Doubly Robust Semiparametric Inference Using Regularized Calibrated Estimation with High-dimensional Data

Satyajit Ghosh\textsuperscript{1} & Zhiqiang Tan\textsuperscript{1}

August 16, 2021

Abstract. Consider semiparametric estimation where a doubly robust estimating function for a low-dimensional parameter is available, depending on two working models. With high-dimensional data, we develop regularized calibrated estimation as a general method for estimating the parameters in the two working models, such that valid Wald confidence intervals can be obtained for the parameter of interest under suitable sparsity conditions if either of the two working models is correctly specified. We propose a computationally tractable two-step algorithm and provide rigorous theoretical analysis which justifies sufficiently fast rates of convergence for the regularized calibrated estimators in spite of sequential construction and establishes a desired asymptotic expansion for the doubly robust estimator. As concrete examples, we discuss applications to partially linear, log-linear, and logistic models and estimation of average treatment effects. Numerical studies in the former three examples demonstrate superior performance of our method, compared with debiased Lasso.

Key words and phrases. Average treatment effect; Calibration estimation; Debiased Lasso; Double robustness; High-dimensional data; Lasso penalty; Partially linear model; Semiparametric estimation.

1 Introduction

Semiparametric modeling and estimation aims to draw inference about low-dimensional parameters of interest, while allowing flexible specification for nuisance parameters, which are often in the form of smooth functions of covariates (Bickel et al. 1993; Tsiatis 2007). With low-dimensional covariates, various methods and theory have been developed, using non-parametric smoothing techniques to estimate those unknown functions. There are increasing difficulties, as the complexity of functions increases with a fixed number of covariates, or the number of covariates increases with parametric specifications for the unknown functions. These two problems are fundamentally related. For concreteness, we focus on the latter setting, where the number of covariates is large, while the unknown functions are modeled using known basis functions, for example, main effects or interactions. This setting also allows connections to high-dimensional statistics (Bühlmann & Van de Geer 2011).

In this article, we study a broad class of semiparametric problems, where a doubly robust estimating function $\tau(U; \theta, \alpha, \gamma)$ for the parameter of interest $\theta$ is available as follows. Here $U$ denotes a data vector including a possibly high-dimensional covariate vector $X$, and $(\alpha, \gamma)$ are two nuisance parameters defined through working models $g(x; \alpha)$ and $f(x; \gamma)$ for unknown functions $g^*(x)$ and $f^*(x)$. The estimating function $\tau$ is assumed to be unbiased, $E\{\tau(U; \theta, \alpha, \gamma)\} = 0$, when $\theta$ is set to the true value $\theta^*$, and either $\alpha$ or $\gamma$, but not necessarily both, is set to the true value $\alpha^*$ or $\gamma^*$ defined respectively such that $g(x; \alpha^*) \equiv g^*(x)$ or $f(x; \gamma^*) \equiv f^*(x)$ if model $g(\cdot; \alpha)$ or $f(\cdot; \gamma)$ is correctly specified. In general, doubly robust estimation using $\tau$ consists of two stages: some estimators $(\hat{\alpha}, \hat{\gamma})$ are first defined, and then $\hat{\theta}$ is defined by solving the estimating equation $\tilde{E}\{\tau(U; \theta, \hat{\alpha}, \hat{\gamma})\} = 0$, where $\tilde{E}()$ denotes a sample average. Conventionally, the estimators $(\hat{\alpha}, \hat{\gamma})$ are derived by maximum likelihood or variations associated with models $g(\cdot; \alpha)$ and $f(\cdot; \gamma)$ for $g^*$ and $f^*$.

While such doubly robust estimation is perhaps most extensively studied in missing-data problems and estimation of average treatment effects (Scharfstein et al. 1999; Kang & Schafer 2007; Tan 2010), doubly robust methods have been developed in various semiparametric problems, including partially linear and log-linear models (Robins & Rotnitzky 2001), instrumental variable analysis (Tan 2006b; Okui et al. 2012), mediation analysis (Tch-
etgen Tchetgen & Shpitser 2012), and dimension reduction (Ma & Zhu 2012) among others. As a somewhat under-appreciated result, we point out that the familiar least-squares estimator for each individual coefficient in linear regression is doubly robust in the context of a partially linear model. This result is also closely related to debiased Lasso estimation in high-dimensional linear regression (Zhang & Zhang 2014; Van de Geer et al. 2014; Javanmard & Montanari 2014). See Examples 5 and 10 for further discussion.

The main contribution of our work can be summarized as follows. Given a doubly robust estimating function \( \tau \), we develop a general method as an alternative to maximum likelihood for constructing estimators \((\hat{\alpha}, \hat{\gamma})\) of nuisance parameters, which are used to define an estimator \( \hat{\theta} \) as a solution to \( \tilde{E}\{\tau(U; \theta, \hat{\alpha}, \hat{\gamma})\} = 0 \). For this method, the limit values \((\bar{\alpha}, \bar{\gamma})\) of \((\hat{\alpha}, \hat{\gamma})\) are designed to satisfy a pair of population estimating equations, called calibration equations. If either model \( g(\cdot; \alpha) \) or \( f(\cdot; \gamma) \) is correctly specified, then the resulting estimator \( \hat{\theta} \) can be shown to be not only consistent for \( \theta^* \), but also achieve an asymptotic expansion in the following manner under suitable conditions with a sample size \( n \).

- In low-dimensional settings, the expansion of \( \hat{\theta} \) is in the usual order \( O_p(n^{-1/2}) \), but not affected by the variation of \((\hat{\alpha}, \hat{\gamma})\), which is also of order \( O_p(n^{-1/2}) \).
- In high-dimensional settings, the expansion of \( \hat{\theta} \) remains in the order \( O_p(n^{-1/2}) \), even though the convergence of \((\hat{\alpha}, \hat{\gamma})\) to \((\bar{\alpha}, \bar{\gamma})\) is slower than \( O_p(n^{-1/2}) \).

In fact, with high-dimensional data, we propose a computationally tractable two-step algorithm using Lasso regularized estimation. We provide rigorous theoretical analysis which justifies sufficiently fast convergence rates for \((\hat{\alpha}, \hat{\gamma})\) in spite of sequential construction and establishes the desired asymptotic expansion and variance estimation for \( \hat{\theta} \). Doubly robust Wald confidence intervals can be obtained, based on \( \hat{\theta} \) and consistent variance estimation. As concrete examples, we discuss applications to partially linear, log-linear, and logistic models and a missing-response problem related to estimation of average treatment effects.

**Related work.** There is an extensive literature related to our work. In low-dimensional settings, estimating equations similar to our calibration equations are proposed by Vermeulen & Vansteelandt (2015), where a similar asymptotic expansion similar as described above is obtained. The two methods are equivalent in some problems such as estimation of average
treatment effects, where a similar method is also proposed in Kim & Haziza (2014). However, there exists a general difference: estimating equations in Vermeulen & Vansteelandt (2015) are defined from the influence function of a doubly robust estimator as originally motivated to achieve bias reduction, whereas our calibration equations are defined from a doubly robust estimating function to achieve a desired asymptotic expansion. For instance, see Examples 2 and 7 for differences of the two methods in partially log-linear models.

In high-dimensional settings, doubly robust estimating functions are used with regularized likelihood (or quasi-likelihood) estimators of \((\alpha, \gamma)\) in Belloni et al. (2014) and Farrell (2015). Valid confidence intervals are established under suitable sparsity conditions, when both models \(g(\cdot; \alpha)\) and \(f(\cdot; \gamma)\) are correctly specified. For inference about average treatment effects, doubly robust confidence intervals are obtained in Tan (2020a) if either a propensity score model or a linear outcome model is correctly specified. In this case, regularized calibration estimators of \(\alpha\) and then \(\gamma\) are determined sequentially, independent of \(\theta\). For a nonlinear outcome model, only model-assisted confidence intervals are established, provided a propensity score model is correctly specified but the outcome model may be misspecified. In this case and other problems (see Examples 7–9), there are computational and theoretical complications due to coupled calibration equations. To tackle these issues, we develop the two-step algorithm and appropriate high-dimensional analysis, to obtain doubly robust confidence intervals which are not only computationally tractable but also theoretically justified in general settings where doubly robust estimating functions are available.

For estimating average treatment effects, Avagyan & Vansteelandt (2017) proposed a regularized version of estimating equations in Vermeulen & Vansteelandt (2015). But their theoretical analysis appears to presume standard convergence rates for the estimators of \((\alpha, \gamma)\) without handling additional data-dependency in loss functions. Ning et al. (2020) proposed doubly robust confidence intervals, but their method is operationally more complicated than Tan (2020a) and our work. With a nonlinear outcome model, the method in Ning et al. (2020) involves first three steps which yield the same estimators \((\hat{\alpha}_2, \hat{\gamma}_2)\) as in our Example 13, but then performs a fourth step to adjust the fitted propensity score before applying the augmented inverse probability weighted estimator. In addition, the fourth step relies on variable selection properties, which may require stronger technical conditions.
than convergence of estimation errors used in our method. An artificial constraint on the parameter set is also added in the proofs of Theorems 1 and 2 in Ning et al. (2020).

Smucler et al. (2019) made a distinction between two types of doubly robust estimation in high-dimensional settings. Our method as well as those in Avagyan & Vansteelandt (2017), Tan (2020a) and Ning et al. (2020) achieves model double robustness: an estimator of $\theta$ is obtained of order $O_p(n^{-1/2})$ if either of models $g(\cdot; \alpha)$ and $f(\cdot; \gamma)$ is correctly specified, under sparsity conditions $s_{\bar{\alpha}} = o(n^{1/2})$ and $s_{\bar{\gamma}} = o(n^{1/2})$ up to log($p$) terms, where $s_{\bar{\alpha}}$ or $s_{\bar{\gamma}}$ is the number of nonzero elements of the target values $\bar{\alpha}$ or $\bar{\gamma}$. By comparison, several methods have been proposed to achieve rate double robustness: an estimator of $\theta$ is obtained of order $O_p(n^{-1/2})$ if both models $g(\cdot; \alpha)$ and $f(\cdot; \gamma)$ are correctly specified, under sparsity conditions $s_{\bar{\alpha}}s_{\bar{\gamma}} = o(n)$ or weaker (Chernozhukov et al. 2018; Smucler et al. 2019; Bradic et al. 2019). All of these methods appear to rely on sample splitting and cross fitting, which is not pursued in our work. In particular, the method of Smucler et al. (2019) is shown to achieve rate and model double robustness simultaneously in general settings where the parameter $\theta$ has an influence function in a certain bilinear form. However, our method is applicable to any doubly robust estimating function including that in a partially logistic model in our Example 3, which does not satisfy the bilinear condition.

Finally, our work is also connected to debiased Lasso mentioned earlier and extensions (Neykov et al. 2018) to obtain confidence intervals and tests for low-dimensional coefficients in high-dimensional models. These methods in general do not achieve double robustness. See Examples 10–12 on partially linear models for further discussion.

## 2 Double robustness and calibrated estimation

### 2.1 Doubly robust estimation

Let $\{U_i : i = 1, \ldots, n\}$ be independent and identically distributed observations as $U$, which is assumed to include a covariate vector $X$ taking values $x$ in a space $\mathcal{X}$. Consider semiparametric estimation based on an estimating equation

$$0 = \mathbb{E}\{\tau(U; \theta, g, f)\} = \frac{1}{n} \sum_{i=1}^{n} \tau(U_i; \theta, g, f),$$

(1)
where $\bar{E}()$ denotes a sample average, $\tau(U; \theta, g, f)$ is an estimating function, $\theta$ is a scalar parameter of interest in $\Theta$, and $g$ and $f$ are two variation-independent nuisance parameters, defined in some function spaces $G$ and $F$ on $X$. Denote by $(\theta^*, g^*, f^*)$ the true values (i.e., data-generating values) of $(\theta, g, f)$. Assume that the estimating function $\tau(U; \theta, g, f)$ is doubly robust in satisfying the following two properties:

\[
0 = E\{\tau(U; \theta^*, g^*, f)\} \text{ for any } f \in F, \tag{2}
\]

\[
0 = E\{\tau(U; \theta^*, g, f^*)\} \text{ for any } g \in G. \tag{3}
\]

In other words, $\tau(U; \theta, g, f)$ is unbiased for estimation of $\theta^*$ if either $g = g^*$ or $f = f^*$. Several examples of doubly robust estimating functions are as follows. Construction of doubly robust estimating functions is problem-dependent and not discussed here. See Robins & Rotnitzky (2001), Tchetgen Tchetgen et al. (2010) and Tan (2019) among others.

**Example 1.** Suppose that an outcome $Y$ is related to a covariate $Z$ and additional covariates $X$ in a partially linear model

\[
E(Y|Z, X) = \theta^*Z + g^*(X), \tag{4}
\]

where $\theta^*$ is the true value of a coefficient $\theta$ and $g^*(x)$ is the true value of a function $g(x)$. In addition to $g(\cdot)$, define a nuisance parameter $f(\cdot)$ such that $f^*(X) = E(Z|X)$. Then the following estimating function is doubly robust (Robins & Rotnitzky 2001),

\[
\tau(U; \theta, g, f) = \{Y - \theta Z - g(X)\}\{Z - f(X)\}, \tag{5}
\]

where $U = (Y, Z, X)$. The true value $\theta^*$ can be regarded as a homogeneous additive treatment effect, in the setting where $Z$ is a treatment variable.

**Example 2.** Consider a partially log-linear model

\[
E(Y|Z, X) = \exp\{\theta^*Z + g^*(X)\}, \tag{6}
\]

where $\theta^*$ is the true value of a coefficient $\theta$ and $g^*(x)$ is the true value of a function $g(x)$. The nuisance parameter $f(x)$ is still defined such that $f^*(X) = E(Z|X)$. Then the following estimating function is doubly robust (Robins & Rotnitzky 2001),

\[
\tau(U; \theta, g, f) = \{Ye^{-\theta Z} - e^{g(X)}\}\{Z - f(X)\}, \tag{7}
\]
where \( U = (Y, Z, X) \). The true value \( \theta^* \) can be regarded as a homogeneous multiplicative treatment effect, in the setting where \( Z \) is a treatment variable.

**Example 3.** Consider a partially logistic model with binary \( Y \),

\[
E(Y|Z, X) = \text{expit}\{\theta^* Z + g^*(X)\},
\]

where \( \text{expit}(c) = (1 + e^{-c})^{-1} \), \( \theta^* \) is the true value of \( \theta \) and \( g^*(x) \) is the true value of \( g(x) \). In contrast with Examples 1–2, define a nuisance parameter \( f(\cdot) \) such that \( f^*(X) = E(Z|Y = 0, X) \). Then a doubly robust estimating function is (Tan 2019)

\[
\tau(U; \theta, g, f) = e^{-\theta ZY} \{Y - \text{expit}(g(X))\} \{Z - f(X)\},
\]

where \( U = (Y, Z, X) \). The true value \( \theta^* \) can be regarded as a homogeneous treatment effect in the scale of log odds, in the setting where \( Z \) is a treatment variable.

**Example 4.** Let \( Y \) be an outcome variable, \( X \) a covariate vector, and \( Z \) a binary variable such that \( Z = 1 \) or \( 0 \) if \( Y \) is observed or missing respectively. Assume that the missing data mechanism is ignorable: \( Y \) and \( Z \) are conditionally independent given \( X \) (Rubin 1976). It is of interest to estimate the mean \( \theta^* = E(Y) \). The nuisance parameters \( g(\cdot) \) and \( f(\cdot) \) are defined such that the true values are

\[
g^*(X) = E(Y|Z = 1, X), \quad f^*(X) = P(Z = 1|X),
\]

which are called outcome regression function and propensity score. Then the following estimating function is doubly robust (Scharfstein et al. 1999),

\[
\tau(U; \theta, g, f) = \frac{ZY}{f(X)} - \left\{ \frac{Z}{f(X)} - 1 \right\} g(X) - \theta,
\]

where \( U = (ZY, Z, X) \). The true value \( \theta^* \) represents the mean of a potential outcome associated with a treatment when \( Z \) encodes the receipt of the treatment.

Typically, estimating equation (1) is used in the form of two-stage semiparametric estimation, depending on some modeling restrictions, \( g(x; \alpha) \) and \( f(x; \gamma) \) with parameters \( \alpha \) and \( \gamma \), postulated on \((g^*, f^*)\). For concreteness, consider the following two models,

\[
g^*(x) = g(x; \alpha) = \psi_g\{\alpha^T \xi(x)\},
\]

\[
f^*(x) = f(x; \gamma) = \psi_f\{\gamma^T \xi(x)\},
\]
where $\psi_g$ and $\psi_f$ are inverse link functions similarly as in generalized linear models (McCullagh & Nelder 1989), $\xi(x)$ is a $p \times 1$ vector of known functions on $\mathcal{X}$ such as $\xi(x) = (1, x^T)^T$, and $\alpha$ and $\gamma$ are $p \times 1$ vectors of unknown coefficients. Models (11) and (12) may be misspecified. We say that model (11) is correctly specified if there exists a true value $\alpha^*$ such that $g^*(x) \equiv g(x; \alpha^*)$, or misspecified otherwise. Similarly, model (12) is correctly specified if there exists a true value $\gamma^*$ such that $f^*(x) \equiv f(x; \gamma^*)$, or misspecified otherwise. By definition, a true value $\alpha^*$ or $\gamma^*$ exists only if model (11) or (12) is correctly specified.

Given working models (11)–(12), the first-stage estimation involves constructing some estimators $\hat{\alpha}$ and $\hat{\gamma}$ and setting $\hat{g} = g(x; \hat{\alpha})$ and $\hat{f} = f(x; \hat{\gamma})$. Then an estimator for $\theta^*$, denoted as $\hat{\theta}(\hat{\alpha}, \hat{\gamma})$, is defined as a solution to (1) with $(g, f)$ replaced by $(\hat{g}, \hat{f})$, i.e.,

$$0 = \tilde{E}\{\tau(U; \theta, \hat{g}, \hat{f})\}. \quad (13)$$

Conventionally, $(\hat{\alpha}, \hat{\gamma})$ are defined by maximum likelihood (or quasi-likelihood) including least squares in generalized linear models associated with (11)–(12). Our main subject is, however, calibrated estimation as an alternative approach. To facilitate discussion in Section 2.2, we describe some general asymptotic results about $(\hat{\alpha}, \hat{\gamma})$ and $\hat{\theta}(\hat{\alpha}, \hat{\gamma})$, based on theory of estimation with possibly misspecified models (White 1982; Manski 1988), in the classical setting where $\alpha$ and $\gamma$ are fixed-dimensional as the sample size $n$ grows. To focus on main issues, assume that $\hat{\alpha}$ is consistent for $\alpha^*$ if model (11) is correctly specified, and $\hat{\gamma}$ is consistent for $\gamma^*$ if model (12) is correctly specified.

With possible model misspecification, $\hat{\alpha}$ can be shown to converge at rate $O_p(n^{-1/2})$ to a target value $\bar{\alpha}$, which coincides with the true value $\alpha^*$ (i.e., $\hat{\alpha}$ is consistent) if model (11) is correctly specified, but remains well-defined even though $\alpha^*$ is undefined if model (11) is misspecified. Similarly, $\hat{\gamma}$ can be shown to converge at rate $O_p(n^{-1/2})$ to a target value $\bar{\gamma}$, which coincides with the true value $\gamma^*$ (i.e., $\hat{\gamma}$ is consistent) if model (11) is correctly specified, but remains well-defined even though $\gamma^*$ is undefined if model (12) is misspecified. As a result, unbiasedness properties (2)–(3) can be used to show that $\hat{\theta}(\hat{\alpha}, \hat{\gamma})$ is doubly robust, i.e., remains consistent for $\theta^*$ if either model (11) or (12) is correctly specified. Moreover, it can be shown that if model (11) is correctly specified with $\bar{\alpha} = \alpha^*$ or model (12) is correctly
specified with \( \tilde{\gamma} = \gamma^* \), then \( \hat{\theta}(\hat{\alpha}, \tilde{\gamma}) \) admits the asymptotic expansion,

\[
\hat{\theta}(\hat{\alpha}, \tilde{\gamma}) - \theta^* = E^{-1} \left( \frac{\partial \tau}{\partial \theta} \right) \left\{ \tilde{E}(\tau) + E^T \left( \frac{\partial \tau}{\partial \alpha} \right) (\hat{\alpha} - \tilde{\alpha}) + E^T \left( \frac{\partial \tau}{\partial \gamma} \right) (\tilde{\gamma} - \gamma) \right\} + o_p(n^{-1/2}),
\]

(14)

where \( \tau = \tau(U; \theta, g(x; \alpha), f(x; \gamma)) \), and \( \tau \) and its partial derivatives \( (\partial \tau / \partial \theta, \partial \tau / \partial \alpha, \partial \tau / \partial \gamma) \) are evaluated above at \( (\theta^*, \tilde{\alpha}, \tilde{\gamma}) \). The preceding expansion (14) indicates how the asymptotic behavior of \( \hat{\theta}(\hat{\alpha}, \tilde{\gamma}) \) is affected by the estimators \( (\hat{\alpha}, \tilde{\gamma}) \) through the second and third terms in the curly brackets. In fact, removing these two terms in (14) yields the asymptotic expansion of the infeasible estimator \( \hat{\theta}(\tilde{\alpha}, \tilde{\gamma}) \), with \( (\hat{\alpha}, \tilde{\gamma}) \) replaced by \( (\tilde{\alpha}, \tilde{\gamma}) \).

**Example 5.** We point out a somewhat under-appreciated result that the familiar least squares estimator for each individual coefficient in linear regression is doubly robust in the context of a partially linear model in Example 1. Let \( \psi_g(\cdot) \) be an identity function in model (11). For \( \tau \) in (5), the estimator \( \hat{\theta}(\hat{\alpha}, \tilde{\gamma}) \) as a solution to (13) is of closed form with \( \xi = \xi(x) \),

\[
\hat{\theta}(\hat{\alpha}, \tilde{\gamma}) = \frac{\tilde{E}\{(Y - \hat{\alpha}^T \xi)(Z - \psi_f(\tilde{\gamma}^T \xi))\}}{\tilde{E}\{Z(Z - \psi_f(\tilde{\gamma}^T \xi))\}},
\]

depending on some estimators \( (\hat{\alpha}, \tilde{\gamma}) \). Suppose that \( \psi_f(\cdot) \) is also an identity function, i.e., a linear model is specified for \( E(Z|X) \). Let \( (\hat{\theta}_0, \hat{\alpha}) \) be the least-squares estimators of \( (\theta, \alpha) \) in the linear regression of \( Y \) on \( Z \) and \( \xi(X) \), and \( \hat{\gamma} \) be that of \( \gamma \) in the linear regression of \( Z \) on \( \xi(X) \). Then \( \hat{\theta}(\hat{\alpha}, \tilde{\gamma}) \) is identical to \( \hat{\theta}_0 \), the least squares estimator of \( \theta \):

\[
\hat{\theta}(\hat{\alpha}, \tilde{\gamma}) - \hat{\theta}_0 = \frac{\tilde{E}\{(Y - \hat{\theta}_0 Z - \hat{\alpha}^T \xi)(Z - \tilde{\gamma}^T \xi)\}}{\tilde{E}\{Z(Z - \tilde{\gamma}^T \xi)\}} = 0,
\]

because \( \tilde{E}\{(Y - \hat{\theta}_0 Z - \hat{\alpha}^T \xi)Z\} = 0 \) and \( \tilde{E}\{(Y - \hat{\theta}_0 Z - \hat{\alpha}^T \xi)\xi\} = 0 \). Hence the least-squares estimator \( \hat{\theta}_0 \) is doubly robust for \( \theta^* \) in the partially linear model (4), if either a linear model for \( g^*(x) \) or a linear model for \( f^*(x) = E(Z|X = x) \) is correctly specified. Furthermore, the sandwich variance estimator for \( \hat{\theta}_0 \) (White 1980) can be written as \( n^{-1} \hat{V} \) with

\[
\hat{V} = \frac{\tilde{E}\{(Y - \hat{\theta}_0 Z - \hat{\alpha}^T \xi)^2(Z - \tilde{\gamma}^T \xi)^2\}}{\tilde{E}^2\{Z(Z - \tilde{\gamma}^T \xi)\}}.
\]

By Corollary 2 later, an asymptotic \((1-c)\)-confidence interval for \( \theta^* \) is \( \hat{\theta}_0 \pm z_{c/2} \sqrt{\hat{V}/n} \) if either a linear model for \( E(Y|Z, X) \) or that for \( E(Z|X) \) is correctly specified. A high-dimensional version of this result is Corollary 4 later on debiased Lasso for least-squares estimation.
2.2 Calibrated estimation

We derive and discuss implications of basic mean-zero identities for a doubly robust estimating function \( \tau(U; \theta, g, f) \). In particular, we study calibrated estimation converting these identities into estimating equations in \((\alpha, \gamma)\). Here we assume the classical setting where asymptotic expansion (14) directly holds. See Section 3 for high-dimensional development.

For a function \( h(x) \) and a constant \( \delta > 0 \), denote by \( h + L_2(\delta) \) the set \( \{h(x) + c(x) : E(c^2(X)) \leq \delta^2\} \). Denote by \( \partial \tau / \partial g \) and \( \partial \tau / \partial f \) the partial derivatives of \( \tau = \tau(U; \theta, g, f) \) with respect to \( G = g(x) \) and \( F = f(x) \) as free arguments. Whenever the dependency of \( \tau \) on \((\alpha, \gamma)\) is mentioned, \( \tau \) is parameterized as \( \tau(U; \theta, \alpha, \gamma) = \tau(U; \theta, g(x; \alpha), f(x; \gamma)) \).

For differentiation of \( \tau \) with respect to \((\alpha, \gamma)\), it is convenient to introduce linear predictors \((\eta_g, \eta_f)\) such that \( g(x) = \psi_g(\eta_g(x)) \) and \( f(x) = \psi_f(\eta_f(x)) \). Hence models (11) and (12) can be stated as \( \eta_g(x; \alpha) = \alpha^T\xi(x) \) and \( \eta_f(x; \gamma) = \gamma^T\xi(x) \). Denote by \( \partial \tau / \partial \eta_g \) and \( \partial \tau / \partial \eta_f \) the partial derivatives of \( \tau \) with respect to \( \eta_g(x) \) and \( \eta_f(x) \) as free arguments. By the chain rule, \( \partial \tau / \partial \alpha = (\partial \tau / \partial \eta_g)\xi = (\partial \tau / \partial g)\psi_g'(\alpha^T\xi)\xi \) and \( \partial \tau / \partial \gamma = (\partial \tau / \partial \eta_f)\xi = (\partial \tau / \partial f)\psi_f'(\gamma^T\xi)\xi \), where \( \psi_g' \) or \( \psi_f' \) denotes the derivative of \( \psi_g \) or \( \psi_f \).

**Proposition 1.** Under suitable regularity conditions, property (2) implies that

\[
0 = E\left\{\frac{\partial \tau}{\partial f}(U; \theta^*, g^*, f)|X\right\},
\]

(15)

for any \( f \) such that \( f + L_2(\delta_1) \subset \mathcal{F} \) for some \( \delta_1 > 0 \). Similarly, property (3) implies that

\[
0 = E\left\{\frac{\partial \tau}{\partial g}(U; \theta^*, g, f^*)|X\right\},
\]

(16)

for any \( g \) such that \( g + L_2(\delta_2) \subset \mathcal{G} \) for some \( \delta_2 > 0 \).

**Proof.** For \( f \) such that \( f + L_2(\delta_1) \subset \mathcal{F} \), (2) implies that for any \( h \in L_2(1) \) and \( a \in [-\delta_1, \delta_1] \),

\[
0 = E\{f(U; \theta^*, g^*, f + ah)\}.
\]

Taking the derivative of the above with respect to \( a \) with \( f \) and \( h \) fixed, and assuming the differentiation and expectation are interchangeable, we have

\[
0 = E\left\{\frac{\partial \tau}{\partial f}(U; \theta^*, g^*, f)h(X)\right\}.
\]

Hence (15) follows because \( h \in L_2(1) \) is arbitrary. Similarly, (16) can be proved.
Similar reasoning as above can be applied to the derivatives of \( \tau \) with respect to \((\alpha, \gamma)\), given models (11)–(12). Differentiation of (2) or (3) with respect to \(\gamma\) or \(\alpha\) respectively and interchanging differentiation and expectation shows that for any \((\alpha, \gamma)\),
\[
0 = \mathbb{E}\left\{ \frac{\partial \tau}{\partial \gamma}(U; \theta^*, g^*, f(x; \gamma)) \right\} = \mathbb{E}\left\{ \xi(X) \frac{\partial \tau}{\partial \eta_f}(U; \theta^*, g^*, f(x; \gamma)) \right\}, \tag{17}
\]
\[
0 = \mathbb{E}\left\{ \frac{\partial \tau}{\partial \alpha}(U; \theta^*, g(x; \alpha), f^*) \right\} = \mathbb{E}\left\{ \xi(X) \frac{\partial \tau}{\partial \eta_g}(U; \theta^*, g(x; \alpha), f^*) \right\}. \tag{18}
\]
Equivalently, (17)–(18) can also be deduced from the more general identities (15)–(16), which involve conditional expectations given \(X\). Model (11) with \(g(x; \alpha)\) may be misspecified in (18), and model (12) with \(f(x; \gamma)\) may be misspecified in (17).

We stress that identities (15)–(16) and (17)–(18) are derived from double-robustness properties (2)–(3) in a general manner. To some extent, identities (17)–(18) are intriguingly reminiscent of the score identity in likelihood inference with a parametric model: the expectation of the gradient of the log-likelihood, evaluated at the true parameter value, is zero. However, \(\tau\) is an estimating function in \(\theta\), not a log-likelihood function in \(\alpha\) or \(\gamma\).

There are various implications of basic identities (17)–(18). First, these identities show that \(\mathbb{E}(\partial \tau / \partial \gamma)\) or \(\mathbb{E}(\partial \tau / \partial \alpha)\) reduces to 0 in asymptotic expansion (14) for \(\hat{\theta}(\hat{\alpha}, \hat{\gamma})\), depending on whether model (11) or (12) is correctly specified. If model (11) with \(g(x; \alpha)\) is correctly specified and \(\hat{\alpha}\) is consistent, then, by (17), asymptotic expansion (14) reduces to
\[
\hat{\theta}(\hat{\alpha}, \hat{\gamma}) - \theta^* = -E^{-1} \left( \frac{\partial \tau}{\partial \theta} \right) \left\{ \hat{\varnothing}(\tau) + E^\tau \left( \frac{\partial \tau}{\partial \alpha} \right) (\hat{\alpha} - \alpha^*) \right\} + o_p(n^{-1/2}), \tag{19}
\]
where \(\tau\) and its partial derivatives are evaluated at \((\theta, \alpha, \gamma) = (\theta^*, \alpha^*, \bar{\gamma})\). As the term associated with \(\hat{\gamma} - \bar{\gamma}\) vanishes in (19), the asymptotic behavior of \(\hat{\theta}(\hat{\alpha}, \hat{\gamma})\) does not depend on the definition of \(\hat{\gamma}\), as long as model (11) is correctly specified and \(\hat{\alpha}\) is consistent. Similarly, if model (12) with \(f(x; \gamma)\) is correctly specified and \(\hat{\gamma}\) is consistent, then, by (18), the asymptotic behavior of \(\hat{\theta}(\hat{\alpha}, \hat{\gamma})\) does not depend on the definition of \(\hat{\alpha}\):
\[
\hat{\theta}(\hat{\alpha}, \hat{\gamma}) - \theta^* = -E^{-1} \left( \frac{\partial \tau}{\partial \theta} \right) \left\{ \hat{\varnothing}(\tau) + E^\tau \left( \frac{\partial \tau}{\partial \gamma} \right) (\hat{\gamma} - \gamma^*) \right\} + o_p(n^{-1/2}), \tag{20}
\]
where \(\tau\) and its partial derivatives are evaluated at \((\theta, \alpha, \gamma) = (\theta^*, \bar{\alpha}, \gamma^*)\). Combining the preceding arguments leads to Corollary 1: if both models (11) and (12) are correctly specified, then the asymptotic behavior of \(\hat{\theta}(\hat{\alpha}, \hat{\gamma})\) remains the same for all consistent estimators \((\hat{\alpha}, \hat{\gamma})\).
This result, related to local efficiency in specific examples (e.g., Robins et al. 1994; Tan 2006a), is obtained here as a general consequence of double robustness of \( \tau \).

**Corollary 1.** If both models (11) and (12) are correctly specified and \((\hat{\alpha}, \hat{\gamma})\) are consistent, then as \( p \) is fixed and \( n \to \infty \), asymptotic expansion (14) reduces to

\[
\hat{\theta}(\hat{\alpha}, \hat{\gamma}) - \theta^* = -E^{-1} \left( \frac{\partial \tau}{\partial \theta} \right) \tilde{E}(\tau) + o_p(n^{-1/2}),
\]

where \( \tau \) and \( \partial \tau / \partial \theta \) are evaluated at \((\theta, \alpha, \gamma) = (\theta^*, \alpha^*, \gamma^*)\).

Second, methodologically, identities (17)–(18) can also be exploited to construct specific estimators \((\hat{\alpha}, \hat{\gamma})\), for which the simple expansion (21) is valid with the true values \((\alpha^*, \gamma^*)\) replaced by target values \((\bar{\alpha}, \bar{\gamma})\) if either model (11) or (12), but not necessarily both, is correctly specified. Suppose that estimators \((\hat{\alpha}_{\text{CAL}}, \hat{\gamma}_{\text{CAL}})\) are defined such that they converge in probability to target values \((\bar{\alpha}_{\text{CAL}}, \bar{\gamma}_{\text{CAL}})\) satisfying the simultaneous equations

\[
0 = E \left\{ \frac{\partial \tau}{\partial \gamma} (U; \theta^*, \alpha, \gamma) \right\} = E \left\{ \xi \frac{\partial \tau}{\partial \gamma} (U; \theta^*, \alpha, \gamma) \right\}, \tag{22}
\]
\[
0 = E \left\{ \frac{\partial \tau}{\partial \alpha} (U; \theta^*, \alpha, \gamma) \right\} = E \left\{ \xi \frac{\partial \tau}{\partial \gamma} (U; \theta^*, \alpha, \gamma) \right\}, \tag{23}
\]

that is, the coefficients of \( \hat{\gamma} - \bar{\gamma} \) and \( \hat{\alpha} - \bar{\alpha} \) are set to 0 in expansion (14) for \( \hat{\theta}(\hat{\alpha}, \hat{\gamma}) \). Assume that there exists at most one value \( \alpha \) satisfying (22) for each fixed \( \gamma \), and at most one value \( \gamma \) satisfying (23) for each fixed \( \alpha \). From our discussion below, this implies that \((\bar{\alpha}_{\text{CAL}}, \bar{\gamma}_{\text{CAL}})\) is a unique solution to (22)–(23) if model (11) or (12) is correctly specified.

If model (11) with \( g(x; \alpha) \) is correctly specified, then by (17), \( \bar{\alpha}_{\text{CAL}} \) coincides with \( \alpha^* \) as a solution to (22) for fixed \( \gamma = \bar{\gamma}_{\text{CAL}} \), i.e., \( \bar{\alpha}_{\text{CAL}} \) is consistent. In this case, (22) can be seen as an unbiased population estimating equation for \( \alpha^* \) with fixed \( \gamma \). Similarly, if model (12) with \( f(x; \gamma) \) is correctly specified, then by comparison of (18) and (23), \( \bar{\gamma}_{\text{CAL}} \) coincides with \( \gamma^* \), i.e., \( \bar{\gamma}_{\text{CAL}} \) is consistent. In this case, (23) can be seen as an unbiased population estimating equation for \( \gamma^* \) with fixed \( \alpha \). (An interesting asymmetry is that differentiation of \( \tau \) with respect to \( \gamma \) leads to an estimating equation in \( \alpha \), whereas that of \( \tau \) with respect to \( \alpha \) leads to an estimating equation in \( \gamma \).) Combining the two cases and applying asymptotic expansion (14) leads to the Corollary 2, where, due to (22)–(23) again, the two terms associated with \( \hat{\gamma} - \bar{\gamma} \) and \( \hat{\alpha} - \bar{\alpha} \) are dropped from the expansion (14). Alteratively, to help understanding,
asymptotic expansion (24) for \(\hat{\theta}(\hat{\alpha}_{\text{CAL}}, \hat{\gamma}_{\text{CAL}})\) can also be obtained from expansion (19) with \(E(\partial \tau / \partial \alpha) = 0\) due to (23) if model (11) is correctly specified, or from expansion (20) with \(E(\partial \tau / \partial \gamma) = 0\) due to (22) if model (12) is correctly specified.

**Corollary 2.** If model (11) or (12) is correctly specified, then \(\hat{\alpha}_{\text{CAL}}\) or \(\hat{\gamma}_{\text{CAL}}\) is consistent for \(\alpha^*\) or \(\gamma^*\) respectively. In either case, the estimator \(\hat{\theta}(\hat{\alpha}_{\text{CAL}}, \hat{\gamma}_{\text{CAL}})\) satisfies

\[
\hat{\theta}(\hat{\alpha}_{\text{CAL}}, \hat{\gamma}_{\text{CAL}}) - \theta^* = -E^{-1} \left( \frac{\partial \tau}{\partial \theta} \right) \bigg|_{(\theta, \alpha, \gamma) = (\theta^*, \hat{\alpha}_{\text{CAL}}, \hat{\gamma}_{\text{CAL}})} + o_p(n^{-1/2}), \tag{24}
\]

provided that expansion (14) holds for \((\hat{\alpha}, \hat{\gamma}) = (\hat{\alpha}_{\text{CAL}}, \hat{\gamma}_{\text{CAL}})\) as \(p\) is fixed and \(n \to \infty\).

We refer to equations (22)–(23) as population calibration equations and \((\hat{\alpha}_{\text{CAL}}, \hat{\gamma}_{\text{CAL}})\) as calibrated estimators for two reasons, following Tan (2020a). For the missing-data problem in Example 4, related to estimation of average treatment effects, this method leads to calibrated estimation for fitting propensity score models \(f(x; \gamma)\), which can be traced to the literature on survey calibration (Folsom 1991). See Example 9 below. More generally, as indicated by Corollaries 1–2, using estimating equations (22)–(23) can be seen as carefully choosing (or calibrating) estimators \((\hat{\alpha}, \hat{\gamma})\) for the nuisance parameters \((\alpha, \gamma)\), such that the resulting estimator \(\hat{\theta}(\hat{\alpha}, \hat{\gamma})\) behaves as if both models (11) and (12) were correctly specified, while it is only assumed that either model (11) or (12) is correctly specified.

A benefit of achieving asymptotic expansion (24) is to allow simple variance estimation for \(\hat{\theta}(\hat{\alpha}_{\text{CAL}}, \hat{\gamma}_{\text{CAL}})\), without the need to account for the variations of \((\hat{\alpha}_{\text{CAL}}, \hat{\gamma}_{\text{CAL}})\). This benefit is mainly computationally in the setting of low-dimensional \((\alpha, \gamma)\), where variance estimation can in general be performed for \(\hat{\theta}(\hat{\alpha}, \hat{\gamma})\) by using asymptotic expansion (14) and usual influence functions for \((\hat{\alpha}, \hat{\gamma})\), allowing for model misspecification (White 1982; Manski 1988). However, the influence-function based approach is not applicable in the high-dimensional setting where regularized estimation is involved. In Section 3, we develop regularized calibration estimation to achieve a simple expansion similar to (24) for the resulting estimator of \(\theta^*\), so that valid variance estimation and confidence intervals can be obtained.

**Remark 1.** It is important to distinguish the two expansions (21) and (24), although they appear similar to each other. The expansion (21) holds for any consistent estimators \((\hat{\alpha}, \hat{\gamma})\) provided that both models (11) and (12) are correctly specified. The two terms \(E(\partial \tau / \partial \alpha)\)
and $E(\partial \tau / \partial \gamma)$ in (14) reduce to 0 by the assumption of both models (11) and (12) being correctly specified, while appealing to the two identities (17)–(18) simultaneously. In contrast, the expansion (24) is valid for estimators $(\hat{\alpha}_{\text{CAL}}, \hat{\gamma}_{\text{CAL}})$ constructed such that (22)–(23) are satisfied, if either model (11) or (12), but not necessarily both, is correctly specified. The two terms $E(\partial \tau / \partial \alpha)$ and $E(\partial \tau / \partial \gamma)$ in (14) reduce to 0 by the construction of population estimating equations (22)–(23). Identity (17) is involved to show consistency of $\hat{\alpha}_{\text{CAL}}$ if model (11) is correct or, separately, identity (18) is involved to show consistency of $\hat{\gamma}_{\text{CAL}}$ if model (12) is correct, whereas consistency of $(\hat{\alpha}, \hat{\gamma})$ is presumed in Corollary 1.

Our preceding discussion leaves open the question how calibrated estimators $(\hat{\alpha}_{\text{CAL}}, \hat{\gamma}_{\text{CAL}})$ can be defined such that (22)–(23) are satisfied. A direct approach would be to take $(\hat{\alpha}_{\text{CAL}}, \hat{\gamma}_{\text{CAL}})$ as a solution to the sample version of calibration equations (22)–(23), where the expectation $E(\cdot)$ is replaced by the sample average $\bar{E}(\cdot)$. However, there are various complications for this approach even in the classical setting with low-dimensional $(\alpha, \gamma)$. First, equations (22)–(23) and the sample version may depend on $\theta^*$ to be estimated. A preliminary doubly robust estimator can be substituted for $\theta^*$. But the resulting sample version of (22)–(23) remains a system of nonlinear equations in $(\alpha, \gamma)$. Numerical solution of such equations with finite data may suffer the issue of no solution or multiple solutions (Small et al. 2000). Theoretical analysis of estimators from nonlinear estimating equations may require cumbersome regularity conditions which would be avoided when using conventional estimators of $(\alpha, \gamma)$. These issues can be illustrated with the following examples.

**Example 6.** For Example 1 with a partially linear model, let $\psi_g(\cdot)$ be an identity function. The calibration equations (22)–(23) based on $\tau$ in (5) are

$$0 = E \left( \frac{\partial \tau}{\partial \gamma} \right) = -E \left\{ (Y - \theta^* Z - \alpha^T \xi) \psi_f'(\gamma^T \xi) \xi \right\}, \quad (25)$$

$$0 = E \left( \frac{\partial \tau}{\partial \alpha} \right) = -E \left\{ (Z - \psi_f(\gamma^T \xi)) \xi \right\}, \quad (26)$$

where $\xi = \xi(X)$ and $\tau$ is evaluated at $\theta = \theta^*$. Because (26) does not depend on $\alpha$, the sample version of simultaneous equations (25)–(26) can be solved sequentially: the sample version of (26) can be first solved, and then that of (25) be solved, provided that $\theta^*$ is replaced by a preliminary doubly robust estimator.
Example 7. For Example 2 with a partially log-linear model, let \( \psi_g(\cdot) \) be an identity function. The calibration equations (22)–(23) based on \( \tau \) in (7) are

\[
0 = E \left( \frac{\partial \tau}{\partial \gamma} \right) = -E \left\{ (Ye^{-\sigma Z} - e^{\alpha^T \xi})\psi_f'(\gamma^T \xi) \xi \right\},
\]

(27)

\[
0 = E \left( \frac{\partial \tau}{\partial \alpha} \right) = -E \left\{ (Z - \psi_f(\gamma^T \xi))e^{\alpha^T \xi} \xi \right\},
\]

(28)

where \( \xi = \xi(X) \) and \( \tau \) is evaluated at \( \theta = \theta^* \). Unlike (25)–(26) in Example 6, the sample version of (27)–(28) cannot be solved sequentially even after \( \theta^* \) is appropriately estimated. Therefore, algorithms for solving nonlinear equations need to be used. We point out that calibration equations (27)–(28) are simpler than estimating equations proposed in (Vermeulen & Vansteelandt 2015, Section 5.2), \( 0 = E(\partial \tau_{IP}/\partial \gamma) \) and \( 0 = E(\partial \tau_{IP}/\partial \alpha) \), where \( \tau_{IP} \) is the influence function, \( \tau_{IP}(U; \theta, \alpha, \gamma) = -E^{-1}(\partial \tau/\partial \theta)\tau(U; \theta, \alpha, \gamma) \), evaluated at \( \theta = \theta^* \).

Example 8. For Example 3 with a logistic partially linear model, let \( \psi_g(\cdot) \) be an identity function. The calibration equations (22)–(23) based on \( \tau \) in (9) are

\[
0 = E \left( \frac{\partial \tau}{\partial \gamma} \right) = -E \left\{ e^{-\theta^* Z Y} (Y - \expit(\alpha^T \xi))\psi_f'(\gamma^T \xi) \xi \right\},
\]

(29)

\[
0 = E \left( \frac{\partial \tau}{\partial \alpha} \right) = -E \left\{ e^{-\theta^* Z Y} \expit_2(\alpha^T \xi)(Z - \psi_f(\gamma^T \xi)) \xi \right\},
\]

(30)

where \( \expit_2(c) = \expit(c)(1 - \expit(c)) \) and \( \tau \) is evaluated at \( \theta = \theta^* \). Similarly as (27)–(28), the sample version of (29)–(28) cannot be solved sequentially, due to dependency on both \( \alpha \) and \( \gamma \), even after \( \theta^* \) is appropriately estimated.

Example 9. For the missing-data problem in Example 4, the calibration equations (22)–(23) based on \( \tau \) in (10) are

\[
0 = E \left( \frac{\partial \tau}{\partial \gamma} \right) = -E \left\{ \psi_f'(\gamma^T \xi) Z (Y - \psi_g(\alpha^T \xi)) \xi \right\},
\]

(31)

\[
0 = E \left( \frac{\partial \tau}{\partial \alpha} \right) = -E \left\{ \frac{Z}{\psi_f(\gamma^T \xi)} - 1 \right\} \psi_g'(\alpha^T \xi) \xi \right\},
\]

(32)

where \( \xi = \xi(X) \) and \( \tau \) is evaluated at \( \theta = \theta^* \). In the case where \( \psi_g(\cdot) \) is an identity function, i.e., a linear model (11) is specified for \( E(Y|Z = 1, X) \), the sample version of (31)–(32) can be solved sequentially, because (32) does not depend on \( \alpha \). But such sequential solution is infeasible with a nonlinear function \( \psi_g(\cdot) \), because equations (31)–(32) are intrinsically coupled, each depending on both \( \alpha \) and \( \gamma \) (Tan 2020a, Section 3.5).
3 Regularized calibrated estimation

We develop regularized calibrated estimation for $(\alpha, \gamma)$, such that the resulting estimator of $\theta^*$ achieves an asymptotic expansion similar to (24), hence allowing valid confidence intervals, under suitable conditions in high-dimensional settings. The estimators of $(\alpha, \gamma)$ are derived from a numerically tractable two-step algorithm. Moreover, high-dimensional analysis is provided to demonstrate the desired asymptotic expansion and consistent variance estimation, which lead to valid Wald confidence intervals.

Conceptually, regularized calibrated estimation involves constructing regularized estimators of $(\alpha, \gamma)$, which converge in probability to the target values $(\bar{\alpha}_{\text{CAL}}, \bar{\gamma}_{\text{CAL}})$ satisfying population calibration equations (22)–(23). As discussed in Section 2.2 in low-dimensional settings, there may be numerical and theoretical complications with directly using the sample version of (22)–(23) as estimating equations. With high-dimensional data, estimating equations can be regularized by generalizing the Dantzig selector (Candes & Tao 2007), which seeks to minimize $\|\alpha\|_1 + \|\gamma\|_1$ subject to

$$\left\| \tilde{E} \left\{ \frac{\partial \tau}{\partial \gamma}(U; \hat{\theta}_1, g(x; \alpha), f(x; \gamma)) \right\} \right\|_\infty \leq \lambda,$$

$$\left\| \tilde{E} \left\{ \frac{\partial \tau}{\partial \alpha}(U; \hat{\theta}_1, g(x; \alpha), f(x; \gamma)) \right\} \right\|_\infty \leq \lambda,$$

where $\hat{\theta}_1$ is a preliminary doubly robust estimator, $\lambda$ is a tuning parameter, and $\| \cdot \|_1$ or $\| \cdot \|_\infty$ denotes $L_1$ or $L_\infty$ norm. While theoretical analysis of generalized Dantzig selectors can be performed, this approach is not pursued here mainly because the required optimization problem seems numerically difficult to solve with complex nonlinear estimating functions. The generalized Dantzig-selector algorithm in Radchenko & James (2011) can potentially be modified for the above problem, but its effectiveness seems uncertain. Further investigation of the Dantzig-selector approach can be of interest in future work.

3.1 Two-step algorithm

We propose a two-step algorithm, shown as Algorithm 1, for regularized calibrated estimation. The algorithm is facilitated by exploiting the following convexity assumption, which is satisfied in various settings including Examples 1–4 as shown in Section 4. In principle, our
Algorithm 1 Two-step algorithm

1: procedure INITIAL ESTIMATION
2: Compute \( (\hat{\alpha}_1, \hat{\gamma}_1) \) as model-based estimators of \( (\alpha, \gamma) \);
3: Compute \( \hat{\theta}_1 = \hat{\theta}(\hat{\alpha}_1, \hat{\gamma}_1) \) as a solution to \( \tilde{E}\{\tau(U; \theta, \hat{\alpha}_1, \hat{\gamma}_1)\} = 0 \).
4: end procedure

5: procedure CALIBRATED ESTIMATION
6: Compute \( \hat{\gamma}_2 = \arg\min_{\gamma} [\tilde{E}\{\ell_2(U; \hat{\theta}_1, \hat{\alpha}, \gamma)\} + \lambda_1 \|\gamma\|_1] \), also denoted as \( \hat{\gamma}_{\text{RCAL}} \);
7: Compute \( \hat{\alpha}_2 = \arg\min_{\alpha} [\tilde{E}\{\ell_1(U; \hat{\theta}_1, \alpha, \hat{\gamma}_2)\} + \lambda_2 \|\alpha\|_1] \), also denoted as \( \hat{\alpha}_{\text{RCAL}} \);
8: Compute \( \hat{\theta}_2 = \hat{\theta}(\hat{\alpha}_2, \hat{\gamma}_2) \) as a solution to \( \tilde{E}\{\tau(U; \theta, \hat{\alpha}_2, \hat{\gamma}_2)\} = 0 \), also denoted as \( \hat{\theta}_{\text{RCAL}} \).
9: end procedure

The population calibration equations (22)–(23) can be expressed in the form of alternating minimization: \( E\{\ell_1(U; \theta^*, \alpha, \gamma)\} \) is minimized at \( \alpha = \bar{\alpha}_{\text{CAL}} \) for fixed \( \gamma = \bar{\gamma}_{\text{CAL}} \), and \( E\{\ell_2(U; \theta^*, \alpha, \gamma)\} \) is minimized at \( \gamma = \bar{\gamma}_{\text{CAL}} \) for fixed \( \alpha = \bar{\alpha}_{\text{CAL}} \). This reasoning would suggest

**Assumption 1.** There exist two loss functions \( \ell_1(U; \theta, \alpha, \gamma) \) and \( \ell_2(U; \theta, \alpha, \gamma) \) such that \( E\{\ell_1(U; \theta, \alpha, \gamma)\} \) is strictly convex in \( \alpha \), \( E\{\ell_2(U; \theta, \alpha, \gamma)\} \) is strictly convex in \( \gamma \), and
\[
\frac{\partial \ell_1}{\partial \alpha} = \frac{\partial \tau}{\partial \gamma}, \quad \frac{\partial \ell_2}{\partial \gamma} = \frac{\partial \tau}{\partial \alpha}, \quad (33)
\]
where \( \tau \) is parameterized as \( \tau(U; \theta, \alpha, \gamma) = \tau(U; \theta, g(x; \alpha), f(x; \gamma)) \).

From Assumption 1, various equations in Section 2.2 can be restated in terms of minimization of convex loss functions. The basic identities (17)–(18) can be translated to minimization properties. If model (11) with \( g(x; \alpha) \) is correctly specified, then (17) amounts to \( E\{(\partial/\partial \alpha)\ell_1(U; \theta^*, \alpha, \gamma)\}_{\alpha=\alpha^*} = 0 \) and hence for fixed \( \gamma \), the expected loss \( E\{\ell_1(U; \theta^*, \alpha, \gamma)\} \), convex in \( \alpha \), attains a minimum at \( \alpha^* \) with zero gradient under interchangeability of the differentiation and expectation. Similarly, if model (12) with \( f(x; \gamma) \) is correctly specified, then (18) amounts to \( E\{(\partial/\partial \gamma)\ell_2(U; \theta^*, \alpha, \gamma)\}_{\gamma=\gamma^*} = 0 \) and hence for fixed \( \alpha \), the expected loss \( E\{\ell_2(U; \theta^*, \alpha, \gamma)\} \), convex in \( \gamma \), is minimized at \( \gamma^* \).
the following iterative algorithm for computing \((\bar{\alpha}_{\text{CAL}}, \bar{\gamma}_{\text{CAL}})\) at a population level.

**Population calibration algorithm.**

- Determine initial target values \((\bar{\alpha}_1, \bar{\gamma}_1)\);
- For \(t = 2, 3, \ldots\), determine \(\bar{\gamma}_t\) as a solution to 
  \[E\left\{\frac{\partial}{\partial \alpha} \tau(U; \theta^*, \bar{\alpha}_{t-1}, \gamma)\right\} = 0\] 
  or a minimizer of \(E\{\ell_2(U; \theta^*, \bar{\alpha}_{t-1}, \gamma)\}\) in \(\gamma\), and then determine \(\bar{\alpha}_t\) as a solution to 
  \[E\left\{\frac{\partial}{\partial \gamma} \tau(U; \theta^*, \alpha, \bar{\gamma}_t)\right\} = 0\] 
  or a minimizer of \(E\{\ell_1(U; \theta^*, \alpha, \bar{\gamma}_t)\}\) in \(\alpha\).

The limit \((\bar{\alpha}_\infty, \bar{\gamma}_\infty) = \lim_{t \to \infty} (\bar{\alpha}_t, \bar{\gamma}_t)\), if exists, can be shown to satisfy (22)–(23). However, remarkably, we show in Proposition 2 that if the initial target values \((\bar{\alpha}_1, \bar{\gamma}_1)\) are determined from model-based estimators of \((\alpha, \gamma)\) which are consistent in the case of model (11) or (12) being correctly specified, then the iterative process can be terminated by the second step (i.e., by \(t = 2\)), as far as doubly robust estimation is concerned. It should also be mentioned that if both models (11) and (12) are misspecified, then the second-step target values \((\bar{\alpha}_2, \bar{\gamma}_2)\) may in general not satisfy calibration equations (22)–(23).

**Proposition 2.** If model (11) is correctly specified and \(\bar{\alpha}_1 = \alpha^*\) but \(\bar{\gamma}_1\) is arbitrary, or if model (12) is correctly specified and \(\bar{\gamma}_1 = \gamma^*\) but \(\bar{\alpha}_1\) is arbitrary, then \(\bar{\alpha}_2 = \alpha^*\) or \(\bar{\gamma}_2 = \gamma^*\) respectively, and \((\bar{\alpha}_2, \bar{\gamma}_2)\) jointly satisfy calibration equations (22)–(23).

**Proof.** By definition, \((\bar{\alpha}_2, \bar{\gamma}_2)\) satisfy the equations

\[
E\left\{\frac{\partial \tau}{\partial \alpha}(U; \theta^*, \bar{\alpha}_1, \bar{\gamma}_2)\right\} = 0, \quad (34)
\]

\[
E\left\{\frac{\partial \tau}{\partial \gamma}(U; \theta^*, \bar{\alpha}_2, \bar{\gamma}_2)\right\} = 0. \quad (35)
\]

If model (11) is correctly specified and \(\bar{\alpha}_1 = \alpha^*\), then by comparison of (17) and (35), \(\bar{\alpha}_2 = \alpha^*\), and hence (35) and (34) yield (22) and (23) respectively for \((\bar{\alpha}_2, \bar{\gamma}_2)\). If model (12) is correctly specified and \(\bar{\gamma}_1 = \gamma^*\), then by comparison of (18) and (34), \(\bar{\gamma}_2 = \gamma^*\), and by (18),

\[
E\left\{\frac{\partial \tau}{\partial \alpha}(U; \theta^*, \bar{\alpha}_2, \gamma^*)\right\} = 0. \quad (36)
\]

In this case, (35) and (36) lead to (22) and (23) respectively for \((\bar{\alpha}_2, \bar{\gamma}_2)\).

Algorithm 1 is a sample version of the population calibration algorithm with two steps, using regularized estimation with Lasso penalties to deal with high-dimensional data.
initial estimators $(\hat{\alpha}_1, \hat{\gamma}_1)$ can be Lasso-regularized maximum likelihood (or quasi-likelihood) estimators in generalized linear models associated with (11)–(12). The two-step estimators, $(\hat{\alpha}_{\text{RCAL}}, \hat{\gamma}_{\text{RCAL}}) = (\hat{\alpha}_2, \hat{\gamma}_2)$, serves as an adjustment to the usual estimators $(\hat{\alpha}_1, \hat{\gamma}_1)$, such that calibration equations (22)–(23) are satisfied if either model (11) or (12) is correct.

3.2 Theoretical analysis

We provide high-dimensional analysis of the two-step estimators $(\hat{\alpha}_{\text{RCAL}}, \hat{\gamma}_{\text{RCAL}}) = (\hat{\alpha}_2, \hat{\gamma}_2)$ and the resulting estimator $\hat{\theta}_{\text{RCAL}} = \hat{\theta}(\hat{\alpha}_2, \hat{\gamma}_2)$. Throughout this section, we assume that either model (11) or (12), but not necessarily both, is correctly specified.

Our main result, summarized as Proposition 3, can be deduced from Theorems 1–3 later. For initial estimators $(\hat{\alpha}_1, \hat{\gamma}_1)$ defined as Lasso-regularized maximum likelihood (or quasi-likelihood) estimators, the rates of convergence in Assumption 2(iv) later are satisfied under suitable conditions with $M_0 = O(1)/(|S_{\hat{\alpha}_1}| + |S_{\hat{\gamma}_1}|)$, where $|S_{\hat{\alpha}_1}|$ or $|S_{\hat{\gamma}_1}|$ denotes the number of nonzero coefficients of the target value $\bar{\alpha}_1$ or $\bar{\gamma}_1$ respectively (Bühlmann & Van de Geer 2011; Negahban et al. 2012). For the two-step estimators $(\hat{\alpha}_2, \hat{\gamma}_2)$, denote by $|S_{\bar{\alpha}_2}|$ or $|S_{\bar{\gamma}_2}|$ denotes the number of nonzero coefficients of the target value $\bar{\alpha}_2$ or $\bar{\gamma}_2$ respectively. Suppose that the Lasso tuning parameters are specified as $\lambda_1 = A_1^1 r_0$ and $\lambda_2 = A_2^1 r_0$ for sufficiently large constants $A_1^1$ and $A_2^1$, where $r_0 = \{\log(ep)/n\}^{1/2}$.

**Proposition 3.** Suppose that Assumptions 1–7 hold, and $(M_0 + |S_{\bar{\alpha}_2}| + |S_{\bar{\gamma}_2}|) r_0^2 = o(n^{-1/2})$, i.e., $(M_0 + |S_{\bar{\alpha}_2}| + |S_{\bar{\gamma}_2}|) \log(ep) = o(n^{1/2})$. If model (11) with $g(x; \alpha)$ is correctly specified or model (12) is correctly specified with $f(x; \gamma)$, then $\hat{\theta}_{\text{RCAL}} = \hat{\theta}(\hat{\alpha}_2, \hat{\gamma}_2)$ satisfies

$$\hat{\theta}_{\text{RCAL}} - \theta^* = -E^{-1}(\frac{\partial \tau}{\partial \theta}) \bar{E}(\tau)|_{(\theta, \alpha, \gamma) = (\theta^*, \bar{\alpha}_2, \bar{\gamma}_2)} + o_p(n^{-1/2}).$$

Furthermore, the following results hold in either case:

(i) $\sqrt{n}(\hat{\theta}_{\text{RCAL}} - \theta^*) \overset{D}{\rightarrow} N(0, V)$, where $V = \text{var}(\tau)/E^2(\partial \tau/\partial \theta)|_{(\theta, \alpha, \gamma) = (\theta^*, \bar{\alpha}_2, \bar{\gamma}_2)}$;

(ii) A consistent estimator $\hat{V}$ of $V$ is

$$\hat{V} = \bar{E}(\tau^2)/\bar{E}^2(\partial \tau/\partial \theta)|_{(\theta, \alpha, \gamma) = (\theta_{\text{RCAL}}, \bar{\alpha}_2, \bar{\gamma}_2)};$$

(iii) An asymptotic $(1-c)$ confidence interval for $\theta^*$ is $\hat{\theta}_{\text{RCAL}} \pm z_{c/2} \sqrt{\hat{V}/n}$, where $z_{c/2}$ is the $(1-c/2)$ quantile of $N(0, 1)$. 

18
Hence a doubly robust confidence interval for \( \theta^* \) is obtained.

In the remainder of Section 3.2, we present several formal results underlying Proposition 3. Our analysis of the estimators \((\hat{\alpha}_2, \hat{\gamma}_2)\), while building on the existing literature on Lasso penalized \(M\)-estimation (Bühlmann & Van de Geer 2011; Negahban et al. 2012), needs to tackle the dependency of \(\hat{\gamma}_2\) on \((\hat{\theta}_1, \hat{\alpha}_1)\) and subsequently that of \(\hat{\alpha}_2\) on \((\hat{\theta}_1, \hat{\gamma}_2)\). The situation is more general and more complicated than studied in Tan (2020a). We develop a technical strategy to control such dependency through use of the \(L_1\) norm, so that the usual rates of convergence are obtained. See Lemma S6 in the Supplement.

We first discuss theoretical analysis of \(\hat{\gamma}_2\), with the Lasso tuning parameter \(\lambda_1 = A_1\lambda_0\) for a constant \(A_1\), where \(\lambda_0 = \{\log(p/\epsilon)/n\}^{1/2}\). The loss function for defining \(\hat{\gamma}_2\) is

\[
L_2(\gamma; \hat{\theta}_1, \hat{\alpha}_1) = \mathbb{E}\{\ell_2(U; \hat{\theta}_1, \hat{\alpha}_1, \gamma)\},
\]

where \(\ell_2\) is from Assumption 1. As \(L_2(\gamma; \hat{\theta}_1, \hat{\alpha}_1)\) is convex in \(\gamma\), the corresponding Bregman divergence is defined as

\[
D_2(\gamma'; \gamma; \hat{\theta}_1, \hat{\alpha}_1) = L_2(\gamma'; \hat{\theta}_1, \hat{\alpha}_1) - L_2(\gamma; \hat{\theta}_1, \hat{\alpha}_1) - (\gamma' - \gamma)^T \frac{\partial L_2}{\partial \gamma}(\gamma; \hat{\theta}_1, \hat{\alpha}_1).
\]

The symmetrized Bregman divergence is easily shown to be

\[
D_2^\dagger(\gamma'; \gamma; \hat{\theta}_1, \hat{\alpha}_1) = (\gamma' - \gamma)^T \left\{ \frac{\partial L_2}{\partial \gamma}(\gamma'; \hat{\theta}_1, \hat{\alpha}_1) - \frac{\partial L_2}{\partial \gamma}(\gamma; \hat{\theta}_1, \hat{\alpha}_1) \right\}
\]

\[
= (\gamma' - \gamma)^T \mathbb{E} \left[ \xi \left\{ \frac{\partial \tau}{\partial \eta}(U; \hat{\theta}_1, \hat{\alpha}_1, \gamma') - \frac{\partial \tau}{\partial \eta}(U; \hat{\theta}_1, \hat{\alpha}_1, \gamma) \right\} \right]. \tag{38}
\]

The target value \(\bar{\gamma}_2\) is defined as a solution to \(E\{\partial \tau / \partial \alpha\}(U; \theta^*, \bar{\alpha}_1, \gamma) = 0\) or equivalently a minimizer of the expected loss \(E\{\ell_2(U; \theta^*, \bar{\alpha}_1, \gamma)\}\), where \((\theta^*, \bar{\alpha}_1)\) are the target values (i.e., probability limits) of the initial estimators \((\hat{\theta}_1, \hat{\alpha}_1)\). After statement of the assumptions required, Theorem 1 establishes the convergence of \(\hat{\gamma}_2\) to \(\bar{\gamma}_2\) in the both \(L_1\) norm \(\|\hat{\gamma}_2 - \bar{\gamma}_2\|_1\) and the symmetrized Bregman divergence \(D_2^\dagger(\hat{\gamma}_2, \bar{\gamma}_2; \hat{\theta}_1, \bar{\alpha}_1)\).

A variable \(Y\) is said to be sub-exponential with parameter \((B_{01}, B_{02})\) if \(E(|Y - E(Y)|^k) \leq \frac{k!}{2}B_{01}^2B_{02}^{k-2}\) for each \(k \geq 2\). For a \(p \times p\) matrix \(\Sigma\), a compatibility condition (Bühlmann & Van de Geer 2011) is said to hold with a subset \(S \subseteq \{1, \ldots, p\}\) and constants \(\nu_1 > 0\) and \(\mu_1 > 1\) if \(\nu_1^2(\sum_{j \in S} |b_j|^2) \leq |S|(b^T \Sigma b)\) for any vector \(b = (b_1, \ldots, b_k)^T \in \mathbb{R}^k\) satisfying \(\sum_{j \notin S} |b_j| \leq \mu_1 \sum_{j \in S} |b_j|\). Throughout, \(|S|\) denotes the size of a set \(S\).

**Assumption 2.** Suppose that the following conditions are satisfied.
Assumption 3. Suppose that Assumptions 1–3 hold and $N_\gamma = E\{\xi^\tau \frac{\partial^2 \tau}{\partial \eta_0 \partial \eta_f} (U; \theta^*, \alpha_1, \gamma)\}$ with the subset $S_{\gamma_2} = \{j : (\gamma_2)_j \neq 0, j = 1, \ldots, p\}$ and some constants $\nu_1 > 0$ and $\mu_1 > 1$.

(iv) For some constants $c_0 > 0$ and $M_0 \geq 1$, possibly depending on $(\alpha_1, \gamma_1)$, and any small $\epsilon > 0$, it holds with probability at least $1 - c_0 \epsilon$ that $(\hat{\alpha}_1 - \alpha_1)^T \hat{\Sigma}_0 (\hat{\alpha}_1 - \alpha_1) \leq M_0 \lambda_0^2$, $\|\hat{\alpha}_1 - \alpha_1\|_1 \leq M_0 \lambda_0$, and $|\hat{\theta}_1 - \theta^*| \leq M_0^{1/2} \lambda_0$, where $\lambda_0 = \{(\log(p/\epsilon)/n)^{1/2}, \text{ and } \alpha_1 = \alpha^* \text{ if model (11) is correctly specified or } \hat{\gamma}_1 = \gamma^* \text{ if model (12) is correctly specified.}$

Assumption 3. There exist positive constants $c_1, c_2, B_1, B_2, C_1, C_2, \varrho_0$, and $\varrho_1$ such that the following conditions are satisfied, where $N_1 = \{((\theta, \alpha)) : |\theta - \theta^*| \leq c_1, \|\alpha - \alpha_1\|_1 \leq c_1\}$.

(i) The variables $T_{\eta_0}^{(1)}(U; \theta^*, \alpha_1, \gamma) = \sup_{(\theta, \alpha) \in N_1} |\frac{\partial^2 \tau}{\partial \eta_0 \partial \eta_f} (U; \theta, \alpha, \gamma)|$ and $T_{\eta_0}^{(1)}(U; \theta^*, \alpha_1, \gamma) = \sup_{(\theta, \alpha) \in N_1} |\frac{\partial^2 \tau}{\partial \eta_0 \partial \eta_f} (U; \theta, \alpha, \gamma)|$ are sub-exponential with parameter $(B_1, B_2)$, and $E\{T_{\eta_0}^{(1)}(U; \theta^*, \alpha_1, \gamma)|X\} \leq C_1$ and $E\{T_{\eta_0}^{(1)}(U; \theta^*, \alpha_1, \gamma)|X\} \leq C_1$ almost surely.

(ii) The variable $\frac{\partial^2 \tau}{\partial \eta_0 \partial \eta_f} (U; \theta^*, \alpha_1, \gamma)$ is sub-exponential with parameter $(B_1, B_2)$, and $E\{\frac{\partial^2 \tau}{\partial \eta_0 \partial \eta_f} (U; \theta^*, \alpha_1, \gamma)|X\} \geq c_2$ almost surely.

(iii) For any $(\theta, \alpha) \in N_1$ and $\gamma \in \mathbb{R}^p$, it holds that almost surely

$$\frac{\partial^2 \tau}{\partial \eta_0 \partial \eta_f} (U; \theta, \alpha, \gamma) \leq \frac{\partial^2 \tau}{\partial \eta_0 \partial \eta_f} (U; \theta^*, \alpha_1, \gamma) e^{-C_2 (|\theta - \theta^*| + |\alpha - \alpha_1|^T \xi + |\gamma - \gamma_2|^T \xi)}.$$

(iv) $M_0 \lambda_0 \leq \varrho_0 \leq c_1$ and $|S_{\gamma_2}| \lambda_0 \leq \varrho_1$ such that $\varrho_2 = \nu_1^2 (1 + \mu_1)^2 \varrho_1 B_1 < 1$, $\varrho_3 = C_0 C_2 A_{11}^2 \mu_1^2 \nu_1^2 \varrho_1 e^{\varrho_5} < 1$, and $\varrho_4 = C_0 C_2 A_{11}^4 \mu_{11}^2 C_{12} \varrho_0 e^{\varrho_6} < 1$, where $\varrho_5 = C_2 (1 + C_0) \varrho_0$, $A_{11} = A_1 - B_0 - C_{13}$, $\mu_{11} = 1 - 2A_1/(\mu_1 + 1) A_{11}$ $\in (0, 1)$, $\mu_{12} = (\mu_1 + 1) A_{11}$, $\nu_{11} = \nu_1 (1 - \varrho_2)^{1/2}$, $B_0 = C_0 (B_0 + \sqrt{2} B_0)$, $B_{15}$ is defined in Lemma S2 depending on $(C_0, C_1, B_{11}, B_{12})$, and $(C_{12}, C_{13})$ are defined in Lemma S6 depending on $(\varrho_0, c_2, C_0, C_1, B_{11}, B_{12})$.

Theorem 1. Suppose that Assumptions 1–3 hold and $\lambda_0 \leq 1$. Then for $\lambda_1 = A_{11} \lambda_0$ and $A_1 > (B_0 + C_{13})/(\mu_1 + 1)/(\mu_1 - 1)$, we have with probability at least $1 - (c_0 + 10) \epsilon$,

$$D_2^T (\hat{\gamma}_2, \hat{\gamma}_2; \hat{\theta}_1, \hat{\alpha}_1) + A_{11} \lambda_0 \|\hat{\gamma}_2 - \gamma_2\|_1 \leq \left\{ e^{\varrho_5} (1 - \varrho_3)^{-1} \nu_2 \|S_{\gamma_2} \lambda_0^2 \| \right\} \lor \left\{ e^{\varrho_6} (1 - \varrho_4)^{-1} \mu_{11}^2 C_{12} (M_0 \lambda_0^2) \right\}, \quad (39)$$

20
where \( \lor \) denotes the maximum between two numbers, and \((\mu_{11}, \mu_{12}, \nu_{11}, \varrho_3, \varrho_4, \varrho_5, A_{11}, B_0, C_{12}, C_{13})\) are defined in Assumption 3(iv).

**Remark 2.** Assumptions 2(iii) and 3(iii) are standard in high-dimensional analysis of \(M\)-estimation (e.g., Bühlmann & Van de Geer 2011; Tan 2020b). Assumptions 3(i)–(ii) are used to control the deviation of \((\hat{\theta}_1, \hat{\alpha}_1)\) from \((\theta^*, \bar{\alpha}_1)\) in the basic inequality. Given Assumption 3(ii), the compatibility condition on \(\Sigma_\gamma\) in Assumption 2(iii) can be equivalently replaced by a compatibility condition on the matrix \(\Sigma_0 = E(\xi \xi^T)\), independent of \((\theta^*, \bar{\alpha}_1, \bar{\gamma}_2)\).

**Remark 3.** Assumption 2(iv) is concerned with the convergence of the initial estimators \((\hat{\theta}_1, \hat{\alpha}_1, \hat{\gamma}_1)\). In fact, \(\hat{\theta}_1\) is required to converge to \(\theta^*\) at rate \(M_0^{1/2}\lambda_0\) if model (11) or (12) is correctly specified. Hence \(\hat{\theta}_1\) is pointwise doubly robust, although it does not in general admit doubly robust confidence intervals. For \(\hat{\theta}_1 = \hat{\theta}(\hat{\alpha}_1, \hat{\gamma}_1)\) in Algorithm 1, the required convergence for \(\hat{\theta}_1\) can be deduced from the stated rates of convergence for \((\hat{\alpha}_1, \hat{\gamma}_1)\) under suitable conditions, similar to Assumptions 6–7 for Theorem 3 later. For simplicity, the convergence of \(\hat{\theta}_1\) is included as part of Assumption 2(iv). This formulation also allows Theorem 1 to be applied with other possible choices of \(\hat{\theta}_1\). See the proof of Corollary 4.

The following corollary provides a bound on the prediction \(L_2\) norm (in the scale of linear predictors \(\eta_f\), \(\hat{\theta}_f[\{(\hat{\gamma}_2 - \bar{\gamma}_2)^T \xi\}^2] = (\hat{\gamma}_2 - \bar{\gamma}_2)^T \hat{\Sigma}_0 (\hat{\gamma}_2 - \bar{\gamma}_2)\), where \(\hat{\Sigma}_0 = \hat{E}(\xi \xi^T)\).

**Corollary 3.** In the setting of Theorem 1, with probability at least \(1 - (c_0 + 10)\epsilon\), we have, in addition to (39),

\[
(\hat{\gamma}_2 - \bar{\gamma}_2)^T \hat{\Sigma}_0 (\hat{\gamma}_2 - \bar{\gamma}_2) \leq \left\{ c_2^{-1}e^{c_3} (1 - \varrho_3 \lor \varrho_4)^{-1} + (1 + c_2^{-1}) B_1 A_{11}^{-2} C_3 (\varrho_0 \lor \varrho_1) \right\} C_3 (|S_{\gamma_2}| \lor M_0) \lambda_0^2,
\]

(40)

where \(B_1 = (4C_0^2) \lor B_{15}\), and \(C_3\) is a constant such that the right hand side of (39) is upper bounded by \(C_3 (|S_{\gamma_2}| \lor M_0) \lambda_0^2\).

From Theorem 1 and Corollary 3, let \(M_1 (\geq M_0)\) be a constant such that the right hand side of (39) is upper bounded by \(A_{11} M_1 \lambda_0^2\) and that of (40) is upper bounded by \(M_1 \lambda_0^2\). Then with probability at least \(1 - (c_0 + 10)\epsilon\), we have

\[
(\hat{\gamma}_2 - \bar{\gamma}_2)^T \hat{\Sigma}_0 (\hat{\gamma}_2 - \bar{\gamma}_2) \leq M_1 \lambda_0^2, \quad \|\hat{\gamma}_2 - \bar{\gamma}_2\|_1 \leq M_1 \lambda_0.
\]

(41)
These bounds can be used to justify a rate condition on the convergence of \( \hat{\gamma}_2 \) corresponding to Assumption 2(iv), and to obtain a similar result to Theorem 1 about the convergence of \( \hat{\alpha}_2 \) to a target value \( \bar{\alpha}_2 \), which is defined as a solution to \( E\{(\partial \tau/\partial \gamma)(U; \theta^*, \alpha, \hat{\gamma}_2)\} = 0 \) or equivalently a minimizer of the expected loss \( E\{\ell_1(U; \theta^*, \alpha, \hat{\gamma}_2)\} \).

**Assumption 4.** Suppose that the conditions (ii)–(iii) in Assumption 2 hold, with \((\bar{\alpha}_1, \bar{\gamma}_2)\) replaced by \((\hat{\gamma}_2, \bar{\alpha}_2)\), \(\partial \tau/\partial \eta_g\) by \(\partial \tau/\partial \beta_f\), and \((B_{01}, B_{02}, \mu_1, \nu_1)\) replaced by some alternative constants throughout.

**Assumption 5.** Suppose that the conditions (i)–(iv) in Assumption 3 hold, with \((\bar{\alpha}_1, \bar{\gamma}_2)\) replaced by \((\hat{\gamma}_2, \bar{\alpha}_2)\), \((\partial^2 \tau/\partial \eta_g^2, \partial^2 \tau/(\partial \eta_g \partial \theta))\) by \((\partial^2 \tau/\partial \eta_f^2, \partial^2 \tau/(\partial \eta_f \partial \theta))\), \(M_0\) by \(M_1\), and \((c_1, c_2, B_{11}, B_{12}, C_1, C_2, \varrho_0, \varrho_1)\) by some alternative constants throughout.

**Theorem 2.** In the setting of Theorem 1, suppose that Assumptions 4–5 also hold. Then for \( \lambda_2 = A_2 \lambda_0 \) and sufficiently large \( A_2 \), we have with probability at least \( 1 - (c_0 + 18)\epsilon \), in addition to (41),

\[
(\hat{\alpha}_2 - \bar{\alpha}_2)^T \tilde{\Sigma}_0 (\hat{\alpha}_2 - \bar{\alpha}_2) \leq M_2 \lambda_0^2, \quad \|\hat{\alpha}_2 - \bar{\alpha}_2\|_1 \leq M_2 \lambda_0, \tag{42}
\]

where \( M_2 \) is a constant determined similarly as \( M_1 \) in (41).

With the preceding results about \((\hat{\alpha}_2, \hat{\gamma}_2)\), we are ready to study the convergence of \( \hat{\theta}_2 = \hat{\theta}(\hat{\alpha}_2, \hat{\gamma}_2) \). As convergence in probability is of main interest, the high-probability bounds (41) and (42) can be used to deduce the following in-probability statements: \((\hat{\alpha}_2 - \bar{\alpha}_2)^T \tilde{\Sigma}_0 (\hat{\alpha}_2 - \bar{\alpha}_2) = O_p(M_2 r_0^2), \|\hat{\alpha}_2 - \bar{\alpha}_2\|_1 = O_p(M_2 r_0), (\hat{\gamma}_2 - \bar{\gamma}_2)^T \tilde{\Sigma}_0 (\hat{\gamma}_2 - \bar{\gamma}_2) = O_p(M_2 r_0^2), \) and \( \|\hat{\gamma}_2 - \bar{\gamma}_2\|_1 = O_p(M_2 r_0) \), where \( r_0 = \{\log(ep)/n\}^{1/2} \). After statement of assumptions required, Theorem 3 establishes the desired convergence result for \( \hat{\theta}_2 \).

**Assumption 6.** Suppose that the following conditions are satisfied.

(i) \( E \{\tau(U; \theta^*, \hat{\alpha}_2, \hat{\gamma}_2)\} = 0 \) and \( \inf_{\theta \in \Theta, |\theta - \theta^*| \leq \delta} | E \{\tau(U; \theta, \hat{\alpha}_2, \hat{\gamma}_2)\}| > 0 \) for each \( \delta > 0 \).

(ii) \( E \{ \sup_{\theta \in \Theta} |\tau(U; \theta, \hat{\alpha}_2, \hat{\gamma}_2)\| < \infty \).

(iii) There exists a neighborhood \( \mathcal{N}_2 = \{ (\alpha, \gamma) : \|\alpha - \hat{\alpha}_2\|_1 \leq c_3, \|\gamma - \bar{\gamma}_2\|_1 \leq c_3 \} \) for a constant \( c_3 > 0 \) such that \( E\{T_{\eta^2}(U; \alpha, \hat{\gamma}_2)\} < \infty \) and \( E\{T_{\eta^2}(U; \alpha, \hat{\gamma}_2)\} < \infty \), where \( T_{\eta^2}(U; \alpha, \hat{\gamma}_2) = \sup_{\theta \in \Theta, (\alpha, \gamma) \in \mathcal{N}_2} | \frac{\partial \tau}{\partial \eta}(U; \theta, \alpha, \gamma) | \) and \( T_{\eta^2}(U; \alpha, \hat{\gamma}_2) = \sup_{\theta \in \Theta, (\alpha, \gamma) \in \mathcal{N}_2} | \frac{\partial \tau}{\partial \eta}(U; \theta, \alpha, \gamma) | \).
Assumption 7. There exist positive constants $c_4$ and $C_4$ such that the following conditions are satisfied, where $N_3 = \{(\theta, \alpha, \gamma) : |\theta - \theta^*| \leq c_4, \|\alpha - \bar{\alpha}_2\|_1 \leq c_4, \|\gamma - \bar{\gamma}_2\| \leq c_4\}$.

(i) $E\{\sup_{(\theta, \alpha, \gamma) \in N_3} \tau^2(U; \theta, \alpha, \gamma)\} < \infty$.

(ii) $H = E\{\partial\tau/\partial \theta(U; \theta^*, \bar{\alpha}_2, \bar{\gamma}_2)\} \neq 0$ and $E\{\sup_{(\theta, \alpha, \gamma) \in N_3} |\partial\tau/\partial \theta(U; \theta, \alpha, \gamma)|\} < \infty$.

(iii) The variables $\partial\tau/\partial \theta(U; \theta^*, \bar{\alpha}_2, \bar{\gamma}_2)$ and $\partial\tau/\partial \eta(U; \theta^*, \bar{\alpha}_2, \bar{\gamma}_2)$ are sub-exponential.

(iv) The variables $T_{\eta_0}^{(2)}(U; \theta^*, \bar{\alpha}_2, \bar{\gamma}_2) = \sup_{(\theta, \alpha, \gamma) \in N_3} \partial^2\tau/\partial \eta^2(U; \theta, \alpha, \gamma)$ and $T_{\eta_0\eta_1}^{(2)}(U; \theta^*, \bar{\alpha}_2, \bar{\gamma}_2) = \sup_{(\theta, \alpha, \gamma) \in N_3} \partial^2\tau/\partial \eta\partial \eta(U; \theta, \alpha, \gamma)$ are sub-exponential, and $E\{T_{\eta_0}^{(2)}(U; \theta^*, \bar{\alpha}_2, \bar{\gamma}_2)\} \leq C_4$, $E\{T_{\eta_0\eta_1}^{(2)}(U; \theta^*, \bar{\alpha}_2, \bar{\gamma}_2)\} \leq C_4$, and $E\{T_{\eta_0\eta_1}^{(2)}(U; \theta^*, \bar{\alpha}_2, \bar{\gamma}_2)\} \leq C_4$ almost surely.

Theorem 3. In the setting of Theorem 2, suppose that Assumption 6 and 7 hold and $M_2r_0 = o(1)$. Then $\hat{\theta}_2$ is consistent for $\theta^*$ and admits the asymptotic expansion

$$\hat{\theta}_2 - \theta^* = -H^{-1} \hat{E}\{\tau(U; \theta^*, \bar{\alpha}_2, \bar{\gamma}_2)\} + O_p(M_2r_0^2),$$

where $H = E\{\partial^2\tau/\partial \theta(U; \theta^*, \bar{\alpha}_2, \bar{\gamma}_2)\}$. Moreover, a consistent estimator of $V = \text{var}\{\tau(U; \theta^*, \bar{\alpha}_2, \bar{\gamma}_2)\}/H^2$ is $\hat{V} = \hat{E}\{\tau^2(U; \hat{\theta}_2, \bar{\alpha}_2, \bar{\gamma}_2)\}/\hat{H}^2$, where $\hat{H} = \hat{E}\{\partial\tau/\partial \theta(U; \hat{\theta}_2, \bar{\alpha}_2, \bar{\gamma}_2)\}$.

Remark 4. Assumption 6 is involved to show the consistency of $\hat{\theta}_2$ for $\theta^*$. Assumptions 6(i)–(ii) are standard for showing consistency if $\tau(U; \theta, \bar{\alpha}_2, \bar{\gamma}_2)$ were employed as an estimating function in $\theta$ (e.g., Van der Vaart 2000). Assumption 6(iii) is used to control the deviation of $(\bar{\alpha}_2, \bar{\gamma}_2)$ from the target values, with unrestricted $\theta \in \Theta$. Moreover, Assumption 7 is involved to show the asymptotic expansion (43). Assumption 7(i)–(ii) is adapted from classical asymptotic theory for maximum likelihood estimation (e.g., Ferguson 1996). Assumption 7(iv) is used to control the deviation of $(\hat{\theta}_2, \hat{\alpha}_2, \hat{\gamma}_2)$.

Combining Theorems 1–3 leads to Proposition 3 provided $M_2r_0^2 = o(n^{-1/2})$, i.e., the remainder term in (43) reduces to $o_p(n^{-1/2})$. As motivated in Section 2.2 and made explicit in the proofs, the primary reason for $\hat{\theta}_2$ to achieve asymptotic expansion (43) is that the two-step estimators $(\hat{\alpha}_2, \hat{\gamma}_2)$ are constructed such that according to Proposition 2, the target values $(\bar{\alpha}_2, \bar{\gamma}_2)$ satisfy the calibration equations (22)–(23) if model (11) or (12) is correctly specified. In this case, both the linear and quadratic terms in $(\hat{\alpha}_2 - \bar{\alpha}_2, \hat{\gamma}_2 - \bar{\gamma}_2)$ are $O_p(M_2r_0^2)$ from a Taylor expansion argument. Otherwise, the linear term would in general be $O_p(M_2^{1/2}r_0)$, as reflected in the convergence rate for the initial estimator $\hat{\theta}_1$ in Assumption 2(iv).
4 Applications

**Example 10.** Return to Examples 1 and 6 with a partially linear model (4). For \( g(x; \alpha) = \alpha^T \xi \) and \( f(x; \gamma) = \psi_f(\gamma^T \xi) \), models (11) and (12) can be stated as

\[
E(Y|Z, X) = \theta Z + \alpha^T \xi, \quad (44)
\]
\[
E(Z|X) = \psi_f(\gamma^T \xi). \quad (45)
\]

For estimating function \( \tau \) in (5) and any estimators \((\hat{\alpha}, \hat{\gamma})\), \( \hat{\theta} = \hat{\theta}(\hat{\alpha}, \hat{\gamma}) \) as a solution to \( \tilde{E}\{\tau(U; \theta, \hat{\alpha}, \hat{\gamma})\} = 0 \) is of closed form:

\[
\hat{\theta}(\hat{\alpha}, \hat{\gamma}) = \frac{\tilde{E}\{(Y - \hat{\alpha}^T \xi)(Z - \psi_f(\hat{\gamma}^T \xi))\}}{\tilde{E}\{Z(Z - \psi_f(\hat{\gamma}^T \xi))\}}.
\]

For initial estimation, let \((\hat{\theta}_0, \hat{\alpha}_1)\) be Lasso regularized least-squares estimators in model (44), \( \hat{\gamma}_1 \) be a Lasso regularized quasi-likelihood estimator in model (45), and \( \hat{\theta}_1 = \hat{\theta}(\hat{\alpha}_1, \hat{\gamma}_1) \). For second-step estimation, the regularized calibrated estimator \( \hat{\gamma}_2 \) is defined with a Lasso penalty and the loss function

\[
L_2(\gamma) = \tilde{E}\{\ell_2(U; \gamma)\} = \tilde{E}\{-Z\gamma^T \xi + \Psi_f(\gamma^T \xi)\}, \quad (46)
\]

and \( \hat{\alpha}_2 \) is defined with a Lasso penalty and the loss function

\[
L_1(\alpha; \hat{\theta}_1, \hat{\gamma}_2) = \tilde{E}\{\ell_1(U; \hat{\theta}_1, \alpha, \hat{\gamma}_2)\} = \tilde{E}\{\psi'_f(\hat{\gamma}_2^T \xi)(Y - \hat{\theta}_1 Z - \alpha^T \xi)^2 \}, \quad (47)
\]

where \( \Psi_f(t) = \int_0^t \psi_f(u) \, du \) and \( \psi'_f \) is the derivative of \( \psi_f \), and \( \ell_1 \) and \( \ell_2 \) are determined from (33), with \( (\partial \tau/\partial \alpha, \partial \tau/\partial \gamma) \) in (25)–(26). The estimator \( \hat{\gamma}_2 \) coincides with the usual estimator \( \hat{\gamma}_1 \) with a canonical link in (45), whereas \( \hat{\alpha}_2 \) can be interpreted as a regularized weighted least squares estimator. The resulting estimator of \( \theta \) is then \( \hat{\theta}_2 = \hat{\theta}(\hat{\alpha}_2, \hat{\gamma}_2) \).

We stress that the loss (47) is for estimation of \( \alpha \) with \((\hat{\theta}_1, \hat{\gamma}_2)\) fixed, and \( \hat{\theta}_1 \) is determined as \( \hat{\theta}(\hat{\alpha}_1, \hat{\gamma}_1) \) and hence pointwise doubly robust (see Remark 3). In other words, for \( \hat{\theta}_2 \) to admit doubly robust confidence intervals as in Proposition 3, it is in general incorrect to (i) replace \( \hat{\theta}_1 \) in (47) by \( \hat{\theta}_0 \) computed from the first step, or (ii) to redefine \((\hat{\theta}_1, \hat{\alpha}_2)\) jointly as a regularized weighted least squares estimator for \( Y|(Z, X) \), with weight \( \psi'_f(\hat{\gamma}_2^T \xi) \). Nevertheless, these simple options become valid in the special situation where \( \psi_f() \) is an identity function,
i.e., (45) is a linear model. In this case, \( \hat{\gamma}_2 \) can be taken the same as \( \hat{\gamma}_1 \) because (46) becomes the usual least-squares loss, and then either option (i) or (ii) can be shown to yield \( \hat{\theta}_2 \) identical to the first-step estimator \( \hat{\theta}(\hat{\alpha}_1, \hat{\gamma}_1) \), provided that the same Lasso tuning parameter is used in computing \( \hat{\alpha}_2 \) as in computing \( (\hat{\theta}_0, \hat{\alpha}_1) \). See the proof of Corollary 4. Moreover, \( \hat{\theta}(\hat{\alpha}_1, \hat{\gamma}_1) \) can be expressed as a debiased Lasso estimator of \( \theta \) in linear regression (44) (Zhang & Zhang 2014; Van de Geer et al. 2014; Javanmard & Montanari 2014):

\[
\hat{\theta}_{DB} = \hat{\theta}(\hat{\alpha}_1, \hat{\gamma}_1) = \frac{\hat{E}\{(Y - \hat{\alpha}_1^T \xi)(Z - \hat{\gamma}_1^T \xi)\}}{\hat{E}\{Z(Z - \hat{\gamma}_1^T \xi)\}} = \hat{\theta}_0 + \frac{\hat{E}\{(Y - \hat{\theta}_0 Z - \hat{\alpha}_1^T \xi)(Z - \hat{\gamma}_1^T \xi)\}}{\hat{E}\{Z(Z - \hat{\gamma}_1^T \xi)\}},
\]

where \((\hat{\theta}_0, \hat{\alpha}_1)\) are jointly Lasso estimators in linear regression of \( Y|(Z, X) \), and \( \hat{\gamma}_1 \) is that in linear regression of \( Z|X \). Suppose that the Lasso tuning parameters are sufficiently large, of order \( O\{\log(ep)/n\}^{1/2} \). The following result can be deduced from Proposition 3.

**Corollary 4.** Suppose that Assumption 2(i) and a compatibility condition holds for \( \Sigma_0 = E(\xi \xi^T) \), \( Y - \theta^* Z - \tilde{\alpha}_1^T \xi \) and \( Z - \tilde{\gamma}_1^T \xi \) are sub-exponential, \( V = E\{(Y - \theta^* Z - \tilde{\alpha}_1^T \xi)^2(Z - \tilde{\gamma}_1^T \xi)^2\} < \infty \), and \( H = -E\{Z(Z - \tilde{\gamma}_1^T \xi)\} \neq 0 \). If model (44) or model (45) with \( \psi_f \equiv 1 \) is correctly specified, then the conclusions in Proposition 3 are valid for \( \hat{\theta}_{DB} = \hat{\theta}(\hat{\alpha}_1, \hat{\gamma}_1) \), where

\[
\hat{V} = \hat{E}\{(Y - \hat{\theta}_{DB} Z - \hat{\alpha}_1^T \xi)^2(Z - \hat{\gamma}_1^T \xi)^2\}/\hat{E}^2\{Z(Z - \hat{\gamma}_1^T \xi)\}.
\]

Hence a doubly robust confidence interval for \( \theta^* \) is obtained in partially linear model (4).

From Corollary 4, the debiased Lasso estimator \( \hat{\theta}_{DB} \) in linear regression (44) can be used to obtain doubly robust confidence intervals for \( \theta^* \) in a partially linear model. This finding appears new and gives a high-dimensional extension of the double robustness (including pointwise and confidence intervals) of least-squares estimation in low-dimensional settings (Example 5). It is helpful to make several comments. First, although \( \hat{\theta}_{DB} \) is the same point estimator, the variance estimator \( \hat{V} \) differs from those originally in debiased Lasso, in the context of linear regression with a constant error variance, which then needs to be estimated (Zhang & Zhang 2014; Van de Geer et al. 2014; Javanmard & Montanari 2014).

Second, Bühlmann & Van de Geer (2015) studied debiased Lasso in possibly misspecified linear regression. They employed the same point estimator \( \hat{\theta}_{DB} \) and proposed a variance estimator similar to \( \hat{V} \),

\[
\hat{V}_{BG} = \hat{E}\{\tilde{\varepsilon} \tilde{Z} - \hat{E}(\tilde{\varepsilon} \tilde{Z})\}^2}/\hat{E}^2(Z \tilde{Z}),
\]
\[ \hat{\varepsilon} = Y - \hat{\theta}Z - \hat{\alpha}^T \xi \text{ and } \hat{Z} = Z - \hat{\gamma}^T \xi. \] Specifically, \( \hat{V}_{BG} \) can be obtained from \( \hat{V} \) by replacing \( \hat{\theta}_{DB} \) with \( \hat{\theta}_0 \) and the sample second-moment of the product \( (Y - \hat{\theta}Z - \hat{\alpha}^T \xi)(Z - \hat{\gamma}^T \xi) \) with the sample variance. Bühlmann & Van de Geer (2015) showed that under suitable conditions, \( \hat{\theta}_{DB} \pm z_c/2 \hat{V}_{BG} \) is a \( (1 - c) \) confidence interval for \( \bar{\theta}_0 \), defined such that

\[ (\bar{\theta}_0, \bar{\alpha}_1) = \arg\min_{(\theta, \alpha)} E \left\{ (Y - \theta Z - \alpha^T \xi)^2 \right\}, \]

with possible misspecification of linear model (44). This result is compatible with ours, because, from the proof of Corollary 4, \( \bar{\theta}_0 \) identifies \( \theta^* \) in partially linear model (4) if linear model (44) is misspecified but a linear model for \( E(Z|X) \) is correctly specified.

Finally, for a nonlinear model (12) with \( \psi_f \) a non-identity function (for example when \( Z \) is binary or nonnegative), our estimator \( \hat{\theta}_2 \) and associated confidence intervals are distinct from debiased Lasso including Bühlmann & Van de Geer (2015). Although \( \hat{\theta}_{DB} \pm z_c/2 \hat{V}_{BG} \) remains a \( (1 - c) \) confidence interval for \( \bar{\theta}_0 \) under suitable conditions, the target value \( \bar{\theta}_0 \) may in general differ from \( \theta^* \) in partially linear model (4) even if model (44) is misspecified but a nonlinear model for \( E(Z|X) \) is correctly specified.

Example 11. Return to Examples 2 and 7 with a partially log-linear model (6). For \( g(x; \alpha) = \alpha^T \xi \) and \( f(x; \gamma) = \psi_f(\gamma^T \xi) \), models (11) and (12) can be stated as

\[ E(Y|Z, X) = \exp(\theta Z + \alpha^T \xi), \] \hspace{1cm} (48)
\[ E(Z|X) = \psi_f(\gamma^T \xi). \] \hspace{1cm} (49)

For estimating function \( \tau \) in (7) and any estimators \( (\hat{\alpha}, \hat{\gamma}) \), \( \hat{\theta} = \hat{\theta}(\hat{\alpha}, \hat{\gamma}) \) is a solution to

\[ 0 = \hat{E}\{\tau(U; \theta, \hat{\alpha}, \hat{\gamma})\} = \hat{E}\{(Y e^{-\theta Z} - e^{\hat{\alpha}^T \xi})(Z - \psi_f(\hat{\gamma}^T \xi))\}. \] \hspace{1cm} (50)

For initial estimation, let \( (\hat{\theta}_0, \hat{\alpha}_1) \) be Lasso regularized quasi-likelihood estimators in model (48), \( \hat{\gamma}_1 \) be that in model (49), and \( \hat{\theta}_1 = \hat{\theta}(\hat{\alpha}_1, \hat{\gamma}_1) \). For second-step estimation, the regularized calibrated estimator \( \hat{\gamma}_2 \) is defined with a Lasso penalty and the loss function

\[ L_2(\gamma; \hat{\alpha}_1) = \hat{E}\{\ell_2(U; \hat{\alpha}_1, \gamma)\} = \hat{E}\left[ e^{\hat{\alpha}_1^T \xi} \{ -Z \gamma^T \xi + \psi_f(\gamma^T \xi) \} \right], \] \hspace{1cm} (51)

and \( \hat{\alpha}_2 \) is defined with a Lasso penalty and the loss function

\[ L_1(\alpha; \hat{\theta}_1, \hat{\gamma}_2) = \hat{E}\{\ell_1(U; \hat{\theta}_1, \alpha, \hat{\gamma}_2)\} = \hat{E}\left\{ \psi'_f(\hat{\gamma}_2^T \xi) \left( -Ye^{-\hat{\theta}_1 Z} \alpha^T \xi + e^{\hat{\alpha}_2^T \xi} \right) \right\}, \]
where $\ell_1$ and $\ell_2$ are determined from (33), with $(\partial \tau / \partial \alpha, \partial \tau / \partial \gamma)$ in (27)–(28). Unlike (46), the loss (51) in $\gamma$ depends on $\hat{\alpha}_1$. The resulting estimator of $\theta$ is then $\hat{\theta}_2 = \hat{\theta}(\hat{\alpha}_2, \hat{\gamma}_2)$.

In contrast with Example 10, our method is distinct from debiased Lasso, even when $\psi_f \equiv 1$, i.e., (49) is a linear model. Similarly as in our method, let $(\hat{\theta}_0, \hat{\alpha}_1)$ be the Lasso estimators associated with the loss $\hat{E}\{-Y(\theta Z + \alpha^T \xi) + e^{\theta Z + \alpha^T \xi}\}$, and $\hat{\gamma}_1$ be that associated with the loss $\hat{E}\{e^{\theta_0 Z + \hat{\alpha}_1^T \xi}(Z - \gamma^T \xi)^2\}$. The debiased Lasso estimator in Van de Geer et al. (2014), also called the one-step estimator in Ning & Liu (2017), is

$$\hat{\theta}_{DB} = \hat{\theta}_0 + \frac{\hat{E}\{(Y - e^{\theta_0 Z + \hat{\alpha}_1^T \xi})(Z - \hat{\gamma}_1^T \xi)\}}{\hat{E}\{e^{\theta_0 Z + \hat{\alpha}_1^T \xi}Z(Z - \gamma^T \xi)\}}.$$

A variation of debiased Lasso in Neykov et al. (2018) is to define $\hat{\theta}_{DB2}$ as a solution to

$$\hat{E}\{(Y - e^{\theta Z + \hat{\alpha}_1^T \xi})(Z - \hat{\gamma}_1^T \xi)\} = 0. \tag{52}$$

Equation (52) is somewhat similar to (50) with $\psi_f \equiv 1$, but there is an important difference. Equation (50) is doubly robust: its limit version, with $(\hat{\alpha}_1, \hat{\gamma}_1)$ replaced by their limit values and $\hat{E}(\cdot)$ replaced by $E(\cdot)$, holds at $\theta = \theta^*$ in partially log-linear model (6) if either model (48) or model (49) is correctly specified. In contrast, (52) is not doubly robust: its limit version in general holds at $\theta = \tilde{\theta}_0$, defined such that

$$(\tilde{\theta}_0, \tilde{\alpha}_1) = \arg\min_{\theta, \alpha} E\{-Y(\theta Z + \alpha^T \xi) + e^{\theta Z + \alpha^T \xi}\}.$$

The target value $\tilde{\theta}_0$ coincides with $\theta^*$ if model (48) is correctly specified, but in general may differ from $\theta^*$ otherwise including when model (49) with $\psi_f \equiv 1$ is correctly specified.

**Example 12.** Return to Examples 3 and 8 with a partially log-linear model (8). For $g(x; \alpha) = \alpha^T \xi$ and $f(x; \gamma) = \psi_f(\gamma^T \xi)$, models (11) and (12) can be stated as

$$E(Y|Z, X) = \expit(\theta Z + \alpha^T \xi), \tag{53}$$

$$E(Z|Y = 0, X) = \psi_f(\gamma^T \xi). \tag{54}$$

For estimating function $\tau$ in (9) and any estimators $(\hat{\alpha}, \hat{\gamma})$, $\hat{\theta} = \hat{\theta}(\hat{\alpha}, \hat{\gamma})$ is a solution to

$$0 = \hat{E}\{\tau(U; \theta, \hat{\alpha}, \hat{\gamma})\} = \hat{E}\{e^{-\theta Y}(Y - \expit(\hat{\alpha}^T \xi))(Z - \psi_f(\hat{\gamma}^T \xi))\}.$$

27
For initial estimation, let \((\hat{\theta}_0, \hat{\alpha}_1)\) be Lasso likelihood estimators in model (53), \(\hat{\gamma}_1\) be a Lasso quasi-likelihood estimator in model (54), and \(\hat{\theta}_1 = \hat{\theta}(\hat{\alpha}_1, \hat{\gamma}_1)\). For second-step estimation, the regularized calibrated estimator \(\hat{\gamma}_2\) is defined with a Lasso penalty and the loss function
\[
L_2(\gamma; \hat{\theta}_1, \hat{\alpha}_1) = \tilde{E}\{\ell_2(U; \hat{\theta}_1, \hat{\alpha}_1, \gamma)\} = \tilde{E}\left[e^{-\hat{\theta}_1 Z Y \expit(\hat{\gamma}_1^T \xi)} \left\{ -Z \gamma^T \xi + \Psi_f(\gamma^T \xi) \right\} \right],
\]
and \(\hat{\alpha}_2\) is defined with a Lasso penalty and the loss function
\[
L_1(\alpha; \hat{\theta}_1, \hat{\gamma}_2) = \tilde{E}\{\ell_1(U; \hat{\theta}_1, \alpha, \hat{\gamma}_2)\} = \tilde{E}\left[e^{-\hat{\theta}_1 Z Y \expit(\hat{\gamma}_2^T \xi)} \left\{ -Y \alpha^T \xi + \log(1 + e^{\alpha^T \xi}) \right\} \right],
\]
where \(\ell_1\) and \(\ell_2\) are determined from (33), with \((\partial \tau / \partial \alpha, \partial \tau / \partial \gamma)\) in (29)–(30). The resulting estimator of \(\theta\) is then \(\hat{\theta}_2 = \hat{\theta}(\hat{\alpha}_2, \hat{\gamma}_2)\).

Our method in Example 12 differs from debiased Lasso even more substantially than in Examples 10–11. The debiased Lasso estimator in van de Geet et al. (2014) is
\[
\hat{\theta}_{db} = \hat{\theta}_0 + \frac{\tilde{E}\{(Y - \expit(\hat{\theta}_0 Z + \hat{\alpha}_1^T \xi))(Z - \hat{\gamma}_1^T \xi)\}}{\tilde{E}\{\expit(\hat{\theta}_0 Z + \hat{\alpha}_1^T \xi)Z(Z - \hat{\gamma}_1^T \xi)\}}
\]
and a variation \(\hat{\theta}_{db2}\) in Neykov et al. (2018) is a solution to
\[
\tilde{E}\{(Y - \expit(\theta Z + \hat{\alpha}_1^T \xi))(Z - \hat{\gamma}_1^T \xi)\} = 0,
\]
where \((\hat{\theta}_0, \hat{\alpha}_1)\) are Lasso estimators in model (53) as in our method, but \(\hat{\gamma}_1\), different from \(\hat{\gamma}_1\), is a Lasso estimator associated with the loss \(\tilde{E}\{\expit(\hat{\theta}_0 Z + \hat{\alpha}_1^T \xi)(Z - \gamma^T \xi)^2\}\), corresponding to a model \(E(Z|X) = \gamma^T \xi\) instead of model (54) in our method. Confidence intervals based on \(\hat{\theta}_{db}\) or \(\hat{\theta}_{db2}\) would not be valid for \(\theta^*\) in partially linear model (8) if model (53) is misspecified, irrespective of whether model (54) is correctly specified.

**Example 13.** Return to Examples 4 and 9. For \(g(x; \alpha) = \psi_g(\alpha^T \xi)\) and \(f(x; \gamma) = \psi_f(\gamma^T \xi)\), models (11) and (12) can be stated as
\[
E(Y|Z = 1, X) = \psi_g(\alpha^T \xi), \quad \text{(56)}
\]
\[
P(Z = 1|X) = \psi_f(\gamma^T \xi). \quad \text{(57)}
\]
For estimating function \(\tau\) in (10) and any estimators \((\hat{\alpha}, \hat{\gamma})\), \(\hat{\theta} = \hat{\theta}(\hat{\alpha}, \hat{\gamma})\) is of closed form
\[
\hat{\theta}(\hat{\alpha}, \hat{\gamma}) = \tilde{E}\left[\frac{Z Y}{\psi_f(\hat{\gamma}^T \xi)} - \left\{ \frac{Z}{\psi_f(\hat{\gamma}^T \xi)} - 1 \right\} \psi_g(\hat{\alpha}^T \xi) \right]. \quad \text{(58)}
\]
For initial estimation, let $\hat{\alpha}_1$ be a Lasso quasi-likelihood estimator in model (56), $\hat{\gamma}_1$ be that in model (57), and $\tilde{\theta}_1 = \tilde{\theta}(\hat{\alpha}_1, \hat{\gamma}_1)$. For second-step estimation, the regularized calibrated estimator $\hat{\gamma}_2$ is defined with a Lasso penalty and the loss function

$$L_2(\gamma; \hat{\alpha}_1) = \tilde{E}\{\ell_2(U; \hat{\alpha}_1, \gamma)\} = \tilde{E}\left[\psi'_g(\hat{\alpha}_1^T \xi) \{-Z\Psi_f(\gamma^T \xi) + \gamma^T \xi\}\right],$$

and $\hat{\alpha}_2$ is defined with a Lasso penalty and the loss function

$$L_1(\alpha; \hat{\gamma}_2) = \tilde{E}\{\ell_1(U; \alpha, \hat{\gamma}_2)\} = \tilde{E}\left[\psi'_f(\hat{\gamma}_2^T \xi) \frac{\Psi_g(u)}{\psi'_g(\hat{\gamma}_2^T \xi)} Z \{-Y\alpha^T \xi + \Psi_g(\alpha^T \xi)\}\right],$$

where $\Psi_f(u) = \int_0^u \psi_f^{-1}(t) \, dt$, $\Psi_g(u) = \int_0^u \psi_g(t) \, dt$, and $\ell_1$ and $\ell_2$ are determined from (33), with $(\partial \tau / \partial \alpha, \partial \tau / \partial \gamma)$ in (31)–(32). The resulting estimator of $\theta$ is then $\hat{\theta}_2 = \hat{\theta}(\hat{\alpha}_2, \hat{\gamma}_2)$.

By Proposition 3, valid confidence intervals based on $\hat{\theta}_2$ can be obtained for $\theta^* = E(Y)$ if either model (56) or (57) is correctly specified. Hence our work extends Tan (2020a), where doubly robust confidence intervals are obtained for $\theta^*$ only with linear outcome model (56). With a nonlinear outcome model, valid confidence intervals are obtained in Tan (2020a), depending on propensity score model (57) being correctly specified.

### 5 Simulation studies

Consider the settings of partially linear, log-linear, and logistic models (Examples 10–12). Assume that the covariate of interest $Z$ is binary (for example a treatment variable), and hence the coefficient $\theta^*$ represents some homogeneous treatment effect. The link function for $Z$ given $X$ is taken to be logistic: $\psi_f = \text{expit}(\cdot)$.

We investigate the performance of our two-step estimator $\hat{\theta}_2$, compared with the debiased Lasso estimator $\hat{\theta}_{db}$ and the initial estimator $\hat{\theta}_1$ using regularized likelihood (or quasi-likelihood) estimation, as described in Section 4. For all point estimators, the Lasso tuning parameters are selected via 5-fold cross validation. Wald confidence intervals based on $\hat{\theta}_2$ are obtained by Proposition 3. For comparison, confidence intervals based on $\hat{\theta}_1$ are computed in a similar manner, with $(\hat{\alpha}_1, \hat{\gamma}_1, \hat{\theta}_1)$ in place of $(\hat{\alpha}_2, \hat{\gamma}_2, \hat{\theta}_2)$. Wald confidence intervals based on $\hat{\theta}_{db}$ are computed using a robust variance estimator, which, for linear modeling, is defined as $\hat{V}_{bc}$ in Section 4. See the Supplement for further implementation details.
5.1 Partially linear modeling

Consider the following data-generating configurations for \((Z, X, Y)\), where \(\theta^* = 3\).

(C1) Generate \(Z\) as Bernoulli with \(P(Z = 1) = 0.5\) and \(X\) given \(Z = 0\) or \(1\) as multivariate normal with means \(\mu_0 \neq \mu_1\) and variance matrices \(\Sigma_0 = \Sigma_1\), such that \(Z\) given \(X\) is Bernoulli with \(P(Z = 1 | X) = \expit(-0.4297 - 0.25X_1 + 0.5X_2 + 0.75X_3 + X_4 + 1.25X_5)\).

Then \(Y\) given \((Z, X)\) is generated as normal with variance 0.5 and mean \(E(Y|Z, X) = \theta^*Z + 0.25X_1 + 1.5X_2 + 1.75X_3 + 5X_4\).

(C2) Generate \(Z\) as Bernoulli with \(P(Z = 1) = 0.5\) and \(X\) given \(Z = 0\) or \(1\) as multivariate normal with means \(\mu_0 \neq \mu_1\) and variance matrices \(\Sigma_0 \neq \Sigma_1\), such that \(Z\) given \(X\) is Bernoulli with \(P(Z = 1 | X) = \expit(-0.4687 + \frac{p}{2}\ln 2 - 0.25X_1 + 0.5X_2 + 0.75X_3 + X_4 + 0.5X^T X)\). Then \(Y\) given \((Z, X)\) is generated as in (C1).

(C3) Generate \(Z\) given \(X\) as in (C1) and then \(Y\) given \((Z, X)\) as normal with variance 0.5 and mean \(E(Y|Z, X) = \theta^*Z + \expit(0.5X_1 + X_2) + 4(X_3 - 0.75) + 2(X_4 - 1)^2\).

See the Supplement for details of \((\mu_0, \mu_1)\) and \((\Sigma_0, \Sigma_1)\) and the derivation of \(P(Z = 1 | X)\) stated above, related to Fisher’s discrimination analysis.

Consider models (44) for \(E(Y|Z, X)\) and (45) for \(P(Z = 1 | X)\), with the regressor vector \(\xi = (1, X^T)^T\). Then the two models are both correctly specified in (C1), model (44) is correctly specified but model (45) is misspecified in (C2), and model (44) is misspecified and model (45) is correctly specified in (C3). Hence the simulation settings (C1), (C2), and (C3) are labeled as “Cor Cor”, “Cor Mis”, and “Mis Cor” respectively.

For \(n = 400\) and \(p = 800\), Table 1 summarizes the results for estimation of \(\theta^*\) and Figure 1 shows the QQ plots of \(t\)-statistics. Additional results with \(p = 100\) or \(200\) are included in the Supplement. In settings (C1) and (C2) with model (44) correctly specified for \(E(Y|Z, X)\), the three methods using \(\hat{\theta}_{\text{db}}, \hat{\theta}_1,\) and \(\hat{\theta}_2\) perform similarly to each other. In theory, all the methods in such settings deliver valid confidence intervals. In setting (C3) with model (44) misspecified for \(E(Y|Z, X)\) but model (45) correctly specified for \(P(Z = 1 | X)\), there are important differences between the three methods. The debiased Lasso estimator \(\hat{\theta}_{\text{db}}\) becomes inconsistent for \(\theta^*\), as seen from a large bias and poor coverage proportion. The initial estimator \(\hat{\theta}_1\) is, in theory, consistent but does not yield valid confidence intervals.
Our calibrated estimator $\hat{\theta}_2$ shows the best performance, with a small bias and close to 95% coverage. The improvement of $\hat{\theta}_2$ over $\hat{\theta}_{DB}$ and $\hat{\theta}_1$ is also confirmed in Figure 1, where the QQ plot of t-statistics from $\hat{\theta}_2$ is much better aligned with standard normal.

5.2 Partially log-linear modeling

Consider the following data-generating configurations for $(Z, X, Y)$, where $\theta^* = 2$.

(C4) Generate $(Z, X)$ as in (C1) in Section 5.1 and then $Y$ given $(Z, X)$ as Poisson with mean $\exp(\theta^*Z + 0.1X_1 + 0.25X_2 + 0.5X_3 + 0.75X_4)$.

(C5) Generate $(Z, X)$ as in (C2) in Section 5.1 and then $Y$ as in (C4).
(C6) Generate $(Z, X)$ as in (C1) in Section 5.1 and then $Y$ given $(Z, X)$ as Poisson with mean $\exp(\theta^* Z + X_1 + 0.1X_2^2 + 0.2X_3^2)$.

Consider models (48) for $E(Y|Z, X)$ and (49) for $P(Z = 1|X)$, with the regressor vector $\xi = (1, X^T)^T$. Then the two models are both correctly specified in (C4), model (48) is correctly specified but model (49) is misspecified in (C5), and model (48) is misspecified and model (49) is correctly specified in (C6).

For $n = 600$ and $p = 800$, Table 2 summarizes the results for estimation of $\theta^*$ and Figure 2 shows the QQ plots of t-statistics. Additional results with $p = 100$ or 200 are included in the Supplement. The three methods perform similarly to each other in setting (C4). However, unlike in Section 5.1, our calibrated method achieves the best performance in both settings (C5) and (C6), with a smaller bias, closer to 95% coverage, and better aligned t-statistics with standard normal than the other methods.

Figure 2: QQ plots of t-statistics for partially log-linear modeling ($n = 600, p = 800$)
5.3 Partially logistic modeling

The covariates \( X = (X_1, \ldots, X_p)^T \) are generated as multivariate normal with means 0 and \( \text{cov}(X_j, X_k) = 2^{-|j-k|} \) for \( 1 \leq j, k \leq p \). Then \((Z, Y)\) given \( X \) are generated jointly (rather than sequentially) such that the following configurations are obtained, where \( \theta^* = 2 \).

(C7) \( Z \) given \( Y = 0 \) and \( X \) is Bernoulli with \( P(Z = 1|Y = 0, X) = \expit(0.25 - 0.125X_1 + 0.125X_2 + 0.25X_3 + 0.375X_4) \) and \( Y \) given \((Z, X)\) is Bernoulli with \( P(Y = 1|Z, X) = \expit(\theta^*Z - 0.125X_1 + 0.125X_2 + 0.25X_3 + 0.375X_4) \).

(C8) \( Z \) given \( Y = 0 \) and \( X \) is Bernoulli with \( P(Z = 1|Y = 0, X) = \expit(\theta^*Z - 0.25 + 0.25X_1 + 0.8X_2 + \expit(X_3)) \) and \( Y \) given \((Z, X)\) is the same as in (C7).

(C9) \( Z \) given \( Y = 0 \) and \( X \) is the same as in (C7) and \( Y \) given \((Z, X)\) is Bernoulli with \( P(Y = 1|Z, X) = \expit(\theta^*Z - 0.25 + 0.25X_1 + 0.8X_2 + \expit(X_3)) \).

See the Supplement for details of data generation, related to the odds ratio model in Chen (2007). Consider models (53) for \( E(Y|Z, X) \) and (54) for \( P(Z = 1|Y = 0, X) \), with the regressor vector \( \xi = (1, X^T)^T \). Then the two models are both correctly specified in (C7), model (53) is correctly specified but model (54) is misspecified in (C8), and model (53) is misspecified and model (54) is correctly specified in (C9).

Note: See the footnote of Table 1.
Figure 3: QQ plots of \( t \)-statistics for partially logistic modeling \((n = 600, p = 800)\)

For \( n = 600 \) and \( p = 800 \), Table 3 summarizes the results for estimation of \( \theta^* \) and Figure 3 shows the QQ plots of \( t \)-statistics. Additional results with \( p = 100 \) or 200 are included in the Supplement. While the three methods perform similarly to each other in settings (C7) and (C8), our calibrated method achieves substantially better performance in setting (C9) than the other methods, similarly as in Section 5.1.

6 Conclusion

We develop regularized calibrated estimation as a general method for obtaining doubly robust confidence intervals in high-dimensional settings, provided a doubly robust estimating function is available. While various applications of the method can be pursued, there are interesting topics which warrant further investigation. As an alternative to the two-step algorithm, it is of interest to study the generalized Dantzig selector mentioned in Section 3, including development of practical algorithms and theoretical analysis without a convex loss. This approach has a potential benefit in producing valid confidence intervals centered about the target value in \( \theta \) even if both working models are misspecified, similarly as discussed in Remark 9 of Tan (2020a). Moreover, it is helpful to incorporate sample splitting and cross fitting for our method and study whether both rate and model double robustness can generally be achieved. A related question is raised in Smucler et al. (2019) about construction of such desired estimators beyond bilinear influence functions.

I Technical details

I.1 Probability lemmas

Denote by $\Omega_0$ the event that $(\hat{\alpha}_1 - \bar{\alpha}_1)^T \tilde{\Sigma}_0 (\hat{\alpha}_1 - \bar{\alpha}_1) \leq M_0 \lambda_0^2$, $\|\hat{\alpha}_1 - \bar{\alpha}_1\|_1 \leq M_0 \lambda_0$, $(\hat{\gamma}_1 - \bar{\gamma}_1)^T \tilde{\Sigma}_0 (\hat{\gamma}_1 - \bar{\gamma}_1) \leq M_0 \lambda_0^2$, $\|\hat{\gamma}_1 - \bar{\gamma}_1\|_1 \leq M_0 \lambda_0$, and $|\hat{\theta}_1 - \theta^*| \leq M_0^{1/2} \lambda_0$. Then Assumption 2(iv) says that $P(\Omega_0) \geq 1 - \epsilon$.

**Lemma S1.** Denote by $\Omega_1$ the event that

$$\sup_{j=1, \ldots, p} \left| \tilde{E} \left\{ \xi_j(X) \frac{\partial \tau}{\partial \eta_0}(U; \theta^*, \hat{\alpha}_1, \bar{\gamma}_2) \right\} \right| \leq B_0 \lambda_0,$$

where $B_0 = C_0 (B_{02} + \sqrt{2}B_{01})$. Under Assumption 2(i)–(ii), if $\lambda_0 \leq 1$, then $P(\Omega_1) \geq 1 - 2\epsilon$.

**Proof.** The variable $\frac{\partial \tau}{\partial \eta_0}(U; \theta^*, \hat{\alpha}_1, \bar{\gamma}_2)$ has mean 0 (because $\xi$ includes a constant) and is sub-exponential with parameters $(B_{01}, B_{02})$. For $j = 1, \ldots, p$, the variable $\xi_j(X) \frac{\partial \tau}{\partial \eta_0}(U; \theta^*, \hat{\alpha}_1, \bar{\gamma}_2)$ has mean 0 and is sub-exponential with parameter $(C_0 B_{01}, C_0 B_{02})$. By Bernstein’s inequality (Bühlmann & Van de Geer 2011, Lemma 14.9; Tan 2020a, Lemma 16),

$$P \left\{ |\tilde{E}(Y_j)| \geq C_0 B_{02} t + C_0 B_{01} \sqrt{2t} \right\} \leq 2 \frac{\epsilon}{p}$$

where $t = \log(p/\epsilon)/n = \lambda_0^2$. The result then follows from the union bound. \hfill $\square$

**Lemma S2.** Denote by $\Omega_{21}, \Omega_{22}, \Omega_{23}$ respectively the events that

$$\sup_{j,k=1, \ldots, p} \left| (\tilde{E} - E) \left\{ \xi_j \xi_k T_{n_0}^{(1)}(U; \theta^*, \hat{\alpha}_1, \bar{\gamma}_2) \right\} \right| \leq B_{15} \lambda_0,$$

$$\sup_{j,k=1, \ldots, p} \left| (\tilde{E} - E) \left\{ \xi_j \xi_k T_{n_0}^{(0)}(U; \theta^*, \hat{\alpha}_1, \bar{\gamma}_2) \right\} \right| \leq B_{15} \lambda_0,$$

$$\sup_{j,k=1, \ldots, p} \left| (\tilde{E} - E) \left\{ \xi_j \xi_k \frac{\partial^2 \tau}{\partial \eta_0 \partial \eta_f}(U; \theta^*, \hat{\alpha}_1, \bar{\gamma}_2) \right\} \right| \leq B_{15} \lambda_0,$$
where \( B_{15} = 2(B_{14} + B_{13}) \), \( B_{13} = (2C_0^2B_{11}^2 + 8C_0^4C_1^2)^{1/2} \), and \( B_{14} = 2B_{12} + 2C_0^2C_1 \). Under Assumptions 2(i) and 3(i)–(ii), if \( \lambda_0 \leq 1 \), then \( P(\Omega_{21}) \geq 1 - 2\epsilon^2 \), \( P(\Omega_{22}) \geq 1 - 2\epsilon^2 \), and \( P(\Omega_{23}) \geq 1 - 2\epsilon^2 \).

**Proof.** First, we show that for \( j, k = 1, \ldots, p \), \( \xi_j\xi_kT^{(1)}_{\eta\theta}(U; \theta^*, \bar{\alpha}_1, \bar{\gamma}_2) \) is sub-exponential with parameter \((B_{13}, B_{14})\). Denote \( T^{(1)}_{\eta\theta} = T^{(1)}_{\eta\theta}(U; \theta^*, \bar{\alpha}_1, \bar{\gamma}_2) \). Then for \( k \geq 2 \),

\[
E \left| \xi_j\xi_kT^{(1)}_{\eta\theta} - E \left\{ \xi_j\xi_kT^{(1)}_{\eta\theta} \right\} \right|^k \leq 2^{k-1} \left[ E \left| \xi_j\xi_k \left( T^{(1)}_{\eta\theta} - E(T^{(1)}_{\eta\theta}) \right) \right|^k + E \left| \xi_j\xi_k E(T^{(1)}_{\eta\theta}) - E(\xi_j\xi_kT^{(1)}_{\eta\theta}) \right|^k \right] \leq 2^{k-1} \left\{ C_0^2k!B_{11}^2B_{12}^{k-2} + (2C_0^2C_1)^k \right\} \leq \frac{k!}{2} (2C_0^2B_{11}^2 + 8C_0^4C_1^2)(2B_{12} + 2C_0^2C_1)^{k-2}.
\]

Applying Bernstein’s inequality to \( \xi_j\xi_kT^{(1)}_{\eta\theta}(U; \theta^*, \bar{\alpha}_1, \bar{\gamma}_2) \) yields

\[
P \left\{ \left| (\bar{E} - E)(\xi_j\xi_k) \right| \geq B_{14}t + B_{13}\sqrt{2t} \right\} \leq \frac{2\epsilon^2}{p^2}
\]

where \( t = \log(p^2/\epsilon^2)/n = 2\lambda_0^2 \). Then \( P(\Omega_{21}) \geq 1 - 2\epsilon^2 \) by the union bound. Similarly, \( P(\Omega_{22}) \geq 1 - 2\epsilon^2 \) and \( P(\Omega_{23}) \geq 1 - 2\epsilon^2 \). \( \square \)

**Lemma S3.** Denote by \( \Omega_{24} \) the event that

\[
\sup_{j,k=1,\ldots,p} \left| (\bar{E} - E)(\xi_j\xi_k) \right| \leq 4C_0^2\lambda_0.
\]

Under Assumption 2(i), \( P(\Omega_{24}) \geq 1 - 2\epsilon^2 \).

**Proof.** For \( j, k = 1, \ldots, p \), by Hoeffding’s inequality (Bühlmann & Van de Geer 2011, Lemma 14.11; Tan 2020a, Lemma 14),

\[
P \left\{ \left| (\bar{E} - E)(\xi_j\xi_k) \right| \geq 2C_0^2(\sqrt{2t}) \right\} \leq \frac{2\epsilon^2}{p^2}
\]

where \( |\xi_j\xi_k - E(\xi_j\xi_k)| \leq 2C_0^2 \) and \( t = \{\log(p^2/\epsilon^2)/n\}^{1/2} = \sqrt{2}\lambda_0 \). The result then follows from the union bound. \( \square \)

**Lemma S4.** Denote \( \Omega_2 = \Omega_{21} \cap \Omega_{22} \cap \Omega_{23} \cap \Omega_{24} \). Under Assumptions 2(i) and 3(i)–(ii), if \( \lambda_0 \leq 1 \), then \( P(\Omega_2) \geq 1 - 8\epsilon^2 \). Moreover, in the event \( \Omega_2 \), we have for any vector \( b \in \mathbb{R}^p \),

\[
\bar{E} \left\{ T^{(1)}_{\eta\theta}(U; \theta^*, \bar{\alpha}_1, \bar{\gamma}_2)(b^T\xi)^2 \right\} \leq C_1 \bar{E} \left\{ (b^T\xi)^2 \right\} + (1 + C_1)B_1\lambda_0\|b\|_1^2,
\]

\[
\bar{E} \left\{ T^{(1)}_{\eta\bar{\theta}}(U; \theta^*, \bar{\alpha}_1, \bar{\gamma}_2)(b^T\xi)^2 \right\} \leq C_1 \bar{E} \left\{ (b^T\xi)^2 \right\} + (1 + C_1)B_1\lambda_0\|b\|_1^2,
\]

\[
\bar{E} \left\{ \frac{\partial^2 \tau}{\partial \eta_\theta \partial \eta_f}(U; \theta^*, \bar{\alpha}_1, \bar{\gamma}_2)(b^T\xi)^2 \right\} \geq c_2 \bar{E} \left\{ (b^T\xi)^2 \right\} - (1 + c_2)B_1\lambda_0\|b\|_1^2,
\]

\( 2 \)
where $B_1 = \max(4C_0^2, B_{15})$.

**Proof.** Combining Lemmas S2–S3 shows that $P(\Omega_2) \geq 1 - \epsilon^2$. In the event $\Omega_2$, simple manipulation yields

$$\left| \left( \hat{E} - E \right) \left\{ T_{1g}^{(1)} (U; \theta^*, \bar{\alpha}_1, \bar{\gamma}_2) (b^\top \xi)^2 \right\} \right| \leq B_{15} \lambda_0 \| b \|_1^2,$$

$$\left| \left( \hat{E} - E \right) \left\{ (b^\top \xi)^2 \right\} \right| \leq 4C_0^2 \lambda_0 \| b \|_1.$$  

By the law of iterated expectations and Assumption 3(i),

$$E \left\{ T_{1g}^{(1)} (U; \theta^*, \bar{\alpha}_1, \bar{\gamma}_2) (b^\top \xi)^2 \right\} = E \left[ T_{1g}^{(1)} (U; \theta^*, \bar{\alpha}_1, \bar{\gamma}_2) \right] (b^\top \xi)^2 \leq C_1 E \left\{ (b^\top \xi)^2 \right\}$$

Combining the preceding three inequalities yields the result on $T_{1g}^{(1)}$. Similarly, the results on $T_{1g,\theta}$ and $\frac{\partial^2 \tau}{\partial \eta_0 \partial \eta_f}$ can be shown. □

### I.2 Proofs of Theorem 1, Corollary 3, and Theorem 2

We split the proof of Theorem 1 into a series of lemmas. The first one is usually called a basic inequality for $\hat{\gamma}_2$, but depending on the first-step estimators $(\hat{\theta}_1, \hat{\alpha}_1)$.

**Lemma S5.** For any vector $\gamma \in \mathbb{R}^p$, we have

$$D_2^\dagger (\hat{\gamma}_2; \hat{\theta}_1, \hat{\alpha}_1) + A_1 \lambda_0 \| \hat{\gamma}_2 \|_1 \leq (\hat{\gamma}_2 - \gamma)^\top \hat{E} \left\{ \xi \frac{\partial \tau}{\partial \eta_g} (U; \hat{\theta}_1, \hat{\alpha}_1, \gamma) \right\} + A_1 \lambda_0 \| \gamma \|_1. \quad (S1)$$

**Proof.** For any $u \in (0, 1]$, the definition of $\hat{\gamma}_2$ implies

$$L_2 (\hat{\gamma}_2; \hat{\theta}_1, \hat{\alpha}_1) + A_1 \lambda_0 \| \hat{\gamma}_2 \|_1 \leq L_2 \{(1 - u) \hat{\gamma}_2 + u \gamma; \hat{\theta}_1, \hat{\alpha}_1\} + A_1 \lambda_0 \| (1 - u) \hat{\gamma}_2 + u \gamma \|_1,$$

which, by the convexity of $\| \cdot \|_1$, gives

$$L_2 (\hat{\gamma}_2; \hat{\theta}_1, \hat{\alpha}_1) - L_2 \{(1 - u) \hat{\gamma}_2 + u \gamma; \hat{\theta}_1, \hat{\alpha}_1\} + A_1 \lambda_0 u \| \hat{\gamma}_2 \|_1 \leq A_1 \lambda_0 u \| \gamma \|_1.$$

Dividing both sides of the preceding inequality by $u$ and letting $u \to 0+$ yields

$$-(\hat{\gamma}_2 - \gamma)^\top \hat{E} \left\{ \xi \frac{\partial \tau}{\partial \eta_f} (U; \hat{\theta}_1, \hat{\alpha}_1, \hat{\gamma}_2) \right\} + A_1 \lambda_0 \| \hat{\gamma}_2 \|_1 \leq A_1 \lambda_0 \| \gamma \|_1,$$
which leads to (S1) after a simple rearrangement using (38).

The second lemma deals with the dependency on \((\hat{\theta}_1, \hat{\alpha}_1)\) in the upper bound from the basic inequality (S1). Denote

\[
Q_2(\gamma_2, \bar{\gamma}_2; \theta^*, \bar{\alpha}_1) = \bar{E} \left\{ \frac{\partial^2 \tau}{\partial \eta g \partial \eta f} (U; \theta^*, \bar{\alpha}_1, \gamma_2) (\gamma_2^T \xi - \bar{\gamma}_2^T \xi)^2 \right\}
\]

\[
= (\gamma_2 - \bar{\gamma}_2)^T \bar{\Sigma}_\gamma (\gamma_2 - \bar{\gamma}_2).
\]

where \(\bar{\Sigma}_\gamma = \bar{E} \left\{ \frac{\partial^2 \tau}{\partial \eta g \partial \eta f} (U; \theta^*, \bar{\alpha}_1, \bar{\gamma}_2) \xi \xi^T \right\} \).

**Lemma S6.** Suppose that Assumptions 3(i) and 3(iv) hold. In the event \(\Omega_0 \cap \Omega_2\), we have

\[
(\gamma_2 - \bar{\gamma}_2)^T \bar{E} \left\{ \xi \frac{\partial \tau}{\partial \eta g} (U; \hat{\theta}_1, \hat{\alpha}_1, \gamma) \right\}
\]

\[
\leq (\gamma_2 - \bar{\gamma}_2)^T \bar{E} \left\{ \xi \frac{\partial \tau}{\partial \eta g} (U; \theta^*, \bar{\alpha}_1, \bar{\gamma}_2) \right\}
\]

\[
+ (C_{12} M_0 \lambda_0^2)^{1/2} \{Q_2(\gamma_2, \bar{\gamma}_2; \theta^*, \bar{\alpha}_1) \}^{1/2} + C_{13} \lambda_0 \|\gamma_2 - \bar{\gamma}_2\|_1,
\]

where \(C_{12} = 4c_1^2 C_1 (C_1 + C_{11} \varrho_0), C_{13} = \{C_1^{1/2} + (1 + c_1^{-1})^{1/2} B_1^{1/2} C_1^{1/2}\} \{4(C_1 + C_{11} \varrho_0) \varrho_0 \}^{1/2}, \) and \(C_{11} = (1 + C_1) B_1 \) with \(B_1\) from Lemma S4.

**Proof.** Consider the decomposition

\[
(\gamma_2 - \bar{\gamma}_2)^T \bar{E} \left\{ \xi \frac{\partial \tau}{\partial \eta g} (U; \hat{\theta}_1, \hat{\alpha}_1, \bar{\gamma}_2) \xi \right\}
\]

\[
= (\gamma_2 - \bar{\gamma}_2)^T \bar{E} \left\{ \xi \frac{\partial \tau}{\partial \eta g} (U; \theta^*, \bar{\alpha}_1, \bar{\gamma}_2) \right\} + \Delta_1 + \Delta_2,
\]

where

\[
\Delta_1 = (\gamma_2 - \bar{\gamma}_2)^T \bar{E} \left\{ \xi \left\{ \frac{\partial \tau}{\partial \eta g} (U; \hat{\theta}_1, \hat{\alpha}_1, \bar{\gamma}_2) - \frac{\partial \tau}{\partial \eta g} (U; \theta^*, \bar{\alpha}_1, \bar{\gamma}_2) \right\} \right\},
\]

\[
\Delta_2 = (\gamma_2 - \bar{\gamma}_2)^T \bar{E} \left\{ \xi \left\{ \frac{\partial \tau}{\partial \eta g} (U; \theta^*, \bar{\alpha}_1, \bar{\gamma}_2) - \frac{\partial \tau}{\partial \eta g} (U; \theta^*, \bar{\alpha}_1, \bar{\gamma}_2) \right\} \right\}.
\]

In the event \(\Omega_0\), \((\hat{\theta}_1, \hat{\alpha}_1) \in N_1\) by Assumption 3(iv). By the mean value theorem and the Cauchy–Schwarz inequality, and Assumption 3(i),

\[
|\Delta_2| = \left| \bar{E} \left\{ (\gamma_2 - \bar{\gamma}_2)^T \xi \frac{\partial^2 \tau}{\partial \eta g^2} (U; \theta^*, \bar{\alpha}_1, \bar{\gamma}_2) (\hat{\alpha}_1 - \bar{\alpha}_1)^T \xi \right\} \right|
\]

\[
\leq \bar{E}^{1/2} \left\{ \tilde{T}_{\eta g}^{(1)} (U; \theta^*, \bar{\alpha}_1, \bar{\gamma}_2) (\gamma_2^T \xi - \bar{\gamma}_2^T \xi)^2 \right\} \bar{E}^{1/2} \left\{ \tilde{T}_{\eta g}^{(1)} (U; \theta^*, \bar{\alpha}_1, \bar{\gamma}_2) (\hat{\alpha}_1^T \xi - \bar{\alpha}_1^T \xi)^2 \right\},
\]

where \(\tilde{T}_{\eta g}^{(1)} = \tilde{E} \left\{ \frac{\partial \tau}{\partial \eta g} (U; \theta^*, \bar{\alpha}_1, \bar{\gamma}_2) \right\} \).
where $\tilde{\alpha}$ lies between $\hat{\alpha}_1$ and $\bar{\alpha}_1$. Hence in the event $\Omega_0 \cap \Omega_2$ by Lemma S4,

$$|\Delta_2| \leq \left[ C_1 \tilde{E} \left\{ (\tilde{\gamma}_2^T \xi - \tilde{\gamma}_2^T \xi)^2 \right\} + C_{11} \lambda_0 \| \tilde{\gamma}_2 - \tilde{\gamma}_2 \|_1^{1/2} \right] \left[ C_1 \tilde{E} \left\{ (\hat{\alpha}_1^T \xi - \bar{\alpha}_1^T \xi)^2 \right\} + C_{11} \lambda_0 \| \hat{\alpha}_1 - \bar{\alpha}_1 \|_1^{1/2}, \right.$$ 

where $C_{11} = (1 + C_1)B_1$. Similarly, in the event $\Omega_0 \cap \Omega_2$ by Lemma S4,

$$|\Delta_1| = \left| \tilde{E} \left\{ (\tilde{\gamma}_2 - \tilde{\gamma}_2)^T \xi \frac{\partial^2 \tau}{\partial \eta \partial \theta} (U; \tilde{\theta}, \hat{\alpha}_1, \tilde{\gamma}_2) (\tilde{\theta}_1 - \theta^*) \right\} \right|$$

$$\leq \tilde{E}^{1/2} \left\{ T_{\eta, \theta}^{(1)} (U; \theta^*, \hat{\alpha}_1, \tilde{\gamma}_2) (\tilde{\gamma}_2^T \xi - \tilde{\gamma}_2^T \xi)^2 \right\} \tilde{E}^{1/2} \left\{ T_{\eta, \theta}^{(1)} (U; \theta^*, \hat{\alpha}_1, \tilde{\gamma}_2) (\tilde{\theta}_1 - \theta^*)^2 \right\}$$

$$\leq \left[ C_1 \tilde{E} \left\{ (\tilde{\gamma}_2^T \xi - \tilde{\gamma}_2^T \xi)^2 \right\} + C_{11} \lambda_0 \| \tilde{\gamma}_2 - \tilde{\gamma}_2 \|_1^{1/2} \right] \left[ (C_1 + B_{15} \lambda_0)(\tilde{\theta}_1 - \theta^*)^2 \right]^{1/2},$$

where $\tilde{\theta}$ lies between $\hat{\theta}_1$ and $\theta^*$. Hence in the event $\Omega_0 \cap \Omega_2$,

$$|\Delta_1| + |\Delta_2| \leq 2 \left\{ (C_1 + C_{11} M_0 \lambda_0) M_0^2 \right\} \left( C_{11} \lambda_0 \| \tilde{\gamma}_2 - \tilde{\gamma}_2 \|_1 \right)$$

$$= (M_{01} \lambda_0^2)^{1/2} \tilde{E}^{1/2} \left\{ (\tilde{\gamma}_2^T \xi - \tilde{\gamma}_2^T \xi)^2 \right\} + M_{02} \lambda_0 \| \tilde{\gamma}_2 - \tilde{\gamma}_2 \|_1,$$

where $M_{01} = 4C_1(C_1 + C_{11} M_0 \lambda_0) M_0$ and $M_{02} = \{4C_{11}(C_1 + C_{11} M_0 \lambda_0) M_0 \lambda_0 \}^{1/2}$. Furthermore, in the event $\Omega_2$ by Lemma S4,

$$\tilde{E} \left\{ (\tilde{\gamma}_2^T \xi - \tilde{\gamma}_2^T \xi)^2 \right\}$$

$$\leq c_2^{-1} \tilde{E} \left\{ \frac{\partial^2 \tau}{\partial \eta \partial \theta} (U; \theta^*, \hat{\alpha}_1, \tilde{\gamma}_2)(\tilde{\gamma}_2^T \xi - \tilde{\gamma}_2^T \xi)^2 \right\} + (1 + c_2^{-1}) B_1 \lambda_0 \| \tilde{\gamma}_2 - \tilde{\gamma}_2 \|_1^2.$$

Combining the preceding inequalities shows that in event $\Omega_0 \cap \Omega_2$,

$$|\Delta_1| + |\Delta_2| \leq (M_{03} \lambda_0^2)^{1/2} \tilde{E}^{1/2} \left\{ \frac{\partial^2 \tau}{\partial \eta \partial \theta} (U; \theta^*, \hat{\alpha}_1, \tilde{\gamma}_2)(\tilde{\gamma}_2^T \xi - \tilde{\gamma}_2^T \xi)^2 \right\} + M_{04} \lambda_0 \| \tilde{\gamma}_2 - \tilde{\gamma}_2 \|_1,$$

where $M_{03} = c_2^{-1} M_{01}$ and $M_{04} = M_{02} + (1 + c_2^{-1}) B_1 C_{12} M_0 \lambda_0\lambda_0^{1/2} = \left\{ C_{11}^{1/2} + (1 + c_2^{-1})^{1/2} B_1^{1/2} C_1 \right\}^{1/2} \times \{4(C_1 + C_{11} M_0 \lambda_0) M_0 \lambda_0 \}^{1/2}$. Using $M_0 \lambda_0 \leq \varrho_0$ by Assumption 3(iv) yields the desired result.

The third lemma derives an implication of the basic inequality (S1) using the triangle inequality for the $L_1$ norm, while incorporating the bound from Lemma S6.

**Lemma S7.** Denote $b = \tilde{\gamma}_2 - \tilde{\gamma}_2$. In the event $\Omega_0 \cap \Omega_1 \cap \Omega_2$, (S1) implies that

$$D_1^\dagger(\tilde{\gamma}_2, \tilde{\gamma}_2; \hat{\theta}_1, \hat{\alpha}_1) + A_{11} \lambda_0 \| b \|_1$$

$$\leq 2 A_1 \lambda_0 \sum_{j \in S_{\tilde{\gamma}_2}} \| b_j \| + (C_{12} M_0 \lambda_0^2)^{1/2} \{ Q_2(\tilde{\gamma}_2, \tilde{\gamma}_2; \theta^*, \hat{\alpha}_1) \}^{1/2},$$

where $A_{11} = A_1 - B_0 - C_{13}$, with $B_0$ from Lemma S1.
Proof. In the event $\Omega_1$ from Lemma S1, we have

$$b^T \tilde{E} \left\{ \xi \frac{\partial \tau}{\partial \eta_g}(U; \theta^*, \bar{\alpha}_1, \gamma \; \bar{\alpha}_2) \right\} \leq B_0 \lambda_0 \|b\|_1.$$ 

From (S1), the preceding bound, and Lemma S6, we have in the event $\Omega_0 \cap \Omega_1 \cap \Omega_2$,

$$D_2^j(\gamma \; \bar{\gamma}_2; \hat{\theta}_1, \hat{\alpha}_1) + A_1 \lambda_0 \| \bar{\gamma}_2 \|_1$$
$$\leq B_0 \lambda_0 \|b\|_1 + A_1 \lambda_0 \| \bar{\gamma}_2 \|_1 + (C_{12} M_0 \lambda_0^2)^{1/2} \{Q_2(\gamma \; \bar{\gamma}_2; \theta^*, \bar{\alpha}_1)\}^{1/2} + C_{13} \lambda_0 \|b\|_1.$$

Using the identity $|(\gamma \; \bar{\gamma}_2)_j| = |(\bar{\gamma}_2 - \bar{\gamma}_2)_j|$ for $j \notin S_{\bar{\gamma}_2}$ and the triangle inequality $|(\gamma \; \bar{\gamma}_2)_j| \geq |(\bar{\gamma}_2)_j| - |(\gamma \; \bar{\gamma}_2)_j|$ for $j \in S_{\bar{\gamma}_2}$ and rearranging the result yields (S2).

The following lemma provides a desired bound relating the Bregman divergence $D_2^j(\gamma \; \bar{\gamma}_2; \hat{\theta}_1, \hat{\alpha}_1)$ with the quadratic function $(\gamma \; \bar{\gamma}_2)^T \bar{\Sigma}_\gamma (\gamma \; \bar{\gamma}_2)$. 

Lemma S8. Suppose that Assumptions 2(i) and 3(iii)-(iv) hold. In the event $\Omega_0$, we have for any $\gamma \in \mathbb{R}^p$,

$$D_2^j(\gamma \; \bar{\gamma}_2; \hat{\theta}_1, \hat{\alpha}_1) \geq e^{-\frac{\Delta}{C_0 C_2 \|\bar{\gamma} - \bar{\gamma}_2\|_1}} (b^T \bar{\Sigma}_\gamma b),$$

where $b = \gamma - \bar{\gamma}_2$ and $\Delta = C_2(\|\hat{\theta}_1 - \theta^*\| + C_0 \|\hat{\alpha}_1 - \bar{\alpha}_1\|_1)$. Throughout, set $(1 - e^{-c})/c = 1$ for $c = 0$.

Proof. By direct calculation, we have

$$D_2^j(\gamma \; \bar{\gamma}_2; \hat{\theta}_1, \hat{\alpha}_1) = (\gamma \; \bar{\gamma}_2)^T \tilde{E} \left\{ \xi \left\{ \frac{\partial \tau}{\partial \eta_g}(U; \hat{\theta}_1, \hat{\alpha}_1, \gamma) - \frac{\partial \tau}{\partial \eta_g}(U; \hat{\theta}_1, \hat{\alpha}_1, \gamma) \right\} \right\}$$
$$= \tilde{E} \left\{ \left\{ \int_0^1 \frac{\partial^2 \tau}{\partial \eta_g \partial \eta_f} (U; \hat{\theta}_1, \hat{\alpha}_1, \gamma_u) \, d\gamma_u \right\} \left( \gamma^T \xi - \bar{\gamma}_2^T \xi \right)^2 \right\},$$

where $\gamma_u = \bar{\gamma}_2 + u(\gamma - \bar{\gamma}_2)$. In the event $\Omega_0$, $(\hat{\theta}_1, \hat{\alpha}_1) \in \mathcal{N}_1$ by Assumption 3(iv). Then by Assumption 2(i) and 3(iii), we have

$$D_2^j(\gamma \; \bar{\gamma}_2; \hat{\theta}_1, \hat{\alpha}_1)$$
$$\geq \tilde{E} \left\{ \int_0^1 e^{-C_2(\|\hat{\theta}_1 - \theta^*\| + \|\hat{\alpha}_1 - \bar{\alpha}_1\|_1 + u \|\gamma - \bar{\gamma}_2\|_1)} \, d\gamma_u \right\} \frac{\partial^2 \tau}{\partial \eta_g \partial \eta_f} (U; \theta^*, \bar{\alpha}_1, \gamma) (\gamma^T \xi - \bar{\gamma}_2^T \xi)^2$$
$$\geq \left\{ \int_0^1 e^{-C_2(\|\hat{\theta}_1 - \theta^*\| + \|\hat{\alpha}_1 - \bar{\alpha}_1\|_1 + u \|\gamma - \bar{\gamma}_2\|_1)} \, d\gamma_u \right\} \tilde{E} \left\{ \frac{\partial^2 \tau}{\partial \eta_g \partial \eta_f} (U; \theta^*, \bar{\alpha}_1, \gamma) (\gamma^T \xi - \bar{\gamma}_2^T \xi)^2 \right\}. $$
The desired result follows because $\int_0^1 e^{-cu} \, du = (1 - e^{-c})/c$ for $c \geq 0$. \qed

The following lemma shows that Assumption 2(iii), a theoretical compatibility condition for $\Sigma_\gamma$, implies an empirical compatibility condition for $\hat{\Sigma}_\gamma$.

**Lemma S9.** Suppose that Assumption 3(iv) holds. In the event $\Omega_2$, Assumption 2 (iii) implies that for any vector $b \in \mathbb{R}^p$ such that $\sum_{j \in S_{t_2}} |b_j| \leq \mu_1 \sum_{j \in S_{t_2}} |b_j|$, we have

$$
\nu_{11}^2 \left( \sum_{j \in S_{t_2}} |b_j| \right)^2 \leq |S_{t_2}| \left( \hat{b}^T \hat{\Sigma}_\gamma b \right),
$$

where $\nu_{11} = \nu_1 \left\{ 1 - \nu_1^{-2} (1 + \mu_1)^2 \varrho_1 B_{15} \right\}^{1/2} = \nu_1 (1 - \varrho_2)^{1/2}$.

**Proof.** In the event $\Omega_2$, we have $|b^T (\hat{\Sigma}_\gamma - \Sigma_\gamma) b| \leq B_{15} \lambda_0 \|b\|^2_1$ from Lemma S2. Then Assumption 2(iii) implies that for any $b = (b_1, \ldots, b_p)^T$ satisfying $\sum_{j \in S_{t_2}} |b_j| \leq \mu_1 \sum_{j \in S_{t_2}} |b_j|$, $\nu_2^2 \|b_{S_{t_2}}\|^2_1 \leq |S_{t_2}| (b^T \Sigma_\gamma b) \leq |S_{t_2}| \left( \hat{b}^T \hat{\Sigma}_\gamma b + B_{15} \lambda_0 \|b\|^2_1 \right) \leq |S_{t_2}| \left( b^T \Sigma_\gamma b \right) + B_{15} |S_{t_2}| \lambda_0 (1 + \mu_1)^2 \|b_{S_{t_2}}\|^2_1,$

where $\|b_{S_{t_2}}\|_1 = \sum_{j \in S_{t_2}} |b_j|$. The last inequality uses $\|b\|_1 \leq (1 + \mu_1) \|b_{S_{t_2}}\|_1$. The desired result follows because $|S_{t_2}| \lambda_0 \leq \varrho_1$ and $\varrho_2 = \nu_1^2 B_{15} (1 + \mu_1)^2 \varrho_1 < 1$ by Assumption 3(iv). \qed

The final lemma completes the proof of Theorem 1, because $P(\Omega_0 \cap \Omega_1 \cap \Omega_2) \geq 1 - (c_0 + 10) \epsilon$ by Assumption 2(iv) and Lemmas S1 and S4.

**Lemma S10.** Suppose that Assumptions 2–3 hold and $\lambda_0 \leq 1$. Then for $A_1 > (B_0 + C_{13})(\mu_1 + 1)/(\mu_1 - 1)$, inequality (39) holds in the event $\Omega_0 \cap \Omega_1 \cap \Omega_2$:

$$
D_1^\dagger (\hat{\gamma}_2, \hat{\gamma}_2; \hat{\theta}_1, \hat{\alpha}_1) + A_{11} \lambda_0 \|\gamma_2 - \bar{\gamma}_2\|_1
\leq \left\{ e^{\epsilon_5} (1 - \varrho_3)^{-1} \mu_2 \nu_{11}^{-2} (|S_{t_2}| \lambda_0^2) \right\} \vee \left\{ e^{\epsilon_5} (1 - \varrho_4)^{-1} \mu_{11}^{-2} C_{12} (M_0 \lambda_0^2) \right\}.
$$

**Proof.** Denote $b = \hat{\gamma}_2 - \bar{\gamma}_2$, $D_2^\dagger = D_1^\dagger (\hat{\gamma}_2, \hat{\gamma}_2; \hat{\theta}_1, \hat{\alpha}_1)$, $D_2^\dagger = D_1^\dagger (\hat{\gamma}_2, \bar{\gamma}_2; \hat{\theta}_1, \hat{\alpha}_1) + A_{11} \lambda_0 \|b\|_1$, $Q_2 = Q_2 (\hat{\gamma}_2, \bar{\gamma}_2; \hat{\theta}_1, \hat{\alpha}_1) = b^T \Sigma_\gamma b$. In the event $\Omega_0 \cap \Omega_1 \cap \Omega_2$, inequality (S2) from Lemma S7 leads to two possible cases:

$$
\mu_{11} D_2^\dagger \leq (C_{12} M_0 \lambda_0^2)^{1/2} Q_2^{1/2}, \tag{S3}
$$
or \((1 - \mu_{11})D_2^\dagger \leq 2A_1\lambda_0 \sum_{j \in S_{\tau_2}} |b_j|\), that is,

\[
D_2^\dagger \leq (\mu_1 + 1)A_{11}\lambda_0 \sum_{j \in S_{\tau_2}} |b_j| = \mu_{12}\lambda_0 \sum_{j \in S_{\tau_2}} |b_j|,
\]

(S4)

where \(\mu_{11} = 1 - 2A_1/\{(\mu_1 + 1)A_{11}\} \in (0, 1)\) because \(A_1 > (B_0 + C_{13})(\mu_1 + 1)/(\mu_1 - 1)\), and

\(\mu_{12} = (\mu_1 + 1)A_{11}\). We deal with the two cases separately as follows.

In the case where (S4) holds, \(\sum_{j \notin S_{\tau_2}} |b_j| \leq \mu_1 \sum_{j \in S_{\tau_2}} |b_j|\). Then by Lemma S9,

\[
\sum_{j \in S_{\tau_2}} |b_j| \leq \nu_{11}^{-1} |S_{\tau_2}|^{1/2} \left(\hat{b}^T\tilde{\Sigma}_\gamma\hat{b}\right)^{1/2}.
\]

(S5)

By Lemma S8, we have

\[
D_2^\dagger \geq e^{-\Delta} \frac{1 - e^{-C_0C_2||b||_1}}{C_0C_2||b||_1} \left(\hat{b}^T\tilde{\Sigma}_\gamma\hat{b}\right),
\]

(S6)

where \(\Delta = C_2(\hat{\gamma}_1 - \theta^*) + C_0||\hat{\alpha}_1 - \tilde{\alpha}_1||_1\). Combining (S3), (S5), and (S6) yields

\[
D_2^\dagger \leq \nu_{11}^{-2} |S_{\tau_2}| \lambda_0^2 e^{-\Delta} \frac{C_0C_2||b||_1}{1 - e^{-C_0C_2||b||_1}}.
\]

(S7)

But \(A_{11}\lambda_0||b||_1 \leq D_2^\dagger\). Then (S7) along with \(|\Delta| \leq C_2(1 + C_0)\gamma_0\) implies that \(1 - e^{-C_0C_2||b||_1} \leq C_0C_2A_{11}^{-1}\mu_{12}^2\nu_{11}^{-2}|S_{\tau_2}|\lambda_0^2 e^{C_2(1 + C_0)\gamma_0} \leq \gamma_3 < (1)\) by Assumption 3(iv). As a result, \(C_0C_2||b||_1 \leq -\log(1 - \gamma_3)\) and hence

\[
\frac{1 - e^{-C_0C_2||b||_1}}{C_0C_2||b||_1} = \int_0^1 e^{-C_0C_2||b||_1} u \, du \geq e^{-C_0C_2||b||_1} \geq 1 - \gamma_3.
\]

(S8)

From this bound, (S7) leads to \(D_2^\dagger \leq e^{C_2(1 + C_0)\gamma_0}(1 - \gamma_3)^{-1}\mu_{12}^2\nu_{11}^{-2}|S_{\tau_2}|\lambda_0^2\).

In the first case where (S3) holds, simple manipulation using (S6) yields

\[
D_2^\dagger \leq \mu_{11}^{-2}(C_{12}M_0\lambda_0^2)e^{\Delta} \frac{C_0C_2||b||_1}{1 - e^{-C_0C_2||b||_1}}.
\]

(S9)

Similarly as above, using \(A_{11}\lambda_0||b||_1 \leq D_2^\dagger\) and (S9) along with \(|\Delta| \leq C_2(1 + C_0)\gamma_0\), we find \(1 - e^{-C_0C_2||b||_1} \leq C_0C_2A_{11}^{-1}\mu_{12}^2C_{12}M_0\lambda_0 e^{C_2(1 + C_0)\gamma_0} \leq \gamma_4 < (1)\) by Assumption 3(iv). As a result, \(C_0C_2||b||_1 \leq -\log(1 - \gamma_4)\) and hence

\[
\frac{1 - e^{-C_0C_2||b||_1}}{C_0C_2||b||_1} = \int_0^1 e^{-C_0C_2||b||_1} u \, du \geq e^{-C_0C_2||b||_1} \geq 1 - \gamma_4.
\]

(S10)

From this bound, (S9) leads to \(D_2^\dagger \leq e^{C_2(1 + C_0)\gamma_0}(1 - \gamma_4)^{-1}\mu_{11}^{-2}C_{12}M_0\lambda_0^2\). Therefore, (39) holds through (S3) and (S4) in the event \(\Omega_0 \cap \Omega_1 \cap \Omega_2\). \[\Box\]
Proof of Corollary 3. Return to the proof of Lemma S10, where (S3) or (S4) holds in the event $\Omega_0 \cap \Omega_1 \cap \Omega_2$. If (S4) holds, then we have, by (S6) and (S8), $b^\top \Sigma_{\gamma} b \leq e^{\epsilon_4}(1 - \varrho_3)^{-1}D_2^I$. If (S3) holds, then we have, by (S6) and (S10), $b^\top \Sigma_{\gamma} b \leq e^{\epsilon_5}(1 - \varrho_3)^{-1}D_2^I$. Hence

$$b^\top \Sigma_{\gamma} b \leq e^{\epsilon_4}(1 - \varrho_3 \lor \varrho_4)^{-1}D_2^I \leq e^{\epsilon_5}(1 - \varrho_3 \lor \varrho_4)^{-1}C_3(|S_{\gamma_2}| \lor M_0)\lambda_0^2.$$ Moreover, by (39), we have $\|b\|_1 \leq A_1^{-1}C_3(|S_{\gamma_2}| \lor M_0)\lambda_0$ and hence $\lambda_0\|b\|_1^2 \leq A_1^{-2}C_3^2(\varrho_0 \lor \varrho_1)(|S_{\gamma_2}| \lor M_0)\lambda_0^2$, because $(|S_{\gamma_2}| \lor M_0)\lambda_0 \leq \varrho_0 \lor \varrho_1$ by Assumption 3(iv). Then (40) follows from the third inequality in Lemma S4.  

Proof of Theorem 2. The proof follows from similar steps as in that of Theorem 1. The probability decreases from $1 - (c_0 + 10)\epsilon$ to $1 - (c_0 + 18)\epsilon$, due to additional restriction to the events similar to $\Omega_1$, $\Omega_2$, $\Omega_22$, and $\Omega_23$, while $\Omega_24$ is unchanged.  

I.3 Proof of Theorem 3

We split the proof into three lemmas. The first one shows the consistency of $\hat{\theta}_2$ for $\theta^*$. 

Lemma S11. In the setting of Theorem 2, suppose that Assumption 6 holds and $M_2r_0 = o(1)$. Then $\hat{\theta}_2$ is consistent for $\theta^*$, i.e., $|\hat{\theta}_2 - \theta^*| = o_p(1)$.

Proof. By Theorem 2 and $M_2r_0 = o(1)$, we have $\|\hat{\alpha}_2 - \alpha_2\|_1 = o_p(1)$ and $\|\hat{\gamma}_2 - \gamma_2\|_1 = o_p(1)$. Hence for any small $\epsilon > 0, (\hat{\alpha}_2, \hat{\gamma}_2) \in \mathcal{N}_2$ with probability at least $1 - \epsilon$ for all sufficiently large $n$. In the following, we restrict analysis within this event.

To show $|\hat{\theta}_2 - \theta^*| = o_p(1)$, by standard consistency arguments (e.g., Van der Vaart 2000) using Assumption 6(i)–(ii), it suffices to show that $\tilde{E}\{\tau(U; \hat{\theta}_2, \hat{\alpha}_2, \hat{\gamma}_2)\} = o_p(1)$. Because $\tilde{E}\{\tau(U; \hat{\theta}_2, \hat{\alpha}_2, \hat{\gamma}_2)\} = 0$ by definition of $\hat{\theta}_2$, consider the decomposition

$$\tilde{E}\{\tau(U; \hat{\theta}_2, \hat{\alpha}_2, \hat{\gamma}_2)\} - \tilde{E}\{\tau(U; \hat{\theta}_2, \alpha_2, \gamma_2)\} = \Delta_1 + \Delta_2,$$

where

$$\Delta_1 = \tilde{E}\{\tau(U; \hat{\theta}_2, \hat{\alpha}_2, \hat{\gamma}_2)\} - \tilde{E}\{\tau(U; \hat{\theta}_2, \alpha_2, \hat{\gamma}_2)\},$$

$$\Delta_2 = \tilde{E}\{\tau(U; \hat{\theta}_2, \hat{\alpha}_2, \hat{\gamma}_2)\} - \tilde{E}\{\tau(U; \hat{\theta}_2, \hat{\alpha}_2, \hat{\gamma}_2)\}.$$

By the mean value theorem, the Cauchy–Schwartz inequality and Assumption 6 (iii),

\[ |\Delta_1| = \left| (\hat{\alpha}_2 - \tilde{\alpha}_2)^T \tilde{E} \left\{ \xi \frac{\partial \tau}{\partial \alpha}(U; \hat{\theta}_2, \tilde{\alpha}, \tilde{\gamma}_2) \right\} \right| \]

\[ \leq \tilde{E}^{1/2} \left\{ (\hat{\alpha}_2^T \xi - \tilde{\alpha}_2^T \xi)^2 \right\} \tilde{E}^{1/2} \left\{ T_{yy}^{(2)}(U; \tilde{\alpha}_2, \tilde{\gamma}_2) \right\} = O_p(M_2^{1/2}r_0), \]

\[ |\Delta_2| = \left| (\hat{\gamma}_2 - \tilde{\gamma}_2)^T \tilde{E} \left\{ \xi \frac{\partial \tau}{\partial \gamma}(U; \hat{\theta}_2, \tilde{\alpha}_2, \tilde{\gamma}) \right\} \right| \]

\[ \leq \tilde{E}^{1/2} \left\{ (\hat{\gamma}_2^T \xi - \tilde{\gamma}_2^T \xi)^2 \right\} \tilde{E}^{1/2} \left\{ T_{yy}^{(2)}(U; \tilde{\alpha}_2, \tilde{\gamma}_2) \right\} = O_p(M_2^{1/2}r_0), \]

where \( \tilde{\alpha} \) lies between \( \hat{\alpha}_2 \) and \( \tilde{\alpha}_2 \), and \( \tilde{\gamma} \) lies between \( \hat{\gamma}_2 \) and \( \tilde{\gamma}_2 \). Hence \( |\Delta_1| + |\Delta_2| = o_p(1) \) because \( M_2^{1/2}r_0 \leq M_2r_0 = o(1) \) with \( M_2 \geq M_0 \geq 1 \).

The following lemma establishes the asymptotic expansion (43) for \( \hat{\theta}_2 \).

**Lemma S12.** In the setting of Theorem 2, suppose that Assumption 6 and 7(ii)–(iv) hold and \( M_2r_0 = o(1) \). Then \( \hat{\theta}_2 \) admits the asymptotic expansion (43),

\[ \hat{\theta}_2 - \theta^* = -H^{-1} \tilde{E} \left\{ \tau(U; \theta^*, \tilde{\alpha}_2, \tilde{\gamma}_2) \right\} + O_p(M_2r_0^2), \]

where \( H = E \left\{ \frac{\partial \tau}{\partial \theta}(U; \theta^*, \tilde{\alpha}_2, \tilde{\gamma}_2) \right\} \).

**Proof.** By Theorem 2, Lemma S11, and \( M_2r_0 = o(1) \), we have \( \|\hat{\alpha}_2 - \tilde{\alpha}_2\| = o_p(1) \), \( \|\hat{\gamma}_2 - \tilde{\gamma}_2\| = o_p(1) \), and \( |\hat{\theta}_2 - \theta^*| = o_p(1) \). Hence for any small \( \epsilon > 0 \), \( (\hat{\theta}_2, \hat{\alpha}_2, \hat{\gamma}_2) \in \mathcal{N}_3 \) with probability at least \( 1 - \epsilon \) for all sufficiently large \( n \). In the following, we restrict analysis within this event. Consider the decomposition

\[ \tilde{E} \left\{ \tau(U; \hat{\theta}_2, \hat{\alpha}_2, \hat{\gamma}_2) \right\} - \tilde{E} \left\{ \tau(U; \theta^*, \tilde{\alpha}_2, \tilde{\gamma}_2) \right\} = \Delta_3 + \Delta_4, \]

(S11)

where

\[ \Delta_3 = \tilde{E} \left\{ \tau(U; \hat{\theta}_2, \hat{\alpha}_2, \hat{\gamma}_2) \right\} - \tilde{E} \left\{ \tau(U; \theta^*, \hat{\alpha}_2, \hat{\gamma}_2) \right\}, \]

\[ \Delta_4 = \tilde{E} \left\{ \tau(U; \theta^*, \hat{\alpha}_2, \hat{\gamma}_2) \right\} - \tilde{E} \left\{ \tau(U; \theta^*, \tilde{\alpha}_2, \tilde{\gamma}_2) \right\}. \]

We deal with the two terms \( \Delta_3 \) and \( \Delta_4 \) respectively.
By a Taylor expansion, $\Delta_4 = \Delta_{41} + \Delta_{42}$ with

$$\Delta_{41} = (\hat{\alpha}_2 - \bar{\alpha}_2)^T \hat{E} \left\{ \xi \frac{\partial \tau}{\partial \eta_9} (U; \theta^*, \bar{\alpha}_2, \bar{\gamma}_2) \right\} + (\hat{\gamma}_2 - \bar{\gamma}_2)^T \hat{E} \left\{ \xi \frac{\partial \tau}{\partial \eta_f} (U; \theta^*, \bar{\alpha}_2, \bar{\gamma}_2) \right\}$$

$$\Delta_{42} = \frac{1}{2} (\hat{\alpha}_2 - \bar{\alpha}_2)^T \hat{E} \left\{ \xi \frac{\partial^2 \tau}{\partial \eta_9^2} (U; \theta^*, \bar{\alpha}, \bar{\gamma}) \xi^T \right\} (\hat{\alpha}_2 - \bar{\alpha}_2)$$

$$+ \frac{1}{2} (\hat{\gamma}_2 - \bar{\gamma}_2)^T \hat{E} \left\{ \xi \frac{\partial^2 \tau}{\partial \eta_f^2} (U; \theta^*, \bar{\alpha}, \bar{\gamma}) \xi^T \right\} (\hat{\gamma}_2 - \bar{\gamma}_2)$$

$$+ (\hat{\alpha}_2 - \bar{\alpha}_2)^T \hat{E} \left\{ \xi \frac{\partial^2 \tau}{\partial \eta_9 \partial \eta_f} (U; \theta^*, \bar{\alpha}, \bar{\gamma}) \xi^T \right\} (\hat{\gamma}_2 - \bar{\gamma}_2)$$

where $(\bar{\alpha}, \bar{\gamma})$ lie between $(\hat{\alpha}_2, \bar{\gamma}_2)$ and $(\bar{\alpha}_2, \bar{\gamma}_2)$. As model (11) or (12) is correctly specified, Proposition 2 implies that calibration equations (22)–(23) are satisfied by $(\alpha, \gamma) = (\bar{\alpha}_2, \bar{\gamma}_2)$, that is, the variables $\xi_j \frac{\partial \tau}{\partial \eta_9} (U; \theta^*, \bar{\alpha}_2, \bar{\gamma}_2)$ and $\xi_j \frac{\partial \tau}{\partial \eta_f} (U; \theta^*, \bar{\alpha}_2, \bar{\gamma}_2)$ have mean 0 for $j = 1, \ldots, p$.

By Assumption 7(iii) and similar reasoning as in Lemma S1, we have

$$\sup_j |\hat{E}\{\xi_j \frac{\partial \tau}{\partial \eta_9} (U; \theta^*, \bar{\alpha}_2, \bar{\gamma}_2)\}| = O_p(r_0), \quad \sup_j |\hat{E}\{\xi_j \frac{\partial \tau}{\partial \eta_f} (U; \theta^*, \bar{\alpha}_2, \bar{\gamma}_2)\}| = O_p(r_0).$$

By Theorem 2, $\|\hat{\alpha}_2 - \bar{\alpha}_2\|_1 = O_p(M_2 r_0)$ and $\|\hat{\gamma}_2 - \bar{\gamma}_2\|_1 = O_p(M_2 r_0)$. Hence

$$|(\hat{\alpha}_2 - \bar{\alpha}_2)^T \hat{E} \left\{ \xi \frac{\partial \tau}{\partial \eta_9} (U; \theta^*, \bar{\alpha}_2, \bar{\gamma}_2) \right\}| = O_p(r_0) \|\hat{\alpha}_2 - \bar{\alpha}_2\|_1 = O_p(M_2 r_0^2),$$

$$|(\hat{\gamma}_2 - \bar{\gamma}_2)^T \hat{E} \left\{ \xi \frac{\partial \tau}{\partial \eta_f} (U; \theta^*, \bar{\alpha}_2, \bar{\gamma}_2) \right\}| = O_p(r_0) \|\hat{\gamma}_2 - \bar{\gamma}_2\|_1 = O_p(M_2 r_0^2),$$

and $|\Delta_{41}| = O_p(M_2 r_0^2)$. Moreover, by Assumption 7(iv) and similar reasoning as in Lemma S4, we have

$$|(\hat{\alpha}_2 - \bar{\alpha}_2)^T \hat{E} \left\{ \xi \frac{\partial^2 \tau}{\partial \eta_9^2} (U; \theta^*, \bar{\alpha}_2, \bar{\gamma}_2) \xi^T \right\} (\hat{\alpha}_2 - \bar{\alpha}_2)|$$

$$\leq (\hat{\alpha}_2 - \bar{\alpha}_2)^T \hat{E} \left\{ \xi T_{\eta_9}^{(2)} (U; \theta^*, \bar{\alpha}_2, \bar{\gamma}_2) \xi^T \right\} (\hat{\alpha}_2 - \bar{\alpha}_2)$$

$$\leq C_4 \hat{E} \{(\hat{\alpha}_2^T \xi - \bar{\alpha}_2^T \xi)^2\} + (1 + C_4)O_p(r_0) \|\hat{\alpha}_2 - \bar{\alpha}_2\|_1^2 = O_p(M_2 r_0^2),$$

where $\hat{E}\{(\hat{\alpha}_2^T \xi - \bar{\alpha}_2^T \xi)^2\} = O_p(M_2 r_0^2)$ and $O_p(r_0)O_p(M_2^2 r_0) = o_p(M_2^2 r_0^2)$ because $M_2 r_0 = o(1)$.

Similarly, we have

$$|(\hat{\gamma}_2 - \bar{\gamma}_2)^T \hat{E} \left\{ \xi \frac{\partial^2 \tau}{\partial \eta_f^2} (U; \theta^*, \bar{\alpha}, \bar{\gamma}) \xi^T \right\} (\hat{\gamma}_2 - \bar{\gamma}_2)| = O_p(M_2 r_0^2).$$
and by the Cauchy–Schwartz inequality,
\[
\left| (\hat{\alpha}_2 - \tilde{\alpha}_2)^T \tilde{E} \left\{ \xi \frac{\partial^2 \tau}{\partial \eta \partial \eta_i}(U; \theta^*, \bar{\alpha}, \bar{\gamma}) \xi^T \right\} (\hat{\gamma}_2 - \tilde{\gamma}_2) \right| \\
\leq \left[ (\hat{\alpha}_2 - \tilde{\alpha}_2)^T \tilde{E} \left\{ \xi T_{\eta \eta_i}^{(2)}(U; \theta^*, \bar{\alpha}_2, \bar{\gamma}_2) \xi^T \right\} (\hat{\alpha}_2 - \tilde{\alpha}_2) \right]^{1/2} \\
\times \left[ (\hat{\gamma}_2 - \tilde{\gamma}_2)^T \tilde{E} \left\{ \xi T_{\eta \eta_i}^{(2)}(U; \theta^*, \bar{\gamma}_2, \bar{\gamma}_2) \xi^T \right\} (\hat{\gamma}_2 - \tilde{\gamma}_2) \right]^{1/2} = O_p(M_2 r_0^2).
\]
Hence $|\Delta_4| = O_p(M_2 r_0^2)$ and $|\Delta_4| = O_p(M_2 r_0^2)$.

Next, by the mean value theorem, we have
\[
\Delta_3 = (\hat{\theta}_2 - \theta^*) \tilde{E} \left\{ \frac{\partial \tau}{\partial \theta}(U; \tilde{\theta}, \bar{\alpha}_2, \bar{\gamma}_2) \right\},
\]
where $\bar{\theta}$ lies between $\hat{\theta}_2$ and $\theta^*$. Consider the decomposition
\[
\tilde{E} \left\{ \frac{\partial \tau}{\partial \theta}(U; \tilde{\theta}, \bar{\alpha}_2, \bar{\gamma}_2) \right\} = E \left\{ \frac{\partial \tau}{\partial \theta}(U; \theta^*, \bar{\alpha}_2, \bar{\gamma}_2) \right\} + \Delta_{31} + \Delta_{32},
\]
where
\[
\Delta_{31} = E \left\{ \frac{\partial \tau}{\partial \theta}(U; \tilde{\theta}, \bar{\alpha}_2, \bar{\gamma}_2) \right\} - E \left\{ \frac{\partial \tau}{\partial \theta}(U; \tilde{\theta}, \bar{\alpha}_2, \bar{\gamma}_2) \right\},
\]
\[
\Delta_{32} = E \left\{ \frac{\partial \tau}{\partial \theta}(U; \theta^*, \bar{\alpha}_2, \bar{\gamma}_2) \right\} - E \left\{ \frac{\partial \tau}{\partial \theta}(U; \theta^*, \bar{\alpha}_2, \bar{\gamma}_2) \right\}.
\]
By Assumption 7(ii) and the uniform law of large numbers (Ferguson 1996, Theorem 16),
\[
|\Delta_{31}| \leq \sup_{(\theta, \alpha, \gamma) \in \mathcal{N}_3} |(\tilde{E} - E) \{ \frac{\partial \tau}{\partial \theta}(U; \theta, \alpha, \gamma) \}| = o_p(1).
\]
Moreover, by $|\tilde{\theta} - \theta^*| \leq |\hat{\theta}_2 - \theta^*| = o_p(1)$ and the continuous mapping theorem, $|\Delta_{32}| = o_p(1)$. Hence $E \{ \frac{\partial \tau}{\partial \theta}(U; \tilde{\theta}, \bar{\alpha}_2, \bar{\gamma}_2) \} = H + o_p(1)$ and $\Delta_3 = (\hat{\theta}_2 - \theta^*) \{ H + o_p(1) \}$.

Finally, from the preceding analysis, (S11) yields
\[
-\tilde{E} \{ \tau(U; \theta^*, \bar{\alpha}_2, \bar{\gamma}_2) \} = (\hat{\theta}_2 - \theta^*) \{ H + o_p(1) \} + O_p(M_2 r_0^2).
\]
The desired result then follows because $H \neq 0$.

The following lemma establishes the consistency of $\hat{V}$ for $V$.

**Lemma S13.** In the setting of Theorem 2, suppose that Assumption 6 and 7 hold and $M_2 r_0 = o(1)$. Then a consistent estimator of $V = \text{var}\{ \tau(U; \theta^*, \bar{\alpha}_2, \bar{\gamma}_2) \}/H^2$ is
\[
\hat{V} = \tilde{E} \{ \tau^2(U; \hat{\theta}_2, \bar{\alpha}_2, \bar{\gamma}_2) \}/\hat{H}^2,
\]
where $\hat{H} = \tilde{E} \{ \frac{\partial \tau}{\partial \theta}(U; \hat{\theta}_2, \bar{\alpha}_2, \bar{\gamma}_2) \}$. 

12
Proof. First, \( \hat{H} = H + o_p(1) \) can be shown similarly as \( \hat{E}\{ \theta_{\theta}(U; \hat{\theta}, \hat{\alpha}, \hat{\gamma}) \} = H + o_p(1) \) in the proof of Lemma S12. Next, we show that \( \hat{G} = G + o_p(1) \), where \( G = E\{ \tau^2(U; \theta^*, \hat{\alpha}, \hat{\gamma}) \} \) and \( \hat{G} = \hat{E}\{ \tau^2(U; \hat{\theta}, \hat{\alpha}, \hat{\gamma}) \} \). Similarly as (S12), consider the decomposition

\[
\hat{E}\{ \tau^2(U; \hat{\theta}, \hat{\alpha}, \hat{\gamma}) \} = E\{ \tau^2(U; \theta^*, \hat{\alpha}, \hat{\gamma}) \} + \Delta_{51} + \Delta_{52},
\]

where

\[
\Delta_{51} = \hat{E}\{ \tau^2(U; \hat{\theta}, \hat{\alpha}, \hat{\gamma}) \} - E\{ \tau^2(U; \hat{\theta}, \hat{\alpha}, \hat{\gamma}) \},
\]

\[
\Delta_{52} = E\{ \tau^2(U; \hat{\theta}, \hat{\alpha}, \hat{\gamma}) \} - E\{ \tau^2(U; \theta^*, \hat{\alpha}, \hat{\gamma}) \}.
\]

By Assumption 7(i) and the uniform law of large numbers (Ferguson 1996, Theorem 16), \( |\Delta_{51}| \leq \sup_{(\theta, \alpha, \gamma) \in N_3} |(\hat{E} - E)\{ \tau^2(U; \theta, \alpha, \gamma) \} = o_p(1) \). Moreover, by \( |\hat{\theta} - \theta^*| = o_p(1) \) and the continuous mapping theorem, \( |\Delta_{52}| = o_p(1) \). Hence \( \hat{G} = G + o_p(1) \). \( \square \)

I.4 Proof of Corollary 4

Assume that \( \psi_f \equiv 1 \) in model (45) and \( \hat{\gamma}_2 = \hat{\gamma}_1 \). First, we show that option (i) or (ii) in the discussion preceding Corollary 4 yields \( (\hat{\theta}_1, \hat{\alpha}_2) = (\hat{\theta}_0, \hat{\alpha}_1) \) and hence \( \hat{\theta}_2 = \hat{\theta}(\hat{\alpha}_1, \hat{\gamma}_1) \), provided that the same Lasso tuning parameter is used in computing \( \hat{\alpha}_2 \) as in computing \( (\hat{\theta}_0, \hat{\alpha}_1) \). Suppose that \( (\hat{\theta}_0, \hat{\alpha}_1) \) are Lasso least square estimators as

\[
(\hat{\theta}_0, \hat{\alpha}_1) = \arg\min_{(\theta, \alpha)} \left\{ \hat{E}\{ (Y - \theta Z - \alpha^T \xi)^2 \} + \lambda |\theta| + \lambda \|\alpha\|_1 \right\}.
\]

(S13)

For option (ii), if \( (\hat{\theta}_1, \hat{\alpha}_2) \) are redefined as Lasso least square estimators with the same tuning parameter \( \lambda \), then \( (\hat{\theta}_1, \hat{\alpha}_2) = (\hat{\theta}_0, \hat{\alpha}_1) \) by definition. For option (i), \( \hat{\theta}_1 \) is replaced by \( \hat{\theta}_0 \) in (47). If \( \hat{\alpha}_2 \) is redefined as follows, with the same tuning parameter \( \lambda \) as in (S13),

\[
\hat{\alpha}_2 = \arg\min_{\alpha} \left\{ \hat{E}\{ (Y - \hat{\theta}_0 Z - \alpha^T \xi)^2 \} + \lambda \|\alpha\|_1 \right\},
\]

(S14)

then \( \hat{\alpha}_2 = \hat{\alpha}_1 \), because for any \( \alpha \),

\[
\hat{E}\{ (Y - \hat{\theta}_0 Z - \alpha^T \xi)^2 \} + \lambda |\hat{\theta}_0| + \lambda \|\alpha\|_1 \geq \hat{E}\{ (Y - \hat{\theta}_0 Z - \hat{\alpha}_1^T \xi)^2 \} + \lambda |\hat{\theta}_0| + \lambda \|\hat{\alpha}_1\|_1
\]

\( \iff \)

\[
\hat{E}\{ (Y - \hat{\theta}_0 Z - \alpha^T \xi)^2 \} + \lambda \|\alpha\|_1 \geq \hat{E}\{ (Y - \hat{\theta}_0 Z - \hat{\alpha}_1^T \xi)^2 \} + \lambda \|\hat{\alpha}_1\|_1,
\]

13
and hence \( \hat{\alpha}_1 \) is also a minimizer to the objective in (S14).

Now suppose that option (ii) is used, i.e., \( \hat{\theta}_1 \) is redefined as \( \hat{\theta}_0 \), in our two-step algorithm. Then \( \hat{\alpha}_2 = \hat{\alpha}_1 \) as shown above. Proposition 3 can be applied with \((\hat{\theta}_1, \hat{\alpha}_2, \hat{\gamma}_2)\) replaced by \((\hat{\theta}_0, \hat{\alpha}_1, \hat{\gamma}_1)\) and \( \hat{\theta}_{\text{RCAL}} = \hat{\theta}_2 \) by \( \hat{\theta}(\hat{\alpha}_1, \hat{\gamma}_1) \), because \( \hat{\theta}_0 \) can be shown to be pointwise doubly robust and hence Assumption 2(iv) is satisfied under the stated regularity conditions. In fact, the target value (i.e., probability limit) \( \hat{\theta}_1 \) for \( \hat{\theta}_0 \), by definition, satisfies
\[
E\{(Y - \hat{\theta}_0 Z - \hat{\alpha}_1^T \xi)(Z, \xi^T)\} = 0,
\]
which implies the population doubly robust estimating equation
\[
E\{(Y - \hat{\theta}_0 Z - \hat{\alpha}_1^T \xi)(Z - \hat{\gamma}_1^T \xi)\} = 0
\]
or equivalently
\[
\hat{\theta}_0 = \frac{E\{(Y - \hat{\alpha}_1^T \xi)(Z - \hat{\gamma}_1^T \xi)\}}{E\{Z(Z - \hat{\gamma}_1^T \xi)\}}.
\]
Hence \( \hat{\theta}_0 \) coincides with \( \theta^* \) if model (44) or model (45) with \( \psi_f \equiv 1 \) is correctly specified. This reasoning is a sample analogue of that in Example 5.
II Additional material for simulation studies

We provide implementation details and additional simulation results.

II.1 Partially linear modeling

We describe the data-generating configurations used for \((Z, X)\), related to Fisher’s discrimination analysis. For setting (C1), we first generate \(Z\) such that \(P(Z = 1) = q\). Next we generate \(X|Z = 1 \sim N(\mu_1, \Sigma)\) and \(X|Z = 0 \sim N(\mu_0, \Sigma)\). Then

\[
P(Z = 1|X) = \frac{1}{1 + \exp(-\beta_0 - \beta_1^T X)},
\]

where \(\beta_0 = -\frac{1}{2} \mu_1^T \Sigma^{-1} \mu_1 + \frac{1}{2} \mu_0^T \Sigma^{-1} \mu_0 + \log(q/(1-q))\) and \(\beta_1 = \Sigma^{-1}(\mu_1 - \mu_0)\). In our experiments, we choose \(q = 0.5\), \(\Sigma = I\) (identity matrix), \(\mu_0 = 0\) and \(\mu_1\) a sparse \(p \times 1\) vector with first 5 components being \((-0.25, 0.5, 0.75, 1, 1.25)\), which leads to \(\beta_0 = -\frac{1}{2} \mu_1^T \mu_1 = -0.4297\) and \(\beta_1 = \mu_1 = (-0.25, 0.5, 0.75, 1, 1.25, 0, \ldots, 0)^T\) in (S15). This gives the stated expression of \(P(Z = 1|X)\) in setting (C1).

For setting (C2), we first generate \(Z\) such that \(P(Z = 1) = q\). Next we generate \(X|Z = 1 \sim N(\mu_1, \Sigma_1)\) and \(X|Z = 0 \sim N(\mu_0, \Sigma_0)\). Then

\[
P(Z|X) = \frac{1}{1 + \exp(-\beta_0 - \beta_1^T X - X^T \Omega X)},
\]

where \(\beta_0 = -\frac{1}{2} \mu_1^T \Sigma_1^{-1} \mu_1 + \frac{1}{2} \mu_0^T \Sigma_0^{-1} \mu_0 + \log(q/(1-q) \Sigma_0^{-1/2})\), \(\beta_1 = \Sigma_1^{-1}(\mu_1 - \Sigma_0^{-1} \mu_0)\), \(\Omega = \frac{1}{2}(\Sigma_0^{-1} - \Sigma_1^{-1})\). In our experiments, we choose \(q = 0.5\), \(\Sigma_0 = I\), \(\Sigma_1^{-1} = 2I\), \(\mu_0 = 0\), and \(\mu_1\) a sparse \(p \times 1\) vector with first 4 components being \((-0.25, 0.5, 0.75, 1)/2\), which leads to \(\beta_0 = -\mu_1^T \mu_1 + \log(2^{p/2}) = -0.4687 + \frac{p}{2} \log 2\) and \(\beta_1 = 2\mu_1 = (-0.25, 0.5, 0.75, 1, 0, \ldots, 0)^T\) in (S16). This gives the stated expression of \(P(Z = 1|X)\) in setting (C2).

Our two-step Algorithm 1, specialized to partially linear modeling, is presented in Algorithm S1, including associated commands from R package glmnet (Friedman et al. 2010). Here \(Y\) and \(Z\) are \(n \times 1\) vectors of observations \(\{Y_i : i = 1, \ldots, n\}\) and \(\{Z_i : i = 1, \ldots, n\}\), and \(X\) and \(ZX\) are the design matrix of dimension \(n \times p\) and \(n \times (p+1)\) with \(i\)th row being \(X_i^T\) and \((Z_i, X_i^T)\) respectively. In Step 7 of Algorithm S1, \texttt{offset} is a vector with components \(\hat{\beta}_i^T Z_i\), and \texttt{weights} is a vector with components \(\psi'_f(\hat{\gamma}_i^T X_i) = \expit(\hat{\gamma}_i^T X_i)(1 - \expit(\hat{\gamma}_i^T X_i))\) for \(\psi_f = \expit(\cdot)\). The argument \texttt{alpha=1} stands for the \(\ell_1\) penalty.
Algorithm S1 Two-step algorithm for partially linear modeling

1: procedure INITIAL ESTIMATION

2: Compute \((\hat{\theta}_0, \hat{\alpha}_1) = \arg\min_{\theta, \alpha} \left\{ \tilde{E}(Y - \theta Z - \alpha^T X)^2 + \lambda_1 (|\theta| + \|\alpha\|_1) \right\} \)
   using \texttt{glmnet}(ZX, y=Y, alpha=1, family="gaussian").

3: Compute \(\hat{\gamma}_1 = \arg\min_{\gamma} \left[ \tilde{E}\{Z\gamma^T X + \log(1 + e^{\gamma^T X})\} + \lambda_2 \|\gamma\|_1 \right] \)
   using \texttt{glmnet}(X, y=Z, alpha=1, family="binomial").

4: Compute \(\hat{\theta}_1 = \frac{\tilde{E}((Y-\hat{\alpha}_1^T X)(Z-\hat{\gamma}_1^T X))}{\tilde{E}(Z-\hat{\gamma}_1^T X)} \).

5: end procedure

6: procedure CALIBRATED ESTIMATION

7: Compute \(\hat{\alpha}_2 = \arg\min_{\alpha} \left\{ \tilde{E} \psi_f(\hat{\gamma}_1^T X)(Y - \hat{\theta}_1 Z - \alpha^T X)^2 + \lambda_3 \|\alpha\|_1 \right\} \)
   using \texttt{glmnet}(X, y=Y, alpha=1, offset=theta1*Z, weights).

8: Compute \(\hat{\theta}_2 = \frac{\tilde{E}((Y-\hat{\alpha}_2^T X)(Z-\psi_f(\hat{\gamma}_1^T X)))}{\tilde{E}(Z-\psi_f(\hat{\gamma}_1^T X))} \),
   and \(\tilde{V} (\hat{\theta}_2) = \frac{\tilde{E}((Y-\hat{\alpha}_2^T X)^2(Z-\psi_f(\hat{\gamma}_1^T X))^2)}{\tilde{E}^2(Z-\psi_f(\hat{\gamma}_1^T X))} \).

9: end procedure

Algorithm S2 Debiased Lasso for linear modeling

1: procedure LINEAR PROJECTION

2: Compute \((\hat{\theta}_0, \hat{\alpha}_1) = \arg\min_{\theta, \alpha} \left\{ \tilde{E}(Y - \theta Z - \alpha^T X)^2 + \lambda_1 (|\theta| + \|\alpha\|_1) \right\} \)
   using \texttt{glmnet}(ZX, y=Y, alpha=1, family="gaussian").

3: Compute \(\hat{\gamma}_1 = \arg\min_{\gamma} \left[ \tilde{E}\{(Z - \gamma^T X)^2\} + \lambda_2 \|\gamma\|_1 \right] \)
   using \texttt{glmnet}(X, y=Z, alpha=1, family="gaussian").

4: Compute \(\hat{\theta}_{DB} = \theta_0 + \frac{\tilde{E}((Y-\hat{\theta}_0 Z-\hat{\alpha}_1^T X)(Z-\hat{\gamma}_1^T X))}{\tilde{E}(Z-\hat{\gamma}_1^T X)} \)
   and \(\tilde{V} (\hat{\theta}_{DB}) = \frac{\tilde{E}((Y-\hat{\alpha}_2^T X)^2(Z-\psi_f(\hat{\gamma}_1^T X))^2)}{\tilde{E}^2(Z-\psi_f(\hat{\gamma}_1^T X))} \).

5: end procedure

The tuning parameters \(\lambda_1, \lambda_2, \lambda_3\) are sequentially selected from 5-fold cross validation, using \texttt{cv.glmnet()} in the R package \texttt{glmnet}. For linear regression we set \texttt{type.measure="MSE"} and for logistic or log-linear regression, we set \texttt{type.measure="deviance"}. By default, there are 100 values of \(\lambda\) in the grid search over \(\lambda\) (Friedman et al. 2010).

The debiased Lasso method used in our experiments is shown in Algorithm S2, where robust variance estimation is employed (Zhang & Zhang 2014; Van de Geer et al. 2014;
Bühlmann & Van de Geer 2015). Step 3 in Algorithm S2 involves fitting a linear model of \( Z \) given \( X \), instead of a logistic model in Algorithm S1.

Table S1 presents simulation results and Figures S1–S3 show QQ plots of estimates and \( t \)-statistics for \( n = 400 \) and \( p = 100, 200 \) as well as \( p = 800 \) (for completeness). Comparison between the three methods is similar as discussed in the main paper.

II.2 Partially log-linear modeling

Our two-step Algorithm 1, specialized to partially log-linear modeling, is presented in Algorithm S3, including associated commands from R package \texttt{glmnet}. Because \( Z_i \)'s are binary, a closed-form solution can be obtained from the doubly robust estimating equation:

\[
e^{-\theta} = \frac{\sum_{Z_i=1} e^{\alpha^T X_i}(1 - \expit(\gamma^T X_i)) + \sum_{Z_i=0} (Y_i - e^{\alpha^T X_i})\expit(\gamma^T X_i)}{\sum_{Z_i=1} Y_i(1 - \expit(\gamma^T X_i))}. \tag{S17}
\]

Steps 7 and 8 are implemented as regularized weighted maximum likelihood estimation, by specifying weights in \texttt{glmnet} as follows: \texttt{weights1} is a vector with components \( e^{\hat{\alpha}^T X_i} \) and \texttt{weights2} is a vector with components \( e^{-\hat{\theta}Z_i}\expit(\hat{\gamma}_2^T X_i)(1 - \expit(\hat{\gamma}_2^T X_i)) \).

The debiased Lasso method used in our experiments is shown in Algorithm S4, where robust variance estimation is employed. Step 3 is implemented as regularized least square estimation, where \texttt{weights3} is a vector with components \( e^{\theta_0 Z_i + \hat{\alpha}^T X_i} \).

Table S2 presents simulation results and Figure S4–S5 show QQ plots of estimates and \( t \)-statistics for \( n = 400 \) and \( p = 100, 200 \) as well as \( p = 800 \) (for completeness). Comparison between the three methods is similar as discussed in the main paper.
Algorithm S3 Two-step algorithm for partially log-linear modeling

1: procedure INITIAL ESTIMATION
2: Compute \( (\hat{\theta}_0, \hat{\alpha}_1) = \arg\min_{\theta, \alpha} \left[ \tilde{E}\{-Y(\theta Z + \alpha^T X) + e^{\theta Z + \alpha^T X}\} + \lambda_1 (|\theta| + ||\alpha||_1) \right] \)
   using glmnet(ZX, y=Y, alpha=1, family="poisson").
3: Compute \( \hat{\gamma}_1 = \arg\min_\gamma \left[ \tilde{E}\{-Z\gamma^T X + \log(1 + e^{\gamma^T X})\} + \lambda_2 ||\gamma||_1 \right] \)
   using glmnet(X, y=Z, alpha=1, family="binomial").
4: Compute \( \hat{\theta}_1 \) from (S17) with \( \alpha = \hat{\alpha}_1 \) and \( \gamma = \hat{\gamma}_1 \).
5: end procedure

6: procedure CALIBRATED ESTIMATION
7: Compute \( \hat{\gamma}_2 = \arg\min_\gamma \tilde{E}e^{\hat{\alpha}_1^T X}\{-Z\gamma^T X + \log(1 + e^{\gamma^T X})\} + \lambda_3 ||\gamma||_1 \)
   using glmnet(X, y=Z, alpha=1, weights3, family="gaussian").
8: Compute \( \hat{\alpha}_2 = \arg\min_\alpha \tilde{E}\psi'((\hat{\gamma}_2 X)e^{-\hat{\theta}_1 Z}\{-Y(\hat{\theta}_1 Z + \alpha^T X) + e^{\hat{\theta}_1 Z + \alpha^T X}\} + \lambda_4 ||\alpha||_1 \)
   using glmnet(X, y=Y, alpha=1, offset=theta1*Z, weights2, family="poisson").
9: Compute \( \hat{\theta}_2 \) from (S17) with \( \alpha = \hat{\alpha}_2 \) and \( \gamma = \hat{\gamma}_2 \)
   and \( \hat{V}(\hat{\theta}_2) = \tilde{E}\{(Ye^{-\hat{\theta}_2 Z} - e^{\hat{\alpha}_2^T X}Z - \expit(\hat{\gamma}_2 X))^2\}/\tilde{E}\{e^{-\hat{\theta}_2 Z}YZ(Z - \expit(\hat{\gamma}_2 X))^2\} \).
10: end procedure

Algorithm S4 Debias Lasso for log-linear modeling

1: procedure LINEAR PROJECTION
2: Compute \( (\hat{\theta}_0, \hat{\alpha}_1) = \arg\min_{\theta, \alpha} \left[ \tilde{E}\{-Y(\theta Z + \alpha^T X) + \alpha^T X\} + \lambda_1 (|\theta| + ||\alpha||_1) \right] \)
   using glmnet(ZX, y=Y, alpha=1, family="poisson").
3: Compute \( \hat{\gamma}_1 = \arg\min_\gamma \left[ \tilde{E}\{\hat{\theta}_0^T Z + \hat{\alpha}_1 X(Z - \gamma^T X)^2\} + \lambda_2 ||\gamma||_1 \right] \)
   using glmnet(X, y=Z, alpha=1, weights3, family="gaussian").
4: Compute \( \hat{\theta}_{DB} = \hat{\theta}_0 + \tilde{E}\{(Y - e^{\hat{\theta}_0 Z + \hat{\alpha}_1 X})(Z - \hat{\gamma}_1^T X))\}/\tilde{E}\{e^{\theta_0 Z + \hat{\alpha}_1 X}Z(Z - \hat{\gamma}_1^T X)^2\} \)
   and \( \hat{V}(\hat{\theta}_{DB}) = \tilde{E}\{(Y - e^{\hat{\theta}_0 Z + \hat{\alpha}_1 X})^2(Z - \hat{\gamma}_1^T X)^2\}/\tilde{E}\{e^{\theta_0 Z + \hat{\alpha}_1 X}Z(Z - \hat{\gamma}_1^T X)^2\} \).
5: end procedure
II.3 Partially logistic modeling

We describe the data-generating configurations used for \((Z, Y, X)\), related to the odds ratio model in Chen (2007). We first generate \(X \sim N(0, \Sigma)\), where \(\Sigma = \text{Toeplitz}(\rho = 0.5)\). Given \(X\), we generate binary variables \((Z, Y)\) according to the probabilities proportional to the entries in the following \(2 \times 2\) table:

<table>
<thead>
<tr>
<th>(Z = 0)</th>
<th>(Z = 1)</th>
</tr>
</thead>
<tbody>
<tr>
<td>(Y = 0)</td>
<td>1</td>
</tr>
<tr>
<td>(Y = 1)</td>
<td>(e^{\beta_1 + h_1(X)})</td>
</tr>
</tbody>
</table>

Here \(e^{\theta^*Z + h_2(X)}\) and \(e^{\theta^*Z + \beta_1 + h_2(X)}\) are functions in \(X\) such that \(h_3(X) = h_1(X) + h_2(X)\). The implied conditional probabilities are

\[
P(Y = 1|X, Z) = \text{expit}(\theta^*Z + h_2(X)), \tag{S18}
\]
\[
P(Z = 1|X, Y = 0) = \text{expit}(\beta_1 + h_1(X)). \tag{S19}
\]

In our experiments, we set \(\theta^* = 2, \beta_1 = 0.25, \beta_2 = -0.25\), both \(\alpha\) and \(\gamma\) as a sparse vector with first four components being \((-0.25, 0.25, 0.5, 0.75)/2\). The functions \(h_1\) and \(h_2\) are chosen differently, depending on settings (C7)–(C9).

(i) Taking \(h_1(X) = \gamma^T X\) and \(h_2(X) = \alpha^T X\) in (S18)–(S19) leads to the stated expressions for \(P(Y = 1|X, Z)\) and \(P(Z = 1|X, Y = 0)\) in settings (C7).

(ii) Taking \(h_1(X) = \gamma^T X\) and \(h_2(X) = 0.25X_1 + 5X_2 + \text{expit}(X_3)\) in (S18)–(S19) leads to the stated expressions for \(P(Y = 1|X, Z)\) and \(P(Z = 1|X, Y = 0)\) in settings (C8).

(iii) Taking \(h_2(X) = \alpha^T X\) and \(h_1(X) = 0.25X_1 + 0.8X_2 + \text{expit}(X_3)\) in (S18)–(S19) leads to the stated expressions for \(P(Y = 1|X, Z)\) and \(P(Z = 1|X, Y = 0)\) in settings (C9).

6: **procedure** CALIBRATED ESTIMATION

7: Compute $\hat{\gamma}_2 = \arg\min_{\gamma} \left[ \tilde{E}e^{-\theta_1 Z Y} \expit(\hat{\alpha}_1^TX)\{-Z\gamma^TX + \log(1 + e^{\gamma^TX})\} + \lambda_3 ||\gamma||_1 \right]$
   using `glmnet(X, y=Z, alpha=1, weights1, family="binomial")`.

8: Compute $\hat{\alpha}_2 = \arg\min_{\alpha} \left[ \tilde{E}e^{-\theta_1 Z Y} \expit(\hat{\alpha}_2^TX)\{-Y\alpha^TX + \log(1 + e^{\alpha^TX})\} + \lambda_4 ||\alpha||_1 \right]$
   using `glmnet(X, y=Y, alpha=1, weights2, family="binomial")`.

9: Compute $\hat{\theta}_2$ from (S20) with $\alpha = \hat{\alpha}_2$ and $\gamma = \hat{\gamma}_2$
   and $\hat{V}(\hat{\theta}_2) = \frac{\tilde{E}\{e^{-2\theta_2 Z Y}(Y-\expit(\hat{\alpha}_2^TX))^2(Z-\expit(\hat{\gamma}_2^TX))^2\}}{\tilde{E}^2\{ZY e^{-2\theta_2 Z Y}(Y-\expit(\hat{\alpha}_2^TX))(Z-\expit(\hat{\gamma}_2^TX))\}}$.

10: **end procedure**

**Algorithm S6** Debiased Lasso for logistic modeling

1: **procedure** LINEAR PROJECTION

2: Compute $\hat{\theta}_0, \hat{\alpha}_1 = \arg\min_{\theta, \alpha} \left[ \tilde{E}\{-Y(\theta Z + \alpha^TX) + \log(1 + e^{\theta Z + \alpha^TX})\} + \lambda_1 (|\theta| + ||\alpha||_1) \right]$
   using `glmnet(XZ, y=Y, alpha=1, family="binomial")`.

3: Compute $\hat{\gamma}_1 = \arg\min_{\gamma} \left[ \tilde{E}\{\expit(\hat{\theta}_0 Z + \hat{\alpha}_1 X)(Z - \gamma^TX)^2\} + \lambda_2 ||\gamma||_1 \right]$
   using `glmnet(X, y=Z, alpha=1, weights3, family="gaussian")`.

4: Compute $\hat{\theta}_{DB} = \theta_0 + \frac{\tilde{E}\{(Y-\expit(\hat{\theta}_0 Z + \hat{\alpha}_1 X))(Z-\gamma_1^TX))}{\tilde{E}\{\expit(\hat{\theta}_0 Z + \hat{\alpha}_1 X)(Z-\gamma_1^TX)^2\}}$ and $\hat{V}(\hat{\theta}_{DB}) = \frac{\tilde{E}\{(Y-\expit(\hat{\theta}_0 Z + \hat{\alpha}_1 X))^2(Z-\gamma_1^TX)^2\}}{\tilde{E}^2\{\expit(\hat{\theta}_0 Z + \hat{\alpha}_1 X)(Z-\gamma_1^TX)^2\}}$.

5: **end procedure**

Our two-step Algorithm 1, specialized to partially logistic modeling, is presented in Algorithm S5, including associated commands from R package `glmnet`. Because $Z_i$’s are binary,
a closed-form solution can be obtained from the doubly robust estimating equation:

\[
e^{-\theta} = \frac{-\sum_{Z_i=0 \text{ or } Y_i=0} (Y_i - \expit(\alpha^T X_i))(Z_i - \expit(\gamma^T X_i))}{\sum_{Z_i=1 \text{ and } Y_i=1} (1 - \expit(\gamma^T X_i))(1 - \expit(\alpha^T X_i))}.
\]  

(S20)

In Step 3, the sample average \( \bar{E}_{Y=0}() \) is computed on over the subsample with \( Y_i = 0 \), i.e., \( \{(Z_i, X_i) : Y_i = 0, i = 1, \ldots, n\} \). Here \( Z_0 \) denotes \( \{Z_i : Y_i = 0\} \) and the \( X_0 \) is the design matrix with \( i \)th row being \( \{X_i^T : Y_i = 0, i = 1, \ldots, n\} \). Steps 7 and 8 are implemented as regularized weighted maximum likelihood estimation by specifying weights in \texttt{glmnet} as follows: \texttt{weights1} is a vector with components \( e^{-\hat{\theta}_1 Z_i Y_i \expit(\hat{\alpha}_1^T X_i) (1 - \expit(\hat{\alpha}_1^T X_i))} \) and \texttt{weights2} is a vector with components \( e^{-\hat{\theta}_1 Z_i Y_i \expit(\hat{\gamma}_1^T X_i) (1 - \expit(\hat{\gamma}_1^T X_i))} \).

The debiased Lasso method used in our experiments is shown in Algorithm S6, where robust variance estimation is employed. Step 3 is implemented as regularized least square estimation, where \texttt{weights3} is a vector with components \( \expit_2(\hat{\theta}_0 Z_i + \hat{\alpha}_1 X_i) = \expit(\hat{\theta}_0 Z_i + \hat{\alpha}_1 X_i) \).

Table S3 presents simulation results and Figures S7–S9 show QQ plots of estimates and \( t \)-statistics for \( n = 400 \) and \( p = 100, 200 \) as well as \( p = 800 \) (for completeness). Comparison between the three methods is similar as discussed in the main paper.
