are

$$SEC : \quad \ddot{\rho} + 3\dot{\rho} - \frac{2}{f_L}(f - F\dot{R}) + 2L(1 + \dot{\phi}^2)^2$$
$$\quad + \frac{6}{f_L(1 - \phi^2)}[\ddot{F}(1 - \frac{2}{3}\dot{\phi}^2) + H\dot{F}(1 - \dot{\phi}^2 + \frac{2}{3}\dot{\phi}^4)] \geq 0,$$  \hspace{1cm} (82)

$$NEC : \quad \ddot{\rho} + \ddot{p} + \frac{2}{f_L}(\ddot{F} - H\dot{F}\dot{\phi}^2) \geq 0,$$ \hspace{1cm} (83)

where $\ddot{\rho} = \rho(1 + \dot{\phi}^2)$ and $\ddot{p} = p(1 + \dot{\phi}^2)$.

To evaluate the effective density $\bar{\rho}^{eff}$ and effective pressure $\bar{p}^{eff}$ in the $K$-essence emergent $f(\bar{R}, L(X))$ gravity, we consider two following equations

$$T^{\rho}_{\mu\nu} \ddot{u}^\mu \ddot{u}^\nu - \frac{1}{2} \bar{G}_{\mu\nu} T^{\rho}_{\rho\nu} \ddot{u}^\mu \ddot{u}^\nu = \bar{\rho}^{eff} + 3\bar{p}^{eff}$$  \hspace{1cm} (84)

and

$$T^{\rho}_{\mu\nu} k^\mu k^\nu = \bar{\rho}^{eff} + \bar{p}^{eff}.$$  \hspace{1cm} (85)

Solving these Eqs. (49) and (50), we get

$$\bar{\rho}^{eff} = \ddot{\rho} + \frac{1}{f_L}(f - F\dot{R}) - \frac{6}{f_L(1 - \phi^2)}[\ddot{F}(1 - \frac{2}{3}\dot{\phi}^2) + H\dot{F}(1 - \dot{\phi}^2 + \frac{2}{3}\dot{\phi}^4)] - L(1 + \dot{\phi}^2)^2,$$ \hspace{1cm} (86)

$$\bar{p}^{eff} = \ddot{p} - \frac{1}{f_L}(f - F\dot{R}) + \frac{3}{f_L(1 - \phi^2)}[\ddot{F}(2 - \dot{\phi}^2)$$
$$\quad + H\dot{F}(1 - \frac{2}{3}\dot{\phi}^2 + \frac{1}{3}\dot{\phi}^4)] + L(1 + \dot{\phi}^2)^2.$$ \hspace{1cm} (87)

From the above Eqs. (86) and (87), we have WEC and DEC respectively for the $K$-essence emergent $f(\bar{R}, L(X))$ gravity as

$$WEC : \quad \bar{\rho} + \frac{1}{f_L}(f - F\dot{R}) - \frac{6}{f_L(1 - \phi^2)}[\ddot{F}(1 - \frac{1}{3}\dot{\phi}^4)] - L(1 + \dot{\phi}^2)^2 \geq 0,$$ \hspace{1cm} (88)

$$DEC : \quad \bar{\rho} - \ddot{p} + \frac{2}{f_L}(f - F\dot{R}) - \frac{2}{f_L(1 - \phi^2)}[\ddot{F}(1 + \frac{1}{2}\phi^2)$$
$$\quad + 3H\dot{F}(\frac{3}{2} - \frac{1}{3}\dot{\phi}^2 - \frac{1}{6}\dot{\phi}^4)] - 2L(1 + \dot{\phi}^2)^2 \geq 0.$$ \hspace{1cm} (89)

These energy conditions (82), (83), (88) and (89) of the $K$-essence emergent $f(\bar{R}, L(X))$ gravity are different from the usual $f(R, L_m)$-gravity (A13) and $f(R)$-gravity (A12) in the presence of the $K$-essence scalar field $\phi$. Also note that if we consider $f(\bar{R}, L(X)) \equiv R$ and $G_{\mu\nu} \equiv g_{\mu\nu}$, then we can get back to the usual energy conditions of GR, i.e.,

$$SEC : \quad \rho + 3p \geq 0; \quad NEC : \quad \rho + p \geq 0; \quad WEC : \quad \rho \geq 0 \quad \text{and} \quad DEC : \quad \rho \geq |p|.$$

One may notice that we briefly have discussed the energy conditions of $f(R)$ and $f(R, L_m)$ gravity in Appendix.

### A. Constraints on $K$-essence emergent $f(\bar{R}, L(X))$-gravity

The inequalities of the energy conditions (82), (83), (88) and (89) can also be expressed in terms of the deceleration $(q)$, jerk $(j)$, and snap $(s)$ parameters such that the Ricci scalar and its derivatives for a spatially flat $K$-essence...
where [11, 19, 74–77]

\[ q = -\frac{1}{H^2 a}, \quad j = \frac{\dot{a}}{H^3 a}, \quad s = \frac{\ddot{a}}{H^4 a}. \]  

Now from Eq. (51), we evaluate the values of \( \dot{F} \) and \( \ddot{F} \) (using Eq. (38)) in terms of \( q, j, s \) as

\[ \dot{F} = \frac{6H^3}{1 - \dot{\phi}^2} F_{R}(j - q - 2 + 2\dot{\phi}^2(1 - 2q)) - HF_{L}L_{X}\dot{\phi}^2(1 - \dot{\phi}^2), \]

\[ \ddot{F} = \frac{6H^4}{1 - \dot{\phi}^2} F_{R}(s + q^2 + 8q + 6) - 2\dot{\phi}^2(3 + 3j + 10q + 2q^2) \]

\[ + \frac{36H^6}{(1 - \dot{\phi}^2)^2} F_{RR}(j - q - 2 + 2\dot{\phi}^2(1 - 2q)^2 + H\dot{\phi}^4(1 - \dot{\phi}^2)^2 (F_{LL}L_{X}^2 + F_{L}L_{XX})) \]

\[ - F_{L}L_{X}\dot{\phi}^2(1 - \dot{\phi}^2)(\dot{H} - 2H^2(1 - 2\dot{\phi}^2)). \]  

Therefore, putting these values of \( \dot{F} \) and \( \ddot{F} \) in the energy conditions (82), (83), (88) and (89) we have the energy conditions in terms of \( q, j, s \). We can easily check that these energy conditions in terms of \( q, j, s \) are also different from the \( f(R, L_m) \)-gravity [19] in the presence of the K-essence scalar field \( \phi \).

### B. An example of the energy conditions

Considering the Starobinsky Model, i.e., Eq. (54) and hence we obtain the following results as \( f_{L} = 1, \quad F = 1 + 2\alpha \dot{R}, \quad \dot{F} = 2\alpha \dot{R} \) and \( \ddot{F} = 2\dot{\alpha} \).

Using these results we get the energy conditions from (82), (83), (88) and (89) as follows:

\[ SEC : \bar{\rho} + 3\bar{p} + 2 \left[ \alpha \bar{R}^2 + L\dot{\phi}^2(2 + \dot{\phi}^2) \right] + \frac{12\alpha \ddot{R}}{1 - \dot{\phi}^2} \left( 1 - \frac{2}{3} \dot{\phi}^2 \right) + \frac{12\alpha H \dot{R}}{1 - \dot{\phi}^2} \left( 1 - \dot{\phi}^2 + \frac{2}{3} \dot{\phi}^4 \right) \geq 0 \]  

\[ NEC : \bar{\rho} + \bar{p} + 4\alpha \left( \dot{R} - H\dot{R}\dot{\phi}^2 \right) \geq 0 \]  

\[ WEC : \bar{\rho} - \alpha \bar{R}^2 - \frac{4\alpha}{1 - \dot{\phi}^2} \left[ \dot{R}\dot{\phi}^2 - 3\dot{R} \left( 1 - \frac{1}{3} \dot{\phi}^4 \right) - L\dot{\phi}^2(2 + \dot{\phi}^2) \right] \geq 0 \]  

\[ DEC : \bar{\rho} - \bar{p} - 2\alpha \bar{R}^2 - \frac{4\alpha}{1 - \dot{\phi}^2} \left[ \ddot{R}(1 - \frac{1}{2} \dot{\phi}^2) - 3H\ddot{R} \left( \frac{3}{2} \frac{1}{3} \dot{\phi}^2 - \frac{1}{6} \dot{\phi}^4 \right) - 2L\dot{\phi}^2(2 + \dot{\phi}^2) \right] \geq 0 \]

Again, if we put the values of \( \ddot{R}, \dot{R} \) and \( \bar{R} \) from (90), (91) and (92) in the above equations (96), (97), (98) and (99), we easily reconstruct the energy conditions in terms of the deceleration \( q \), jerk \( j \), and snap \( s \) parameters.
VII. DISCUSSION AND CONCLUSION

In this work, we present a new type of modified theory, viz. \( f(R, L(X)) \)-gravity, with a general formalism in the context of the dark energy (using K-essence emergent geometry) where \( R \) is the Ricci scalar of this geometry, \( L(X) \) is the DBI type non-canonical Lagrangian with \( X = \frac{1}{2}g^{\mu\nu}\nabla_\mu\phi\nabla_\nu\phi \). \( \phi \) is the K-essence scalar field. The K-essence emergent metric \( G_{\mu\nu} \) is not conformally equivalent to the gravitational metric \( g_{\mu\nu} \). This new type of modified theory is a general mixing between \( f(R) \) gravity and K-essence emergent gravity based on the DBI model.

Let us discuss some salient features of the present study which are as follows:

1. It is to be noted that the modified field equation (27) is different from the usual \( f(R) \) and \( f(R, L_m) \) gravities. If we consider \( f(R, L(X)) \equiv R \) and \( G_{\mu\nu} \equiv g_{\mu\nu} \) then we can easily get back to the standard Einstein field equation. The effective functional relation for the requirement of the conservation of the energy-momentum tensor is also different from the \( f(R, L_m) \)-gravity. We derive the modified Friedmann equations for the \( f(R, L(X)) \)-gravity considering the background gravitational metric as flat FLRW and the K-essence scalar field \( \phi \) being simply a function of time only, which are quite different from the Friedmann equations of the standard \( f(R) \) gravity.

2. For the particular choice (viz. Starobinksky type), Eq. (54) of \( f(R, L) \) and from the requirement of the energy-momentum conservation (32), the kinetic energy of the K-essence scalar field is a constant. This value of \( \dot{\phi}^2 = 0.888 \) is less than unity which is comparable with the range of \( \dot{\phi}^2 \). It is also to be noted that the K-essence theory can be used to investigate the effects of the presence of dark energy on cosmological scenarios. In this context, if we consider \( \dot{\phi}^2 \) be dark energy density in unit of critical density as \([26–28]\), then the value of dark energy density, i.e., \( \dot{\phi}^2 = \frac{\dot{\phi}^2}{\ddot{\phi}^2} = 0.888 \) indicates that the present universe is dark energy dominated.

It is well known that the present observational value \([79, 80]\) of dark energy density is approximately 0.75. Therefore, we note that in the context of dark energy regime our result is in good agreement with the observational data. Nowadays people believe that the dark energy is one of the reasons for the accelerating Universe. So, our value of dark energy density may indicate that the Universe is more accelerating. From Figs. 3 and 4, we also observe that our model is observationally verified for certain values of parameters. According to Fig. 3, the negativity of pressure can be achieved after a certain value of time which may be responsible for the accelerating universe. The variation of EOS (\( \omega \)) with time (\( t \)) in Fig. 4 shows that \( \omega \) approaches the negative values which corresponds to observational result \([82]\) of the present universe.

Also, we would like to put here the following two special aspects which emerge from of the present investigation:

(i) This model can open up an alternative window to explore the current cosmic acceleration without a stringent condition of invoking an exotic component as the dark energy. In other words, this theory seems interesting from a purely gravitational theory standpoint, rather than the cosmological context of dark energy whose very existence is still an issue of doubt \([78]\) in the context of the latest analysis of data from the Planck consortium \([79, 80]\). However, the arbitrariness in the choice of different functional forms of \( f(R, L(X)) \) based on DBI Lagrangian gives rise to the problem of how to constrain the many possible \( f(R, L(X)) \) gravity theories on physical grounds. In this context, we have shed some light on this issue by discussing some constraints on general \( f(R, L(X)) \) gravity from the so-called energy conditions.

(ii) Also, we have derived the null, strong, weak and dominant energy conditions in the framework of \( f(R, L(X)) \) gravity from the Raychaudhuri equations. These energy conditions are different from the usual \( f(R, L_m) \) and \( f(R) \) theories. With the help of the specific form of \( f(R, L(X)) \), we also have derived these energy conditions in the \( f(R, L(X)) \)-gravity.

However, we intend to report on this interesting theory in the near future encompassing the multifarious aspects of Cosmology.

Appendix A: Appendix:

1. The modified field equation in \( f(R, L_m) \)-Gravity

Let us consider here the well known \( f(R) \) and \( f(R, L_m) \) gravity, where \( R \) is the Ricci scalar with respect to the gravitational metric \( g_{\mu\nu} \) and \( L_m \) is the matter Lagrangian. The total action for the \( f(R) \) gravity is \([6, 7]\)

\[
S = \frac{1}{2\kappa} \int d^4x \sqrt{-g} f(R) + S_M(g_{\mu\nu}, \psi),
\]

(A1)

where \( S_M \) is matter term, \( \psi \) denotes the matter fields, \( \kappa = 8\pi G \), \( G \) is the gravitational constant, \( g \) is the determinant of the gravitational metric and \( R (= g^{\mu\nu}R_{\mu\nu}) \) is the Ricci scalar.
Varying which with respect to the gravitational metric we achieve the modified field equation as

\[ f'(R)R_{\mu\nu} - \frac{1}{2} f(R)g_{\mu\nu} - [\nabla_\mu \nabla_\nu - g_{\mu\nu} \Box] f'(R) = \kappa T_{\mu\nu}, \quad (A2) \]

with

\[ T_{\mu\nu} = -\frac{2}{g} \frac{\delta S_m}{\delta g^{\mu\nu}}, \quad (A3) \]

where \( f'(R) = \frac{\partial f(R)}{\partial R} \), \( \nabla_\mu \) is covariant derivative with respect to the gravitational metric and \( \Box \equiv \nabla^\nu \nabla_\nu \).

On the other hand, the action for the \( f(R, L_m) \) gravity is \([18, 19]\)

\[ S = \frac{1}{2\kappa} \int d^4x \sqrt{-g} f(R, L_m), \quad (A4) \]

where \( f(R, L_m) \) is an arbitrary function of the Ricci scalar \( R \), and the Lagrangian density corresponding to matter \( L_m \). The energy-momentum tensor is

\[ T_{\mu\nu} = -\frac{2}{\sqrt{-g}} \frac{\delta \left( \sqrt{-g} L_m \right)}{\delta g^{\mu\nu}} = -\frac{\partial L_m}{\partial g^{\mu\nu}} + g_{\mu\nu} L_m, \quad (A5) \]

where the Lagrangian density \( L_m \) is only matter dependent on the metric tensor components \( g_{\mu\nu} \).

The modified field equations of the \( f(R, L_m) \)-gravity model is

\[ f_R(R, L_m)R_{\mu\nu} + (g_{\mu\nu} \Box - \nabla_\mu \nabla_\nu) f_R(R, L_m) - \frac{1}{2} [f(R, L_m) - L_m f_L(R, L_m)] g_{\mu\nu} \]

\[ = \frac{1}{2} f_L(R, L_m) T_{\mu\nu}, \quad (A6) \]

where \( f_R(R, L_m) = \partial f(R, L_m)/\partial R \) and \( f_L(R, L_m) = \partial f(R, L_m)/\partial L_m \). However, if \( f(R, L_m) = R/2 + L_m \), then the above Eq. (A6) reduces to the usual field equation \( R_{\mu\nu} - (1/2)g_{\mu\nu}R = \kappa T_{\mu\nu} \).

2. : Brief review of energy conditions in General Relativity

Following most of the techniques of \([10–14, 19, 73]\), we will derive the energy conditions for modified \( (f(R), f(R, L_m), \text{etc.}) \) gravities. From these theories we can approach to the Null Energy Condition (NEC) and Strong Energy Condition (SEC) in the context of GR. The origin of these energy conditions comes from the Raychaudhuri equations. Let \( u^\mu \) be the tangent vector field to a congruence of time-like geodesics in a space-time manifold endowed with a metric \( g_{\mu\nu} \). Therefore, the Raychaudhuri equation \([68–72]\) is

\[ \frac{d\theta}{d\tau} = -\frac{1}{3} \theta^2 - \sigma_{\mu\nu}\sigma^{\mu\nu} + \omega_{\mu\nu}\omega^{\mu\nu} - R_{\mu\nu} u^\mu u^\nu, \quad (A7) \]

where \( R_{\mu\nu} \) is the Ricci tensor corresponding to the metric \( g_{\mu\nu} \), and \( \theta, \sigma_{\mu\nu}, \text{and} \omega_{\mu\nu} \) are the expansion, shear, and rotation associated with the congruence, respectively. While in the case of a congruence of null geodesics defined by the vector field \( k^\mu \), the Raychaudhuri equation \([71]\) is given by

\[ \frac{d\theta}{d\tau} = -\frac{1}{2} \theta^2 - \sigma_{\mu\nu}\sigma^{\mu\nu} + \omega_{\mu\nu}\omega^{\mu\nu} - R_{\mu\nu} k^\mu k^\nu. \quad (A8) \]

These equations are purely based on geometric statements, and as such it makes no reference to any gravitational field equations. In other words, the Raychaudhuri equation can be thought of as geometrical identities which do not depend on any gravitational theory. These equations are provide the evolution of the expansion of a geodesic congruence. However, since the GR field equations relate \( R_{\mu\nu} \) to the energy-momentum tensor \( T_{\mu\nu} \), the combination of Einstein and Raychaudhuri equations can be used to restrict energy-momentum tensors on physical ground. Indeed, the shear is a “spatial” tensor, given by \( \sigma^2 \equiv \sigma_{\mu\nu}\sigma^{\mu\nu} \geq 0 \).

Thus it is clear from Raychaudhuri equation that for any hypersurface orthogonal congruences \( (\omega_{\mu\nu} \equiv 0) \) the condition for attractive gravity (convergence of timelike geodesics or geodesic focusing) reduces to \( (R_{\mu\nu} u^\mu u^\nu \geq 0) \), which by virtue of Einstein’s equation implies

\[ R_{\mu\nu} u^\mu u^\nu = (T_{\mu\nu} - \frac{T}{2} g_{\mu\nu}) u^\mu u^\nu \geq 0, \quad (A9) \]
where $T$ is trace of the energy momentum tensor $T_{\mu\nu}$ ($\kappa = 1$). Here Eq. (A9) is nothing but the SEC stated in a coordinate-invariant way in terms of $T_{\mu\nu}$ and vector fields of fixed (time-like) character. Thus, in the context of GR, the SEC ensures the fact that the gravity is attractive. In particular, for a perfect fluid of density $\rho$ and pressure $p$

$$T_{\mu\nu} = (\rho + p)u_\mu u_\nu - pg_{\mu\nu} \quad \text{(A10)}$$

and the restriction given by Eq. (A9) takes the familiar form for the SEC, i.e., $\rho + 3p \geq 0$.

On the other hand, the condition for the convergence (geodesic focusing) of hypersurface orthogonal ($\omega_{\mu\nu} \equiv 0$) congruences of null geodesics along with Einstein’s equation implies

$$R_{\mu\nu}k^\mu k^\nu = T_{\mu\nu}k^\mu k^\nu \geq 0 \quad \text{(A11)}$$

which is the condition for NEC written in a coordinate-invariant way.

Thus, in GR the NEC ultimately encodes the null geodesic focusing due to the gravitational attraction. For the energy-momentum tensor of a perfect fluid (A10) the above condition (A11) reduces to the well-known form of the NEC, i.e., $\rho + p \geq 0$.

The Weak Energy Condition (WEC) states that $T_{\mu\nu}u^\mu u^\nu \geq 0$ for all time-like vectors $u^\mu$, or equivalently for perfect fluid it is $\rho > 0$ and $\rho + p > 0$. The Dominant Energy Condition (DEC) includes the WEC as well as the additional requirement that $T_{\mu\nu}u^\mu$ is a non space-like vector i.e., $T_{\mu\nu}u^\mu u^\lambda \leq 0$. For a perfect fluid, these conditions together are equivalent to the simple requirement that $\rho \geq |p|$, the energy density must be nonnegative, and greater than or equal to the magnitude of the pressure.

In $f(R)$-gravity [10, 11], the energy conditions for perfect fluid are given by

$$\text{SEC} : \quad \rho + 3p - f + Rf' + 3(\dot{R} + \ddot{R})f'' + 3\dot{R}^2 f''' \geq 0,$$

$$\text{NEC} : \quad \rho + p + (\ddot{R} - \dot{R}^2)f'' + \dot{R}^2 f''' \geq 0,$$

$$\text{WEC} : \quad \rho + \frac{1}{2}(f - Rf') - 3\dot{R}Hf'' \geq 0,$$

$$\text{DEC} : \quad \rho - p - f - Rf' - (\dot{R} + 5\dot{R}H)f'' - \dot{R}^2 f''' \geq 0, \quad \text{(A12)}$$

where $f' = \frac{\partial f(R)}{\partial R}$.

In $f(R, L_m)$-gravity [19], the energy conditions are

$$\text{SEC} : \quad \rho + 3p - \frac{2}{f_{L_m}}[f - Rf'] + \frac{6}{f_{L_m}}[\dot{R}^2 f''' + \dot{R}f'' + H\dot{R}f''] - 2L_m \geq 0,$$

$$\text{NEC} : \quad \rho + p + \frac{2}{f_{L_m}}[\dot{R}^2 f''' + \dot{R}f''] \geq 0,$$

$$\text{WEC} : \quad \rho + \frac{1}{f_{L_m}}[f - Rf'] - \frac{6}{f_{L_m}}H\dot{R}f'' + L_m \geq 0,$$

$$\text{DEC} : \quad \rho - p + \frac{2}{f_{L_m}}[f - Rf'] - \frac{2}{f_{L_m}}[\dot{R}^2 f''' + \dot{R}f'' + 6H\dot{R}f''] + 2L_m \geq 0, \quad \text{(A13)}$$

where $f' = \frac{\partial f(R, L_m)}{\partial R}$.

**ACKNOWLEDGEMENT**

A.P. and G.M. acknowledge the DSTB, Government of West Bengal, India for financial support through the Grants No.: 322(Sanc.)/ST/P/S&T/16G-3/2018 dated 06.03.2019. The authors also thank to Dr. Pradipta Panchadhyayee, Associate Professor, Department of Physics, Prabhat Kumar College, Contai for his valuable suggestions.
