Abstract

We study the non-parametric estimation of an unknown density \( f \) with support on \( \mathbb{R}^+ \) based on an i.i.d. sample with multiplicative measurement errors. The proposed fully-data driven procedure is based on the estimation of the Mellin transform of the density \( f \), a regularisation of the inverse of the Mellin transform by a spectral cut-off and a data-driven model selection in order to deal with the upcoming bias-variance trade-off. We introduce and discuss further Mellin-Sobolev spaces which characterize the regularity of the unknown density \( f \) through the decay of its Mellin transform. Additionally, we show minimax-optimality over Mellin-Sobolev spaces of the data-driven density estimator and hence its adaptivity.

Keywords: Density estimation, multiplicative measurement errors, Mellin-transform, Mellin-Sobolev space, minimax theory, inverse problem, adaptation

1 Introduction

In this paper we are interested in estimating the unknown density \( f : \mathbb{R}^+ \rightarrow \mathbb{R}^+ \) of a positive random variable \( X \) given independent and identically distributed (i.i.d.) copies of \( Y = XU \),
where $X$ and $U$ are independent of each other and $U$ has a known density $g : \mathbb{R}^+ \to \mathbb{R}^+$. In this setting the density $f_Y : \mathbb{R}^+ \to \mathbb{R}^+$ of $Y$ is given by

$$f_Y(y) = [f \ast g](y) := \int_0^\infty f(x)g(y/x)x^{-1}dx \quad \forall y \in \mathbb{R}^+$$

such that $\ast$ denotes multiplicative convolution. The estimation of $f$ using an i.i.d. sample $Y_1, \ldots, Y_n$ from $f_Y$ is thus an inverse problem called multiplicative deconvolution.

Vardi [1989] and Vardi and Zhang [1992] introduce and study intensively multiplicative censoring, which corresponds to the particular multiplicative deconvolution problem with multiplicative error $U$ uniformly distributed on $[0, 1]$. This model is often applied in survival analysis as explained and motivated in Van Es et al. [2000]. The estimation of the cumulative distribution function of $X$ is considered in Vardi and Zhang [1992] and Asgharian et al. [2012]. Series expansion methods are studied in Andersen and Hansen [2001] treating the model as an inverse problem. The density estimation in a multiplicative censoring model is considered in Brunel et al. [2016] using a kernel estimator and a convolution power kernel estimator. Assuming a uniform error distribution on an interval $[1 - \alpha, 1 + \alpha]$ for $\alpha \in (0, 1)$ Comte and Dion [2016] analyze a projection density estimator with respect to the Laguerre basis. Belomestny et al. [2016] study a beta-distributed error $U$.

In this work, covering all those three variations of the multiplicative censoring model we consider a density estimator using the Mellin transform and a spectral cut-off regularization of its inverse, which borrows ideas from Belomestny et al. [2020]. The key to the analysis of the multiplicative deconvolution problem is the multiplication theorem of the Mellin transform $\mathcal{M}$, which roughly states $\mathcal{M}[f_Y] = \mathcal{M}[f]\mathcal{M}[g]$ for a density $f_Y = f \ast g$. Exploiting the multiplication theorem Belomestny et al. [2020] introduce a kernel density estimator of $f$ allowing more generally $X$ and $U$ to be real-valued. Moreover, they point out that the following widely used naive approach is a special case of their estimation strategy. Transforming the data by applying the logarithm the model $Y = XU$ writes $\log(Y) = \log(X) + \log(U)$. In other words, multiplicative convolution becomes convolution for the log-transformed data.

As a consequence, the density of $\log(X)$ is eventually estimated employing usual strategies for non-parametric deconvolution problems (see for example Meister [2009]) and then transformed back to an estimator of $f$. However, it is difficult to interpret regularity conditions on the density of $\log(X)$. Furthermore, the analysis of a global risk of an estimator using this naive approach is challenging as Comte and Dion [2016] pointed out.

Our strategy differs in the following way. Making use of the multiplication theorem of the Mellin transform and applying an additional spectral cut-off on the inversion of the Mellin-transform we define a density estimator. We measure the accuracy of the estimator by introducing a global risk in terms of a weighted $\mathbb{L}_2^2$-norm. Exploiting properties of the Mellin transform we characterize the underlying inverse problem and natural regularity conditions.
which borrow ideas from the inverse problems community (Engl et al. [2000]). The regularity conditions expressed in the form of Mellin-Sobolev spaces and their relations to the analytical properties of the density \( f \) are discussed in more details. The proposed estimator, however, involves a tuning parameter which is selected by a data-driven method. We establish an oracle inequality for the fully-data driven spectral cut-off estimator under fairly mild assumptions on the error density \( g \). Moreover we show that uniformly over Mellin-Sobolev spaces the proposed data-driven estimator is minimax-optimal. Precisely, we state both an upper bound for the mean weighted integrated squared error of the fully-data driven spectral cut-off estimator and a general lower bound for estimating the density \( f \) based on i.i.d. copies from \( f_Y = f * g \).

The paper is organized as follows. In section 2 we collect properties of the Mellin transform. We explain our general estimation strategy by first introducing and analyzing an estimator based on direct observations \( X_1, \ldots, X_n \) from \( f \). The estimator relies on an inversion of the Mellin-transform which we stabilize using a spectral cut-off. Exploiting then the multiplication theorem of the Mellin-transform we propose a fully-data driven estimator of \( f \) based on the sample \( Y_1, \ldots, Y_n \). We derive an oracle type upper bound for its mean weighted integrated squared error. We finish the theoretical part by showing in section 3 that our fully-data driven estimator is minimax optimal over Mellin-Sobolev spaces for a large class of error densities \( g \). Finally, results of a simulation study are reported in section 4 which visualize the reasonable finite sample performance of our estimators. The proof of section 2 and section 3 are postponed to the appendix.

2 Adaptive weighted \( \mathbb{L}^2_{\mathbb{R}^+} \) estimation

In this section we introduce the Mellin transform and collect some of its properties. For a more detailed introduction we refer to Paris and Kaminski [2001] and Barucq et al. [2015].

**Mellin transform** Let \( \mathbb{L}^1_{\mathbb{R}^+} \) denote the set of locally integrable real-valued functions. For \( h \in \mathbb{L}^1_{\mathbb{R}^+} \) the Mellin transform of \( h \) in the point \( c + it \in \mathbb{C} \) is defined by

\[
\mathcal{M}_c[h](t) := \mathcal{M}[h](c + it) := \int_0^\infty x^{c-1+it} h(x) dx
\]

provided that the integral is absolutely convergent. If there exists a \( c \in \mathbb{R} \) such that the mapping \( x \mapsto x^{c-1}h(x) \) is integrable over \( \mathbb{R}^+ \) then the region \( \Xi_h \subseteq \mathbb{C} \) of absolute convergence of the integral in (2.1) is either a vertical strip \( \{ s + it \in \mathbb{C} : s \in (a,b), t \in \mathbb{R} \} \) for \( a < b \) with \( c \in (a,b) \) or a vertical line \( \{ c + it \in \mathbb{C} : t \in \mathbb{R} \} \). In the case that \( \Xi_h \) is a vertical strip the function \( s + it \mapsto \mathcal{M}_s[h](t) \) is analytical on this strip. In the literature \( \Xi_h \) is often called *strip of analyticity*. In the following illustration we give some techniques to determine \( \Xi_h \).
Illustration 2.1. Note that for any density \( h_1 \in \mathbb{L}^{1,\text{loc}}_R \) the vertical strip \( \{ 1+it : t \in \mathbb{R} \} \) belongs to \( \Xi_{h_1} \), and hence the Mellin transform \( \mathcal{M}_1[h_1] \) is well-defined. Furthermore the region \( \Xi_{h_2} \) of \( h_2 \in \mathbb{L}^{1,\text{loc}}_R \) is a superset of the vertical strip \( \{ c+it : c \in (a,b), t \in \mathbb{R} \} \) if \( h_2(x) = O(x^{-\alpha + \epsilon}) \) for \( x \downarrow 0 \) and \( h_2(x) = O(x^{-\alpha - \epsilon}) \) for \( x \to \infty \) and for all \( \epsilon > 0 \) small enough. The latter property implies that for the family \( \{ g_k(x) : k \in \mathbb{N} \} \) the function \( \mathcal{M}_1[g_k] \) is analytical on \( \{ c+it : c > 0, t \in \mathbb{R} \} \) since for all \( b, x > 0, \epsilon \in (0, b) \) holds \( |x^b g_k(x)| \vee |x^{b-\epsilon} g_k(x)| \leq k \).

For \( c \in \Xi_h \) the inversion formula of the Mellin transform is given by

\[
h(x) = \frac{1}{2\pi} \int_{-\infty}^{\infty} x^{-c-it} \mathcal{M}_c[h](t) dt, \quad for \ x > 0,
\]

whenever \( \Xi_h \) is not a vertical line (c.f. Paris and Kaminski [2001]) or alternatively if the function \( t \mapsto \mathcal{M}_c[h](t) \) is square integrable over \( \mathbb{R} \) (c.f. Barucq et al. [2015]). Considering Illustration 2.1 we see that the assumption on \( \Xi_h \) not being a vertical line is rather weak. It is fulfilled for almost all functions in the upcoming theory. However, in all the other cases we make use of the second assumption without further reference.

It can be shown that \( \int_0^\infty h^2(x) x^{2\alpha-1} dx < \infty \) for \( \alpha \geq 0 \) implies that \( \alpha \in \Xi_h \) and also that \( \int_0^\infty h^2(x) x^{2\alpha-1} dx = (2\pi)^{-1} \int_0^{\infty} |\mathcal{M}_\alpha[h](t)|^2 dt \). This result combined with the Mellin inversion formula implies an isometry in the following way. For \( \alpha \geq 0 \) define the weight function \( \omega_\alpha(x) := x^{2\alpha - 1}, x \in \mathbb{R} \), and the corresponding weighted norm by \( \| h \|_\omega_\alpha := \int_0^\infty h^2(x) \omega_\alpha(x) dx \) for a measurable function. Denote by \( \mathbb{L}^2_{\omega_\alpha} \) the set of all measurable functions with finite \( \| \cdot \|_{\omega_\alpha} \)-norm and by \( \langle h_1, h_2 \rangle_{\omega_\alpha} := \int_0^\infty h_1(x) h_2(x) \omega_\alpha(x) dx \) for \( h_1, h_2 \in \mathbb{L}^2_{\omega_\alpha} \) the corresponding weighted scalar product. Similarly, define \( \mathbb{L}^2 := \{ h : \mathbb{R} \to \mathbb{C} \text{ measurable} : \| h \|_\mathbb{R}^2 := (2\pi)^{-1} \int_0^\infty h(t) \overline{h(t)} dt < \infty \} \). Now, following Barucq et al. [2015] both operators \( \mathcal{M}_\alpha : \mathbb{L}^2_{\omega_\alpha} \to \mathbb{L}^2 \) and

\[
\mathcal{M}^{-1}_\alpha : \mathbb{L}^2 \to \mathbb{L}^2_{\omega_\alpha}, \quad h \mapsto (x) \mapsto \mathcal{M}^{-1}_\alpha[h](x) := (2\pi)^{-1} \int_{-\infty}^{\infty} x^{-\alpha-it} h(t) dt
\]

are isometries. We will first construct an estimator for \( f \) given an i.i.d. sample \( X_1, \ldots, X_n \), that is the direct case, and afterwards we construct an estimator based on the i.i.d. sample \( Y_1, \ldots, Y_n \), which constitutes the censored case.

Case of direct observation In this paragraph we define the estimator of \( f \in \mathbb{L}^2_{\omega_\alpha} \) given the direct observations \( X_1, \ldots, X_n \) by using the Mellin transform and spectral cut-off regularised inverse. Since \( f \in \mathbb{L}^2_{\omega_\alpha} \) the Mellin transform \( \mathcal{M}_\alpha[f] \) is well-defined and a natural unbiased estimator of \( \mathcal{M}_\alpha[f] \) for each \( t \in \mathbb{R} \) is given by \( \hat{\mathcal{M}}_\alpha (t) := n^{-1} \sum_{j=1}^n X_j^{\alpha-1+it} \). It is worth pointing out that this estimator is bounded in \( t \in \mathbb{R} \) by \( |\hat{\mathcal{M}}_\alpha (t)| \leq |\mathcal{M}_\alpha(0)| \) which
is finite almost surely. Thus \( \mathbb{1}_{[-k,k]} \mathcal{M}_\alpha \in L^2_{\R} \) for all \( k \in \R^+ \) which allows us to apply the operator in (2.3) to define

\[
\hat{f}_k(x) := \mathcal{M}^{-1}_\alpha [\mathbb{1}_{[-k,k]} \mathcal{M}_\alpha](x) = \frac{1}{2\pi} \int_{-k}^{k} x^{-\alpha-it} \mathcal{M}_\alpha(t) dt, \quad x \in \R^+,
\]

(2.4)
as an unbiased estimator of \( f_k := \mathcal{M}^{-1}_\alpha [\mathbb{1}_{[-k,k]} \mathcal{M}_\alpha] \). Additionally, we see that \( \| f - f_k \|^2_{\omega_\alpha} = \pi^{-1} \int_{-k}^{\infty} |\mathcal{M}_\alpha[f](t)|^2 dt \) tending to zero for \( k \) going to infinity, that is \( f_k \) approximates \( f \) in the weighted \( L^2_{\omega_\alpha} \) sense.

Furthermore, we have \( \| \hat{f}_k \|^2_{\omega_\alpha} = (2\pi)^{-1} \int_{-k}^{\infty} |\mathcal{M}_\alpha(t)|^2 dt \) which as a random variable has only a finite first moment if and only if the by \( f \) induced distribution has a finite \( 2(\alpha - 1) \) moment by application of Fubini-Tonelli theorem. We state the following proposition which implies the consistency of the estimator for a suitable choice of the cut-off parameter \( k \in \R^+ \).

**Proposition 2.2.** Assume that \( f \in L^2_{\omega_\alpha} \) and that \( \sigma^2 := \mathbb{E}_f(X^{2(\alpha - 1)}) < \infty. \) Then, for all \( k \in \R \) we have

\[
\mathbb{E}_f(\| f - \hat{f}_k \|^2_{\omega_\alpha}) \leq \| f - f_k \|^2_{\omega_\alpha} + \pi^{-1}\sigma^2 k n^{-1}.
\]

By choosing \( k = k_n \) such that \( n^{-1} k_n \to 0 \) and \( k_n \to \infty \), \( \hat{f}_{k_n} \) is a consistent estimator of \( f \).

The proof of Proposition 2.2 can be found in appendix B. Note that, if one would like to consider the case \( \alpha = 1/2 \), that is \( \omega_\alpha = 1 \), it is necessary to assume a finite first moment of \( X^{-1} \). On the other hand, a less restrictive situation would be to consider the case of \( \alpha = 1 \) which needs no additional moment condition on \( f \) (respectively on \( g \)) since in this case \( \sigma^2 = 1 \).

The corresponding weight function would be \( \omega(x) := \omega_1(x) = x \) for \( x \in \R^+ \). For the estimation of densities without a compact support assumption, the intervals far away from zero are of special interest. A weighted \( L^2_{\omega_\alpha} \)-norm could model this and may allow us to capture more interesting characteristics of the density like being heavy-tailed or compactly supported. From now on, we will restrict ourselves to this special case while we want to remark that the upcoming theory can be expanded to different values of \( \alpha \geq 0 \) under additional assumptions.

Before we start to define the estimator in the case of censored observation let us briefly discuss the upcoming bias term \( \| f - f_k \|^2_{\omega_\alpha} \) in Proposition 2.2. A natural condition which allows a more sophisticated study on the bias, is to assume that the Mellin-transform decays with a polynomial rate, that is for \( s \geq 0 \),

\[
f \in W^s := \{ h \in L^2_{\R} : |h|^2 := \int_{-\infty}^{\infty} |\mathcal{M}_1[h](t)|^2 (1 + t^2)^s dt < \infty \}.
\]

(2.5)
The definition of these spaces strongly resemble to the frequently considered Sobolev spaces which are defined as \( W^s := \{ H \in L^2_{\R} : \int_{-\infty}^{\infty} |\mathcal{F}[H](t)|^2 (1 + t^2)^s dt < \infty \} \) for \( s \geq 0 \) where \( \mathcal{F}[H](t) := \int_{-\infty}^{\infty} H(x) \exp(-ixt) dx \) denotes the usual Fourier-transform for an integrable
function $H : \mathbb{R} \rightarrow \mathbb{R}$. To distinguish between them, we refer $\mathbb{W}^s$ as Mellin-Sobolev space and $W^s$ as Fourier-Sobolev space. But not just the general motivation seems to be similar as we can easily see by the following relationship between Fourier transformation and Mellin transformation. For $h \in L^2_{\mathbb{R}^+}(\omega)$ we have $\mathcal{M}_1[h] = \mathcal{M}_0[\omega h] = \mathcal{F}[(\omega h) \circ \varphi]$ with $\varphi : \mathbb{R} \rightarrow \mathbb{R}^+, x \mapsto \exp(-x)$. Setting $H := (\omega h) \circ \varphi$ we see that $h \in \mathbb{W}^s$ is equivalent to $H \in W^s$. Therefore, it does not seem to be a suprise that it is possible to characterise the Mellin-Sobolev spaces via analytical properties as done in the case of the Fourier-Sobolev spaces. This is stated in the following proposition while its proof is postponed to the appendix.

**Proposition 2.3.** Let $s \in \mathbb{N}$. Then $f \in \mathbb{W}^s$ if and only if $f$ is $s - 1$-times continuously differentiable where $f^{(s-1)}$ is locally absolutely continuous with derivative $f^{(s)}$ and $\omega^i f^{(j)} \in L^2_{\mathbb{R}^+}(\omega)$ for all $j \in [0, s]$.

If a positive random variable $R$ has the density $h$, the real-valued random variable $T = \log(R)$ has the density $f_T(y) = H(-y) = (\omega h) \circ \varphi(-y)$ for $y \in \mathbb{R}$. Again, we observe the strong connection between the Mellin transform of $h$ and the Fourier transform of $H$. This has the following interesting implication for the multiplicative measurement error model.

**Remark 2.4.** As already mentioned the application of the logarithm to the random variable $Y$, $Z := \log(Y) = \log(X) + \log(U) =: V + \varepsilon$, where $V$ and $\varepsilon$ are independent, can be used to transfer the model to a regular deconvolution setting. This technique was used for instance by Comte and Dion [2016]. Given an estimator $\hat{f}_V$ of $f_V$ it is possible to derive an estimator of $f$ through $\hat{f} := \omega^{-1} \hat{f}_V \circ \log$. In fact, one can show that $\|\hat{f}_V - f_V\|_2^2 = \|\hat{f} - f\|_2^2$ which illustrate the difficulties which arise when considering the global risk. Furthermore, in the deconvolution approach via a Fourier transformation one usually assume that the densities $f_V, f_\varepsilon \in L^2_{\mathbb{R}}$ which again correspond to the fact that $f, g \in L^2_{\mathbb{R}^+}(\omega)$ using the considerations above.

In the next part we define an estimator of $f$ based on the censored observation $Y_1, \ldots, Y_n$. Since $Y = XU$, in the multiplicative measurement error model we would need to assume that both $X$ and $U$ have a finite $-1$-moment to consider the unweighted norm. Especially the latter scenario would exclude several interesting examples, for instance the multiplicative censoring model where $U$ is uniformly distributed on $[0, 1]$.

**Case of censored observation** The key property which makes the Mellin transform useful for multiplicative deconvolution is that for two function $h_1, h_2 \in L^1_{\mathbb{R}^+} \cap L^1_{\mathbb{R}^+}$ with $c \in \Xi_{h_1} \cap \Xi_{h_2}$,

$$\mathcal{M}_c[h_1 \ast h_2](t) = \mathcal{M}_c[h_1](t) \cdot \mathcal{M}_c[h_2](t) \quad \text{for } t \in \mathbb{R}. \quad (2.6)$$

We will refer to it from now on as the multiplication theorem. In the context of deconvolution a similar property addressing the convolution and its Fourier transform is frequently used to
construct deconvolution estimators. Since \( f \) and \( g \) are both densities we have \( 1 \in \mathbb{E}_f \cap \mathbb{E}_g \) which implies that for all \( t \in \mathbb{R}, \mathcal{M}_1[f_Y](t) = \mathcal{M}_1[f](t) \mathcal{M}_1[g](t) \). Under the assumption that \( \mathcal{M}_1[g](t) \neq 0 \) for all \( t \in \mathbb{R} \), which we do in the upcoming theory without further reference, we see that using (2.6) we can express the functions (2.5).

Proposition is very similar to the proof of Proposition 2.2 and thus omitted.

Let us now have a closer look at the second summand in Proposition 2.5 which bounds for all \( k \in \mathbb{R}^+ \),

\[ \int_{-k}^{k} |\mathcal{M}_1[g](t)|^{-2} dt < \infty. \]  

Note that \( \mathcal{M}_1[\hat{f}_k](t) = 1_{[-k,k]}(t) \frac{\hat{\mathcal{M}}(t)}{\mathcal{M}_1[g](t)} \) by definition of \( \hat{f}_k \), and hence the estimator defined in (2.7) and (2.4) coincide when setting \( \mathcal{M}_1[g](t) = 1 \) for \( t \in \mathbb{R} \). The proof of the next proposition is very similar to the proof of Proposition 2.2 and thus omitted.

**Proposition 2.5.** Assume that \( f \in \mathbb{L}_n^2(\omega) \) and that \( [G0] \) holds. Then for all \( k \in \mathbb{N} \) we have

\[ \mathbb{E}_n^k(\|f - \hat{f}_k\|^2_{\omega}) \leq \|f - f_k\|^2_{\omega} + (2\pi n)^{-1} \int_{-k}^{k} |\mathcal{M}_1[g](t)|^{-2} dt. \]

By choosing \( k = k_n \) such that \( n^{-1} \int_{-k_n}^{k_n} |\mathcal{M}_1[g](t)|^{-2} dt \to 0 \) and \( k_n \to \infty \), \( \hat{f}_{k_n} \) is a consistent estimator of \( f \).

Let us now have a closer look at the second summand in Proposition 2.5 which bounds the variance term of the estimator. In the following, we use for two functions \( f, g \) the notation \( f \sim g \) over a set \( A \subset \mathbb{R} \) if the function \( f/g \) is bounded away both from zero and infinity over the set \( A \). In analogy to the usual deconvolution setting and to the work of Belomestny et al. [2020] we say that the error density is smooth if there exist parameters \( \gamma, \tau_1 \in \mathbb{R}^+ \) such that

\[ \forall |t| \geq \tau_1 : |\mathcal{M}_1[g](\tau)| \sim t^{-\gamma} \text{ and } \forall |t| \leq \tau_1 : |\mathcal{M}_1[g](t)| \sim 1. \]  

([G1])

Now [G1] implies that \( \int_{-k}^{k} |\mathcal{M}_1[g](t)|^{-2} dt \leq C_g k^{2\gamma+1} \) where \( C_g > 0 \) is a positive constant introduced in the following corollary.
Theorem 2.7. Assume that \( f \in L^2_+(\omega) \) and that \([G1]\) holds. Then for all \( k \in \mathbb{N} \) we have
\[
\mathbb{E}^{f_Y}_Y(\|f - \hat{f}_k\|_\omega^2) \leq \|f - f_k\|_\omega^2 + C_g(2\pi n)^{-1}k^{2\gamma+1}
\]
where \( C_g \) is a constant only dependent on \( g \). By choosing \( k_n \) such that \( n^{-1}k_n^{2\gamma+1} \to 0 \) and \( k_n \to \infty \), \( \hat{f}_{k_n} \) is a consistent estimator of \( f \).

Under the assumptions of Corollary 2.6 it is natural to restrict the set of suitable parameters \( k \) to \( K_n := [1, K_n] \) with \( K_n := n^{1/(2\gamma+1)} \) and to choose \( k_n := \arg \min \{\|f - f_k\|_\omega^2 + C_g(2\pi n)^{-1}k^{2\gamma+1} : k \in K_n\} \). Unfortunately, this choice is not feasible since it depends on the unknown density \( f \) itself. We note that the bias \( \|f - f_k\|_\omega^2 = \|f\|_\omega^2 - \|f_k\|_\omega^2 \) behaves like \(-\|f_k\|_\omega^2\). Exchanging \(-\|f_k\|_\omega^2\) with its empirical counterpart \(-\|\hat{f}_k\|_\omega^2\) we define a fully data-driven model selection \( \hat{k} \) by
\[
\hat{k} \in \arg \min \{-\|\hat{f}_k\|_\omega^2 + \text{pen}(k) : k \in K_n\}
\]
for \( \chi > 0 \). The following theorem shows that this procedure is adaptive up to a negligible term.

Theorem 2.7. Assume that \( f \in L^2_+(\omega) \), \([G1]\) and that \( \|\omega f_Y\|_\infty := \sup_{y > 0} |y f_Y(y)| < \infty \). Then for \( \chi > 12C_g\pi^{-1} \)
\[
\mathbb{E}^{\omega}_Y(\|f - \hat{f}_{\chi}\|_\omega^2) \leq 4 \inf_{k \in K_n} (\|f - f_k\|_\omega^2 + \text{pen}(k)) + C(\|\omega f_Y\|_\infty, g)n^{-1}
\]
where \( C(\|\omega f_Y\|_\infty, g) > 0 \) is a constant depending on \( \|\omega f_Y\|_\infty \) and \( g \).

The proof of Theorem 2.7 is postponed to appendix appendix B. The assumption that \( \|\omega f_Y\|_\infty < \infty \) is rather weak. In fact, since \( 1 \in \Xi_f \cap \Xi_g \) we are able to write \( |y f_Y(y)| = |y^{1/2} \int_{-\infty}^{\infty} y^{-1-it} M_1[f](t)M_1[g](t)dt| \leq \|f\|_\omega(\int_{-\infty}^{\infty} |M_1[g](t)|^2 dt)^{1/2} < \infty \) if \( \gamma > 1/2 \) in \([G1]\).

The last assertion establishes an oracle inequality assuming a smooth error density as in \([G1]\). For a super smooth error density with exponentially decay of its Mellin transform (see Belomestny et al. [2020]) a result similar to Theorem 2.7 can be derived from Lemma B.4 in the appendix provided the upper bound \( K_n \) and the penalty terms \( \text{pen}(k) \), \( k \in [1, K_n] \) are chosen accordingly. However, we omit the details, since the minimax theory presented in the next chapter does not cover a super smooth error density.

3 Minimax theory

In this section we develop the minimax theory for the proposed estimator in section 2. Over the Mellin-Sobolev spaces we derive an upper and lower bound for the mean weighted integrated squared error, which are equal up to a multiplicative constant, showing that our estimator is minimax-optimal over these spaces.
Regularity assumptions Let us define for \( s \geq 0 \) and the ellipsoids \( \mathbb{W}^s(L) := \{ h \in \mathbb{W}^s : \|h\|_s^2 \leq L \} \) for any \( L \geq 0 \) which correspond to the \textit{Mellin-Sobolev spaces} defined in (2.5). We see that for any \( f \in \mathbb{W}^s(L) \) we have \( \int_{[-k,k]} |\mathcal{M}_1[f](t)|^2 dt \leq Lk^{-2s} \) and \( \|f\|_s^2 = (2\pi)^{-1} \int_{-\infty}^{\infty} |\mathcal{M}_1[f](t)|^2 dt \leq L(2\pi)^{-1} \). We denote the subset of densities by
\[
\mathbb{D}^s_{k,L} := \{ f \in \mathbb{W}^s(L) : f \text{ is a density} \}. \tag{3.1}
\]
Again, assuming \( [G1] \) implies that \( \int_{-k}^k |\mathcal{M}_1[g](t)|^{-2} dt \leq C_gk^{2\gamma+1} \) where \( C_g > 0 \) is a constant only dependent on the error density \( g \). These considerations imply the following theorem whose proof is omitted.

**Theorem 3.1.** Assume that \( g \) satisfies assumption \( [G1] \). Then for \( k_o := n^{1/(2s+2\gamma+1)} \),
\[
\sup_{f \in \mathbb{D}^s_{k,L}} \mathbb{E}_f^n(\|f - \hat{f}_{k_o}\|_2^2) \leq C(g, L, s)n^{-2s/(2s+2\gamma+1)}.
\]

As mentioned before for \( \gamma > 1/2 \) we have \( \|\omega f_Y\|_\infty \leq \|f\|_\omega\|g\|_\omega \). Thus, we can state the following corollary which is a direct consequence of Theorem 2.7 and Theorem 3.1.

**Corollary 3.2.** Assume that \( [G1] \) holds for \( \gamma > 1/2 \). Then for \( \chi > 12C_g\pi^{-1} \),
\[
\sup_{f \in \mathbb{D}^s_{k,L}} \mathbb{E}_f^n(\|f - \hat{f}_k\|_\omega^2) \leq C(g, L, s)n^{-2s/(2s+2\gamma+1)},
\]
where \( \chi \) is defined in (2.8).

**Remark 3.3.** For \( g(x) = k(1-x)^{k-1}1_{(0,1)}(x) \) with \( k \in \mathbb{N}, x > 0 \) and \( c > 0 \) its Mellin transform is given by \( \mathcal{M}_c[g](t) = \prod_{j=1}^{k} \frac{1}{c-1+j+t} \) and satisfies \( [G1] \) with \( \gamma = k \). In fact this covers the model considered by Belomestny et al. [2016] as a generalisation of the multiplicative censoring where we consider a uniform distributed error density, that is \( k = 1 \). Again, we can include the case of direct observations, getting a rate of \( n^{-2s/(2s+1)} \) over the ellipsoid.

To prove that the rate of Theorem 3.1 is minimax-optimal over the ellipsoids under certain assumptions on \( g \) we finish this section by stating a lower bound result. We want to emphasize that up to now we had no constraints on the support of \( g \). To prove the lower bound we will need to assume that \( g \) has a bounded support. For the sake of simplicity we will assume that \( g \) has a support in \( (0,1] \). We assume that there exist parameters \( \gamma, \tau_1 \in \mathbb{R}^+ \) such that
\[
\forall |\tau| \geq \tau_1 : |\mathcal{M}_{1/2}[g](\tau)| \sim t^{-\gamma}, \forall |\tau| \leq \tau_1 : |\mathcal{M}_{1/2}[g](\tau)| \sim 1 \text{ and } \forall x > 1 : g(x) = 0. \quad ([G1'])
\]

**Theorem 3.4.** Let \( s, \gamma \in \mathbb{N} \), assume that \( [G1'] \) holds. Then there exist constants \( C_g, L_{s,g}, n_{s,\gamma} \geq 0 \) such that for all \( L \geq L_{s,g}, n \geq n_{s,\gamma} \) and for any estimator \( \hat{f} \) of \( f \) based on \( n \) i.i.d. sample \( (Y_j)_{j=1}^{n} \),
\[
\sup_{f \in \mathbb{D}^s_{k,L}} \mathbb{E}_f^n(\|f - \hat{f}\|_\omega^2) \geq C_g n^{-2s/(2s+2\gamma+1)}.
\]

We want to emphasize that the error densities \((g_k)_{k \in \mathbb{N}}\) with \(g_k(x) = k(1 - x)^{k-1}1_{(0,1)}, x \in \mathbb{R}^+\), fulfill both the assumption \([G1]\) and \([G1']\). Thus, in this situation our estimation strategy is minimax-optimal. The proof of the lower bound can be extended to the case of directly observed \(X_1, \ldots, X_n\) or for different weight functions \(\omega_{\alpha}, \alpha \geq 0\).

4 Numerical study

Let us illustrate the performance of the estimator \(\hat{f}_k\) defined in (2.7) and (2.8) in the cases \(U \sim U_{[0,1]}, U \sim U_{(0.5,1.5)}\) and \(U \sim \text{Beta}_{1,2}\). For the density \(g\) of an uniform distribution on \([0.5, 1.5]\) we get that \(\mathcal{M}_1[g](t) = (1 + it)^{-1}(1.5^{1+it} - 0.5^{1+it}), t \in \mathbb{R}\), which corresponds to the case of \(\gamma = 1\) in \([G1]\). We consider the densities

(i) **Gamma Distribution**: \(f(x) = \frac{x^4}{4!} \exp(-x)\),

(ii) **Gamma Mixture**: \(f(x) = 0.4 \cdot 3.2^2 x \exp(-3.2x) + 0.6 \cdot \frac{6.8^{16}x^{15}}{15!} \exp(-6.8x)\),

(iii) **Beta Distribution**: \(f(x) = \frac{1}{560}(0.5x)^3(1 - 0.5x)^41_{[0,1]}(0.5x)\) and

(iv) **Weibull Distribution**: \(f(x) = 2x \exp(-x^2)\).

By minimising an integrated weighted squared error over a family of histogram densities with randomly drawn partitions and weights we select \(\chi = 1.2, \chi = 0.8\) and \(\chi = 0.01\) for the cases \(\gamma = 0, \gamma = 1\) and \(\gamma = 2\), respectively, where \(\chi\) is the penalty constant, see (2.8).

In the direct case we compare the estimator \(\hat{f}_k\) with the data-driven density estimator \(\tilde{f}\) from the work of Brenner Miguel and Johannes [2020] which is based on the adaptive aggregation of projection estimators with respect to the Laguerre basis.
Figure 1: Considering the estimators $\hat{f}_E$ (top) and $\hat{f}$ (bottom) are depict for 50 Monte-Carlo simulations with sample size $n = 1000$ in the case (i) (left), (ii) (middle) and (iii) (right) with direct observations. The true density $f$ is given by the red curve while the dark blue curve is the point-wise empirical median of the 50 estimates.
Figure 2: Considering the estimator $\hat{f}_K$ and a sample size $n = 2000$ the adaptive estimators are depicted for 50 Monte-Carlo simulations with $U \sim U_{[0, s]}$ (left), $U \sim U_{[1/2, 3/2]}$ (middle) and $U \sim \beta(1, 2)$ (right) in the cases (i) (first row), (iv) (second row) and (iii) (third row). The true density $f$ is given by the red curve while the dark blue curve is the point-wise empirical median of the 50 estimates.

**Comment**  Since the estimator $\hat{f}_K$ is built to minimize the weighted global risk, it seems natural that the estimator $\hat{f}_K$ behaves worse in the region close to zero then the estimator $\tilde{f}$ which is built to minimize the unweighted global risk. This effect is observable in fig. 1. Furthermore, the developed minimax theory suggests that the cases of $U \sim U_{[0, 1]}$ and $U \sim U_{[0.5, 1.5]}$ are of similar complexity which is reflected in the plots of fig. 2. For the case $U \sim \beta(1, 2)$, parameter $\gamma = 2$ in [G1], both theory and simulation imply that the recovering of the density $f$ based on the noise sample $Y_1, \ldots, Y_n$ leads to a more difficult inverse problem than in the other cases.
Appendix

A Preliminaries

Properties of the Mellin transform  By assuming that \( h \in \mathbb{R}^{1, loc} \) is a at least \( b \)-time differentiable function \( h \), where \( h^{(b)} \) denotes its \( b \)-th derivative, \( b \in \mathbb{N} \), and that \( c - b \in \Xi_h \) and \( c + a \in \Xi_h, a \in \mathbb{N} \), we get that

\[
\mathcal{M}_c[x^a h](t) = \mathcal{M}_{c+a}[h](t) \text{ respec. } \mathcal{M}_c[h^{(b)}](t) = (-1)^b \frac{\Gamma(c + it)}{\Gamma(c - b + it)} \mathcal{M}_{c-b}[h](t) \quad (A.1)
\]

Combining both results in (A.1) we get that \( \mathcal{M}_c[xh^{(1)}](t) = (-c - it)\mathcal{M}_c[h](t) \) if \( c + 1 \in \Xi_h \) and \( h \) differentiable. Further for \( h_1, h_2 \in \mathbb{L}^2_{a+} \) with \( c \in \Xi_{h_1} \) and \( 1 - c \in \Xi_{h_2} \) we get that \( \int_0^\infty h_1(x)h_2(x)dx = \frac{1}{2 \pi} \int_{-\infty}^{\infty} \mathcal{M}_c[h_1](t)\mathcal{M}_{1-c}[h_2](t)dt \). Combining this and (A.1) we conclude that for \( h_1, h_2 \in \mathbb{L}^2(\omega_\alpha) \) it holds \( \langle h_1, h_2 \rangle_{\omega_\alpha} = \frac{1}{2 \pi} \int_{-\infty}^{\infty} \mathcal{M}_\alpha[h_1](t)\mathcal{M}_\alpha[h_2](t)dt \).

Lemma A.1. (Talagrand’s inequality) Let \( X_1, \ldots, X_n \) be independent \( \mathbb{Z} \)-valued random variables and let \( \tilde{\nu}_n = n^{-1} \sum_{i=1}^n \{ [\nu_h(X_i)] - \mathbb{E}(\nu_h(X_i)) \} \) for \( \nu_h \) belonging to a countable class \( \{\nu_h, h \in \mathcal{H}\} \) of measurable functions. Then,

\[
\mathbb{E}(\sup_{h \in \mathcal{H}} |\tilde{\nu}_n|^2 - 6 \Psi^2) \leq C \left[ \frac{\tau}{n} \exp \left( \frac{-n \Psi^2}{6} \right) + \frac{\psi^2}{n} \exp \left( \frac{-Kn \Psi}{\psi} \right) \right] \quad (A.2)
\]

with numerical constants \( K = (\sqrt{2} - 1)/(21\sqrt{2}) \) and \( C > 0 \) and where

\[
\sup_{h \in \mathcal{H}} \sup_{z \in \mathcal{Z}} |\nu_h(z)| \leq \psi, \quad \mathbb{E}(\sup_{h \in \mathcal{H}} |\tilde{\nu}_h|) \leq \Psi, \quad \sup_{h \in \mathcal{H}} \frac{1}{n} \sum_{i=1}^n \text{Var}(\nu_h(X_i)) \leq \tau.
\]

Remark A.2. Keeping the bound (A.2) in mind, let us specify particular choices \( K, \) in fact \( K \geq 1 \). The next bound is now an immediate consequence,

\[
\mathbb{E}(\sup_{h \in \mathcal{H}} |\tilde{\nu}_n|^2 - 6 \Psi^2) \leq C \left( \frac{\tau}{n} \exp \left( \frac{-n \Psi^2}{6} \right) + \frac{\psi^2}{n} \exp \left( \frac{-n \Psi}{100 \psi} \right) \right) \quad (A.3)
\]

In the sequel we will make use of the slightly simplified bounds (A.3) rather than (A.2). □

B Proofs of section 2

Proof of Proposition 2.2. Since \( \mathcal{M}_\alpha[f - f_k](t) = 0 \) for \( |t| \geq k \) we get that \( \langle f - f_k, f_k - \hat{f}_k \rangle_{\omega_\alpha} = \frac{1}{2 \pi} \int_{-k}^k \mathcal{M}_\alpha[f - f_k](t)\mathcal{M}_\alpha[f - f_k](t)dt = 0 \) and thus \( \|f - \hat{f}_k\|^2_{\omega_\alpha} = \|f - f_k\|^2_{\omega_\alpha} + \|f_k - \hat{f}_k\|^2_{\omega_\alpha} \).

Finally we see \( \|\hat{f}_k - f_k\|^2_{\omega_\alpha} = \frac{1}{2 \pi} \int_{-k}^k |\mathcal{M}_\alpha[f](t) - \hat{\mathcal{M}}_\alpha(t)|^2 dt \) and \( \mathbb{E}_f(\|\mathcal{M}_\alpha[f](t) - \hat{\mathcal{M}}_\alpha(t)\|^2) = \mathbb{E}_f(\|\mathcal{M}_\alpha(t)\|^2) \leq \frac{1}{\pi^2} \mathbb{E}_f(\|X_1^{\alpha-1+it}\|^2) = \sigma^2 n^{-1} \). Now by using Fubini we get \( \mathbb{E}_f(\|\hat{f}_k - f_k\|^2_{\omega_\alpha}) \leq \sigma^2 \pi^{1} n^{-1} k n^{-1} \). □
Proof of Proposition 2.3. The main strategy of this proofs relies on the well-known fact that
\[ W^s = \{ H \in \mathbb{L}^2_{\mathbb{R}} : H \text{ weakly differentiable up to the order } s, H^{(i)} \in \mathbb{L}^2_{\mathbb{R}}, i \in [0, s] \} \]
for \( s \in \mathbb{N} \) and the already discussed connection between the Mellin transform and the Fourier transform. Further we want to stress out that for a function \( H \in \mathbb{L}^2_{\Omega}, \Omega \subset \mathbb{R} \) open, being weakly differentiable corresponds to being locally absolutely continuous on \( \Omega \), that is \( h \) is absolutely continuous on all compact intervals \([a, b] \subset \Omega, a < b \in \Omega\).

Let us start by assuming \( f \in W^s \) then \( F := (\omega f) \circ \varphi \in W^s \) which means that \( F \) is \( s \)-times weakly differentiable with \( F^{(i)} \in \mathbb{L}^2_{\mathbb{R}} \) for \( i \in [0, s] \). Thus we get that \( F \) is a \( s - 1 \)-times continuously differentiable function, more precisely there exists a representant of the equivalence class of \( F \) such that it is \( s - 1 \)-times continuously differentiable. Now since \( f = \omega^{-1}F(\varphi^{-1}) \) we can deduce that \( f \) itself is \( s - 1 \)-times continuously differentiable. Let us define the operator \( T : C^1(\mathbb{R}^+) \rightarrow C^0(\mathbb{R}^+), f \mapsto (\omega f)^{(1)}, T^0 := \text{Id} \) denote the identity and \( T^j = T \circ T^{j-1} \) for \( j \in \mathbb{N} \). Since \( T(\omega^j f^{(j)}) = (j+1)\omega^j f^{(j)} + \omega^{j+1} f^{(j+1)} \) for \( j \in [0, s - 1] \) we conclude \( T^j[f] = \sum_{i=0}^{j} \omega_i \omega f^{(i)}, \omega \geq 1 \). Now we can use the following Lemma to deduce that \( \|T^j[f]\| \leq \|\omega T^j[f] \circ \varphi\|_R^2 = \|F^{(j)}\|_R^2 < \infty \).

**Lemma B.1.** For \( h \in C^k(\mathbb{R}^+) \) and all \( j \in [0, k] \), it holds \((\omega T^j[h]) \circ \varphi = (-1)^j(\varphi h(\varphi))^{(j)} \).

From this follows directly that \( \omega^j f^{(j)} \in \mathbb{L}_{\mathbb{R}^+}^2(\omega) \) for \( j \in [0, s] \). As the next step we show that \( f^{(s-1)} \) is locally absolutely continuous. To do so, we see first for \( j \in [0, s] \) we have that \( T^j[f] \in \mathbb{W}^1 \). Now using the following lemma implies that \( \omega^{s-1} f^{(s-1)} \) is absolutely continuous as linear combination of \( \{T^j[f] : j \in [0, s] \} \).

**Lemma B.2.** Let \( h \in \mathbb{W}^1 \). Then \( h \) is a locally absolutely continuous function with derivative \( h' : \mathbb{R}^+ \rightarrow \mathbb{R} \) and \( h, \omega h' \in \mathbb{L}_{\mathbb{R}^+}^2(\omega) \).

Let now \( \delta \) denote the derivative of \( \omega^{s-1} f^{(s-1)} \). Then by Lemma B.2 we see that \( \omega \delta \in \mathbb{L}^2_{\mathbb{R}^+}(\omega) \). Defining now \( f^{(s)} := \omega^{s+1} \delta -(s - 1) \omega^{s} f^{(s-1)} \in \mathbb{L}_{\mathbb{loc}}^1(\mathbb{R}^+) \) we get for any \( a, b \in \mathbb{R}^+, a < b \), \( \int_a^b f^{(s)}(x)dx = f^{(s-1)}(b) - f^{(s-1)}(a) \) using the integration by part rule for absolutely continuous function (see Cohn [2013]). Finally we have that \( \omega^s f^{(s)} = \delta \omega -(s - 1) \omega^{s} f^{(s-1)} \in \mathbb{L}_{\mathbb{R}^+}^2(\omega) \).

Let us now show the other direction, indeed let us assume that \( f \) is \( s - 1 \)-times continuously differentiable, \( f^{(s-1)} \) is locally absolutely continuous with derivative \( f^{(s)} \) and \( \omega^j f^{(j)} \in \mathbb{L}^2_{\mathbb{R}^+}(\omega) \) for \( j \in [0, s] \). Thus for \( T^j[f] = \sum_{i=0}^{j} c_i j \omega f^{(i)} \in \mathbb{L}^2_{\mathbb{R}^+}(\omega) \) with \( j \in [0, s - 1] \) we have that \( \omega(T^j[f])^{(1)} = T^{j+1}[f] - T^j[f] \in \mathbb{L}^2_{\mathbb{R}^+}(\omega) \). We can conclude that \( T^j[f] \in \mathbb{W}^1 \) for \( j \in [0, s - 1] \) applying the following lemma.

**Lemma B.3.** Let \( h : \mathbb{R}^+ \rightarrow \mathbb{R} \) be locally absolutely continuous function with derivative \( h' : \mathbb{R}^+ \rightarrow \mathbb{R} \) and \( h, \omega h' \in \mathbb{L}^2_{\mathbb{R}^+}(\omega) \). Then \( h \in \mathbb{W}^1 \).
Now setting \( \delta = (s - 1)\omega^{s-2}f^{(s-1)} + \omega^{s-1}f^{(s)} \in \mathbb{L}_{4\text{oc}}(\mathbb{R}^+) \) we have that \( f^b_a \delta(x)dx = b^{s-1}f^{(s-1)}(b) - a^{s-1}f^{(s-1)}(a) \) and \( \omega \delta \in \mathbb{L}_{2+}^+(\omega) \). Thus again applying Lemma B.3 on \( \omega^{s}f^{(s)} \) again shows that \( \omega^{s}f^{(s)} \in \mathbb{W}^1 \) and thus \( T^{s-1}[f] \in \mathbb{W}^1 \). Now we use that \( M_1[T^{s-1}](t) = (-1)^{s-1}F[F^{(s-1)}(t)] = \omega^{s-1}M_1[f](t) \) which implies that \( f \in \mathbb{W}^s \).

\[ \square \]

**Proof of Lemma B.1.** For \( j = 0 \) the claim is trivially correct. Assume that the claim hold for \( j \in [1, k] \) then

\[
(\omega T^{j+1}[f]) \circ \varphi = (\omega T^{j}[f + \omega f^{(1)}]) \circ \varphi = (-1)^{j-1}(\varphi f(\varphi) + \varphi^2 f^{(1)}(\varphi))^{(j)}
\]

and thus \( (\varphi f(\varphi))^{(1)} = -\varphi f(\varphi) - \varphi^2 f^{(1)}(\varphi) \) implies the claim.

**Proof of Lemma B.2.** Since \( h \in \mathbb{W}^1 \) we have that \( H = (\omega h) \circ \varphi \) lies in the Sobolev space of order 1. In equal \( H \) is locally absolutely continuous with derivative \( H' \) and \( H', H' \in \mathbb{L}^2_\text{loc} \). From this we can conclude that \( h \) is locally absolutely continuous. Indeed for \( h' := -\omega^{-2}(H' + H) \circ \varphi^{-1} \in \mathbb{L}^1_\text{loc}(\mathbb{R}^+) \) and \( a, b \in \mathbb{R}^+, a < b \) holds

\[
\int_a^b -x^{-2}H'(\varphi^{-1})(x)dx = \int_{\varphi^{-1}(a)}^{\varphi^{-1}(b)} \exp(x)H'(x)dx = h(b) - h(a) + \int_a^b x^{-2}H(\varphi^{-1})(x)dx
\]

applying the integration by part rule for absolutely continuous function. Further we have that

\[
||h'||_\omega = ||\omega^{-1}(H' + H) \circ \varphi^{-1}||_\omega \leq ||H'||_\omega + ||H||_\omega < \infty.
\]

**Proof of Lemma B.3.** Since \( h \in \mathbb{L}^2_\text{loc}(\omega) \) we have for \( H := (\omega h) \circ \varphi \) that \( ||H||_\omega = ||h||_\omega < \infty \). Further \( H \) is locally absolutely continuous with derivative \( -\varphi h(\varphi) - \varphi^2 h'(\varphi) \) since for \( a, b \in \mathbb{R} \) with \( a < b \) holds

\[
\int_a^b -\varphi^2(x)h'(\varphi(x))dx = \int_{\varphi(a)}^{\varphi(b)} xh'(x)dx = \int_{\varphi(a)}^{\varphi(b)} h(x)dx - \int_{\varphi(a)}^{\varphi(b)} h(x)dx.
\]

Now since \( ||\varphi^2 h'(\varphi)||_\omega = ||\omega f'||_\omega < \infty \) we deduce that \( H \) is in the Sobolev space of order 1 and thus \( (1 + \ell^2)^{1/2}M_1[h] = (1 + \ell^2)^{1/2}F[H] \in \mathbb{L}^2(\mathbb{C}) \) and thus \( h \in \mathbb{W}^1 \).

**Proof of Theorem 2.7.** Let us define the nested subspaces \( (S_k)_{k \in \mathbb{R}^+} \) by \( S_k := \{ h \in \mathbb{L}^2_\text{loc}(\omega) \text{ : } \forall |t| \geq k : \mathcal{M}_1[h](t) = 0 \} \). For any \( h \in S_k \) we consider the empirical contrast

\[
\gamma_n(h) = ||h||_\omega^2 - 2\frac{1}{2\pi} \int_{-\infty}^{\infty} \frac{M_1[h](t)}{M_1[g](t)} dt = ||h||_\omega^2 - 2n^{-1} \sum_{j=1}^{n} \nu(h(Y_j))
\]

with \( \nu(h(Y_j)) := \frac{1}{2\pi} \int_{-\infty}^{\infty} Y_j M_1[h](t) M_1[g](t) dt \). One can easily see that \( \tilde{f}_k = \arg \min \{ \gamma_n(h) : h \in S_k \} \) with \( \gamma_n(\tilde{f}_k) = -||\tilde{f}_k||_\omega^2 \). For \( h \in S_k \) define the empirical process \( \tilde{v}_h := n^{-1} \sum_{j=1}^{n} \nu(h(Y_j)) - \langle h, f \rangle_\omega \). Then we have that for \( h_1, h_2 \in S_k \) that

\[
\gamma_n(h_1) - \gamma_n(h_2) = ||h_1 - f||_\omega^2 - ||h_2 - f||_\omega^2 - 2\tilde{v}_{h_1-h_2}.
\]
Now since $\gamma_n(\hat{f}_k) \leq \gamma_n(f_k)$ we get $\|f - \hat{f}_k\|_\omega^2 \leq \|f - f_k\|_\omega^2 + 2\hat{\nu}_{f_k - f_k}$. By definition of $\hat{k}$ we have that $\gamma_n(\hat{f}_k) - \text{pen}(\hat{k}) \leq \gamma_n(f_k) - \text{pen}(k)$ for any $k \in \mathcal{K}_n$. Now using (B.1) we get that

$$\|f - \hat{f}_k\|_\omega^2 \leq \|f - f_k\|_\omega^2 + 2\hat{\nu}_{f_k - f_k} + \text{pen}(k) - \text{pen}(\hat{k}).$$

First we note that $S_{k_1} \subseteq S_{k_2}$ for $k_1 \leq k_2$. Let us now denote by $a \vee b := \max(a, b)$ and define for all $k \in \mathcal{K}_n$ the unit balls $B_k := \{h \in S_k : \|h\|_\omega \leq 1\}$. Next we deduce from $2ab \leq a^2 + b^2$ that $2\hat{\nu}_{f_k - f_k} \leq 4^{-1}\|\hat{f}_k - f_k\|_\omega^2 + 4\sup_{h \in B_{\hat{k}/k}}\hat{\nu}_h^2$. Further we see that $4^{-1}\|\hat{f}_k - f_k\|_\omega^2 \leq 2^{-1}(\|\hat{f}_k - f\|_\omega^2 + \|f - f_k\|_\omega^2)$. Putting all this together and define

$$p(\hat{k} \vee k) := 6(2\pi n)^{-1}\Delta_g(\hat{k} \vee k)$$

where $\Delta_g(k) := \int_{-k}^k |\mathcal{M}_1[g](t)|^{-2}dt$ (B.2) we get

$$\|f - \hat{f}_k\|_\omega^2 \leq 3\|f - f_k\|_\omega^2 + 8\left(\sup_{h \in B_{\hat{k}/k}}\hat{\nu}_h^2 - p(\hat{k} \vee k)\right)_+ + 8p(\hat{k} \vee k) + 2\text{pen}(k) - 2\text{pen}(\hat{k})$$

Assuming now that $\chi \geq 12C_g\pi^{-1}$ we get that $4p(\hat{k} \vee k) \leq \text{pen}(k) + \text{pen}(\hat{k})$ and thus

$$\|f - \hat{f}_k\|_\omega^2 \leq 4\left(\|f - f_k\|_\omega^2 + \text{pen}(k)\right) + 8\max_{k' \in \mathcal{K}_n} \left(\sup_{h \in B_{\hat{k}'}}\hat{\nu}_h^2 - p(k')\right)_+$$

We will use the following lemma which we will be proven afterwards.

**Lemma B.4.** Assuming that $\|\omega f_Y\|_\infty < \infty$ and that for all $k \in \mathcal{K}_n$ the function $G_k : \mathbb{R} \rightarrow \mathbb{R}, t \mapsto 1_{[-k,k]}(t)|\mathcal{M}_1[g](t)|^{-2}$ is bounded we have

$$\mathbb{E}_{f_Y}^n\left(\sup_{h \in B_k}\hat{\nu}_h^2 - p(k)\right)_+ \leq \frac{C}{n}\left(\|G_k\|_\infty\|\omega f_Y\|_\infty \exp\left(-\frac{\Delta_g(k)}{12\pi\|\omega f_Y\|_\infty\|G_k\|_\infty}\right) + \frac{\Delta_g(k)}{(2\pi)^2n}\exp(-\frac{\sqrt{n}}{50})\right),$$

where $\Delta_g$ is defined in (B.2).

Now under [G1] we have that $\Delta_g(k) \geq c_gk^{2\gamma + 1}$ and for all $t \in \mathbb{R}$ holds $|G_k(t)| \leq C_gk^{2\gamma}$ thus we have that the first summand is bounded by $C_gk^{2\gamma}\|\omega f_Y\|_\infty \exp\left(-\frac{c_gk}{12\pi\|\omega f_Y\|_\infty C_g}\right)$ which is bounded over $\mathbb{N}$. For the second summand we use that $n^{-1}\Delta_g(k) \leq C_gn^{-1}k^{2\gamma + 1} \leq C_g$ and thus bounded in $\mathbb{N}$. Applying the lemma we get that

$$\mathbb{E}_{f_Y}^n(\|f - \hat{f}_k\|_\omega^2) \leq 4\left(\|f - f_k\|_\omega^2 + \text{pen}(k)\right) + C(\|\omega f_Y\|_\infty, g)n^{-1}.$$ 

Since this inequality holds for all $k \in \mathcal{K}_n$ this implies the claim. \qed
Proof of Lemma B.4. We will use the Talagrand inequality (A.3) to show the claim. We want to emphasize that we are able to apply the Talagrand inequality on the sets $B_k$ since $B_k$ has a dense countable subset and due to continuity arguments. To do so we start to determine the constant $\Psi^2$. We have for any $h \in B_k$ that $\hat{\nu}_h^2 = \langle h, \hat{f}_k - f_k \rangle_F^2 \leq \|h\|_2^2 \|\hat{f}_k - f_k\|_2^2$. Since $\|h\|_2 \leq 1$ we get
\[
\mathbb{E}_{f_Y}^n \left( \sup_{h \in B_k} \hat{\nu}_h^2 \right) \leq \mathbb{E}_{f_Y}^n (\|\hat{f}_k - f_k\|_2^2) \leq (2n\pi)^{-1} \Delta_g(k) =: \Psi^2.
\]
Thus $6\Psi^2 = p(k)$. Next we consider $\psi$. Let $y > 0$ and $h \in B_k$ then using the Cauchy Schwartz inequality we get $|\nu_h(y)|^2 = (2\pi)^{-2} \int_{-k}^k y^2 \frac{M_1[h](t)}{M_1[g](t)} dt \leq (2\pi)^{-2} \int_{-k}^k |M_1[g](t)|^{-2} dt \leq (2\pi)^{-2} \Delta_g(k) =: \psi^2$ since $|y^2| = 1$ for all $t \in \mathbb{R}$.

Next we consider $\tau$. In fact for $h \in B_k$ we can conclude $\mathbb{V} \mathbb{A} \mathbb{R}(\nu_h(Y_1)) \leq \mathbb{E}_{f_Y}^n (\nu_h(Y_1)^2) \leq \|\omega f_Y\|_{\infty} \int_0^\infty y^{-1} \nu_h(y)^2 dt = \|\omega f_Y\|_{\infty} \|\nu_h\|_{2,\infty}^2$ with $\nu_h(y) = (2\pi)^{-1} \int_{-k}^k y^2 \frac{M_1[h](t)}{M_1[g](t)} dt$ for $y > 0$. Thus
\[
\|\nu_h\|_{2,\infty}^2 = \frac{1}{2\pi} \int_{-k}^k \frac{|M_1[h](t)|^2}{|M_1[g](t)|^2} dt \leq \frac{\|G_k\|_{\infty}}{2\pi} \int_{-\infty}^\infty |M_1[h](t)|^2 dt
\]
where $\frac{1}{2\pi} \int_{-\infty}^\infty |M_1[h](t)|^2 dt = \|h\|_2^2 \leq 1$. Thus we set $\tau = \|\omega f_Y\|_{\infty} \|G_k\|_{\infty}$. Hence we have that $\frac{\Delta_g(k)}{6\tau} = \frac{\Delta_g(k)}{12 \pi \|\omega f_Y\|_{\infty} \|G_k\|_{\infty}}$ and $\frac{\Delta_g(k)}{\varphi} \approx \sqrt{2 \pi \frac{\Delta_g(k)}{n}}$. We deduce
\[
\mathbb{E}_{f_Y}^n \left( \sup_{h \in B_k} \hat{\nu}_h^2 \right) \leq \frac{C}{n} \left( \frac{\|G_k\|_{\infty}}{\|\omega f_Y\|_{\infty}} \exp(-\frac{\Delta_g(k)}{12 \pi \|\omega f_Y\|_{\infty} \|G_k\|_{\infty}}) \right)
\[
+ \frac{\varphi}{(2\pi)^2 \Delta_g(k) \exp(-\frac{n}{50})}.
\]

C Proofs of section 3

Proof of Theorem 3.4. First we outline here the main steps of the proof. We will construct a family of functions in $\mathbb{D}_{l,\psi}^{h,s}$ by a perturbation of the density $f_\psi : \mathbb{R}^+ \to \mathbb{R}^+$ with small bumps, such that their $L^2(\omega)$-distance and the Kullback-Leibler divergence of their induced distributions can be bounded from below and above, respectively. The claim follows then by applying Theorem 2.5 in Tsybakov [2008]. We use the following construction, which we present first.

Denote by $C_c^\infty(\mathbb{R})$ the set of all smooth functions with compact support in $\mathbb{R}$ and let $\psi \in C_c^\infty(\mathbb{R})$ be a function with support in $[0, 1]$ and $\int_0^1 \psi(x) dx = 0$. For each $K \in \mathbb{N}$ (to be selected below) and $k \in [0, K]$ we define the bump-functions $\psi_{k,K}(x) := \psi(xK - K - k)$, $x \in \mathbb{R}$, and define for $j \in \mathbb{N}$ the finite constant $C_{j,\psi} := \max(\|\psi^{(i)}\|_{\infty}, l \in [0, j])$. Let us further define the operator $S : C_c^\infty(\mathbb{R}) \to C_c^\infty(\mathbb{R})$ with $S[f](x) = xf^{(1)}(x)$ for all $x \in \mathbb{R}$ and define $S^1 := S$ and $S^n := S \circ S^{n-1}$ for $n \in \mathbb{N}$, $n \geq 2$. Now, for $j \in \mathbb{N}$, we define the function
ψ_{k,K,j}(x) := S^j[ψ_{k,K}](x) = \sum_{i=1}^j c_{i,j} x^i K^i \psi^{(i)}(xK - K - k) \text{ for } x \in \mathbb{R}^+ \text{ and } c_{i,j} \geq 1 \text{ and let } 
c

\sum_{i=1}^j c_{i,j}.

For a bump-amplitude \(\delta > 0, \gamma \in \mathbb{N}\) and a vector \(\theta = (\theta_1, \ldots, \theta_K) \in \{0,1\}^K\) we define

\[ f_\theta(x) = f_o(x) + \delta K^{-s} \sum_{k=0}^{K-1} \theta_{k+1} \psi_{k,K,\gamma}(x) \text{ where } f_o(x) := \exp(-x). \tag{C.1} \]

Until now, we did not give a sufficient condition to ensure that our constructed functions \(\{f_\theta : \theta \in \{0,1\}^K\}\) are in fact densities. This condition is given by the following lemma.

**Lemma C.1.** Let \(0 < \delta < \delta_o(\psi, \gamma) := \exp(-2\gamma(C_{\gamma,\infty}c_\gamma)^{-1})\). Then for all \(\theta \in \{0,1\}^K, f_\theta\) is a density.

Further one can show that these densities all lie inside the ellipsoids \(\mathbb{D}^{s,L}_{\mathbb{R}^+}\) for \(L\) big enough. This is captured in the following lemma.

**Lemma C.2.** Let \(s \in \mathbb{N}\). Then, there is \(L_{s,\gamma,\delta} > 0\) such that \(f_o\) and any \(f_\theta\) as in (C.1) with \(\theta \in \{0,1\}^K, K \in \mathbb{N}\), belong to \(\mathbb{D}^{s,L_{s,\gamma,\delta}}\).

For sake of simplicity we denote for a function \(\varphi \in \mathbb{L}^2_{\mathbb{R}^+}\) the multiplicative convolution with \(g\) by \(\tilde{\varphi} := [\varphi \ast g]\). Futher we see that for \(y_2 \geq y_1 > 0\) holds

\[ \tilde{f}_o(y_1) = \int_0^\infty g(x)x^{-1} \exp(-y_1/x)dx \geq \int_0^\infty g(x)x^{-1} \exp(-y_2/x)dx = \tilde{f}_o(y_2) \]

and thus \(\tilde{f}_o\) is monotone decreasing. Further we have that \(\tilde{f}_o(2) > 0\) since otherwise \(g = 0\) almost everywhere. Exploiting Varshamov-Gilbert’s lemma (see Tsybakov [2008]) in **Lemma C.3** we show further that there is \(M \in \mathbb{N}\) with \(M \geq 2^{K/8}\) and a subset \(\{\theta^{(0)}, \ldots, \theta^{(M)}\}\) of \(\{0,1\}^K\) with \(\theta^{(0)} = (0, \ldots, 0)\) such that for all \(j, l \in [0, M], j \neq l\) the \(\mathbb{L}^2_{\mathbb{R}^+}(\omega)\)-distance and the Kullback-Leibler divergence are bounded for \(K \geq K_o(\gamma, \psi)\).

**Lemma C.3.** Let \(K \geq K_o(\psi, \gamma) \vee 8\). Then there exists a subset \(\{\theta^{(0)}, \ldots, \theta^{(M)}\}\) of \(\{0,1\}^K\) with \(\theta^{(0)} = (0, \ldots, 0)\) such that \(M \geq 2^{K/8}\) and for all \(j, l \in [0, M], j \neq l\) holds

\[ \|f_{\theta^{(j)}} - f_{\theta^{(l)}}\|_2^2 \geq \frac{\|\psi(\gamma)\|^2}{2^{s/2}} K^{-2s} \text{ and } KL(\tilde{f}_{\theta^{(j)}}, \tilde{f}_{\theta^{(l)}}) \leq C^{(2)}_{\psi,\theta,\delta,\gamma,\varphi, f_o} \log(M)K^{-2s-2\gamma-1} \]

where \(C^{(2)}_{\psi,\delta,\gamma,\varphi, f_o} < 1/8\) for all if \(\delta \leq \delta_o(\psi, g, \gamma, f_o)\) and \(M \geq 2\) for \(n \geq n_{s,\gamma} := s^{2s+1} \vee K_o(\gamma, \psi)^{2s+2\gamma+1}\). Thereby, we can use Theorem 2.5 of Tsybakov [2008], which in turn for
any estimator \( \hat{f} \) of \( f \) implies
\[
\sup_{f \in D_{k,L}^+} \mathbb{E}_n^f(\|\hat{f} - f\|_\omega^2) \geq \frac{c_{s,\gamma}}{2} n^{-2s/(2s+2\gamma+1)} \geq \frac{\sqrt{M}}{1+\sqrt{M}}(1 - 1/4 - \sqrt{1/4\log(M)}) \geq 0.07.
\]

Note that the constant \( c_{s,\gamma} \) does only depend on \( \psi, \gamma \) and \( \delta \), hence it is independent of the parameters \( s, L \) and \( n \). The claim of Theorem 3.4 follows by using Markov's inequality, which completes the proof. □

Proofs of the lemmata

**Proof of Lemma C.1.** For any \( h \in C_0^\infty(\mathbb{R}) \) we can state that \( \int_{-\infty}^{\infty} S[h](x)dx = [xh(x)]_{-\infty}^{\infty} - \int_{-\infty}^{\infty} h(x)dx = -\int_{-\infty}^{\infty} h(x)dx \) and therefore \( \int_{-\infty}^{\infty} S^j[h](x)dx = (-1)^j \int_{-\infty}^{\infty} h(x)dx \) for \( j \in \mathbb{N} \). Thus \( \int_{-\infty}^{\infty} \psi_{k,K,\gamma}(x)dx = (-1)^\gamma \int_{-\infty}^{\infty} \psi_{k,K}(x)dx = 0 \) which implies that for any \( \delta > 0 \) and \( \theta \in \{0,1\}^k \) we have \( \int_{-\infty}^{\infty} f_\theta(x)dx = 1 \).

Now due to the construction (C.1) of the functions \( \psi_{k,K} \) we easily see that the function \( \psi_{k,K} \) has support on \([1+k/\gamma, 1+(k+1)/\gamma]\) which lead to \( \psi_{k,K} \) and \( \psi_{i,K} \) having disjoint supports if \( k \neq i \). Here, we want to emphasize that \( \text{supp}(S[h]) \subseteq \text{supp}(h) \) for all \( h \in C_0^\infty(\mathbb{R}) \). Which implies that \( \psi_{k,K,\gamma} \) and \( \psi_{i,K,\gamma} \) have disjoint supports if \( k \neq i \), too. For \( x \in [1,2]^c \) we have \( f_\theta(x) = \exp(-x) \geq 0 \). Now let us consider the case \( x \in [1,2] \). In fact there is \( k_o \in [0, K] \) such that \( x \in [1+k_o/\gamma, 1+(k_o+1)/\gamma] \) and hence
\[
f_\theta(x) = f_o(x) + \theta_{k_o+1}\delta K^{-s-\gamma}\psi_{k_o,K,\gamma}(x) \geq \exp(-2) - \delta 2^c C_{\gamma,\gamma} c_x
\]
since \( \|\psi_{k,K,j}\|_\infty \leq 2^j C_{j,\gamma} c_x K^j \) for any \( k \in [0, K] \) and \( j \in \mathbb{N} \) where \( c_j := \sum_{i=1}^j c_{i,j} \). Now choosing \( \delta \leq \delta_o(\psi, \gamma) = \exp(-2)2^{-\gamma}(C_{\gamma,\gamma} c_x)^{-1} \) ensures \( f_\theta(x) \geq 0 \) for all \( x \in \mathbb{R}^+ \). □

**Proof of Lemma C.2.** Our proof starts with the observation that for all \( t \in \mathbb{R} \) we have \( M_1[f_o](t) = \Gamma(1+it) \). Now by applying the Stirling formula (see also Belomestny et al. [2020] ) we get \( |\Gamma(1+it)| \approx |t|^{1/2}\exp(-\pi/2|t|), |t| \geq 2, \) thus for every \( s \in \mathbb{N} \) there exists \( L_s \) such that \( |f_o|_s \leq L_s \) for all \( L \geq L_s \).

Next we consider \( |f_o - f_\theta|_s \). Let us therefore define first \( \Psi_{K} := \sum_{k=0}^{K-1} \theta_{k+1}\psi_{k,K} \) and \( \Psi_{K,j} := S^j[\Psi_{K}] \) for any \( j \in \mathbb{N} \). Then we have \( |f_o - f_\theta|_s^2 = \delta^2 K^{-2s-2\gamma|\Psi_{K,j}|_s^2} \) where \( |.|_s \) is defined in (2.5). Now since for any \( j \in \mathbb{N} \), it holds that \( \text{supp}(\Psi_{K,j}) \subset [1,2], \|\Psi_{K,j}\|_\infty < \infty \) we have that \( (0, \infty) \) is a subset of the strip of analyticity of \( \Psi_{K,j} \). By application of (A.1) we deduce that \( |M_1[\Psi_{K,s+\gamma}](t)|^2 = (1+t^2)^s|M_1[\Psi_{K,s+\gamma}](t)|^2 \) and thus
\[
|\Psi_{K,s+\gamma}|_s^2 = \int_{-\infty}^{\infty} |M_1[\Psi_{K,s+\gamma}](t)|^2 dt = 2\pi \int_0^\infty x|\Psi_{K,s+\gamma}(x)|^2 dx
\]
by the Parseval formula. Since \( \psi_{k,K} \) have disjoint support for different values of \( k \) we follow that \( |\psi_{k,K}|_s^2 = 2\pi \sum_{k=0}^{K-1} \theta_{k+1}^2 \int_0^\infty x|S^j[\psi_{k,K}](x)|^2 dx \). Applying the Jensen inequality and
the fact that \( \text{supp}(\psi_{k,K}) \subset [1,2] \) leads to

\[
|\Psi_{k,\gamma}|^2 \leq 2\pi 2^{\gamma+s-1} \sum_{k=0}^{K-1} \sum_{j=1}^{\gamma+s} c_{j,\gamma+s}^2 \int_1^2 x^{2j+1} K^{2j} \psi^{(j)}(xK - K - k)^2 dx
\]

\[
\leq 2\pi K^{2(\gamma+s)} 2^{\gamma+s} \sum_{k=0}^{K-1} \sum_{j=1}^{\gamma+s} c_{j,\gamma+s}^2 C_{\psi,s,\gamma} K^{-1} \leq C(\gamma,s) K^{2(\gamma+s)}
\]

Thus \( |f_o - f_o|^2 \leq C(s,\delta) \) and \( |f_o|^2 \leq 2(|f_o - f_o|^2 + |f_o|^2) \leq 2(C(s,\delta) + L_o) =: L_{s,\delta}. \)

**Proof of Lemma C.3.**

Using the functions \( (\psi_{k,K,\gamma})_{k \in [0,K]} \) with different index \( k \) have disjoint supports we get

\[
\| f_o - f_o \|_\omega^2 = \delta^2 K^{-2s-2\gamma} \| \sum_{k=0}^{K-1} (\theta_{k+1} - \theta_{k+1}) \psi_{k,K,\gamma} \|_\omega^2 = \delta^2 K^{-2s-2\gamma} \rho(\theta, \theta') \| \psi_{0,K,\gamma} \|_\omega^2
\]

with \( \rho(\theta, \theta') := \sum_{j=0}^{K-1} (\theta_{j+1} - \theta_{j+1}) \) the Hamming distance. Now the first claim follows by showing that by \( \| \psi_{0,K,\gamma} \|_\omega^2 \geq K^{2(\gamma+1)} \| \psi^{(\gamma)} \|^2 \) for \( K \) big enough. To do so we observe that

\[
\| \psi_{0,K,\gamma} \|^2_\omega = \sum_{j=1}^{\gamma} c_{j,\gamma} \int_0^\infty x^{j+1} \psi^{(j)}(x) \psi^{(j)}(x) dx
\]

and define

\[
\Sigma := \| \psi_{0,K,\gamma} \|^2_\omega - \int_0^\infty (x^\gamma \psi_{0,K}(x))^2 dx
\]

as soon as \( |\Sigma| \leq K^{2(\gamma+1)} \| \psi^{(\gamma)} \|^2 \). This is obviously true as soon as \( K \geq K_0(\gamma, \psi) \) and thus

\[
\| f_o - f_o \|_\omega^2 \geq \delta^2 \| \psi^{(\gamma)} \|^2 \| K^{-2s-1} \rho(\theta, \theta') \| \psi_{0,K,\gamma} \|_\omega^2
\]

Now we use the Varshamov-Gilbert Lemma (see Tsybakov [2008]) which states that for \( K \geq 8 \) there exists a subset \( \{ \theta^{(0)}, \ldots, \theta^{(M)} \} \) of \( \{0,1\}^K \) with \( \theta^{(0)} = (0, \ldots, 0) \) such that \( \rho(\theta^{(j)}, \theta^{(k)}) \geq K/8 \) for all \( j, k \in [0,M], j \neq k \) and \( M \geq 2^{K/8} \). Applying this leads to

\[
\| f_o - f_o \|_\omega^2 \geq \frac{\| \psi^{(\gamma)} \|^2_\omega^2 K^{-2s}}{16}
\]

For the second part we have \( f_o = f_o o_y \) and by using \( KL(\tilde{f}_o, \tilde{f}_o) \leq \chi^2(\tilde{f}_o, \tilde{f}_o) := \int_\mathbb{R} x(\tilde{f}_o - \tilde{f}_o)^2 / \tilde{f}_o(x) dx \) it is sufficient to bound the \( \chi \)-squared divergence. We notice that \( f_o - \tilde{f}_o \) has support in \([0,2]\) since \( f_o \) has support in \([1,2]\) and \( g \) has support in \([0,1]\). In fact for \( y > 2 \) holds \( \tilde{f}_o(y) - f_o(y) = \int_\infty^y (f_o - f_o)(x) x^{-1} g(y/x) dx = 0 \). Denote further

\[
\Psi_{K,\gamma} := \sum_{k=0}^{K-1} \theta_{k+1} \psi_{k,K,\gamma} = S^\gamma \sum_{k=0}^{K-1} \theta_{k+1} \psi_{k,K} : = S^\gamma [\Psi_K] \text{.}
\]

Now by using the compact support property and a single substitution we get

\[
\chi^2(\tilde{f}_o, \tilde{f}_o) \leq \tilde{f}_o(2)^{-1} \| \tilde{f}_o - \tilde{f}_o \| = \tilde{f}_o(2)^{-1} \| \tilde{f}_o - \tilde{f}_o \|^2 \leq \tilde{f}_o(2)^{-1} \delta^2 K^{-2s-2\gamma} \| \tilde{f}_o \|^2 \cdot \Psi_{K,\gamma} \|^2 \cdot \tilde{f}_o(2)^{-1}
\]

Let us now consider \( \| \tilde{f}_o \|^2 \). In the first step we see by application of the Parseval that

\[
\| \tilde{f}_o \|^2 = \frac{1}{2\pi} \int_\mathbb{R} |\mathcal{M}_{1/2}[\tilde{f}_o](t)|^2 dt
\]

Now for \( t \in \mathbb{R} \), we see by using the multiplication
theorem for Mellin transforms that 
\[ M_{1/2}[\tilde{\Psi}_{K,\gamma}](t) = M_{1/2}[\hat{g}](t) \cdot M_{1/2}[\hat{S}^\gamma[\Psi_K]](t). \]
Again we have 
\[ M_{1/2}[\hat{S}^\gamma[\Psi_K]](t) = (1/2 + it)^\gamma M_{1/2}[\hat{\Psi}_K](t). \]
Together with assumption [G1'] we get
\[ \|\tilde{\Psi}_{K,\gamma}\|^2 \leq C_1(g) \int_{-\infty}^{\infty} |M_{1/2}[\Psi_K](t)|^2 dt = C_1(g)\|\Psi_K\|^2 \leq C_1(g)\|\psi\|^2. \]
Since \( M \geq 2^K \) we have thus 
\[ KL(\hat{f}_{\theta(\cdot)}, \hat{f}_{\theta(0)}) \leq \frac{C_1(g)\|\psi\|^2}{\log^2(2)} \delta^2 \log(M)K^{-2s-2\gamma-1}. \]
