Temporary Singularities and Axions:
an analytic solution that challenges charge conservation

(Dated: March 18, 2022)

We construct an analytic solution for electromagnetic fields interacting with an axion field that violates global charge conservation, by building on the possibilities demonstrated in [Foundations of Physics 49, 330 (2019)]. Despite providing a specific example where “physics breaks down” at a singularity, it nevertheless demonstrates that the physical laws on the surrounding spacetime still impose constraints on what is allowed to happen. The construction is valid for a spacetime containing a temporary singularity and a Maxwellian electrodynamics containing a proposed “topological” axion field. Further, the concepts of transformation optics can be applied to show that our specific mathematical solution has a much wider applicability.

There is a popular summary in Appendix E.

I. INTRODUCTION

Singularities play an interesting role in physics, and come in many different varieties, from the mathematically and philosophically challenging [1–4] to the more mundane [5–7]. As the place where “physics breaks down” in a black-hole, we have the sense that anything might happen at a singularity. This begs the question: are there things we might drop into a singularity that might happen at a singularity. This begs the question: are there things we might drop into a singularity that have fundamental properties that could be erased absolutely? Crossing the event horizon, for example, can lead to the baryon number of matter falling in to a black-hole not being conserved, even if its mass-energy still persists [8]. Alternatively, the reverse scenario is also intriguing: we may intuitively have a sense that since the laws of physics must then be followed, how could such artefacts manifest themselves?

In this article we consider the conservation of electric charge. In standard approaches to electromagnetism this is sacrosanct, whether for local charge conservation (i.e. the differential version), or for global charge conservation (the integral version). Although local charge conservation is experimentally observed, and is assumed here, this does not of itself guarantee global charge conservation, which instead arises via either of two mechanisms. These mechanisms are: from local charge conservation and the assumption that the region of spacetime is topologically trivial, or from the assumption that the excitation fields $D$ and $H$ are real physical fields. In order to break global charge conservation it is necessary that both of these mechanisms no longer apply\textsuperscript{1}, i.e. we need an extension to Maxwell’s equations where $D$ and $H$ are not fundamental physical fields, but are merely gauge fields for the charge and current, and a topologically non-trivial spacetime $\mathcal{M}$, such as in this article, where we consider spacetimes with a temporary singularity.

In [10] we showed that a non trivial spacetime can in principle break global charge conservation, but without detailing a specific set of electromagnetic constitutive relations that might support this. In [11] a minimal extension to Maxwell’s equations was considered where $D$ and $H$ did not appear, and which provided an additional axionic term to the vacuum Maxwell’s equations. Using this axionic term, we now give in this article an explicit construction of an electromagnetic field configuration which can lead to the breaking of global charge conservation.

In particular, the classical Maxwell vacuum is augmented in quantum field theory to account for vacuum polarization for intense fields. For example, the strong magnetic fields associated with magnetars induce non-trivial dielectric properties on vacuum [12], but longer

\textsuperscript{1} If spacetime $\mathcal{M}$ has a non-zero third de Rham cohomology $H^3_{\mathcal{M}} \neq 0$, then there exists a closed 3–form current $J$ which is not exact, i.e. $dJ = 0$ but $J \neq dH$ for any excitation 2–form field $H$. Hence for 3–surfaces $\mathcal{U}$ enclosing the temporary singularity $\int_{\mathcal{U}} J \neq 0$. 

16 Mar 2022
established alternatives for polarization of the vacuum are (e.g.) the Euler-Heisenberg [13] or the Bopp-Podolski model [14–16]. However, in these, the model corresponds to well defined \( D \) and \( H \), in-effect also demanding they are measurable, when in fact this is not necessary [17–23]. To avoid this unnecessary assumption, an alternative approach based purely on the physically measurable fields \( E \) and \( B \) was developed [11], and this is what we use here.

The extension to Maxwell’s equations [11] considered the constitutive properties of a background medium on the basis that there may be an axion field \( \zeta \) that does not derive from an axion scalar field. In contrast, in this article we posit that such an axion field can exist independently in the vacuum, instead of just being a property of some background medium. We call this axion field a topological axion because it is distinct from a standard axion and because it has more interesting topological properties. In the context of electromagnetism, axions are already an established area of research [24–28], usually arising in the context of an added coupling between the Maxwell fields and the field of an axion particle. Such coupled Maxwell-axion dynamics allow situations where a background axion field can influence the behaviour of electromagnetic fields. In the standard Maxwell theory, a piecewise constant axion field for a medium is detectable at boundaries [29] where the response can be equivalently cast as either a perfect electrical, or perfect magnetic conductor [30]. Axionic responses were apparently observed experimentally [31] via the magneto-electric effect in \( \text{Cr}_2\text{O}_3 \). More recently axionic responses have also been proposed [32] and observed [33] in topological insulators. Observations are, however, still controversial, with claims that evidence of violation of the so-called Post constraint [34] can be explained by an admittance that describes surface states [35].

In the domain of particle physics, axions have been proposed as candidates for dark matter [36], but as yet no particle axions have been observed. Given this context, any self-consistent axionic model, such as the one we propose here, remains a valid candidate for exploration.

In this article we give the explicit construction for the simplest non trivial spacetime, namely Minkowski spacetime with a point removed, which provides us with a both a singularity and a non-trivial topology. However, since the machinery of transformation optics [37–39] can be applied in a spacetime sense [40–42], we also show that this apparently heavily restricted solution is also valid in the more general case of a temporary singularity, as depicted in figure 1. This may include cases where a black hole forms and then subsequently evaporates [8, 43].

In section II we summarise the key points of a Maxwellian electrodynamics based on first-order operators [11] that dispenses with \( D \) and \( H \) and admits the topological axion field. In section III we define a temporary singularity and its future. Next, in Section IV we describe the key parts of the design of both the electromagnetic and the axionic fields, and and then in Section V construct the solution in a way that conforms to the theoretical constraints. Following this, in Section VI we show how a transformation optics style approach allows us to show that our solution is not specific to the simple spacetime manifold in which we construct it, but is also valid for more realistic spacetime metrics, potentially even for the case of a forming then evaporating black-hole. Finally, in Section VII we conclude.

II. TOPOLOGICAL AXIONS

The topological axions we consider here are allowed by a minimal relaxation of Maxwell’s equations where the role of the unmeasurable electromagnetic excitation fields \( D \) and \( H \) is explicitly demoted to that of mere gauge fields for the current. As discussed in [11], this extension permits a new axionic type of interaction with the electromagnetic field. In addition to dispensing with \( D \) and \( H \), and in the presence of a spacetime singularity, it has been shown that Maxwell’s equations no longer need enforce global charge conservation [10]; but although posing some intriguing possibilities, this proposal did not include any explicit examples of constitutive relations, material configurations, or field distributions.

Here, by attributing this axionic interaction to the presence of a particle-like axion field, we find more general Maxwell’s equations for vacuum. Having freed the model from an explicit reference to a material response as implied in [11], we find that there is now scope for an explicit solution that breaks global charge-conservation. The starting point [11] can be briefly summarized as fol-

![Figure 1. Here we show a temporary singularity. The region of spacetime \( N \) has a boundary \( \mathcal{U} = \partial N \) that encloses a singularity with a finite duration. This might occur, for example, due to the formation at \( p_0 \) and subsequent evaporation at \( p_1 \) of a black-hole, which would first create and then remove a metric singularity in spacetime. The temporary singularity \( I \) is not part of \( \mathcal{M} \).](image-url)
In this formalism, the 2–form $F$ poses an extension to the usual vacuum Maxwell equation

$$dF = 0 \quad \text{and} \quad \Psi (F) = J,$$  \hfill (1)

where $F \in \Gamma^2 \mathcal{M}$ is the electromagnetic 2–form, $J \in \Gamma^3 \mathcal{M}$ is the current 3–form, and $\Psi : \Gamma^2 \mathcal{M} \to \Gamma^3 \mathcal{M}$ is a non-tensorial “first order operator” that satisfies

$$\Psi \langle \alpha_1 + \alpha_2 \rangle = \Psi \langle \alpha_1 \rangle + \Psi \langle \alpha_2 \rangle, \quad \Psi \langle \lambda \alpha \rangle = \lambda \Psi \langle \alpha \rangle,$$

and $\Psi \langle f^2 \alpha \rangle - 2f \Psi \langle f \alpha \rangle + f^2 \Psi \langle \alpha \rangle = 0,$

$$\Psi \langle f^2 \alpha \rangle - 2f \Psi \langle f \alpha \rangle + f^2 \Psi \langle \alpha \rangle = 0,$$  \hfill (2)

for all $\alpha, \alpha_1, \alpha_2 \in \Gamma^2 \mathcal{M}, f \in \Gamma^0 \mathcal{M}$ and constants $\lambda \in \mathbb{R}$. The angle brackets $\langle \ldots \rangle$ enclosing the arguments to $\Psi$ are used to emphasise its non tensorial nature: notably we have that $\Psi \langle f \alpha \rangle \neq f \Psi \langle \alpha \rangle$. This formulation permits a range of new possibilities$^3$, but here we focus on the simplest “axionic” scheme. This means we replace the rather general (1) with an expression with a more familiar appearance, namely

$$dF = 0 \quad \text{and} \quad d * (\kappa (F)) + \zeta_{\text{top}} \wedge F = J.$$  \hfill (3)

Here $\kappa$ is the usual constitutive tensor for a medium, and $\zeta_{\text{top}}$ is a 1–form field generating an additional axion-like interaction. By setting $\Psi (F) = d * (\kappa (F)) + \zeta_{\text{top}} \wedge F$ we see that (3) is an example of (2) since

$$\Psi \langle f^2 \alpha \rangle - 2f \Psi \langle f \alpha \rangle + f^2 \Psi \langle \alpha \rangle = d * (\kappa (f^2 \alpha)) + \zeta_{\text{top}} \wedge (f^2 \alpha) - 2f d * (\kappa (f \alpha)) + f^2 \zeta_{\text{top}} \wedge F$$

$$- 2f \zeta_{\text{top}} \wedge (f \alpha) + f^2 d * (\kappa (\alpha)) + f^2 \zeta_{\text{top}} \wedge F = d (f^2 \alpha) + f^2 d * (\kappa (\alpha)) - 2f d \alpha * (\kappa (F))$$

$$- 2f d \alpha * (\kappa (F)) + f^2 d * (\kappa (\alpha)) - 2f d \alpha * (\kappa (F)) + f^2 d \alpha * (\kappa (\alpha)) = 0.$$

In a vacuum (i.e. with a trivial $\kappa$), we find that adding this axionic interaction naturally adapts the combined Maxwell-Ampère-Gauss equation ($\Psi (F) = J$) into

$$\Psi (F) = d * F + \zeta_{\text{top}} \wedge F = J.$$  \hfill (4)

In this formalism, the 2–form $F$ is untwisted, while the $\zeta_{\text{top}}$ and $J$ are twisted. We emphasise that (4) proposes an extension to the usual vacuum Maxwell equation

$$(d \star F = J)$$

in which there is no role (or even sensible definition) for the unmeasurable fields $D$ and $H$.

We denote the axion field $\zeta_{\text{top}}$ a “topological axion” for two reasons: because it has topological consequences distinct from those axions typically used in models of axion–electromagnetism interaction, and because of the similarities with the standard proposal for the still hypothetical axion particle.

The standard axions are given by a twisted scalar field $\phi_{\text{std}} \in \Gamma^0 \mathcal{M}$, and their coupling with the electromagnetic field in vacuum defined in the Lagrangian by

$$\frac{1}{4} \phi_{\text{std}} dA \wedge dA$$

is given by [27, eqns.(3,4)]

$$d \star F + d \phi_{\text{std}} \wedge F = J.$$  \hfill (5)

The similarity between (4) and (5) demonstrates that both interactions are indeed of the same “axionic” type.

We could therefore obtain (4) by insisting that $\zeta_{\text{top}}$ is exact, i.e. $d \phi_{\text{std}} = \zeta_{\text{top}}$. However, it is then no longer possible for a field $Z_{\text{std}}$ to act as a source for topological axions, since this would imply $Z_{\text{std}} = d \zeta_{\text{std}} = d^2 \phi_{\text{std}} = 0$. We show below that to break global charge conservation requires topological axions, for which there is an axion flux $Z_{\text{top}}$, where

$$Z_{\text{top}} = d \zeta_{\text{top}} \neq 0.$$  \hfill (6)

This is consistent with local charge conservation ($dJ = 0$) provided $F$ and $Z_{\text{top}}$ satisfy the constraint $Z_{\text{top}} \wedge F = 0$, as is evident by taking the exterior derivative of (4). The topological axions utilised here are therefore distinct from the standard axion hypothesis, wherein $d \phi_{\text{std}} = \zeta_{\text{std}}$. Nevertheless, since even standard axions have not been detected yet, a widening of axionic theory to include such topological axions is not ruled out by any experimental results to date.

Here we are not directly concerned with the dynamics of $\zeta_{\text{top}}$ or $Z_{\text{top}}$, but it is nevertheless an interesting consideration. For a massless topological axion, we can define an axion source term $\xi_{\text{top}} \in \Gamma^3 \mathcal{M}$, and set

$$\xi_{\text{top}} = d \star Z_{\text{top}}$$  \hfill (7)

so that we could if desired replace (6) with the dynamical equation

$$d \star d \xi_{\text{top}} = \zeta_{\text{top}}.$$  \hfill (8)

In what follows we specify the axion field in terms of the axion flux $Z_{\text{top}}$, but this could be converted into a specification of $\xi_{\text{top}}$ using (7) if desired.

Notwithstanding any wider aspects of the field dynamics and the possibility of a Lagrangian (see Appendix C), neither of which are needed for the work herein, we now proceed to consider the primary requirements for our results.

### III. THE FUTURE REGION OF A TEMPORARY SINGULARITY

Before discussing how global charge conservation can be violated in a spacetime supporting topological axions,
we would like to clarify some aspects of the singularity and its surrounding manifold that together provide the backdrop of our construction.

Specifying whether a spacetime has a temporary singularity is subtle since the singularity itself is not part of the spacetime. There are a plethora of definitions regarding singularities and completeness [1, 3]. The approach taken here is to state that a spacetime $\mathcal{M}$ has a temporary singularity if there exists a topological 3–sphere $U \subset \mathcal{M}$ which is not the boundary of a (compact) 4–dimensional ball. We see for example on figure 1 that $U = \partial \mathcal{N}$, but $\mathcal{N}$ is not a 4–dimensional ball as it has a hole in it. The 3–sphere $U$ separates $\mathcal{M}$ into two regions which can be called the “inside” and “outside”. The inside region is the one that has the temporary singularity, and the outside region goes off to infinity, as depicted on the Penrose diagram [44] on figure 2. In what follows we assume there is precisely one temporary singularity, i.e. inside the 3–sphere $U$ there do not exist two or more 3–spheres inside each of which is a temporary singularity, although it is easy to extend the analysis. Also, if we were to consider the case of a temporary black hole, then in addition to containing a temporary singularity, the spacetime would also require the properties of the metric to be specified, i.e. the existence of an event hori-

FIG. 2. Penrose diagram for a temporary timelike singularity, at the origin, between the points $p_0$ and $p_1$. Since light rays travel at 45° on these diagrams, the future of the singularity (its “causal cone”) consists of both the light cone or null cone (blue line), and the green region within it. This Penrose diagram contains essentially the same information as the more general view given in figure 1, but with its lightlike infinity boundaries mapped nonlinearly down to a finite extent. With time passing vertically upwards, the radial distance extends horizontally rightwards, away from the time axis. The purple line denoted $U$ is a 3–sphere, and the region inside $U$ includes the singularity.

FIG. 3. Penrose diagram for a temporary spatial singularity, perhaps due to a forming then evaporating black-hole. Using the same conventions as figure 2, here the spacelike singularity is instead extended horizontally, thus creating the event horizon, and giving the correct causal structure. The purple line is a 3–sphere $U$, and the region inside $U$ includes the singularity.

FIG. 4. A “singularity event” is excised from spacetime. The causal cone of this singularity is outlined by the light cone (blue) and its interior (green). The resulting non-trivial topology, in concert with the demotion of $D$ and $H$ to mere gauge fields, allows global charge conservation to be broken. Our analytic solution achieves this. In the region inside the causal cone the fields vary in time and space. Outside the causal cone they are everywhere zero.
zon (see figure 3), and the metric becoming singular as the singularity is approached.

Of course there are many such 3-spheres which surround the temporary singularity and we exploit this to define the future $J_+$ of the singularity. We say that a point $p \in J_+$ if for all 3-spheres $U$ surrounding the singularity and with $p$ outside $U$ then there exists a causal curve (timelike or lightlike) which passes from $U$ to $p$. Conversely, we say that $p \notin J_+$ if there exists a 3-sphere $U$ surrounding the singularity, with $p$ on the outside of $U$, which does not intersect the backward causal cone of $p$.

As an example, let $\mathcal{M} = \mathbb{R}^4 \setminus \{0\}$ be Minkowski space excluding the origin, then

$$J_+ = \{(t,x,y,z) \mid t \geq \sqrt{x^2 + y^2 + z^2}\}.$$  \hspace{1cm} (9)

represents the future of the excised origin as shown in figure 4. This example will be used in section V below to construct a combined electromagnetic and axion field configuration which breaks global charge conservation.

A more general example of a temporary singularity can be constructed by considering a spacetime $M_{\text{sup}}$ and then excluding a compact set $I \subset M_{\text{sup}}$, so that $\mathcal{M} = M_{\text{sup}} \setminus I$. Any 3-sphere surrounding $I$ is not the boundary of a compact 4-dimensional ball. An example of $I$ is a finite interval with end points $p_0, p_1 \in I$ as shown in Fig. 1. Let $J_+^{\text{sup}}(I) \subset M_{\text{sup}}$ be the future causal cone of $I$. Then $J_+^{\text{sup}}(I) \setminus I \subset \mathcal{M}$ and

$$J_+ = J_+^{\text{sup}}(I) \setminus I.$$  \hspace{1cm} (10)

This is shown in appendix B. Thus the definition of $J_+$ coincides with the usual definition of the future causal cone for $I$.

However, even this more general construction is still not the same as that for a temporary black hole. In section VI we will link the above examples using the techniques of transformation optics, in order to show that our conclusions based on a point singularity are in fact significantly more general.

IV. TECHNICAL INGREDIENTS FOR GLOBAL CHARGE CONSERVATION VIOLATION

We can now state precisely the technical ingredients leading to our solution that manifests non-conservation of global charge. Since we only consider topological axions, from now on we write the axion field $\Gamma_{\text{top}}$ as just $\zeta$.

In order to break global charge conservation, we require a spacetime $\mathcal{M}$ with a temporary singularity, with the future causal cone $J_+$ as described in section III, and the model of electromagnetism described in section II, with its topological axions, i.e.

(i) An electromagnetic field $F \in \Gamma \Lambda^2 \mathcal{M}$ with support only in $J_+$.

(ii) An electric current $J \in \Gamma \Lambda^3 \mathcal{M}$ with support only in $J_+$.

(iii) An axion current $\zeta \in \Gamma \Lambda^1 \mathcal{M}$ with support only in $J_+$.

The fields $F$, the electric current $J$, the axion field $\zeta$, and the axion flux $Z_{\text{top}}$ all satisfy the following criteria:

(a) The vacuum Maxwell axion relations (4).

(b) The monopole free condition

$$dF = 0.$$  \hspace{1cm} (11)

(c) The local conservation of charge

$$dJ = 0.$$  \hspace{1cm} (12)

(d) The axion field has a source-like flux $Z_{\text{top}}$ where

$$d\zeta = Z_{\text{top}}.$$  \hspace{1cm} (13)

The final and most important criterion that we require (i) to (iii) satisfy is 4

(e) The total charge is not globally conserved.

Obviously, outside the future causal cone $J_+$, the current $J = 0$; and for any spatial hypersurface $\Sigma_-$ which does not intersect the $J_+$ we have

$$\int_{\Sigma_-} J = 0.$$  \hspace{1cm} (14)

Therefore, to show that the last criterion (e) is satisfied we need that for a spatial hypersurface $\Sigma_+$ which intersects $J_+$

$$Q_+ = \int_{\Sigma_+} J \neq 0.$$  \hspace{1cm} (15)

“Away from” the temporary singularity, i.e. if there is a topological 3-sphere which surrounds the temporary singularity, but which does not intersect $\Sigma_+$ (the region

4 Note that there is no axion property (i.e. neither $\zeta$ nor $Z_{\text{top}}$) that contributes directly to the current in Maxwell equations; these axions carry no electric charge. There is therefore a clear distinction between the nature of the conventional current $J$ and the axionic interaction term $\zeta \wedge F$. Nevertheless, it is interesting to note that if one were to claim $\zeta \wedge F$ as part of some new augmented current $J_{\text{new}} = J - \zeta \wedge F$, this $J_{\text{new}}$ would be automatically conserved both globally and locally, since $d\star F = J_{\text{new}}$.  

5
under consideration), local charge conservation (12) implies global charge conservation. Hence \(Q_+\) is independent of \(\Sigma_+\) as long as \(\Sigma_+\) is away from the temporary singularity. Thus for any topological 3–sphere \(U\) surrounding the temporary singularity we deduce (cf. figure 5)

\[
Q_+ = \int_U J.
\]

The axion flux \(Z_{\text{top}}\) is constrained by the electromagnetic field, and from (4), (11), (12) and (13) we have

\[
Z_{\text{top}} \land F = 0.
\]

One way to satisfy this constraint is to have an axion flux entirely separate from the electromagnetic field, i.e. for the supports of \(Z_{\text{top}}\) and \(F\) to be disjoint. We might therefore think of \(Z_{\text{top}}\) as being somewhat analogous to a type-I superconductor that expels magnetic fields. However, this complete separation could be relaxed if we wished to give \(Z_{\text{top}}\) more freedom.

Notably, if we perform the 3+1 splits of \(F\) and \(Z_{\text{top}}\) with respect to a field of observers \(V \in \Gamma T, M, g(V, V) = -1\), to give

\[
F = E \land \tilde{V} + T(B \land \tilde{V})
\]

and

\[
Z_{\text{top}} = Z_{\text{SE}} \land \tilde{V} + T(Z_{\text{SB}} \land \tilde{V})
\]

where \(\tilde{V} = g(V, -) \in \Gamma T, M\) is the metric dual of \(V\). Then (17) becomes

\[
g(E, Z_{\text{SB}}) + g(B, Z_{\text{SE}}) = 0
\]

where \(g\) is the spacetime metric (see proof in Appendix D). With respect to the observer \(V\) the spatial parts of \(Z_{\text{top}}\) are observed to be \((Z_{\text{SE}}, Z_{\text{SB}})\), analogous to the way that the spatial parts of \(F\) are \((E, B)\). Equation (19) implies that to conserve charge locally we only need a single constraint on the polarisations of \((E, B, Z_{\text{SE}}, Z_{\text{SB}})\). Note that below we will ensure this condition holds for our field solution by specifying the supports of \(F\) and \(Z_{\text{top}}\) to be disjoint. This specification is both convenient and simplifying, although not necessary.

V. CONSTRUCTION OF \(\zeta\) AND \(F\)

We now proceed to define explicit forms for \(\zeta\) and \(F\) that satisfy criteria (a)–(e) above. In what follows, for convenience we specify particular sizes \(-\frac{1}{10}, \frac{3}{10}\), and so on – but any other convenient sizing that matches the requirements is equally useful.

Note that outside the causal cone \(J_+\), \(F\) and \(\zeta\) are both zero, and to ensure the solution remains well-behaved we construct them using bump functions. For this construction, \(M\) is Minkowski spacetime excluding the origin and \(J_+\) is given by (9). We will use three bump functions, denoted \(f_1(r), f_2(z),\) and \(f_3(\rho)\). They are smooth, non-negative functions of the type shown in figure 6. Although the functions must have properties that obey specific conditions, they are otherwise arbitrary. The conditions are

\[
f_1(r) = \begin{cases} 
1 & \text{strictly decreasing } \frac{3}{10} < r < \frac{5}{10}, \\
0 & \text{for } r > \frac{5}{10},
\end{cases}
\]

and

\[
f_2(z) = \begin{cases} 
\text{positive for } |z| < \frac{1}{10}, \\
0 & \text{for } |z| > \frac{1}{10},
\end{cases}
\]

and

\[
f_3(\rho) = \begin{cases} 
1 & \text{strictly decreasing } \frac{2}{10} < \rho < \frac{4}{10}, \\
0 & \text{for } \rho > \frac{4}{10}.
\end{cases}
\]

First, note that the above functions can be combined to ensure that the physical axion field \(\zeta\) is non-zero only in the regions where required (in cylindrical polars \((t, r, \theta, z)\), and with \(t > 0\)), i.e.

\[
\zeta = f_1 \left(\frac{r}{l}\right) f_2 \left(\frac{z}{l}\right) d \left(\frac{z}{l}\right),
\]

so that

\[
Z_{\text{top}} = d\zeta = f'_1 \left(\frac{r}{l}\right) f_2 \left(\frac{z}{l}\right) d \left(\frac{z}{l}\right) \land d \left(\frac{z}{l}\right),
\]

where from (20), (21), and (24), the support of \(Z_{\text{top}}\) is in the region when \(|z/l| \leq \frac{1}{10}\) and \(\frac{2}{10} \leq r/l \leq \frac{4}{10}\). This
FIG. 6. The three smooth “bump functions” used to construct our axisymmetric field solutions. There is one bump function defined for each of the radial $r$ coordinate, the longitudinal $z$, and the “torus-radial” $\rho$: i.e. $f_1(r)$, $f_2(z)$, and $f_3(\rho)$.

arrangement of $Z_{\text{top}}$ could be derived from and attributed to its related source $\xi_{\text{top}}$. Note that from (7), the support of $\xi_{\text{top}}$ is contained within that of $Z_{\text{top}}$, i.e. $\text{supp}(\xi_{\text{top}}) \subseteq \text{supp}(Z_{\text{top}})$.

Second, we let the electromagnetic potential $A$, which will define $F$, be given by

$$A = f_3\left(\frac{\rho}{t}\right) d\theta,$$

(25)

where

$$\rho^2 = z^2 + (r - \frac{4}{10})^2.$$  

(26)

so that

$$F = dA = f_3\left(\frac{\rho}{t}\right) d\left(\frac{\rho}{t}\right) \wedge d\theta$$

$$= f_3\left(\frac{\rho}{t}\right) \frac{1}{t^2} \left[ t \, dr \wedge d\theta - \rho \, dt \wedge d\theta \right]$$

$$= f_3\left(\frac{\rho}{t}\right) \frac{1}{t^2} \left[ t \, dz \wedge d\theta + t \left( r - \frac{4}{10} \right) dr \wedge d\theta - \rho^2 dt \wedge d\theta \right]$$

(27)

From (27) we see that the support of $F$ is when $f_3'\left(\rho/t\right) \neq 0$, i.e. when $\frac{2}{10} \leq \rho/t \leq \frac{3}{10}$.

The specifications (23) and (25) mean that for $r^2 + z^2 > t^2$, both $F = 0$ and $\zeta = 0$; thus the support of these lie inside the causal cone $J_+$. Having now defined $\zeta$ and $F$, we can also define $J$ using (4). Further, since the supports of $Z_{\text{top}}$ and $F$ are disjoint, (17) is satisfied, which implies, by taking the exterior derivative of (4), that local charge conservation ($dJ = 0$) is preserved.

Thus, by means of this construction of our fields $F, \zeta, Z_{\text{top}}$, we have satisfied conditions (a)–(d) as follows:

(a) from the definition of $J$, (b) since $F = dA$, (c) from the definition of $J$ in combination with $F$ and $\zeta$ being disjoint, and (d) from either the definition of $Z_{\text{top}}$ itself, or (24). The last condition, (e), is demonstrated below in V B.

The various fields are illustrated in figure 7 which delineates the support of each field at $t = 10$, as well in the 3–dimensional versions of figures 8–11. A cut at time $t = 10$ and $z = 0$ is shown in figure 12. It is also possible to represent the forms $F, Z_{\text{top}}, \zeta, \zeta \wedge F$ as dots, lines and surfaces [45], as described in the Appendix and shown on figure 17.

FIG. 7. The support of the electromagnetic field $F$ (blue annulus), the axion field $\zeta$ (light red and dark red blocks), and the axion flux $Z_{\text{top}}$ (dark red block), at the moment when $t = 10$. The region where $\zeta \wedge F \neq 0$ is given by the intersection of the blue and light red regions. The figure is rotated about the $z$–axis, as seen in figure 12. This means that the support of $F$ (blue) becomes a solid hollow torus (as in figures 10 and 11); the support of $Z_{\text{top}}$ (dark red) becomes a solid torus with a square cross section (as in figures 8 and 11); and the support of $\zeta$ (light and dark red) becomes a thick disc (as in figure 9).

FIG. 8. The support of the axion flux $Z_{\text{top}}$ (dark red), at $t = 10$, as a 3d plot.
FIG. 9. The support of the axion field $\zeta$ (both light red and dark red parts) and the axion flux $Z_{\text{top}}$ (dark red only), at $t = 10$, as a 3d plot.

FIG. 11. The combined support of the axion flux $Z_{\text{top}}$ (red) and a cut of the support of the electromagnetic field $F$ (blue), shown in two views.

B. Breaking of global charge conservation: condition (e)

Since the total charge present before the singularity is exactly zero, any finite amount afterwards indicates that global charge conservation has been violated — despite the eminently reasonable starting points (i) to (iii) and criteria (a) to (d).

We now explicitly calculate $Q_+$ the total charge over any time slice after the singularity. This is given by

$$Q_+ = \int_{\mathbb{R}^3} (d \star F + \zeta \wedge F) = Q_{\text{EM}} + Q_{\text{ax}},$$

(28)

where $Q_{\text{EM}} = \int_{\mathbb{R}^3} d \star F$ and $Q_{\text{ax}} = \int_{\mathbb{R}^3} \zeta \wedge F$. First, let us consider the contribution $Q_{\text{EM}}$. Such a contribution would appear as a current in the blue region of Fig. 7, and the result could easily be calculated. However, we can instead simply observe that for any fixed $t$ time slice, wherein $F$ has compact support, that

$$Q_{\text{EM}} = \int_{\mathbb{R}^3} d \star F = \int_{\text{Boundary}} \star F = 0.$$

(29)

This now leaves us to calculate the contribution due to axionic currents, $Q_+ = Q_{\text{ax}} = \int_{\mathbb{R}^3} \zeta \wedge F$. The fact that $\zeta \wedge F$ is closed (i.e. $d\zeta \wedge F = 0$) implies local charge conservation. However, since $\zeta \wedge F$ is not exact (i.e. it cannot be written as the exterior derivative of a two-form) the above argument using Stokes’ theorem leading to $Q_{\text{EM}} = 0$ does not apply here. In fact, for our constructed $\zeta$ and $F$, we now show that $Q_{\text{ax}} \neq 0$.
This implies $r < \frac{4}{10} t$, so that

$$|z| \leq \frac{1}{10} t, \quad r \leq \frac{3}{10} t, \quad (\frac{2}{10} t)^2 \leq z^2 + (r - \frac{4}{10} t)^2 \leq (\frac{3}{10} t)^2.$$  

This implies $r < \frac{3}{10} t$, so that

$$\zeta = f_2 \left( \frac{z}{t} \right) d \left( \frac{z}{t} \right). \tag{30}$$

Thus

$$\zeta \wedge F = \frac{1}{t} f_2 \left( \frac{z}{t} \right) dz \wedge f_3' \left( \frac{\rho}{t} \right) \frac{1}{t^2 \rho} \times$$

$$\left[ t dz \wedge d\theta + t (r - \frac{4}{10} t) dr \wedge d\theta - \rho dt \wedge d\theta \right]$$

$$= \frac{1}{t\rho} f_2 \left( \frac{z}{t} \right) f_3' \left( \frac{\rho}{t} \right) \times$$

$$\left[ t (r - \frac{4}{10} t) dz \wedge dr \wedge d\theta - \rho dz \wedge dt \wedge d\theta \right].$$

Integrating for some specified time $t > 0$ gives the axion contribution to the total charge $Q_+$:

$$Q_+ = \int_{z=-\frac{1}{10} t}^{\frac{3}{10} t} \int_{r=\frac{2}{10} t}^{\frac{3}{10} t} \frac{z}{t} f_2 \left( \frac{z}{t} \right) f_3' \left( \frac{\rho}{t} \right) dz \wedge dr \wedge d\theta$$

$$= 2\pi \int_{z=-\frac{1}{10} t}^{\frac{3}{10} t} \int_{r=\frac{2}{10} t}^{\frac{3}{10} t} \frac{z}{t} f_2(z) f_3' (\rho) dz \wedge dr$$

$$= 2\pi \int_{z=-\frac{1}{10} t}^{\frac{3}{10} t} \int_{r=\frac{2}{10} t}^{\frac{3}{10} t} \frac{(r - \frac{4}{10} t)}{\sqrt{z^2 + (r - \frac{4}{10} t)^2}} f_2(z) \times$$

$$f_3' \left( \sqrt{z^2 + (r - \frac{4}{10} t)^2} \right) dz \wedge dr.$$  

This is clearly independent of $t$ and so is a conserved quantity for $t > 0$. Now we can see that it is possible for $Q_+ \neq 0$; by inspection of the integrand we have $r - \frac{4}{10} t < 0$, $f_2(z) > 0$ and $f_3'(\rho) < 0$ hence $Q_+ \neq 0$. The non-zero charge originates from both the effusion of $F$ and $\zeta$ from the singularity, and the fact that $\zeta$ is not exact.

As a result, our claim, which would normally be extremely contentious, is that total charge is not globally conserved, i.e. our criterion (e) can be met – at least in the context of the electromagnetic model presented here. Our conclusion is that electromagnetic models do not necessarily enforce charge conservation; and this can be said not merely as an abstract claim [10], but one grounded in the extant mathematical solution we present here. It remains possible, however, that global charge conservation could be enforced by other physical mechanisms.

C. Visualisation in time

Although we have specified the mathematical construction of our non-conserving solution, it is worthwhile describing in more visual terms what such a construction would look like.

This is, in fact, relatively easy. We have already seen the toroidal structure of the axion fluxes and field patterns required in figures 8–11, but only at a single instance in time. Turning this into a dynamic picture now requires us only to observe that the arguments of the bump functions used in (23) and (25) all contain the factor $r/t$. Thus any point notionally fixed on the axion flux distribution must hold $r/t$ constant; as time passes and $t$ increases, $r$ also gets larger. The toroidal construction therefore expands, sized in fixed proportion to the spatial cross-section of the future causal cone of the singularity.

Although we have constructed our solution as if the combined axionic and electromagnetic fields were emerging from the singularity, it is easily recast in a time-reversed form where the construction is instead shrinking and vanishing into the singularity.

In appendix A we see how to visualise the fields $Z_S, \zeta$, and $F$ as submanifolds.

VI. A TEMPORARY SINGULARITY AND TRANSFORMATION ELECTROMAGNETISM

We would now like to extend the results of the previous sections, which treated a point-like singularity, to allow for a singularity that lives for a finite time.

Let $\mathcal{M}$ with metric $\tilde{g}$ be a spacetime which represents a temporary singularity as shown in Fig. 1. We assume that a diffeomorphism $\phi : \mathcal{M} \rightarrow \mathcal{M}$ can be constructed such that

(a) Any topological 3–sphere which surrounds the temporary singularity in $\mathcal{M}$ is mapped to a topological
In the general case, with \( \phi \) satisfying (\( \alpha \)) and (\( \beta \)) above, let \( \star \) be the Hodge dual in \( \mathcal{M} \) corresponding to the metric \( \hat{\gamma} \), and let \( \hat{F} \in \Gamma^{1,2}\mathcal{M} \). Let \( \hat{T} \) be the corresponding fields/sources on \( \hat{\mathcal{M}} \) given respectively by

\[
\hat{F} = \phi^*F, \quad \hat{\zeta} = \phi^*\zeta, \quad \hat{Z}_\text{top} = \phi^*Z_{\text{top}} \quad \text{and} \quad \hat{J} = \phi^*J + d(\star \phi^*F - \phi^* \star F) \tag{33}
\]

In the general case, with \( \phi \) satisfying (\( \alpha \)) and (\( \beta \)) above, let \( \star \) be the Hodge dual in \( \mathcal{M} \) corresponding to the metric \( \hat{\gamma} \), and let \( \hat{F} \in \Gamma^{1,2}\mathcal{M} \). Let \( \hat{T} \) be the corresponding fields/sources on \( \hat{\mathcal{M}} \) given respectively by

\[
\hat{F} = \phi^*F, \quad \hat{\zeta} = \phi^*\zeta, \quad \hat{Z}_\text{top} = \phi^*Z_{\text{top}} \quad \text{and} \quad \hat{J} = \phi^*J + d(\star \phi^*F - \phi^* \star F) \tag{33}
\]

An example with a spacelike temporary singularity by \( \mathcal{M} = \mathbb{R}^4 \backslash \{0, x, 0, 0\} \), \( -1 \leq \hat{x} \leq 1 \) is \( \phi : \hat{\mathcal{M}} \to \mathcal{M} \) given implicitly by

\[
\hat{t} = t \left[ 1 + \left( t^2 + x^2 + y^2 + z^2 \right)^{-1/2} \right], \quad \hat{x} = x, \quad \hat{y} = y \quad \text{and} \quad \hat{z} = z, \tag{31}
\]

as depicted in figure 15. This diffeomorphism demonstrates that even though we cannot use a diffeomorphism to map a point into a line, we can nevertheless map the region around a point, into a region around a line.

An example with a spacelike temporary singularity by \( \mathcal{M} = \mathbb{R}^4 \backslash \{0, x, 0, 0\} \), \( -1 \leq \hat{x} \leq 1 \) is \( \phi : \hat{\mathcal{M}} \to \mathcal{M} \) given implicitly by

\[
\hat{t} = t, \quad \hat{x} = x \left[ 1 + \left( t^2 + x^2 + y^2 + z^2 \right)^{-1/2} \right], \quad \hat{y} = y \quad \text{and} \quad \hat{z} = z, \tag{32}
\]

as depicted in figure 16.
VII. CONCLUSION

In this article, we have investigated the behaviour of charge conservation, a usually sacrosanct principle of standard electromagnetism. It has already been shown that it is possible to break global charge conservation whilst preserving local charge conservation [10], and this was done by considering an extension of Maxwell’s equations where the excitation fields $D$ and $H$ are no longer physical fields, and placing this in a spacetime containing a temporary singularity. This situation is in common with other consequences of singularities, where it is said that since “physics breaks down”, anything might occur as a result. However, bearing in mind the H.G. Wells quote: “If anything is possible, then nothing is interesting”, we were motivated to find examples that constrain this inchoate sense of the possibilities.

Here we have substantiated a situation where a minimally extended Maxwellian electromagnetism with an axionic coupling [11] in a topologically non-trivial spacetime fails to conserve global charge, by mathematically specifying the required space and time dependence of the relevant fields. In this construction there are no fields before the advent of the singularity, and the axions and charge emerge from it; the scheme can even be time reversed so as to destroy correctly configured and collapsing arrangements of axions and charge. Attempts to recover global charge conservation by accounting for the axionic charge “in” the singularity (before it emerges into the universe) are bound to fail as we have deliberately restricted attention to situations that are diffeomorphic to an instantaneous singularity. Further, our specification can be transformed by diffeomorphism to apply also to a range of related scenarios, including that for singularity reversal, having predicted – or perhaps manufactured – the “anything” can happen.

It is, however, certainly arguable that the form of the solutions is somewhat contrived, i.e. that no such field configuration will form randomly or be created naturally. However, in the spirit of Morris and Thorne’s famous paper on wormholes [47] we can ask “What constraints do the laws of physics place on the activities of an arbitrarily advanced civilization?” Suppose an advanced civilization feels it is necessary to adjust the total charge of the universe, having predicted — or perhaps manufactured — the arrival of a temporary singularity. They will then be able to construct the fields $F$, $\zeta_{\text{top}}$ and $Z_{\text{top}}$ in such a way that they will all vanish, along with axionically driven charge $(Q_+ = \int_{\Sigma+} \zeta \wedge F)$, into singularity.

Our conclusion appears to be at once startling and undeniable: global charge conservation cannot be guaranteed in the presence of axionic electromagnetic interaction.

FIG. 17. Representing the four fields on a slice at $\theta = 0$ at $t = 10$, showing the $r, z$ plane. Here the timeslice submanifolds of $F$ overlap the $\theta = 0$ plane, and so are shown as blue circles, as per table I. The two axionic fields – $\zeta$ (light red) and $Z_{\text{top}}$ (dark red) – have timeslice submanifolds that intersect with the $\theta = 0$ plane, and so are depicted as lines and dots. Lastly, the points of the timeslice submanifold for $\zeta \wedge F$ are shown as green diamonds. This is the same view as on figure 7.

FIG. 18. Representing the four fields on a slice $z = 0$ at $t = 10$, showing the $x, y$ (or $r, \theta$) plane. Here $F$ has timeslice submanifolds that intersect with the $z = 0$ plane, and so are depicted as blue dots. The two axionic fields – $\zeta$ (light red) and $Z_{\text{top}}$ (dark red) – have timeslice submanifolds that overlap the $z = 0$ plane, and so are shown as a disc and circles as per table I. Lastly, the points of the timeslice submanifold for $\zeta \wedge F$ are shown as green diamonds. The orientations of $F$ on this diagram are indicated by blue arrows curling around selected dots, and the orientation of $\zeta$ by a white curled arrow. This is the same view as on figure 12.

curls round the blue $F$ dots. Since the blue $F$ circles on figure 17 come out of the $z = 0$ plane in the region $6 < r < 7$, and go into the plane in the region $1 < r < 2$, they have opposite orientations in these two regions. These blue circles also mimic the magnetic field lines. The electric field is then perpendicular to these circles, pointing towards the next circle of the same radius at greater $\theta$.

The 2–form axion flux $Z_{\text{top}}$, depicted in dark red, is represented by circles in the $(r, \theta) = (x, y)$ plane. These are twisted, so have an internal orientation which is shown as anticlockwise in figure 18.

The 1–form axion field $\zeta$, depicted in light red, is represented by discs in the $(r, \theta)$ planes. These are twisted, so have an internal orientation which is shown as shown (in white) as anticlockwise in figure 18. This is because it is compatible with the orientation of $Z_{\text{top}}$.

The 3–form $\zeta \wedge F$, depicted as green diamonds. These diamonds are in the region where the supports of $\zeta$ and $F$ intersect. Since the orientation of $\zeta$ and $F$ are the same in this region, the orientation of $\zeta \wedge F$ is simply “+.” In spacetime this 3–form is depicted as lines, i.e. straight line flowing outward from the origin. The internal orientation are arrows pointing out of the page.

A three dimensional view of the field forms is shown on figure 19. Indeed, this visualization is particularly useful
a causal curve connecting $U^3$-sphere (10) consistent with the axion field $\zeta$ around the main axis, representing a circulating flux can see that the axion flux $Z_p$ not intersect the backward causal cone of $I_p$ then there exists a 3–sphere surrounding which does not intersect the backward causal cone of $I_p$. By contrast if $I_p \not\in J^+_I$ then there is a 3–sphere surrounding which does not intersect the backward causal cone of $I_p$. This will intersect every 3–sphere $U$ between $I$ to $p$. By contrast if $p \not\in J^+_I$ then there exists a 3–sphere surrounding $I$ which does not intersect the backward causal cone of $p$. \hfill \Box

Appendix B: Proof about the future causal cone $J^+_p$

Proof of (10). Observe that if $p \in J^+_I$ then there is a causal curve connecting $I$ to $p$. This will intersect every 3–sphere $U$ between $I$ to $p$. By contrast if $p \notin J^+_I$ then there exists a 3–sphere surrounding $I$ which does not intersect the backward causal cone of $p$. \hfill \Box

Appendix C: Remarks on a Lagrangian

Another interesting question is whether or not it is easy to construct a Lagrangian for our topological axion field: the presence of a Lagrangian would assure us that our model has features convenient for a wider context, such as the derivation of the corresponding stress-energy tensor, consequent conservation laws, and even path-integrals. A Lagrangian can be constructed if we also assume that $A \wedge Z_{top} = 0$, where $A$ is the electromagnetic potential. With this Lagrangian as the integrand, (4) follows by varying the action

$$S[A] = \int \left( \frac{1}{2}dA \wedge \star dA - A \wedge J + \frac{1}{2}A \wedge \zeta \wedge dA \right)$$

with respect to $A$, where $F = dA$.

To motivate this Lagrangian, note that when varying $S$ with respect to $A$ we have

$$\delta S = \int \left( \frac{1}{2}d\delta A \wedge \star dA + \frac{1}{2}dA \wedge \star d\delta A \right) - \delta A \wedge J + \frac{1}{2}\delta A \wedge \zeta \wedge dA - \frac{1}{2}d(A \wedge \zeta) \wedge \delta A \right) = \int \left( \delta A \wedge \star dA - \delta A \wedge J + \frac{1}{2}\delta A \wedge \zeta \wedge dA - \frac{1}{2}dA \wedge \zeta \wedge \delta A - \frac{1}{2}A \wedge \zeta \wedge \delta A \right)$$

However, as stated, although we require that $A \wedge Z_{top} = 0$, it is important to note that, since $A$ is a potential, it is not globally defined. Thus we can only assume we can find a topologically trivial region of $M$ where $A$ is defined such that $A \wedge Z_{top} = 0$. In this case (4), our axionic Maxwell-Ampère-Gauss equation does follow from (C1).

Although we do not claim that it is always possible to find such a region, in the solution presented here $F \wedge Z_{top} = 0$, and we can therefore locally choose gauges where $A \wedge Z_{top} = 0$.

Appendix D: Spacetime metric and the Proof of (19)

Proof. Since

$$Z_{SE} \wedge \tilde{\nabla} \wedge \star (B \wedge \tilde{\nabla}) = Z_{SE} \wedge \tilde{\nabla} \wedge iv \star B = iv(Z_{SE} \wedge \tilde{\nabla}) \wedge \star B$$

$$= -Z_{SE} \wedge (iv \tilde{\nabla}) \wedge \star B = Z_{SE} \wedge \star B = g(Z_{SE}, B) \star 1.$$ 

Likewise

$$\star (dt \wedge Z_{SB}) \wedge (dt \wedge E) = (dt \wedge E) \wedge \star (dt \wedge Z_{SB}) = g(Z_{SB}, E) \star 1.$$ 

Also from the star pivot

$$\star (dt \wedge Z_{SB}) \wedge \star (dt \wedge Z_{SB}) = (dt \wedge Z_{SB}) \wedge \star \star (dt \wedge Z_{SB})$$

$$= - (dt \wedge Z_{SB}) \wedge (dt \wedge Z_{SB}) = 0.$$ 

5 The constraint $A \wedge Z_{top} = 0$ is, however, harder to derive from an action.
From (17) we have

\[
0 = Z_{\text{top}} \wedge F \\
= (dt \wedge Z_{SE} + \star(dt \wedge Z_{SB})) \wedge (dt \wedge E + \star(dt \wedge B)) \\
= dt \wedge Z_{SE} \wedge \star(dt \wedge B) + \star(dt \wedge Z_{SB}) \wedge (dt \wedge E) \\
+ \star(dt \wedge Z_{SB}) \wedge \star(dt \wedge Z_{SB}) \\
= (g(Z_{SB}, E) + g(Z_{SE}, B)) \star 1.
\]
Appendix E: Popular summary

What is an Axion Bomb?

A light-hearted popular summary for “Temporary Singularities and Axions: an analytic solution that challenges charge conservation”

Paul Kinsler

“Physics breaks down at a singularity” is one of the most famous statements in pop-physics. By showing how this might be done\footnote{See “Temporary Singularities and Axions: an analytic solution that challenges charge conservation”. J. Gratus, P. Kinsler, M.W. McCall, Annalen der Physik 533, 2000565 (2021), http://doi.org/10.1002/andp.202000565, https://arxiv.org/abs/2008.02135.}, one of the most cherished laws of physics, the conservation of charge, has come under fire in a recent paper by three physicists: Jonathan Gratus from Lancaster, and Paul Kinsler and Martin McCall, from Imperial. “By dropping an ‘axion-bomb’ into a temporary singularity, such as an evaporating black hole, we can create or destroy electrical charge”, claims Kinsler. Axions are a hypothesised particle that are a candidate for dark matter, although their exact properties are still debated, and they have not yet been detected.

McCall explains further – “This so-called axion-bomb, as just referred to by my somewhat over-enthusiastic colleague, is a mathematical construct that combines electromagnetic fields and axion particle fields in the correct way”. “The construction shinks and disappears into the singularity”, says Gratus, “taking electrical charge with it. And it is the combination of a temporary singularity and a newly proposed type of axion field that is crucial to its success”.

“There are also philosophical implications”, says Kinsler, “although people often like to say that ‘physics breaks down’, here we show that although exotic phenomena might occur, what actually happens still is very constrained by the still-working laws of physics around the singularity”. In parting, Gratus interjects “You know, I first suggested the reverse of this process”, he says wistfully, “and an ‘axion-fountain’ has a much nicer ring to it, don’t you think?”.

Paul Kinsler is now safely working on an entirely different project.
