Hellinger KL-UCB based Bandit Algorithms for Markovian and i.i.d. Settings

Arghyadip Roy, Member, IEEE, Sanjay Shakkottai, Fellow, IEEE and R. Srikant, Fellow, IEEE

Abstract—In the regret-based formulation of multi-armed bandit (MAB) problems, except in rare instances, much of the literature focuses on arms with i.i.d. rewards. In this paper, we consider the problem of obtaining regret guarantees for MAB problems in which the rewards of each arm form a Markov chain which may not belong to a single parameter exponential family. To achieve logarithmic regret in such problems is not difficult: a variation of standard KL-UCB does the job. However, the constants obtained from such an analysis are poor for the following reason: i.i.d. rewards are a special case of Markov rewards and it is difficult to design an algorithm that works well independent of whether the underlying model is truly Markovian or i.i.d. To overcome this issue, we introduce a novel algorithm that identifies whether the rewards from each arm are truly Markovian or i.i.d. using a Hellinger distance-based test. Our algorithm then switches from using a standard KL-UCB to a specialized version of KL-UCB when it determines that the arm reward is Markovian, thus resulting in low regret for both i.i.d. and Markovian settings.

Index Terms—Online learning, regret, multi-armed bandit, rested bandit, KL-UCB, Hellinger distance.

I. INTRODUCTION

In a multi-armed bandit (MAB) problem [1], [2], a player needs to choose arms sequentially to maximize the total reward or minimize the total regret [3]. While there is a plethora of works which focus on arms with i.i.d. reward [2], [4]–[9], there are only a few works which consider bandits with Markovian rewards. When the states of the arms which are not played remain frozen (referred to as rested bandit)–[10]–[13]), the states observed in their next selections do not depend on the interval between successive plays of the arms. In the restless [12], [14], [15] case, states of the arms continue to evolve irrespective of the selections by the player.

In this paper, we focus on the rested bandit setting. Many real-world problems such as gambling, ad placement and clinical trials fall into this category [16]. If a slot-machine (viewed as an arm) produces high reward in a particular play, then the probability that it will produce low reward in the next play is very high. Therefore, it is reasonable to assume that the reward distribution depends on the previous outcome and can be modeled through the rested bandit setting. Another example is in an online advertising setting to a customer (e.g. video ads with IMDb TV or social ads on Facebook), where an agent presents an ad to a customer from a pool of ads, and adapts future displayed ads based on the customer’s past responses. Similarly, in a medical diagnosis problem involving repeated interventions of different medications, the outcome of an intervention depends on the outcome of previous interventions.

As discussed next, existing studies in the literature on rested bandits either consider a particular class of Markov chains (with single-parameter families of transition matrices) [11], [13], or result in large asymptotic regret bounds [10], [12]. In general, however, these Markov chains may not belong to a single parameter family of transition matrices; nevertheless, we would desire low regret. We briefly describe the setting considered by us. We assume that each arm evolves according to a two-state Markov chain. When an arm is chosen, a finite reward is generated based on the present state of the arm. In such a setting, we can obtain logarithmic regret by a variant of standard KL-UCB [8], [9] (which was originally designed for i.i.d. rewards). Although the constant obtained from the regret analysis is better than that of [10], the performance is poor for i.i.d. rewards (special case of Markovian rewards). We address this problem in this paper. The main contributions of this paper are as follows.

1. Hellinger KL-UCB Algorithm: We propose a novel Hellinger Kullback-Leibler Upper Confidence Bound (H-KL-UCB) algorithm which can identify whether the rewards from an arm is truly Markovian or i.i.d. The identification is done using a (time-dependent) Hellinger distance-based test between the sample estimates of transition probabilities from one state to another. The proposed algorithm switches from standard sample mean based KL-UCB to sample transition probability based KL-UCB when it determines that the arm reward is Markovian using the Hellinger distance-based test. The sample transition probability based KL-UCB determines upper confidence bound of the transition probability from the current state of the arm and uses the estimate of the transition probability to the current state while evaluating the mean reward. An arm can be represented uniquely by the transition probability matrix (two parameters).

2. Upper Bound on Regret: We derive finite time and asymptotic upper bounds on the regret of H-KL-UCB for both truly Markovian and i.i.d. rewards. We prove that the proposed algorithm is order-optimal for Markovian rewards and optimal when all arm rewards are i.i.d.
The standard analysis for regret with KL-UCB (either for i.i.d. rewards [8], or rewards from a Markov transition matrix specified through a single-parameter exponential family [9], [11]) crucially relies on the invertibility of the KL divergence function when applied to sample estimates. This allows one to translate concentration guarantees for sums of random variables to one for level crossing of the KL divergence function applied to empirical estimates. In our multi-parameter estimation setting, this invertibility property no longer directly holds. However, we convert this multi-parameter problem into a collection of single parameter problems and derive concentration bounds for individual single parameter problems. Then concentration bounds obtained from individual problems are combined to obtain an upper bound on the regret of H-KL-UCB.

To derive our bound, we establish that a certain condition on the Hellinger distance between estimates of transition probabilities (for using a sample mean based KL-UCB) is satisfied infinitely often if and only if the arm rewards are i.i.d. over time, which in turn implies that the regret due to choosing the incorrect variant of KL-UCB vanishes asymptotically.

Analytical and experimental results establish that H-KL-UCB performs better than the state-of-the-art algorithms [10]. [13] when at least one of the arm rewards is truly Markovian. Moreover, H-KL-UCB is optimal [8] when all arm rewards are i.i.d.

A. Related Work

While much of the literature on MAB focuses on arms with i.i.d. rewards, arms with Markovian rewards have not been studied extensively.

i.i.d. Rewards: In [2], when the parameter space is dense and can be represented using a single-parameter density function, a lower bound on the regret is derived. The authors in [2] also propose policies that asymptotically achieve the lower bound. The work in [2] is extended in [5] for the case when multiple arms can be played at a time. A sample mean based index policy which achieves a logarithmic regret, is proposed in [6] for one-parameter family of distributions. In [8], a KL-UCB based index policy which is shown to be asymptotically optimal for Bernoulli rewards, is proposed. The proposed policy in [8] is further extended in [9] to consider a wider class of reward densities. The proposed KL-UCB policy in [8] performs better than the UCB policy in [7].

Markovian Rewards: [17] provides an overview of the state-of-the-art approach on Markovian bandits. Under the assumption of single-parameter families of transition matrices, an index policy which matches the corresponding lower bound asymptotically, is proposed in [11]. In [10], the authors propose a UCB policy based on sample mean reward. Unlike [11], the analysis in [10] is not restricted to single-parameter family of transition matrices. Moreover, since the index calculation is based on the sample mean, the policy is significantly simpler than that of [11]. Although order-optimal, the proposed policy may be worse than that in [11] in terms of the constant. In [13], the optimal allocation problem involving multiple plays is considered. The authors propose a straightforward extension of KL-UCB using sample mean. However, similar to [11], [13] assumes that the rewards are generated from Markov chains belonging to a one-parameter exponential family.

Following [10] and unlike [11], [13], we do not consider any parameterization on the transition probability matrices. The only assumption we require is that the Markov chains have to be irreducible. The key reasons why our approach achieves lower regret than [10] are (i) unlike us, [10] always uses sample mean-based indices which may not uniquely represent the arms in truly Markovian setting and (ii) usage of KL-UCB provides a tighter confidence bound. Since we do not consider only an one-parameter exponential family of Markov chains, it is unclear that whether our algorithm is the best possible algorithm for this setting. To show that an algorithm is asymptotically optimal, one needs to obtain matching upper and lower bounds which remains an open problem. However, we note that both our theory and simulations show that our results improve upon the performance of the state-of-the-art algorithms.

II. Problem Formulation & Preliminaries

We assume that we have $K$ arms. The reward from each arm is modeled as a two-state irreducible Markov chain with a state space $S = \{0, 1\}$. Let the reward obtained when arm $i$ which is in state $s$, is played be denoted by $r(s, i)$. We assume that $r(s, i) = s$. Let the transition probabilities from state $s = 0$ to state $s = 1$ and from state $s = 1$ to state $s = 0$ of arm $i$ be denoted by $p^0_0$ and $p^1_0$, respectively. Let the stationary distribution of arm $i$ be denoted by $\pi_i = (\pi_i(s), s \in S)$. Therefore, the mean reward of arm $i$ ($\mu_i$, say) is expressed as $\mu_i = \sum_{s \in S} \pi_i(s) = \pi_i(1)$. Let $\mu^* = \max_{1 \leq i \leq K} \mu_i$ denote the mean reward of the best arm. W.l.o.g, we assume that $\mu^* = \mu_1$. Let the suboptimality gap of arm $i$ be $\Delta_i = \mu_1 - \mu_i$. Let $R_\alpha(n)$ denote the regret of policy $\alpha$ up to time $n$. Hence,

$$R_\alpha(n) = n\mu_1 - E_{\alpha}\left[\sum_{t=1}^{n} r(s(\alpha(t)), \alpha(t))\right],$$

where $\alpha(t)$ denotes the arm (which is in state $s(\alpha(t))$, say) selected at time $t$ by policy $\alpha$. A policy $\alpha$ is said to be uniformly good if $R_\alpha(n) = o(n^\beta)$ for every $\beta > 0$. For two arms $i$ and $j$ with associated Markov chains $M_i$ and $M_j$ (say), the KL divergence between them is

$$D(M_i \| M_j) = \pi_i(0)D(p^0_0 || p^0_1) + \pi_i(1)D(p^1_0 || p^1_1),$$

where $D(A \| B) = A \log \frac{A}{B} + (1 - A) \log \frac{1-A}{1-B}$.

In [11], a lower bound on the regret of any uniformly good policy is derived. For a uniformly good policy $\alpha$,

$$\liminf_{n \to \infty} \frac{R_\alpha(n)}{\log n} \geq \sum_{i=2}^{K} \frac{\Delta_i}{I(M_i || M_1)}.$$

The authors in [11] derive the above lower bound when the transition functions belong to a single-parameter family. It is straightforward to show that the lower bound holds more generally but since the proof techniques are standard, we present the proof in Appendix A. We aim to determine an upper bound on $R_\alpha(n)$ as a function of $n$ for a given policy $\alpha$. 

III. HELLINGER KL-UCB ALGORITHM & REGRET UPPER BOUND

Before presenting the H-KL-UCB algorithm, we briefly describe the motivation behind the algorithm. When the rewards of an arm are i.i.d., the arm can be represented uniquely using the mean reward. However, in the truly Markovian reward setting, arm $i$ can be described uniquely by $p_i^0$ and $p_i^1$. Using a variation (we call it KL-UCB-MC) of standard KL-UCB for i.i.d. rewards [8], one can obtain logarithmic regret. The main idea is to obtain a confidence bound for the estimate of $p_i^0$ and use the estimate of $p_i^1$ in state 0 (state 1) of arm $i$ using KL-UCB. For purely Markovian arms, the resulting regret is smaller than the regret of the algorithm in [10]. However, KL-UCB-MC results in large constants in the regret for i.i.d. rewards. Hence, we proceed to introduce the H-KL-UCB algorithm which improves over KL-UCB-MC and performs well in both truly Markovian and i.i.d. settings. Details of KL-UCB-MC is presented in Appendix [7].

A. Hellinger KL-UCB Algorithm

Algorithm 1 Hellinger KL-UCB algorithm (H-KL-UCB)

1: Input $K$ (number of arms).
2: Choose each arm once.
3: if $H^2(p_{01}^i(t-1)\mid 1-p_{10}^i(t-1)) > \frac{1}{(t-1)^{\gamma_0}}$ (procedure STP_PHASE) then
4: if (state of arm $i$ is 0) then
5: \hspace{1cm} $U_i = \log f(t) / T_i(t-1)$;
6: else (procedure SM_PHASE)
7: \hspace{1cm} $U_i = \log f(t) / T_i(t-1)$;
8: end if
9: else (procedure SM_PHASE)
10: \hspace{1cm} $U_i = \log f(t) / T_i(t-1)$;
11: end if
12: \hspace{1cm} $U_i = \log f(t) / T_i(t-1)$;
13: end if
14: Choose $A_t = \arg \max_i U_i$.

We propose an algorithm (H-KL-UCB) based on sample transition probabilities between different states of the arm and sample mean. Our proposed policy is motivated from the KL-UCB algorithm [8].

Let $T_{i,j}(t)$ denote the number of times arm $i$ is selected while it was in state $j$, till time $t$. We assume that $T_{i,j}(t) = \sum_{j' \in S} T_{i,j'}(t)$.

We further assume that $\hat{p}_{01}^i(t)$, $\hat{p}_{10}^i(t)$ and $\hat{\mu}^i(t)$ denote the sample estimate of $p_{01}^i$, sample estimate of $p_{10}^i$ and sample mean of arm $i$ at time $t$, respectively. We compute the square of the Hellinger distance (denoted by $H(\cdot|\cdot)$) between $\hat{p}_{01}^i(t-1)$ and $1-\hat{p}_{10}^i(t-1)$ of arm $i$. If it is greater than $\frac{1}{(t-1)^{\gamma_0}}$ (Line 3), then based on the current state of the arm, we calculate the index of the arm (referred to as STP_PHASE). If arm $i$ is in state 0, then the index is calculated using the confidence bound for the estimate of $p_{01}^i$ at time $t$ (Line 4), else using the confidence bound for the estimate of $p_{10}^i$ (Line 5). We use the estimate of the transition probability from the other state while evaluating the index. However, if $H^2(\hat{p}_{01}^i(t-1)\mid 1-\hat{p}_{10}^i(t-1)) < \frac{1}{(t-1)^{\gamma_0}}$, then the index of the arm is calculated (Line 7) using the confidence bound for the current value of $\hat{\mu}^i$ (referred to as SM_PHASE). Then, we play the arm with the highest index. We take \(f(t) = 1 + t \log^2(t)\). The physical interpretation behind the condition on Hellinger distance is as follows. It is well-known that KL-UCB algorithm (which uses sample mean) [3] is asymptotically optimal for i.i.d. Bernoulli arms. Now, in the special case, when $p_{01}^i = 1-p_{10}^i$, rewards from arm $i$ are i.i.d. In that case, the condition in Line 7 is satisfied frequently often, and arm $i$ uses Equation (5) for calculating the index, similar to [8]. However, when $p_{10}^i + p_{01}^i \neq 1$, the condition in Line 3 is met frequently often. We formally establish these statements in Lemma 5.

Remark 1. A natural choice of a metric for representing the similarity between $\hat{p}_{01}^i(t)$ and $1-\hat{p}_{10}^i(t)$ is the KL distance between them, i.e., $D(\hat{p}_{01}^i(t)\mid 1-\hat{p}_{10}^i(t))$. However, we choose Hellinger distance instead of KL distance because it permits additive separability of the estimates: $\hat{p}_{10}^i(t)$ and $\hat{p}_{01}^i(t)$, which in turn enables the use of standard concentration inequalities for the proof of asymptotic upper bound on regret. We describe this in detail in Appendix X.

B. Regret Upper Bound

We proceed to derive an upper bound on the regret of H-KL-UCB. First, we describe a set of lemmas which are useful in deriving the asymptotic upper bound on the regret.

Lemma 1. Let $p, q, \epsilon \in [0,1]$. The following relations hold:
(a) $D(p||q) \geq 2(p-q)^2$ ( Pinsker’s inequality),
(b) If $p \leq q - \epsilon \leq q$, then $D(p||q-\epsilon) \leq D(p||q) - 2\epsilon^2$,
(c) If $p \leq p + \epsilon \leq q$, then $D(q||p+\epsilon) \leq D(q||p) - 2\epsilon^2$.

Proof. Proof of (a) and (b) are given in [18] Lemma 10.2. Proof of (c): Let $h(q) = D(q||p+\epsilon) - D(q||p)$. Hence, $h(q) = q \log \frac{p}{p+\epsilon} + (1-q) \log \frac{1-p}{1-p-\epsilon}$. We get, $h'(q) = \log \frac{p(1-p-\epsilon)}{(p+\epsilon)(1-p)} < 0$ (since $p \leq p + \epsilon \leq q$). Therefore, $h(q)$ is linear and decreasing in $q$. Thus, using Lemma 10.3, $h(q) \leq h(p + \epsilon) = -D(p + \epsilon||p) \leq -2\epsilon^2$. This completes the proof of the lemma.

Lemma 2. Assume that $W_1, \ldots, W_n$ is a sequence of i.i.d. Bernoulli random variables with mean $\mu$. Let $\bar{\mu} = \frac{1}{n} \sum_{i=1}^{n} W_i$.
Then, for $\epsilon \in [0,1-\bar{\mu}]$, $\mathbb{P}(\bar{\mu} \geq \mu + \epsilon) \leq \exp(-nD(\mu + \epsilon||\mu))$, and for $\epsilon \in [0,\mu]$, $\mathbb{P}(\bar{\mu} \leq \mu - \epsilon) \leq \exp(-nD(\mu - \epsilon||\mu))$.

Proof. Proof is given in [18] Lemma 10.3.
Corollary 1. For any $a \geq 0$, \( \mathbb{P}(D(\mu|\mu) \geq a, \tilde{\mu} \leq \mu) \leq \exp(-na) \) and \( \mathbb{P}(D(\mu|\mu) \geq a, \tilde{\mu} \geq \mu) \leq \exp(-na) \).

**Proof.** Proof is given in [18] Corollary 10.4.

Let the transition probabilities from state 0 to state 1 and state 1 to state 0 of a two-state Markov chain \{\( M_i \)\}_{i \geq 0} be \( P_{01} \) and \( P_{10} \), respectively. Let \( P_{00} = 1 - P_{01} \) and \( P_{11} = 1 - P_{10} \). Let the stationary probabilities of states 0 and 1 be \( \pi_0 \) and \( \pi_1 \), respectively. Let \( N_0(t) = \sum_{i=1}^{t} \mathbb{1}\{M_i = 0\} \) and \( N_1(t) = \sum_{i=1}^{t} \mathbb{1}\{M_i = 1\} \). Let \( N_{ij}(t) \) denote the number of times the Markov chain transitions from state \( i \) to state \( j \) till time \( t \). Let \( \bar{P}_{ij}(t) = \frac{N_{ij}(t)}{N_{\bar{t}}(t)} \). The lemma presented next establishes that the fraction of visits to any state of a Markov chain is never too far from the stationary probability of the state.

Lemma 3. Let \( C_t := \{ \frac{N_{0}(t)}{N_{\bar{t}}(t)} - \pi_0 | > \epsilon_1 \} \). Then, \( \sum_{t=1}^{\infty} \mathbb{P}(C_t) \leq \sum_{t=1}^{\infty} (t+1)^3 \exp(-2(t-1)\epsilon_1^2(P_{01} + P_{10})^2) \).

**Proof.** Proof is provided in Appendix [B].

The lemmas described next depicts that the estimates of the transition probabilities associated with a Markov chain are never too far from the true transition probabilities.

Lemma 4. Let \( D_{0,t} := \{ |\bar{P}_{01}(t) - P_{01}| > \epsilon_1 \} \) and \( D_{1,t} := \{ |\bar{P}_{10}(t) - P_{10}| > \epsilon_1 \} \). Then, \( \sum_{t=1}^{\infty} \mathbb{P}(D_{0,t}) \leq \frac{1}{\epsilon_1^2} + \sum_{t=1}^{\infty} (t+1)^3 \exp(-2(t-1)\epsilon_1^2(P_{01} + P_{10})^2) \), \( \sum_{t=1}^{\infty} \mathbb{P}(D_{1,t}) \leq \frac{1}{\epsilon_1^2} + \sum_{t=1}^{\infty} (t+1)^3 \exp(-2(t-1)\epsilon_1^2(P_{01} + P_{10})^2) \).

**Proof.** Proof is given in Appendix [C].

The following lemma considers two cases, viz., i.i.d. arm reward (i.e., \( P_{01} + P_{10} = 1 \)) and truly Markovian arm reward (i.e., \( P_{01} + P_{10} \neq 1 \)), respectively. It, alongside Borel-Cantelli Lemma, establishes that appropriate conditions on the Hellinger distance are satisfied infinitely often for both cases.

Lemma 5. Let \( B_t := \{ H^2(\hat{P}_{01}(t)|1 - \hat{P}_{10}(t)) < \frac{1}{1+\tau} \} \). If \( P_{01} + P_{10} = 1 \), then \( \sum_{t=1}^{\infty} \mathbb{P}(B_t^c) \leq \sum_{t=1}^{\infty} 4 \exp\left(\frac{2}{9}\sqrt{t}\right) + \sum_{t=1}^{\infty} (t+1)^3 \exp(-2\sqrt{t}-1) \).

If \( P_{01} + P_{10} < 1 \), then for \( \tau \geq \frac{1}{\pi(P_{01} + \epsilon_1)|1 - P_{10} - \epsilon_1|} \), \( \sum_{t=1}^{\tau} \mathbb{P}(B_t) \leq \frac{2}{\epsilon_1^2} + \sum_{t=1}^{\tau} (t+1)^3 \exp(-2(t-1)\epsilon_1^2(P_{01} + P_{10})^2) \), and if \( P_{01} + P_{10} > 1 \), then for \( \tau \geq \frac{1}{\pi(P_{01} - \epsilon_1)|1 - P_{10} + \epsilon_1|} \), \( \sum_{t=1}^{\tau} \mathbb{P}(B_t) \leq \frac{2}{\epsilon_1^2} + \sum_{t=1}^{\tau} (t+1)^3 \exp(-2(t-1)\epsilon_1^2(P_{01} + P_{10})^2) \), where \( \epsilon_1 < \frac{|P_{01} + P_{10} - 1|}{2} \).

**Proof.** Proof is given in Appendix [D].

The lemmas presented next are used to prove that the confidence bounds of transition probabilities associated with the optimal arm are never too far from the respective true transition probabilities.

Lemma 6. Let \( X_1, X_2, \ldots, X_n \) be i.i.d. Bernoulli random variables with mean \( p \in [0, 1] \), and \( \epsilon_p > 0 \). Let \( \tilde{p}_s = \frac{1}{s} \sum_{i=1}^{s} X_i \), where \( s \) is the number of samples till time \( t \). Let \( \tilde{p}_s^* = \max\{\tilde{p} \in [\tilde{p}_s, 1] : D(\tilde{p}_s||\tilde{p}) \leq \frac{\log(f(t))}{s}\} \). Then, \( \sum_{s=1}^{n} \mathbb{P}(\tilde{p}_s^* > p - \epsilon_p) \leq \frac{2}{\epsilon_p^2} \).

**Proof.** Proof is given in Appendix [E].

Lemma 7. Let \( Y_1, Y_2, \ldots, Y_n \) be i.i.d. Bernoulli random variables with mean \( q \in [0, 1] \), and \( \epsilon_q > 0 \). Let \( \tilde{q}_s = \frac{1}{s} \sum_{i=1}^{s} Y_i \), and \( \tilde{q}_s^* = \min\{\tilde{q} \in [0, \tilde{q}_s] : D(\tilde{q}_s||\tilde{q}) \leq \frac{\log(f(t))}{s}\} \). Then, \( \sum_{s=1}^{n} \mathbb{P}(\tilde{q}_s^* > q + \epsilon_q) \leq \frac{2}{\epsilon_q^2} \).

**Proof.** Proof is given in Appendix [F].

The next two lemmas presented subsequently are used to establish that the index associated with a sub-optimal arm is not often much greater than the index of the optimal arm. Let \( p_1, p_2, q_1, q_2 [0, 1] \). Let \( Z(s) \) be a non-negative random variable with \( Z(s) \in [0, 1] \), \( s = 1, 2, \ldots, n \).

Lemma 8. (a) Define \( \kappa_1 = \sum_{s=c}^{n} \mathbb{P}(D(p_2 + \epsilon_1||\frac{(p_1 - \epsilon_1)(q_2 - \epsilon_1)}{q_1 + \epsilon_1} + Z(s)) \leq \frac{a}{s} \). Then \( \kappa_1 \leq \frac{1}{\epsilon_1} \mathbb{P}(D(p_2 + \epsilon_1||\frac{a}{q_1 + \epsilon_1} - (c - 1)^+). \)

(b) Define \( \kappa_2 = \sum_{s=c}^{n} \mathbb{P}(D(q_2 - \epsilon_1||\frac{(q_1 + \epsilon_1)(p_2 + \epsilon_1)}{p_1 - \epsilon_1}) - Z(s)) \leq \frac{a}{s} \). Then \( \kappa_2 \leq \frac{1}{\epsilon_1} \mathbb{P}(D(q_2 - \epsilon_1||\frac{a}{q_1 + \epsilon_1} - (c - 1)^+). \)

**Proof.** Proof is given in Appendix [G].

Let \( W_1, W_2, \ldots, W_n \) be i.i.d. Bernoulli random variables with mean \( \mu \in [0, 1] \), and \( Z(s) \) is measurable with respect to \( \sigma(W_1, \ldots, W_s) \).

Lemma 9. Define \( \kappa_3 = \sum_{s=c}^{n} \mathbb{P}(D(\mu_1||\frac{p - \epsilon_p}{p - \epsilon_p + q + \epsilon_1} + Z(s)) \leq \frac{a}{s} \). Then \( \kappa_3 \leq \frac{1}{\epsilon_1} \mathbb{P}(D(\mu_1||\frac{a}{p - \epsilon_p + q + \epsilon_1} - (c - 1)^+), \) where \( \mu + \epsilon_1 < \frac{p - \epsilon_p}{p - \epsilon_p + q + \epsilon_1} \).

**Proof.** Proof is given in Appendix [H].

We assume that the regret of H-KL-UCB till time \( n \) is \( R_n \). The theorem presented next provides an asymptotic upper bound on the regret of H-KL-UCB.
Theorem 1. Asymptotic regret of Algorithm 1 is bounded by (a) truly Markovian arms:

\[
\limsup_{n \to \infty} \frac{R_n}{\log n} \leq \sum_{i \neq j} \Delta_i \left[ \max \left\{ \frac{1}{D(p_{01}||p_{01}^{10} || p_{10}^{10})}, \frac{1}{\pi_i(0)D(p_{01}^{10}||p_{10}^{10}) + \pi_i(1)D(p_{10}^{10}||p_{10}^{10})} \right\} \right],
\]

(b) i.i.d. optimal and truly Markovian suboptimal arms:

\[
\limsup_{n \to \infty} \frac{R_n}{\log n} \leq \sum_{i \neq j} \Delta_i \left[ \max \left\{ \frac{1}{D(p_{01}||\mu_i p_{10}^{10} \mu_i)}, \frac{1}{\pi_i(0)D(p_{01}^{10}||\mu_i) + \pi_i(1)D(p_{10}^{10}||1 - \mu_i)} \right\} \right],
\]

c) truly Markovian optimal and i.i.d. suboptimal arms:

\[
\limsup_{n \to \infty} \frac{R_n}{\log n} \leq \sum_{i \neq j} \Delta_i \left[ \frac{1}{D(\mu_i || p_{01}^{10})} + \frac{1}{\mu_i D(\mu_i || p_{10}^{10})} \right].
\]

d) i.i.d.:

\[
\limsup_{n \to \infty} \frac{R_n}{\log n} \leq \sum_{i \neq j} \Delta_i \left[ \frac{1}{D(\mu_i || \mu_i)} \right].
\]

Proof. The proof idea is motivated by the regret analysis for i.i.d. rewards in [8]. However, in this paper, unlike [8] which deals with a single parameter (mean reward), we convert a multi-parameter estimation (transition probabilities between different states of a Markov chain) problem into a collection of single-parameter estimation problems and derive corresponding concentration bounds. Since the proof is technical, we first briefly outline the key steps for the truly Markovian arm setting (case (a)). Proof for other cases follow in a similar manner. First, we determine the finite time upper bound on the regret of H-KL-UCB. The key steps in the proof are:

1) We first establish that estimates of transition probabilities of the arms are close to the true transition probabilities. Furthermore, we show that appropriate Hellinger distance condition for an arm \((H^2(\hat{p}_{01}^{10}(t)||1 - \hat{p}_{10}^{10}(t)) > \frac{1}{t^{1/4}} \) for \(i^{th} \) arm) is satisfied infinitely often after a sufficiently large time \(\tau \). Proof follows from Lemmas 4 and 5.

2) We then establish that the confidence bounds for the estimates of transition probabilities of the optimal arm are never too far from respective true values. We consider two cases, corresponding to states 0 and 1 (Equations 1 and 2) of the optimal arm, respectively. Specifically, we prove that the expected number of times \(\hat{p}_{01}^{10}(t)\) is less than \(p_{01}^{10} - \epsilon_p\) and \(\hat{p}_{10}^{10}(t)\) is more than \(p_{10}^{10} + \epsilon_q\), are upper bounded by \(\frac{2}{\epsilon_p}\) and \(\frac{2}{\epsilon_q}\), respectively. We use Pinsker’s inequality, Chernoff’s bound and some algebraic manipulations to complete the proof.

3) We prove that when the estimates of transition probabilities of the arms are close to the true values, the appropriate condition on the Hellinger distance is satisfied and confidence bounds for the estimates of transition probabilities of the optimal arm are close to the corresponding true values, then the index associated with a sub-optimal arm is not often much greater than the index of the optimal arm. We consider four cases for different state-arm combinations of a given sub-optimal arm and the optimal arm. We illustrate the proof sketch when the both arms are in state 0. We prove that \(\sum_{t \geq 0} \mathbb{P}\left[\left\{ \frac{\hat{p}_{01}^{10}(t)}{\hat{p}_{01}^{10}(t) + \hat{p}_{10}^{10}(t)} < \frac{p_{01}^{10}(t)}{p_{01}^{10}(t) + p_{10}^{10}(t)} \right\} \right] \) is finite. When the conditions stated above are true, this is equivalent to proving that \(\sum_{t \geq 0} \mathbb{P}\left[\left\{ \frac{\hat{p}_{10}^{10}(t) + \epsilon_1||\hat{p}_{01}^{10}(t) - \epsilon_1||}{\hat{p}_{01}^{10}(t) + \epsilon_1||p_{01}^{10}(t) - \epsilon_1||} \right\} \right] \) is finite. The rest of the proof uses the monotonicity property of \(D(x||y)\) for \(x < y\). We complete the proof by choosing an appropriate \(\tau\) as a function of \(n\).

Then, we derive an asymptotic upper bound on the regret of H-KL-UCB by selecting \(\epsilon_1 = \epsilon_p = \epsilon_q = \log^{-1/4}(n)\).

1) Truly Markovian Arms: An arm can either be in STP_PHASE or in SM_PHASE at any time \(t\) depending on whether the condition on the Hellinger distance is satisfied or not. When all arms are truly Markovian, we establish that the expected number of times the arms are in SM_PHASE, is finite. In other words, for both optimal and suboptimal arms, the appropriate conditions on the Hellinger distances \((H^2(\hat{p}_{01}^{10}(t)||1 - \hat{p}_{10}^{10}(t)) > \frac{1}{t^{1/4}})\) are satisfied infinitely often. Let \(E_{1,t} := \{ H^2(\hat{p}_{01}^{10}(t - 1)||1 - \hat{p}_{10}^{10}(t - 1)) > \frac{1}{(t - 1)^{1/4}}, H^2(\hat{p}_{01}^{10}(t - 1)||1 - \hat{p}_{10}^{10}(t - 1)) > \frac{1}{(t - 1)^{1/4}} \} \). For \(t_1 = \frac{1}{H^2(\hat{p}_{01}^{10}(t)||1 - \hat{p}_{10}^{10}(t))}, H^2(\hat{p}_{01}^{10}(t)||1 - \hat{p}_{10}^{10}(t)) \leq \frac{1}{t^{1/4}} \), we obtain

\[
\sum_{t = t_1}^{n} \mathbb{P}(E_{1,t}) \leq \sum_{t = t_1 - 1}^{n - 1} \mathbb{P}(H^2(\hat{p}_{01}^{10}(t)||1 - \hat{p}_{10}^{10}(t)) \leq \frac{1}{t^{1/4}}) + \mathbb{P}(H^2(\hat{p}_{01}^{10}(t)||1 - \hat{p}_{10}^{10}(t)) \leq \frac{1}{t^{1/4}}) \\
\leq \frac{4}{\epsilon_1^2} + 2 \sum_{t = 1}^{\infty} (t + 1)^3 \exp(-2(t - 1)\epsilon_1^2(\hat{p}_{01}^{10} + \hat{p}_{10}^{10})^2) + 2 \sum_{t = 1}^{\infty} (t + 1)^3 \exp(-2(t - 1)\epsilon_1^2(\hat{p}_{01}^{10} + \hat{p}_{10}^{10})^2),
\]

where the last inequality follows from Lemma 5.

Next, we show that the estimates of transition probabilities of optimal and suboptimal arms are never too far from respective true values. We assume that \(F_{1,t} := \{ |\hat{p}_{01}^{10}(t) - p_{01}^{10}| \leq \epsilon_1, |\hat{p}_{10}^{10}(t) - p_{10}^{10}| \leq \epsilon_1, |\hat{p}_{10}^{10}(t) - p_{10}^{10}| \leq \epsilon_1 \} \). Hence, similar to Equation 4,

\[
\sum_{t = 1}^{n} \mathbb{P}(F_{1,t}) \leq \frac{4}{\epsilon_1^2} + 2 \sum_{t = 1}^{\infty} (t + 1)^3 \exp(-2(t - 1)\epsilon_1^2(\hat{p}_{01}^{10} + \hat{p}_{10}^{10})^2) \\
+ 2 \sum_{t = 1}^{\infty} (t + 1)^3 \exp(-2(t - 1)\epsilon_1^2(\hat{p}_{01}^{10} + \hat{p}_{10}^{10})^2),
\]

where the last inequality follows from Lemma 4.
Let the number of times sub-optimal arm $i$ is pulled till time $n$ be denoted by $T_i(n)$. Let the state of arm $i$ at time $t$ be denoted by $S_i(t)$.

$$
\mathbb{E}[T_i(n)] = \sum_{t=1}^{\tau} \mathbb{P}(A_t = i) + \sum_{t=\tau+1}^{n} \mathbb{P}(A_t = i, E_{1,t}^c) + \sum_{t=\tau+1}^{n} \mathbb{P}(A_t = i, E_{1,t})
$$

where

$$
\mathbb{E}[T_i(n)] = \sum_{t=1}^{\tau} \mathbb{P}(A_t = i) + \sum_{t=\tau+1}^{n} \mathbb{P}(A_t = i, E_{1,t}^c) + \sum_{t=\tau+1}^{n} \mathbb{P}(A_t = i, E_{1,t}).
$$

(6)

Now, we consider the last term in Equation (6). After each arm is chosen once, a sub-optimal arm is chosen if the index of the sub-optimal arm is higher than the index of the optimal arm. When $E_{1,t}$ occurs, i.e., both the optimal and the suboptimal arms are in STP_PHASE, sub-optimal arm $i$ is chosen if at least one of the following conditions is true.

1. $\hat{p}_{10}^i(t) < p_{10}^i - \epsilon_p$ and $S_1(t) = 0$,
2. $p_{10}^i(t) > p_{10}^i + \epsilon_p$ and $S_1(t) = 1$,
3. $p_{10}^i - \epsilon_p < \hat{p}_{10}^i(t) < p_{10}^i + \epsilon_p$, $S_1(t) = 0$ and $S_1(t) = 0$,
4. $p_{10}^i - \epsilon_p < \hat{p}_{10}^i(t) < p_{10}^i + \epsilon_p$, $S_1(t) = 1$ and $S_1(t) = 0$,
5. $\hat{p}_{10}^i(t) > p_{10}^i + \epsilon_q$, $S_1(t) = 0$ and $S_1(t) = 1$,
6. $\hat{p}_{10}^i(t) > p_{10}^i + \epsilon_q$, $S_1(t) = 1$ and $S_1(t) = 1$.

Therefore,

$$
\sum_{t=\tau+1}^{n} \mathbb{P}(A_t = i, E_{1,t})
$$

$$
\leq \sum_{t=\tau+1}^{n} \mathbb{P}(A_t = i, \hat{p}_{10}^i(t) < p_{10}^i - \epsilon_p, S_1(t) = 0, E_{1,t})
$$

$$
+ \mathbb{P}(A_t = i, \hat{p}_{10}^i(t) > p_{10}^i + \epsilon_q, S_1(t) = 1, E_{1,t})
$$

$$
+ \mathbb{P}(A_t = i, \hat{p}_{10}^i(t) > p_{10}^i + \epsilon_q, S_1(t) = 0, E_{1,t})
$$

$$
+ \mathbb{P}(A_t = i, \hat{p}_{10}^i(t) > p_{10}^i + \epsilon_q, S_1(t) = 1, E_{1,t})
$$

$$
\leq \sum_{t=\tau+1}^{n} \mathbb{P}(A_t = i, \hat{p}_{10}^i(t) < p_{10}^i - \epsilon_p, S_1(t) = 0, E_{1,t})
$$

$$
+ \mathbb{P}(A_t = i, \hat{p}_{10}^i(t) > p_{10}^i + \epsilon_q, S_1(t) = 1, E_{1,t})
$$

$$
+ \mathbb{P}(A_t = i, \hat{p}_{10}^i(t) > p_{10}^i + \epsilon_q, S_1(t) = 0, E_{1,t})
$$

$$
+ \mathbb{P}(A_t = i, \hat{p}_{10}^i(t) > p_{10}^i + \epsilon_q, S_1(t) = 1, E_{1,t}).
$$

(7)

Now, we proceed to derive upper bounds on individual terms of Equation (7).

$$
\sum_{t=\tau+1}^{n} \mathbb{P}(A_t = i, \hat{p}_{10}^i(t) < p_{10}^i - \epsilon_p, S_1(t) = 0, E_{1,t})
$$

$$
\leq \sum_{t=1}^{n} \mathbb{P}(\hat{p}_{10}^i(t) < p_{10}^i - \epsilon_p) \leq \frac{2}{\epsilon_p}.
$$

(8)

Similarly, using Lemma 5, we obtain

$$
\sum_{t=\tau+1}^{n} \mathbb{P}(A_t = i, \hat{p}_{10}^i(t) > p_{10}^i + \epsilon_q, S_1(t) = 1, E_{1,t}) \leq \frac{2}{\epsilon_q}.
$$

(9)

Subsequently, we have

$$
\sum_{t=\tau+1}^{n} \mathbb{P}(A_t = i, \hat{p}_{10}^i(t) > (p_{10}^i - \epsilon_p)p_{10}^i(t), S_1(t) = 0,
$$

$$
S_1(t) = 0, E_{1,t})
$$

$$
= \sum_{t=\tau+1}^{n} \mathbb{P}(A_t = i, \hat{p}_{10}^i(t) > (p_{10}^i - \epsilon_p)p_{10}^i(t),
$$

$$
D(\hat{p}_{10}^i(t)||\hat{p}_{10}^i(t)) \leq \frac{\log f(t)}{T_i(t-1)}, S_1(t) = 0, S_1(t) = 0, E_{1,t})
$$

$$\leq \sum_{t=\tau+1}^{n} \mathbb{P}(A_t = i, \hat{p}_{10}^i(t) > (p_{10}^i - \epsilon_p)p_{10}^i(t),
$$

$$
D(\hat{p}_{10}^i(t)||\hat{p}_{10}^i(t)) \leq \frac{\log f(t)}{T_i(t-1)} + \frac{\log f(n)}{T_i(t-1)} + \frac{\log f(n)}{T_i(t-1)}, F_{1,t} + \sum_{t=\tau+1}^{n} \mathbb{P}(F_{1,t}^c)
$$

$$\leq \sum_{t=\tau+1}^{n} \mathbb{P}(A_t = i, \hat{p}_{10}^i(t) > (p_{10}^i - \epsilon_p)p_{10}^i(t), E_{1,t})
$$

$$\leq \sum_{t=\tau+1}^{n} \mathbb{P}(A_t = i, \hat{p}_{10}^i(t) > (p_{10}^i - \epsilon_p)p_{10}^i(t),
$$

$$
\leq \sum_{t=\tau+1}^{n} \mathbb{P}(A_t = i, \hat{p}_{10}^i(t) > (p_{10}^i - \epsilon_p)p_{10}^i(t),
$$

where the last inequality follows from the definition of $\hat{p}_{10}^i(t)$. The third inequality follows from the fact that $D(x||\hat{p}_{10}^i(t))$ is decreasing in $x \in [p_{10}^i - \epsilon_q, p_{10}^i + \epsilon_q]$ and $p_{10}^i + \epsilon_q < \hat{p}_{10}^i(t) < p_{10}^i$. The last inequality follows from Lemma 5.

In a similar manner, using Lemma 8 we obtain

$$
\sum_{t=\tau+1}^{n} \mathbb{P}(A_t = i, \hat{p}_{10}^i(t) < \hat{p}_{10}^i(t)p_{10}^i(t), S_i(t) = 1,
$$

$$
S_1(t) = 0, E_{1,t})
$$

$$\leq \frac{\log f(n)}{D(p_{10}^i - \epsilon_q||p_{10}^i - \epsilon_q)} - \tau + \sum_{t=\tau+1}^{n} \mathbb{P}(F_{1,t}^c),
$$

(10)

where the first equality follows from the definition of $\hat{p}_{10}^i(t)$. The third inequality follows from the fact that $D(x||\hat{p}_{10}^i(t))$ is decreasing in $x \in [p_{10}^i - \epsilon_q, p_{10}^i + \epsilon_q]$ and $p_{10}^i + \epsilon_q < \hat{p}_{10}^i(t) < p_{10}^i$. The last inequality follows from Lemma 8.

In a similar manner, using Lemma 8 we obtain

$$
\sum_{t=\tau+1}^{n} \mathbb{P}(A_t = i, \hat{p}_{10}^i(t) > \hat{p}_{10}^i(t)p_{10}^i(t), S_i(t) = 1,
$$

$$
S_1(t) = 0, E_{1,t})
$$

$$\leq \frac{\log f(n)}{D(p_{10}^i + \epsilon_q||p_{10}^i + \epsilon_q)} - \tau + \sum_{t=\tau+1}^{n} \mathbb{P}(F_{1,t}^c),
$$

(11)

where the first equality follows from the definition of $\hat{p}_{10}^i(t)$. The third inequality follows from the fact that $D(x||\hat{p}_{10}^i(t))$ is decreasing in $x \in [p_{10}^i - \epsilon_q, p_{10}^i + \epsilon_q]$ and $p_{10}^i - \epsilon_q < \hat{p}_{10}^i(t) < p_{10}^i$. The last inequality follows from Lemma 8.
and
\[
\sum_{t=t+1}^{\infty} \mathbb{P}(A_t = i, \tilde{p}^*_1(t)) < \frac{\bar{p}^*_1(t)(p^1_{10} + \epsilon_q)}{p^*_0(t)}, \quad S_i(t) = 1, \quad S_1(t) = 1, E_{1,t},
\]
where the last inequality follows from Lemma 5.

Combining the upper bounds on individual elements of\( \sum_{t=t+1}^{\infty} \mathbb{P}(A_t = i, E_{1,t}) \) (Equations (8),(9),(11)-(12) and (13)), we obtain
\[
\mathbb{E}[T_i(n)] \leq \tau + \sum_{t=t+1}^{\infty} \mathbb{P}(E_{1,t}) + \sum_{t=t+1}^{\infty} \mathbb{P}(A_t = i, E_{1,t})
\]
\[
\leq \tau + \sum_{t=t+1}^{\infty} \mathbb{P}(E_{1,t}) + \frac{2}{\epsilon_p} + \frac{2}{\epsilon_q} + 4 \sum_{t=t+1}^{\infty} \mathbb{P}(F_{1,t})
\]
\[
+ \left( \frac{\log f(n)}{D(p^*_0 + \epsilon_1)(p^1_{10} + \epsilon_1)} - \tau \right)^+ + \left( \frac{\log f(n)}{D(p^*_0 + \epsilon_1)(p^1_{10} + \epsilon_1)} - \tau \right)^+ + \left( \frac{\log f(n)}{D(p^*_0 + \epsilon_1)(p^1_{10} + \epsilon_1)} - \tau \right)^+ + \left( \frac{\log f(n)}{D(p^*_0 + \epsilon_1)(p^1_{10} + \epsilon_1)} - \tau \right)^+.
\]
Choose \( \tau = t_1 + \max\{ \frac{\log f(n)}{D(p^*_0 + \epsilon_1)(p^1_{10} + \epsilon_1)}, \frac{\log f(n)}{D(p^*_0 + \epsilon_1)(p^1_{10} + \epsilon_1)}, \frac{\log f(n)}{D(p^*_0 + \epsilon_1)(p^1_{10} + \epsilon_1)}, \frac{\log f(n)}{D(p^*_0 + \epsilon_1)(p^1_{10} + \epsilon_1)} \} \).

Therefore, we obtain (using Equations (4) and (5)).
\[
\mathbb{E}[T_i(n)] \leq \tau + \frac{20}{\epsilon_1^2} + \frac{2}{\epsilon_p} + \frac{2}{\epsilon_q}
\]
\[
+ 10 \sum_{t=1}^{\infty} (t+1)^3 \exp(-2(t-1)\epsilon_1^2(p^1_{01} + p^1_{10})^2)
\]
\[
+ 10 \sum_{t=1}^{\infty} (t+1)^3 \exp(-2(t-1)\epsilon_1^2(p^1_{01} + p^1_{10})^2).
\]

We choose \( \epsilon_1 = \epsilon_p = \epsilon_q = \log^{-1/4}(n) \) to complete the proof.

2) i.i.d. Optimal and Truly Markovian Suboptimal Arms:
Similar to the first case, we prove that the expected number of times the optimal arm is in STP PHASE and the suboptimal arm is in SM PHASE, is finite. Let \( E_{2,t} := \{ H^2(p^*_0(t-1)|||p^2_{01} - p^1_{10}(-1)) \leq \frac{1}{(t-1)^{1/2}} \} \). Hence, for \( t_2 = \frac{1}{p^*_0 + p^1_{10} < 1} \),
\[
\sum_{t=t+1}^{\infty} \mathbb{P}(A_t = i, \tilde{p}^*_1(t)) < \frac{\bar{p}^*_1(t)(p^1_{10} + \epsilon_q)}{p^*_0(t)}, \quad S_i(t) = 1, \quad S_1(t) = 1, E_{2,t},
\]
where the last inequality follows from Lemma 6.
Subsequently, we have,

\[ \sum_{t=1}^{n} \mathbb{P}(A_t = i, \tilde{p}_{01}^t(t) > \frac{(\mu_1 - \epsilon_\mu)\tilde{p}_{10}^t(t)}{1 - \mu_1 + \epsilon_\mu}, S_t(t) = 0, E_{2,t}) \]

\[ = \sum_{t=1}^{n} \mathbb{P}(A_t = i, \tilde{p}_{01}^t(t) > \frac{(\mu_1 - \epsilon_\mu)\tilde{p}_{10}^t(t)}{1 - \mu_1 + \epsilon_\mu} , D(\tilde{p}_{01}^t(t)||\tilde{p}_{01}^* t(t)) \leq \log \frac{f(t)}{T(t - 1)}, S_t(t) = 0, E_{2,t}) \]

\[ \leq \sum_{t=1}^{n} \mathbb{P}(A_t = i, \tilde{p}_{01}^t(t) > \frac{(\mu_1 - \epsilon_\mu)\tilde{p}_{10}^t(t)}{1 - \mu_1 + \epsilon_\mu} , D(\tilde{p}_{01}^t(t)||\tilde{p}_{01}^* t(t)) \leq \log \frac{f(t)}{T(t - 1)} \]

\[ \leq \sum_{t=1}^{n} \mathbb{P}(A_t = i, \tilde{p}_{01}^t(t) > \frac{(\mu_1 - \epsilon_\mu)\tilde{p}_{10}^t(t)}{1 - \mu_1 + \epsilon_\mu} , D(\tilde{p}_{01}^t(t)||\tilde{p}_{01}^* t(t)) \leq \log \frac{f(n)}{T(t - 1)} \]

\[ \leq \sum_{t=1}^{n} \mathbb{P}(A_t = i, \tilde{p}_{01}^t(t) > \frac{(\mu_1 - \epsilon_\mu)\tilde{p}_{10}^t(t)}{1 - \mu_1 + \epsilon_\mu} , D(\tilde{p}_{01}^t(t)||\tilde{p}_{01}^* t(t)) \leq \log \frac{f(n)}{T(t - 1)} \]

\[ \leq \frac{\log f(n)}{D(p_{01}^t + \epsilon_1 || p_{01}^* + \frac{H^2(p_{10}^t(t) || p_{10}^* + \epsilon_1)}{f(p_{10}^t(t) || p_{10}^* + \epsilon_1)} - \tau)^+ + \sum_{t=1}^{n} \mathbb{P}(A_t = i, E_{3,t}) \]

where the first equality follows from the definition of \( \tilde{p}_{01}^t(t) \). The third inequality follows from the fact that \( D(x||p_0^* t(t)) \) is decreasing in \( x < \frac{1}{(1 - \mu_1 + \epsilon_\mu)} \) and \( p_{01}^t + \epsilon_1 < \frac{1}{(1 - \mu_1 + \epsilon_\mu)} \). The last inequality follows from Lemma 3.

In a similar manner, using Lemma 3, we get

\[ \sum_{t=1}^{n} \mathbb{P}(A_t = i, \tilde{p}_{01}^t(t) < \frac{\tilde{p}_{01}^t(t)(1 - \mu_1 + \epsilon_\mu)}{\mu_1 - \epsilon_\mu}, S_t(t) = 1 , E_{2,t}) \]

\[ \leq \frac{\log f(n)}{D(p_{01}^t - \epsilon_1 || p_{01}^* + \frac{H^2(p_{10}^t(t) || p_{10}^* + \epsilon_1)}{f(p_{10}^t(t) || p_{10}^* + \epsilon_1)} - \tau)^+ + \sum_{t=1}^{n} \mathbb{P}(A_t = i, E_{3,t}) \]

Combining Equations (17), (18) and (19), we obtain

\[ \mathbb{E}[T_i(n)] \leq \tau + \sum_{t=1}^{n} \mathbb{P}(E_{2,t}) + \sum_{t=1}^{n} \mathbb{P}(A_t = i, E_{2,t}) \]

\[ \leq \tau + \sum_{t=1}^{n} \mathbb{P}(E_{2,t}) + \frac{2}{\epsilon_\mu} \left( \frac{\log f(n)}{D(p_{01}^t + \epsilon_1 || p_{01}^* + \frac{H^2(p_{10}^t(t) || p_{10}^* + \epsilon_1)}{f(p_{10}^t(t) || p_{10}^* + \epsilon_1)} - \tau)^+ + \sum_{t=1}^{n} \mathbb{P}(A_t = i, E_{3,t}) \]

\[ + 2 \sum_{t=1}^{n} \mathbb{P}(A_t = i, E_{3,t}) \]

Choose \( \tau = t_2 + \max \{ \frac{\log f(n)}{D(p_{01}^t + \epsilon_1 || p_{01}^* + \frac{H^2(p_{10}^t(t) || p_{10}^* + \epsilon_1)}{f(p_{10}^t(t) || p_{10}^* + \epsilon_1)}}, \pi_0(0)D(p_{01}^t || p_{01}^* + \frac{H^2(p_{10}^t(t) || p_{10}^* + \epsilon_1)}{f(p_{10}^t(t) || p_{10}^* + \epsilon_1)} \} \}

The proof follows by choosing \( \epsilon_1 = \epsilon_\mu = \log^{-1/4}(n) \) and using Equations (14) and (15).

3) Truly Markovian and i.i.d Suboptimal Arms: Let \( E_{3,t} = \left\{ \frac{H^2(p_{01}^t(t) || p_{10}^t(t))}{(1 + t)^2} \rangle \rangle \frac{H^2(p_{01}^t(t) || p_{10}^t(t))}{(1 + t)^2} \right\} \)

Hence, for \( t_3 = \frac{1}{\mu_1 - \epsilon_\mu} \)

\[ \sum_{t=1}^{n} \mathbb{P}(E_{3,t}) \]

\[ \leq \frac{2}{\epsilon_\mu} \leq 2 \sum_{t=1}^{n} \mathbb{P}(A_t = i, E_{3,t}) \]

\[ \leq \frac{2}{\epsilon_\mu} + 2 \sum_{t=1}^{n} \mathbb{P}(A_t = i, E_{3,t}) \]

where the last inequality follows from Lemma 3.

Let \( F_{3,t} = \left\{ p_{01}^t(t) - p_{01}^t(t) \leq \epsilon_1, p_{10}^t(t) - p_{10}^t(t) \leq \epsilon_1 \right\} \)

\[ \sum_{t=1}^{n} \mathbb{P}(F_{3,t}) \]

\[ \leq \frac{2}{\epsilon_\mu} + 2 \sum_{t=1}^{n} \mathbb{P}(A_t = i, E_{3,t}) \]

where the last inequality follows from Lemma 3.

Similar to Equation (6).

After each arm is chosen once, a sub-optimal arm is chosen if at least one of the following conditions is true.

1. \( \tilde{p}_{01}^t(t) < p_{01}^t(t) - \epsilon_\mu \) and \( S_t(t) = 0 \)
2. \( \tilde{p}_{10}^t(t) > p_{10}^t(t) + \epsilon_\mu \) and \( S_t(t) = 1 \)
3. \( \mu^* = \frac{p_{10}^t(t) + p_{01}^t(t)}{p_{10}^t(t) + p_{01}^t(t)} \) and \( S_t(t) = 0 \)
4. \( \mu^* = \frac{p_{10}^t(t)}{p_{01}^t(t) + p_{10}^t(t)} \) and \( S_t(t) = 1 \).

Therefore,

\[ \sum_{t=1}^{n} \mathbb{P}(A_t = i, E_{3,t}) \]

\[ \leq \sum_{t=1}^{n} \mathbb{P}(A_t = i, \tilde{p}_{01}^t(t) < p_{01}^t(t) - \epsilon_\mu, S_t(t) = 0, E_{3,t}) \]

\[ + \mathbb{P}(A_t = i, \tilde{p}_{10}^t(t) > p_{10}^t(t) + \epsilon_\mu, S_t(t) = 1, E_{3,t}) \]

\[ + \mathbb{P}(A_t = i, \tilde{p}_{01}^t(t) > p_{01}^t(t) - \epsilon_\mu, S_t(t) = 0, E_{3,t}) \]

\[ + \mathbb{P}(A_t = i, \tilde{p}_{10}^t(t) > p_{10}^t(t) + \epsilon_\mu, S_t(t) = 1, E_{3,t}) \]

\[ \sum_{t=1}^{n} \mathbb{P}(A_t = i, \tilde{p}_{10}^t(t) < p_{10}^t(t) - \epsilon_\mu, S_t(t) = 0, E_{3,t}) \]

\[ \leq \sum_{t=1}^{n} \mathbb{P}(A_t = i, \tilde{p}_{10}^t(t) < p_{10}^t(t) - \epsilon_\mu, S_t(t) = 0, E_{3,t}) \]

\[ \leq \sum_{t=1}^{n} \mathbb{P}(A_t = i, \tilde{p}_{10}^t(t) < p_{10}^t(t) - \epsilon_\mu, S_t(t) = 0, E_{3,t}) \]

\[ \leq \frac{2}{\epsilon_\mu^2} \]
where the last inequality follows from Lemma 6. Similarly, using Lemma 7
\begin{equation}
\sum_{t=\tau+1}^{n} \mathbb{P}(A_t = i, \hat{\mu}^*(t) > p_{01}^{-1}(t) + \epsilon, S_1(t) = 1, E_{3,t}) \leq \frac{2}{\epsilon_2^2}.
\end{equation}
(23)

Subsequently, we have,
\begin{equation}
\sum_{t=\tau+1}^{n} \mathbb{P}(A_t = i, \hat{\mu}^*(t) > p_{01}^{-1}(t) + \epsilon, S_1(t) = 0, E_{3,t})
= \sum_{t=\tau+1}^{n} \mathbb{P}(A_t = i, \hat{\mu}^*(t) > p_{01}^{-1}(t) + \epsilon, \mu S_1(t) = 0, E_{3,t})
\end{equation}
\begin{equation}
D(\hat{\mu}^*(t)||\hat{\mu}^*(t)) \leq \frac{\log f(t)}{T_i(t-1)}, S_1(t) = 0, E_{3,t})
\end{equation}
\begin{equation}
\leq \sum_{t=\tau+1}^{n} \mathbb{P}(A_t = i, \hat{\mu}^*(t) > p_{01}^{-1}(t) + \epsilon, \mu S_1(t) = 0, E_{3,t})
\end{equation}
\begin{equation}
D(\hat{\mu}^*(t)||\hat{\mu}^*(t)) \leq \frac{\log f(t)}{T_i(t-1)} + \sum_{t=\tau+1}^{n} \mathbb{P}(F_i^{C, t})
\end{equation}
\begin{equation}
\leq \frac{1}{2\epsilon_1^2} + \left( \frac{\log f(n)}{D(\mu_i + \epsilon_1||\frac{p_{01}}{p_{01}+p_{10}} - \epsilon_1)} - \tau \right)^+
\end{equation}
(24)
where the first equality follows from the definition of $\hat{\mu}^*(t)$. The last inequality follows from Lemma 7. In a similar manner, we obtain
\begin{equation}
\sum_{t=\tau+1}^{n} \mathbb{P}(A_t = i, \hat{\mu}^*(t) > p_{01}^{-1}(t) + \epsilon, S_1(t) = 1, E_{3,t})
\end{equation}
\begin{equation}
\leq \frac{1}{2\epsilon_1^2} + \left( \frac{\log f(n)}{D(\mu_i + \epsilon_1||\frac{p_{01}}{p_{01}+p_{10}} + \epsilon_1)} - \tau \right)^+
\end{equation}
(25)
Combining Equations (24), (23), (24) and (25), we obtain
\begin{equation}
\mathbb{E}[T_i(n)] \leq \tau + \sum_{t=\tau+1}^{n} \mathbb{P}(E_i^{C, t}) + \sum_{t=\tau+1}^{n} \mathbb{P}(A_t = i, E_{3,t})
\end{equation}
\begin{equation}
\leq \tau + \sum_{t=\tau+1}^{n} \mathbb{P}(E_i^{C, t}) + \frac{1}{\epsilon_2^2} + \frac{2}{\epsilon_1^2} + \frac{1}{\epsilon_1}
\end{equation}
\begin{equation}
+ \left( \frac{\log f(n)}{D(\mu_i + \epsilon_1||\frac{p_{01}}{p_{01}+p_{10}} + \epsilon_1)} - \tau \right)^+
\end{equation}
\begin{equation}
+ \left( \frac{\log f(n)}{D(\mu_i + \epsilon_1||\frac{p_{01}}{p_{01}+p_{10}} + \epsilon_1)} - \tau \right)^+ + 2 \sum_{t=\tau+1}^{n} \mathbb{P}(F_i^{C, t}).
\end{equation}
Choose $\tau = t_3 + \max\left\{ \frac{\log f(n)}{D(\mu_i + \epsilon_1||\frac{p_{01}}{p_{01}+p_{10}} + \epsilon_1)}, \mu, D(\mu_i||p_{01} + (1-\mu_i)D(1-\mu_i||p_{10})) \right\},$

The proof follows by choosing $\epsilon_1 = \epsilon_p = \epsilon_q = \log^{-1/4}(n)$ and using Equations (20) and (21).

4) i.i.d. Arms: Let $E_{4,t} := \{H^2(\hat{\mu}^*(t)) < 1 - \hat{\mu}^*(t) \leq \frac{1}{(t+1)^1/4}, H^2(\hat{\mu}^*(t)) < 1 - \hat{\mu}^*(t) \leq \frac{1}{(t+1)^1/4} \}.
\begin{equation}
\sum_{t=1}^{n} \mathbb{P}(E_{4,t})
\end{equation}
\begin{equation}
\leq \sum_{t=1}^{n} 8 \exp(-\frac{2}{9} \sqrt{t}) + 2 \sum_{t=1}^{n} (t+1)^3 \exp(-2\sqrt{t-1}),
\end{equation}
where the last inequality follows from Lemma 6. Similar to Equation (6),
\begin{equation}
\mathbb{E}[T_i(n)] \leq \tau + \sum_{t=\tau+1}^{n} \mathbb{P}(E_{4,t}) + \sum_{t=\tau+1}^{n} \mathbb{P}(A_t = i, E_{4,t})
\end{equation}
\begin{equation}
\leq \sum_{t=\tau+1}^{n} \mathbb{P}(A_t = i, \hat{\mu}^*(t) < \mu_1 - \epsilon_1, E_{4,t})
\end{equation}
\begin{equation}
+ \sum_{t=\tau+1}^{n} \mathbb{P}(A_t = i, \hat{\mu}^*(t) > \mu_1 - \epsilon_1, E_{4,t}).
\end{equation}
We now proceed to analyze individual terms of Equation (27),
\begin{equation}
\sum_{t=\tau+1}^{n} \mathbb{P}(A_t = i, \hat{\mu}^*(t) < \mu_1 - \epsilon_1, E_{4,t}) \leq \frac{2}{\epsilon_2^2},
\end{equation}
where the last inequality follows from Lemma 6. Subsequently, we have,
\begin{equation}
\sum_{t=\tau+1}^{n} \mathbb{P}(A_t = i, \hat{\mu}^*(t) > \mu_1 - \epsilon_1, E_{4,t})
\end{equation}
\begin{equation}
\leq \sum_{t=\tau+1}^{n} \mathbb{P}(A_t = i, \hat{\mu}^*(t) > \mu_1 - \epsilon_1, E_{4,t})
\end{equation}
\begin{equation}
D(\hat{\mu}^*(t)||\hat{\mu}^*(t)) \leq \frac{\log f(t)}{T_i(t-1)}
\end{equation}
\begin{equation}
\leq \frac{1}{2\epsilon_1^2} + \left( \frac{\log f(n)}{D(\mu_i + \epsilon_1||\mu_1 - \epsilon_1) - \tau} \right)^+, where the first inequality follows from the definition of $\hat{\mu}^*(t)$. The last inequality follows from Lemma 6. Combining Equations (28) and (29), we obtain
\begin{equation}
\mathbb{E}[T_i(n)] \leq \tau + \sum_{t=\tau+1}^{n} \mathbb{P}(E_{4,t}) + \sum_{t=\tau+1}^{n} \mathbb{P}(A_t = i, E_{4,t})
\end{equation}
\begin{equation}
\leq \tau + \sum_{t=\tau+1}^{n} \mathbb{P}(E_{4,t}) + \frac{2}{\epsilon_2^2} + \frac{1}{\epsilon_1}
\end{equation}
\begin{equation}
+ \left( \frac{\log f(n)}{D(\mu_i + \epsilon_1||\mu_1 - \epsilon_1) - \tau} \right)^+
\end{equation}
The proof follows by choosing $\tau = \frac{\epsilon_1}{D(\mu_i + \epsilon_1||\mu_1 - \epsilon_1)}, \epsilon_1 = \epsilon_1 = \mu_1 = \log^{-1/4}(n)$ and using Equation (26).
Remark 2. Note that multiplicative factors $\mathbb{1}\{p_{01}^i < p_{10}^i\}$ and $\mathbb{1}\{\mu_1 p_0^i < 1 - \mu_1\}$ are required because the corresponding $D(\cdot\|\cdot)$ do not exist when $\frac{\hat{\mu}_1 p_0^i}{p_1^i}$ and $\frac{\hat{\mu}_1 p_0^i}{1 - \mu_1}$ become more than or equal to 1.

Remark 3. Note that the upper bound on the regret of H-KL-UCB matches the lower bound [8] when all arm rewards are i.i.d. Therefore, our algorithm is optimal for i.i.d. arm rewards.

The next theorem analytically verifies that our bounds are better than the state-of-the-art for a large class of problem parameters. The cases not covered in the theorem are explored in simulations later.

**Theorem 2.** Let the eigenvalue gap of $i$th arm be $\sigma_i$.

1) Truly Markovian suboptimal arms: The asymptotic upper bound on the regret of H-KL-UCB is smaller than that of [10] (we call it UCB-SM) when $\min\sigma_i \geq \frac{1}{2880}$.

2) i.i.d. suboptimal arms: The asymptotic upper bound on the regret of H-KL-UCB is always smaller than that of UCB-SM.

**Proof.** Proof is given in Appendix I. □

**IV. Experimental Evaluation**

In this section, we compare the performance of our algorithm (H-KL-UCB) with UCB policy (UCB-SM) in [10]. We also consider an improvement over [10] (referred to as KL-UCB-SM) in [8]) in the sense that the upper confidence bound on the sample mean is replaced by the KL distance. Specifically, arm $A_t$ is chosen at time $t$ using the following scheme:

$$A_t = \arg\max_{i} \max\{\hat{\mu}_i : D(\hat{\mu}_i(t-1)\|\hat{\mu}_i) \leq \frac{\log T(t-1)}{\sigma_i}\}.$$  

Another algorithm (referred to as KL-UCB-SM2) considered by us is a modification of the algorithm in [13] under the condition that only one arm can be played at a time. We consider two scenarios and average the result over 100 runs.

**Scenario 1:** $p_{01}^1 = 0.5, p_{02}^1 = 0.4, p_{10}^1 = 0.3, p_{01}^2 = 0.2, p_{01}^3 = 0.1, p_{10}^3 = 0.4, p_{02}^3 = 0.5, p_{10}^3 = 0.65, p_{01}^4 = 0.65, p_{10}^4 = 0.7$.

**Scenario 2:** $p_{01}^1 = 0.5, p_{02}^1 = 0.0004, p_{01}^3 = 0.0003, p_{01}^4 = 0.0002, p_{01}^5 = 0.0001, p_{10}^1 = 0.4, p_{02}^1 = 0.00055, p_{10}^3 = 0.00065, p_{10}^4 = 0.0005, p_{10}^5 = 0.0007$.

In the first scenario (Fig. 1a and 1c), H-KL-UCB significantly outperforms other algorithms. Due to the consideration of KL distance for designing a test to detect whether an arm is truly Markovian, one should switch to sample mean based KL-UCB approach to exploit the additional information regarding the arms. We design the algorithm in such a manner that it works well for both scenarios. When the arms are i.i.d., the SM_PHASE is chosen infinitely often by the optimal arm. On the contrary, for the truly Markovian case, we establish that the optimal arm chooses the STP_PHASE infinitely often.

The proposed H-KL-UCB policy is provably order-optimal. The upper bound on the regret of our policy holds uniformly over time. We prove that the asymptotic upper bound on the regret is lower than that of UCB-SM [10] under some assumptions on the eigenvalue gaps of the Markov chains. We also demonstrate using experiments that when the assumption does not hold true, then also the asymptotic upper bound on the regret is lower than that of UCB-SM [10]. In the i.i.d. case, the upper bound on the regrets of KL-UCB-SM and H-KL-UCB matches the lower bound.

For H-KL-UCB, we initialize the estimates of $p_{01}$ and $p_{10}$ to 1. This is done to overcome the issue of high regret associated with zero initialization arising due to high sojourn time in a state when $p_{01}$ and $p_{10}$ of suboptimal arms are close to 0.

**V. Discussions**

H-KL-UCB uses the Hellinger distance between sample estimates of $p_{01}$ and $(1 - p_{10})$ of arm $i$ to switch from STP_PHASE to SM_PHASE. Arm $i$ can be represented uniquely using $p_{01}$ and $p_{10}$. However, if the arm reward is i.i.d. (special case of Markovian reward), then we can represent an arm uniquely using a single parameter, viz., the mean reward. Therefore, if we use the STP_PHASE for i.i.d. arms, then the regret may be large since we do not exploit the additional information that the arms are i.i.d. In that scenario, intuitively, one should switch to sample mean based KL-UCB approach to exploit the additional information regarding the arms. We design the algorithm in such a manner that it works well for both scenarios. When the arms are i.i.d., the SM_PHASE is chosen infinitely often by the optimal arm. On the contrary, for the truly Markovian case, we establish that the optimal arm chooses the STP_PHASE infinitely often.

Another approach is to exploit the additional information regarding the arms. We design the algorithm in such a manner that it works well for both scenarios. When the arms are i.i.d., the SM_PHASE is chosen infinitely often by the optimal arm. On the contrary, for the truly Markovian case, we establish that the optimal arm chooses the STP_PHASE infinitely often.

In this paper, we have designed an algorithm which achieves a significant improvement over state-of-the-art bandit algorithms. The proposed algorithm detects whether the arm reward is truly Markovian or i.i.d. using a Hellinger distance based test. It switches form the standard KL-UCB to a sample transition probability based KL-UCB when it detects that the arm reward is truly Markovian. Logarithmic upper bounds on the regret of the algorithm have been derived for i.i.d. and Markovian settings. The upper bound on the regret of H-KL-UCB matches the lower bound when all arm rewards are i.i.d. Whether instead of Hellinger distance, one can use other metrics such as KL distance for designing a test to detect whether an arm is truly Markovian or i.i.d., remains an open problem.
We do not assume that the transition functions belong to a single-parameter family. Therefore, the lower bound derived in this paper is applicable to a larger class of transition functions (class of irreducible Markov chains) than \([11]\).

The result obtained can be extended easily to a pair of arms. Let \(\mathcal{M}\) be a set of 0 - 1 irreducible Markov chains. Let \(\gamma : \mathcal{M} \rightarrow \mathcal{R}\) be a function which maps \(M \in \mathcal{M}\) to the mean (which is the steady state stationary probability of state 1 of \(M\)) of \(M\). Let \(\mathcal{E} = \mathcal{M}_1 \times \mathcal{M}_2\) where \(\mathcal{M}_1\) and \(\mathcal{M}_2\) are sets of 0 - 1 Markov chains corresponding to arm 1 and arm 2, respectively. Let \(E_0 = (M_1, M_2) \in \mathcal{E}\) such that \(\gamma(M_1) = \mu_1\) and \(\gamma(M_2) = \mu_2\), where \(\mu_1 > \mu_2\). Let \(E_1 = (M_1', M_2')\) be such that \(M_1'\) is identical to \(M_1\) and \(\gamma(M_2') = \mu_1 + \epsilon\), where \(\epsilon > 0\). Note that we consider the two-arm case for the sake of simplicity. The result obtained can be extended easily to \(K\) arms by constructing a \(K\) dimensional space of Markov chains.

Let \(T_{i,N}\) be the number of times arm \(i\) is played till time \(N\). The result will follow if we can show that

\[
\liminf_{n \to \infty} \frac{\mathbb{E}_0[T_{2,N}]}{\log n} \geq \frac{1}{\inf \{I(M_2||M_2') : \gamma(M_2') > \mu_1\}}.
\]

where \(\mathbb{E}_0\) denotes the expectation operator under the probability distribution associated with \(E_0\). Let \(\mathbb{P}_0\) and \(\mathbb{P}_1\) denote the probability distributions under \(E_0\) and \(E_1\), respectively. Hence, \(D(\mathbb{P}_0||\mathbb{P}_1) = \mathbb{E}_0(\log \frac{\mathbb{P}_0(F_N)}{\mathbb{P}_1(F_N)})\), where \(F_N\) is the history of \(N\) arm pulls. Let \(F_{2,N}\) be the part of history till time \(N\) when arm 2 is played. Then, \(\frac{\mathbb{P}_0(F_N)}{\mathbb{P}_1(F_N)} = \frac{\mathbb{P}_0(F_{2,N})}{\mathbb{P}_1(F_{2,N})}\) (since arm 1 is identical in both the cases, and probabilities associated with \(\alpha\) (if randomized) also cancel in the numerator and denominator).

Let \(t_{ij}^{(N)}\) be the number of times arm 2 transitions from state \(i\) to state \(j\) in \(F_{2,N}\). Let \(p_{ij}(k)\) be the probability of

\[
\liminf_{n \to \infty} \frac{\mathbb{E}_0[t_{ij}^{(N)}]}{\log n} \geq \frac{1}{\inf \{I(M_2||M_2') : \gamma(M_2') > \mu_1\}}.
\]

\[
\liminf_{n \to \infty} \frac{\mathbb{E}_0[t_{ij}^{(N)}]}{\log n} \geq \frac{1}{\inf \{I(M_2||M_2') : \gamma(M_2') > \mu_1\}}.
\]
transition from state $i$ to state $j$ of arm 2 under $E_k$. Then,
\[
\frac{P_0(F_N)}{P_1(F_N)} = \prod_{(i,j) \in S} \left( \frac{p_{ij}(0)}{p_{ij}(1)} \right)^{t_{ij}^{(N)}}.
\]
Hence,
\[
\log \frac{P_0(F_N)}{P_1(F_N)} = \sum_{(i,j) \in S} t_{ij}^{(N)} \log \frac{p_{ij}(0)}{p_{ij}(1)}.
\]
and
\[
D(P_0||P_1) = \sum_{(i,j) \in S} E_0(t_{ij}^{(N)}) \log \frac{p_{ij}(0)}{p_{ij}(1)}.
\]
We know that for any event $A$ [18 Chapter 14],
\[
P_0(A) + P_1(A^C) \geq \frac{1}{2} \exp(-D(P_0||P_1)).
\]
Therefore, for any event $A$,
\[
P_0(A) + P_1(A^C) \geq \frac{1}{2} \exp \left( - \sum_{(i,j) \in S} E_0(t_{ij}^{(N)}) \log \frac{p_{ij}(0)}{p_{ij}(1)} \right).
\]
Choose $A = \{T_{1N} \leq T_{2N}\}$. We have,
\[
P_0(A) = P_0(T_{1N} \leq T_{2N}) = P_0(T_{2N} \geq N) = \frac{2}{N} E_0(T_{2N}) = \frac{2}{N} o(N^\beta),
\]
where the second and last equalities follow from $T_{1N} + T_{2N} = N$ and the property of uniformly good policy, respectively. The inequality is a direct application of Markov’s inequality. Similarly,
\[
P_1(A^C) = P_1(T_{1N} \geq T_{2N}) = P_1(T_{1N} \geq N) = \frac{2}{N} E_1(T_{1N}) = \frac{2}{N} o(N^\beta).
\]
Thus, if the policy is uniformly good, then (using Equations [30] and [31]),
\[
\frac{2}{N} o(N^\beta) \geq \frac{1}{2} \exp \left( - \sum_{(i,j) \in S} E_0(t_{ij}^{(N)}) \log \frac{p_{ij}(0)}{p_{ij}(1)} \right).
\]
Hence,
\[
\sum_{(i,j) \in S} E_0(t_{ij}^{(N)}) \log \frac{p_{ij}(0)}{p_{ij}(1)} \geq \log N - \log o(N^\beta) - 4.
\]
Taking appropriate limits we obtain,
\[
\lim_{N \to \infty} \frac{1}{\log N} \sum_{(i,j) \in S} E_0(t_{ij}^{(N)}) \log \frac{p_{ij}(0)}{p_{ij}(1)} \geq 1.
\]
Let $\tau_i^{(N)}$ be the number of times arm 2 is chosen while it was in state $i \in S$ in the first $(N-1)$ plays in the history. Then,
\[
E_0(t_{ij}^{(N)}) = p_{ij}(0) E_0(\tau_i^{(N)}).
\]
Now,
\[
\sum_{(i,j) \in S} E_0(t_{ij}^{(N)}) \log \frac{p_{ij}(0)}{p_{ij}(1)} = \sum_{i \in S} E_0(\tau_i^{(N)}) D(p_{i0}(0)||p_{i0}(1)).
\]
Hence,
\[
\lim_{N \to \infty} \frac{1}{\log N} \sum_{i \in S} E_0(\tau_i^{(N)}) D(p_{i0}(0)||p_{i0}(1)) \geq 1.
\]
We define the regret as $R_\alpha(n) = (\mu_1 - \mu_2)(E_0(\tau_0^{(N)}) + E_0(\tau_1^{(N)}))$ since the regret depends on the number of times arm 2 is chosen.

An asymptotic lower bound on the regret can be obtained by solving the following optimization problem.
\[
\min_{\epsilon > 0, p_{01}(1), p_{10}(1)} (\mu_1 - \mu_2)(x + y)
\]
such that
\[
x D(p_{00}(0)||p_{00}(1)) + y D(p_{10}(0)||p_{10}(1)) \geq 1,
\]
\[
p_{01}(1)(\mu_1 + \epsilon) = p_{10}(1)(1 - \mu_1 - \epsilon),
\]
\[
p_{00}(1) + p_{01}(1) = 1,
\]
\[
p_{10}(1) + p_{11}(1) = 1,
\]
and $p_{ij}(1) \geq 0 \forall i, j$.

Dividing the first constraint by $(x + y)$ on both sides we get,
\[
(x + y) \geq \frac{1}{x+y} D(p_{00}(0)||p_{00}(1)) \leq \frac{1}{x+y} D(p_{01}(0)||p_{10}(1)) + \frac{1}{x+y} D(p_{10}(0)||p_{10}(1)).
\]
Since $\frac{x}{x+y} = \pi_2(0)$ and $\frac{y}{x+y} = \pi_2(1)$, we have,
\[
(x + y) \geq \frac{1}{\pi_2(0) D(p_{00}(0)||p_{00}(1)) + \pi_2(1) D(p_{10}(0)||p_{10}(1))}.
\]
Instead of perturbing the mean of arm 1 (with transition probability functions $p_{01}^1$ and $p_{10}^1$) by $\epsilon$, we can consider a new Markov chain with transition probabilities $p_{01}^1$ and $p_{10}^1$. For fixed values of these parameters, we get
\[
(x + y) \geq \frac{1}{\pi_2(0) D(p_{01}^1||p_{10}^1) + \pi_2(1) D(p_{10}^1||p_{10}^1)}.
\]
Therefore, the optimization problem reduces to the following problem
\[
\inf_{p_{01}^1, p_{10}^1} \frac{1}{\pi_2(0) D(p_{01}^1||p_{01}^1) + \pi_2(1) D(p_{10}^1||p_{10}^1)}
\]
such that the stationary probability of state 1 under the transition law ($p_{01}^1, p_{10}^1)$ is greater than that under ($p_{01}^1, p_{10}^1$).

Assume that the constraint becomes an equality under the optimal solution. Then, we have,
\[
R_\alpha(n) \geq \frac{(\mu_1 - \mu_2)}{\pi_2(0) D(p_{01}^1||p_{01}^1) + \pi_2(1) D(p_{10}^1||p_{10}^1)}
\]
\[
= \frac{(\mu_1 - \mu_2)}{T(M_2||M_1)}.
\]
This completes the proof of the theorem. □
APPENDIX B
PROOF OF LEMMA 3

We first compute the probability that the Markov chain observes the sequence \( m_1, m_2, \ldots, m_t \). Let \( \hat{\pi}(i, t) = \frac{N_i(t)}{N(t)} \).

\[
\mathbb{P}(\{M_1, M_2, \ldots, M_t\} = \{m_1, m_2, \ldots, m_t\}) \\
= \mathbb{P}(M_2 = m_2 | M_1 = m_1) \ldots \mathbb{P}(M_t = m_t | M_{t-1} = m_{t-1}) \\
= \exp(\sum_{(i,j) \in S} N_{ij}(t) \log P_{ij}) \\
= \exp((t-1) \sum_{i \in S} \hat{\pi}(i, t) \sum_{j \in S} \hat{P}_{ij}(t) \log P_{ij}).
\] (32)

Let \( T = \{\hat{\pi}(i, t), \hat{P}_{ij}(t)\} \) be the type of the sequence. We want to find the number of sequences that have type \( T \). We consider a Markov chain where the transition probability from state \( i \) to state \( j \) is \( \hat{P}_{ij}(t) \). Let \( N(T) \) be the number of sequences whose type is \( T \). We have,

\[
1 \geq N(T) \exp((t-1) \sum_{i \in S} \hat{\pi}(i, t) \sum_{j \in S} \hat{P}_{ij}(t) \log \hat{P}_{ij}(t)).
\] (33)

Let \( \mathcal{H} \) be the set of types which satisfy \( |\frac{N_0(t)}{t-1} - \pi_0| > \epsilon_1 \). Clearly, types in \( \mathcal{H} \) also satisfy \( |\frac{N_i(t)}{t-1} - \pi_1| > \epsilon_1 \). Hence,

\[
\mathbb{P}(\frac{N_0(t)}{t-1} - \pi_0 > \epsilon_1) = \sum_{T \in \mathcal{H}} N(T) P(T) \\
= \sum_{T \in \mathcal{H}} \exp(-(t-1)(\hat{\pi}(0,0) D(\hat{P}_{00}(0)||P_00) \\
+ (t-1) D(\hat{P}_0(0)||P_00))) \\
\leq (t+1)^3 \exp(-(t-1) \min_{T \in \mathcal{H}} \hat{\pi}(0,0) D(\hat{P}_0(0)||P_00) \\
+ \hat{\pi}(0,0) D(\hat{P}_0(0)||P_00)),
\]

where the second equality follows from Equations (32) and (33). The inequality follows since each of \( \hat{P}_0(0), P_0(0), \pi(0,0) \) can take \( (t+1) \) possible values and hence, \( |\mathcal{H}| \leq (t+1)^3 \). Therefore the problem reduces to the following problem.

\[
\min_{x,y} \frac{y}{x+y} D(x||P_00) + \frac{x}{x+y} D(y||P_00), \\
\text{subject to } |\frac{y}{x+y} - \pi_0| > \epsilon_1, |\frac{x}{x+y} - \pi_1| > \epsilon_1,
\]

\[
x \geq 0, y \geq 0, \\
x \leq 1, y \leq 1.
\]

Let \((x^*, y^*)\) be a solution to the above problem. Using Pinsker’s inequality, we obtain \( D(x^*||P_00) \geq 2(x^* - P_{00})^2 \) and \( D(y^*||P_00) \geq 2(y^* - P_{00})^2 \). We know that

\[
(x^* - P_{00} + P_{10})^2 > \epsilon_1^2 \text{ and } (x^* + y^* - P_{00} + P_{10})^2 > \epsilon_1^2.
\]

\[
\frac{P_{00}}{P_{00} + P_{10}} \left( \frac{x^*}{P_{00} + P_{10}} - \frac{P_{00}}{P_{00} + P_{10}} \right)^2 \\
= \left( x^* \frac{P_{00}}{P_{00} + P_{10}} - x^* \frac{P_{00}}{P_{00} + P_{10}} \right)^2 \\
+ 2( \frac{P_{00}}{P_{00} + P_{10}} - \frac{P_{00}}{P_{00} + P_{10}} ) ( x^* \frac{P_{00}}{P_{00} + P_{10}} - y^* \frac{P_{00}}{P_{00} + P_{10}} ) \\
\geq \epsilon_1^2 + 2( \frac{P_{00}}{P_{00} + P_{10}} - \frac{P_{00}}{P_{00} + P_{10}} ) \left( x^* \frac{P_{00}}{P_{00} + P_{10}} - y^* \frac{P_{00}}{P_{00} + P_{10}} \right),
\] (34)

where the inequality follows since \( (x^* - P_{00} + P_{10})^2 \geq 0 \).

Similarly, we obtain

\[
\frac{P_{00}}{P_{00} + P_{10}} \left( \frac{P_{00}}{P_{00} + P_{10}} - \frac{P_{00}}{P_{00} + P_{10}} \right)^2 \\
> (1 - \pi_0) \left( \frac{y^*}{P_{00} + P_{10}} - \frac{y^*}{P_{00} + P_{10}} \right)^2 \\
\geq \epsilon_1^2 + 2( \frac{P_{00}}{P_{00} + P_{10}} - \frac{P_{00}}{P_{00} + P_{10}} ) \left( x^* \frac{P_{00}}{P_{00} + P_{10}} - y^* \frac{P_{00}}{P_{00} + P_{10}} \right),
\]

where the first inequality follows from the fact if \( \hat{P}_0(0) \geq 1 - \pi_0(0) \), then \( H^2(P_0(t)||1 - \hat{P}_0(0)) \leq P_0(t) + P_0(t) - 1 \), else \( H^2(P_0(t)||1 - \hat{P}_0(0)) \leq 1 - \hat{P}_0(t) - \hat{P}_0(0) \).

The rest of the proof follows immediately.

APPENDIX C
PROOF OF LEMMA 4

We take \( C_t := \{ |\frac{N_0(t)}{t-1} - \pi_0| > \epsilon_1 \} \). Therefore,

\[
\sum_{t=1}^{\infty} \mathbb{P}(D_{0,t}) = \sum_{t=1}^{\infty} \mathbb{P}(D_{0,t}, C_t) + \mathbb{P}(D_{0,t}, C_t) \\
\leq \sum_{t=1}^{\infty} \sum_{t=1}^{\infty} \mathbb{P}(\hat{P}_0, N_0(t) - P_00 > \epsilon_1, |\frac{N_0(t)}{t-1} - \pi_0| = \epsilon_1 + \sum_{t=1}^{\infty} \mathbb{P}(C_t) \\
\leq \sum_{t=1}^{\infty} 2 \epsilon_1^2 + \sum_{t=1}^{\infty} |C_t|, \\
\leq 1 \epsilon_1^2 + \sum_{t=1}^{(t-1)^3} \epsilon_1^2 (P_{00} + P_{10})^2,
\]

where the third inequality follows from Lemma 1 and the last inequality follows from Lemma 2. Proof for \( \sum_{t=1}^{\infty} \mathbb{P}(D_{1,t}) \) follows in a similar manner.

APPENDIX D
PROOF OF LEMMA 5

Case 1: \( P_{01} + P_{10} = 1 \)

\[
H^2(\hat{P}_0(t)||1 - \hat{P}_0(t)) \\
= 1 - \sqrt{\hat{P}_0(t)(1 - \hat{P}_0(t))} - \sqrt{(1 - \hat{P}_0(t))\hat{P}_0(t)} \\
\leq |\hat{P}_0(t) - \hat{P}_0(t) - 1| \\
\leq |\hat{P}_0(t) - P_{00}| + |\hat{P}_0(t) - P_{10}| + |P_{00} + P_{10} - 1|,
\]

where the first inequality follows from the fact if \( \hat{P}_0(t) \geq 1 - P_{00}(t) \), then \( H^2(P_0(t)||1 - \hat{P}_0(t)) \leq P_{00}(t) + P_{00}(t) - 1 \), else \( H^2(P_0(t)||1 - \hat{P}_0(t)) \leq 1 - \hat{P}_0(t) - \hat{P}_0(t) \). The second
inequality follows from the triangle inequality. We take $C_t := \{ |N_i(t) - \pi_0| > \epsilon \}$ and $\epsilon = \frac{1}{(t-1)^{1/4}}$. Hence,

\[
\sum_{t=1}^{n} \mathbb{P}(H^2(\hat{P}_0(t)||1 - \hat{P}_0(t)) \geq \frac{1}{t^{1/4}})
\]

\[
\leq \sum_{t=1}^{n} \mathbb{P}(|\hat{P}_0(t) - P_0| + |\hat{P}_0(t) - P_0|)
\]

\[
+ |P_0 + P_0 - 1| \geq \frac{1}{t^{1/4}}(C_t) + \mathbb{P}(C_t)
\]

\[
< \sum_{t=1}^{n} \mathbb{P}(3|\hat{P}_{01,N_0(t)} - P_0| \geq \frac{1}{t^{1/4}}, |N_i(t) - \pi_0| \leq \epsilon) + \mathbb{P}(C_t)
\]

\[
< \sum_{t=1}^{n} \mathbb{P}(3|\hat{P}_{01,N_1(t)} - P_0| \geq \frac{1}{t^{1/4}}, |N_i(t) - \pi_1| \leq \epsilon) + \mathbb{P}(C_t)
\]

The rest of the proof follows from Lemma 4.

**APPENDIX E**

**PROOF OF Lemma 6**

\[
\mathbb{P}(\hat{p}_s < p - \epsilon_p) \leq \mathbb{P}(D(\hat{p}_s||p - \epsilon_p) > \frac{\log f(t)}{s}, \hat{p}_s < p - \epsilon_p)
\]

\[
\leq \sum_{s=1}^{n} \mathbb{P}(D(\hat{p}_s||p) > \frac{\log f(t)}{s} + 2\epsilon_p^2, \hat{p}_s < p)
\]

\[
< \sum_{s=1}^{n} \exp(-s(2\epsilon_p^2 + \frac{\log f(t)}{s}))
\]

\[
< \sum_{s=1}^{n} \frac{1}{f(t)} \exp(-2s\epsilon_p^2) \leq \frac{1}{2\epsilon_p^2 f(t)},
\]

where the second and fourth inequalities follow from Lemma 1 and Corollary 1, respectively. The last inequality uses the fact that \(\sum_{s=1}^{\infty} \exp(-sx) = \frac{1}{1-x} \leq \frac{1}{x} \). Hence,

\[
\sum_{s=1}^{n} \mathbb{P}(\hat{p}_s < p - \epsilon_p) \leq \sum_{s=1}^{n} \frac{1}{2\epsilon_p^2 f(t)} \leq \int_{-\infty}^{\infty} \frac{dt}{2\epsilon_p^2 f(t)} \leq \frac{2}{\epsilon_p^2}.
\]

The last inequality follows from the fact that \(1 + x \log^2(x) \geq x \log^2(x) \) and \( \int_{-\infty}^{\infty} \frac{dt}{x \log^2(x)} = 1 \).

**APPENDIX F**

**PROOF OF Lemma 7**

\[
\mathbb{P}(q_s^* > q + \epsilon_q) \leq \mathbb{P}(D(q_s||q + \epsilon_q) > \frac{\log f(t)}{s}, q_s > q + \epsilon_q)
\]

\[
\leq \mathbb{P}(D(q_s||q) > \frac{\log f(t)}{s} + 2\epsilon_q^2, q_s > q)
\]

\[
< \sum_{s=1}^{n} \mathbb{P}(D(q_s||q) > \frac{\log f(t)}{s} + 2\epsilon_q^2, q(s) > q)
\]

\[
\leq \sum_{s=1}^{n} \exp(-s(2\epsilon_q^2 + \frac{\log f(t)}{s})) \leq \frac{1}{2\epsilon_q^2 f(t)},
\]

where the second and fourth inequalities follow from Lemma 1 and Corollary 1, respectively. The rest of the proof is similar to Lemma 6.

**APPENDIX G**

**PROOF OF Lemma 8**

\[
\kappa_1 \leq \sum_{s=1}^{n} \mathbb{P}(D(p_2 + \epsilon_1|| \frac{(p_1 - \epsilon_p)(q_2 - \epsilon_q)}{q_1 + \epsilon_1}) \leq \frac{a}{s})
\]

\[
= \left( \frac{a}{D(p_2 + \epsilon_1|| \frac{(p_1 - \epsilon_p)(q_2 - \epsilon_q)}{q_1 + \epsilon_1}) - (c-1)^+} \right),
\]

where the inequality follows from the fact that \( D(p_2 + \epsilon_1|| \frac{(p_1 - \epsilon_p)(q_2 - \epsilon_q)}{q_1 + \epsilon_1}) + Z(s) \leq \frac{a}{s} \) implies
\( D(p_2 + \epsilon_1 \frac{(p_1 - \epsilon_2)(q_2 - \epsilon_1)}{q_1 + \epsilon_1}) \leq \frac{a}{s} \). The equality follows since \( P(D(p_2 + \epsilon_1 \frac{(p_1 - \epsilon_2)(q_2 - \epsilon_1)}{q_1 + \epsilon_1}) \leq \frac{a}{s}) \) is either 0 or 1 depending on the value of \( s \).

\[
\kappa_2 \leq \sum_{s=1}^{n} \sum_{c} P(D(q_2 - \epsilon_1 \frac{(q_1 + \epsilon_1)(p_2 + \epsilon_1)}{p_1 - \epsilon_p}) \leq \frac{a}{s}
\]

\[
= \left( \frac{a}{D(q_2 - \epsilon_1 \frac{(q_1 + \epsilon_1)(p_2 + \epsilon_1)}{p_1 - \epsilon_p})} \right) - (c-1)^+,
\]

where the inequality follows since \( D(q_2 - \epsilon_1 \frac{(q_1 + \epsilon_1)(p_2 + \epsilon_1)}{p_1 - \epsilon_p}) \leq \frac{a}{s} \) implies \( D(q_2 - \epsilon_1 \frac{(q_1 + \epsilon_1)(p_2 + \epsilon_1)}{p_1 - \epsilon_p}) \leq \frac{a}{s} \).

\textbf{APPENDIX H}

\textbf{PROOF OF LEMMA [2]}

\[
\kappa_3 \leq \sum_{s=1}^{n} \sum_{c} P(D(\hat{\mu}_s \frac{p - \epsilon_p}{p - \epsilon_p + q + \epsilon_1}) \leq \frac{a}{s})
\]

\[
\leq \sum_{s=1}^{n} \sum_{c} P(D(\hat{\mu}_s \frac{p - \epsilon_p}{p - \epsilon_p + q + \epsilon_1}) \leq \frac{a}{s}, \hat{\mu}_s < \mu + \epsilon_1)
\]

\[
+ \sum_{s=1}^{n} \sum_{c} P(D(\hat{\mu}_s \frac{p - \epsilon_p}{p - \epsilon_p + q + \epsilon_1}) \leq \frac{a}{s}, \hat{\mu}_s \geq \mu + \epsilon_1)
\]

\[
\leq \sum_{s=1}^{n} \sum_{c} \left( \frac{a}{D(\mu + \epsilon_1 \frac{p - \epsilon_p}{p - \epsilon_p + q + \epsilon_1})} \right) - (c-1)^+,
\]

where the third inequality follows from Lemma [1].

\textbf{APPENDIX I}

\textbf{PROOF OF THEOREM [2]}

We know that \( \sigma_i = p_{i0} + p_{i1} \). The upper bound on the regret of the UCB-SM \((R_{UCB-SM}, \text{say}) [10] \) for arms modeled as two-state Markov chains (where \( r(s,i) = s \)) is

\[
\lim_{n \to \infty} \frac{R_{UCB-SM}}{\log n} = \sum_{i} \left( \frac{4L}{(\mu_1 - \mu_i)} \right), \quad \text{where } L = \frac{\epsilon_{01} \min \sigma_i}{}.
\]

The asymptotic upper bound on the regret of H-KL-UCB, irrespective of the arm being truly Markovian or i.i.d. Therefore, the asymptotic upper bound on the regret of H-KL-UCB-MC is same as that of H-KL-UCB for truly Markovian arms, irrespective of the arms being truly Markovian or i.i.d.

The resulting asymptotic upper bound on the regret is smaller than that of [10] (See Theorem [2]). However, KL-UCB-MC results in large constants in the regret for i.i.d. rewards (given by Theorem [1] and [2]). Asymptotic performances of KL-UCB-MC and H-KL-UCB are exactly same for arms with truly Markovian rewards. We know that the asymptotic upper bound on the regret of KL-UCB-MC is less than that of [10] if \( \min(p_{i0} + p_{i1}) \geq \frac{1}{2 \epsilon_{01}} \).

\[
\text{(36)}
\]

\textbf{APPENDIX J}

\textbf{KL-UCB-MC ALGORITHM}

\begin{algorithm}
\caption{KL-UCB-MC}
1: Input \( K \) (number of arms).
2: Choose each arm once.
3: if \( i \) (state of arm \( i \) = 0) then
4: \quad Update \( U_i \) using Equation (1).
5: else
6: \quad Update \( U_i \) using Equation (2).
7: end if
8: Choose \( A_i = \arg \max_i U_i \).
\end{algorithm}

KL-UCB-MC is a variation of standard KL-UCB for i.i.d. rewards [8], [9]. The main idea is to obtain a confidence bound for the estimate of \( p_{i0} \) (estimate of \( p_{i10} \)) and use the estimate of \( p_{i0} \) (estimate of \( p_{i10} \)) in state 0 (state 1) of arm \( i \) using KL-UCB. This is represented by Equations (1) and (2), respectively. Intuitively, the main difference between KL-UCB-MC and H-KL-UCB is that KL-UCB-MC is always in the STP_PHASE of H-KL-UCB, irrespective of the arm being truly Markovian or i.i.d. Therefore, the asymptotic upper bound on the regret of KL-UCB-MC is same as that of H-KL-UCB for truly Markovian arms, irrespective of the arms being truly Markovian or i.i.d.

\textbf{APPENDIX K}

\textbf{RATIONAL BEHIND CHOICE OF HELLMINGER DISTANCE}

The rationale behind choice of Hellinger distance over KL distance which is a natural choice for representing
similarity between two probability distributions in the bandit literature, is as follows. In Lemma 5, we prove that if $B_t := \{H^2(\hat{P}_t(1))|1-\hat{P}_t(0)| < \frac{1}{\tau^2}\}$, the events in the sequence $\{B_t\}_{t=0}^{\infty}$ occur infinitely often if $P_0 + P_1 = 0$. This is same as proving $\sum_{t=1}^{\infty} \mathbb{P}(H^2(\hat{P}_t(1))|1-\hat{P}_t(0)| < \frac{1}{\tau^2})$ is finite if $P_0 + P_1 = 0$. To show this, we utilize the relationship

$$H^2(\hat{P}_t(1))|1-\hat{P}_t(0)| \leq |\hat{P}_t(1) + \hat{P}_t(0) - 1| \leq |\hat{P}_t(1) - P_0| + |\hat{P}_t(0) - P_1| + |P_0 + P_1 - 1|. \quad (37)$$

Now, if we replace $H(\cdot)$ by $D(\cdot)$, we need to prove that if $G_t := \{D^2(\hat{P}_t(1)|1-\hat{P}_t(0)) < \frac{1}{\tau^2}\}$, the events in the sequence $\{G_t\}_{t=0}^{\infty}$ occur infinitely often if $P_0 + P_1 = 0$. To prove this, we need to find an appropriate upper bound on KL distance, similar to Equation (37). Pinsker’s inequality which is a well-known bound on the KL distance, provides a lower bound and hence, cannot be used for the proof. In [19], the authors propose the following upper bound on KL distance

$$D(\hat{P}_t(1)|1-\hat{P}_t(0)) \leq \frac{1 - 2(\hat{P}_t(1) + \hat{P}_t(0)) + (\hat{P}_t(1) + \hat{P}_t(0))^2}{\hat{P}_t(1) - \hat{P}_t(0)}. \quad (37)$$

Hence, unlike Equation (37), in this case, $\hat{P}_t(1)$ and $\hat{P}_t(0)$ cannot be separated. Hence, we cannot apply Chernoff’s bound to show the finiteness of $\sum_{t=1}^{\infty} \mathbb{P}(D(\hat{P}_t(1)|1-\hat{P}_t(0)) < \frac{1}{\tau^2})$.
