Abstract

Data in non-Euclidean spaces are commonly encountered in many fields of Science and Engineering. For instance, in Robotics, attitude sensors capture orientation which is an element of a Lie group. In the recent past, several researchers have reported methods that take into account the geometry of Lie Groups in designing parameter estimation algorithms in nonlinear spaces. Maximum likelihood estimators (MLE) are quite commonly used for such tasks and it is well known in the field of statistics that Stein’s shrinkage estimators dominate the MLE in a mean-squared sense assuming the observations are from a normal population. In this paper, we present a novel shrinkage estimator for data residing in Lie groups, specifically, abelian or compact Lie groups. The key theoretical results presented in this paper are: (i) Stein’s Lemma and its proof for Lie groups and, (ii) proof of dominance of the proposed shrinkage estimator over MLE for abelian and compact Lie groups. We present examples of simulation studies of the dominance of the proposed shrinkage estimator and an application of shrinkage estimation to multiple-robot localization.

Keywords: shrinkage estimation, Stein’s identity, Lie groups, Riemannian manifolds

1 Introduction

The goal of this work is to generalize the well-known James-Stein estimator (James and Stein, 1961) to estimate the Fréchet means of normal distributions on connected Lie groups that are either abelian or compact. To achieve this, we will first state and prove the Stein’s lemma for the aforementioned Lie Groups and then prove that our estimator dominates the maximum likelihood estimator (MLE). A Lie group \( G \) is a smooth manifold that is also a group for which the operations of group multiplication and inverse are smooth (a brief review on Lie groups will be given in Section 2). Common examples are \( \text{GL}(N) \) (\( N \times N \) invertible matrices), \( \text{SO}(N) \) (\( N \times N \) orthogonal matrices with determinant one), and many others. Due to the lack of vector space structure, many basic statistics are no longer available, for example the arithmetic mean \( \bar{x} = n^{-1} \sum_{i=1}^{n} x_i \). In the case of arithmetic mean, there is a generalization of the notion of mean to a general metric space, called the Fréchet mean (FM) (Fréchet, 1948). Specifically, given a metric space \( (M, d) \), the FM of a probability measure \( P \) on \( M \) is defined as \( E_P(X) = \arg \min_{m \in M} \int_M d^2(x, m) dP(x) \) and for the special case of an empirical measure \( P = n^{-1} \sum_{i=1}^{n} \delta_{x_i} \) for \( x_1, \ldots, x_n \in M \), the FM of \( P \) is \( \bar{x} = \arg \min_{m \in M} \sum_{i=1}^{n} d^2(x_i, m) \). Note that FM is in general not unique. In our case, since a Lie group is a smooth manifold, it is natural to endow the Lie group with a Riemannian metric, which is a smooth family of inner products on its tangent spaces, and makes \( G \) a Riemannian manifold. The Riemannian metric induces an intrinsic distance between two points that can be defined as the infimum of the length over all the curves connecting them. Hence, for a collection of \( G \)-valued random variables \( X_1, \ldots, X_n \overset{iid}{\sim} P \), it is of practical interest to estimate \( E_P(X) \).

In this work, we assume that the Lie group \( G \) is connected and either

(i) abelian, e.g. \( \mathbb{R}, \text{SO}(2) \cong S^1 \), or

(ii) compact, e.g. \( \text{SO}(N), N > 2 \).

The main reason for this assumption is that in this case, \( G \) will admit a bi-invariant Riemannian metric, i.e. a Riemannian metric that is invariant to both left-translation and right-translation. As a consequence, the Haar measure is also bi-invariant. With these assumptions in mind, we denote the normalized (bi-invariant) Haar measure by \( dx \), i.e. \( \int_G dx = 1 \), and
the (bi-invariant) inner product on the tangent space, $T_xG$ at $x \in M$, by $\langle \cdot, \cdot \rangle_x$. The norm induced by this inner product is denoted $\| \cdot \|_x$. When $x = e$ which is the identity element of $G$, the subscripts are omitted here for convenience. The Riemannian distance is denoted by $d : G \times G \to \mathbb{R}$. With the existence of a bi-invariant Riemannian metric, not only the computation is easier, but the Riemannian structure is compatible with the Lie group structure, i.e. the Riemannian exponential map coincides with the Lie group exponential map and hence the one-parameter subgroup formed by $\exp(tV)$ is a geodesic, where $t \in \mathbb{R}$ and $V \in \mathfrak{g}$.

**Remark 1** Since a compact Lie group possesses a faithful representation (Sepanski, 2007, Theorem 3.28) in $\mathbb{R}^N$, all compact Lie groups are matrix Lie groups, i.e. closed subgroups of $\text{GL}(N)$. Hence without loss of generality, we assume $G$ is a closed Lie subgroup of $\text{GL}(N)$.

We now briefly review the James-Stein estimator in the Euclidean space setting.

### 1.1 The James-Stein Estimator

Let $X \overset{\text{ind}}{\sim} N(\mu, I)$ be a $p$-dimensional normal random variable and $p > 2$. Then the maximum likelihood estimator (MLE) for $\mu \in \mathbb{R}^p$ is $\hat{\mu}^{\text{MLE}} = X$. Consider the loss function $L(\hat{\mu}, \mu) = \| \hat{\mu} - \mu \|^2$ and the risk function $R(\hat{\mu}, \mu) = EL(\hat{\mu}(X), \mu)$. The James-Stein estimator (James and Stein, 1961) given by

$$
\hat{\mu}^{\text{JS}} = \left(1 - \frac{p-2}{|X|^2}\right)X
$$

was shown to dominate the MLE in the sense that $R(\hat{\mu}^{\text{JS}}, \mu) < R(\hat{\mu}^{\text{MLE}}, \mu)$ for all $\mu \in \mathbb{R}^p$. This estimator is often referred to as a shrinkage estimator. The proof of this result relies on the so-called *Stein’s identity*: if $X \sim N(\mu, \sigma^2)$, then $E(f(X)(X - \mu)) = \sigma^2 E(f'(X))$ for all bounded and differentiable $f$ provided that the expectations on both sides exist. Stein (1986) further showed that this identity is a characterization of the normal distribution, i.e. this identity holds if and only if $X \sim N(\mu, \sigma^2)$ (Stein, 1986, Lemma II.1).

### 1.2 Main Results

We now state the main results of our work presented in this paper. For general Riemannian manifolds, Pennec (2006) proposed a generalized normal distribution via the maximum
entropy characterization given that the FM and the covariance matrix are known. In this work, we assume the concentration matrix to be \( \Gamma = \sigma^{-2} I \) and the probability density function (pdf) with respect to the Haar measure is given by 
\[
f(x) = C(\mu, \sigma) \exp(-d^2(x, \mu)/(2\sigma^2))
\]
where \( \mu \) is the FM and assumed to be unique (see Pennec (2006, Theorem 3)). For a \( G \)-valued random variable whose pdf is \( f(x) \), we denote \( X \sim \mathcal{N}(\mu, \sigma^2) \). The probability measure whose Radon-Nikodym derivative with respect to the Haar measure is \( f(x) \) is denoted by \( F \).

The main contribution of this paper is twofold. First, we show (in Lemma 1) that the generalized Stein’s identity for \( X \sim \mathcal{N}(\mu, \sigma^2) \) is given by
\[
E\left[h(X)\langle \log \mu^{-1} X, T_{\log \mu^{-1} X}(V) \rangle \right] = \sigma^2 E(L_V h(X)).
\]
for bounded and differentiable \( h: G \to \mathbb{R} \) and \( V \in \mathfrak{g} \). Furthermore, we show in Theorem 1 that this is a characterization of the normal distribution on \( G \), i.e. \( X \sim \mathcal{N}(\mu, \sigma^2) \) if and only if the above identity holds for all bounded and differentiable \( h \). This is the analog of Stein’s characterization for the compact/abelian Lie groups setting.

Second, with these results in hand, we show in Theorem 3 (for abelian Lie groups) and Theorem 4 (for compact Lie groups) that for \( X_i \overset{\text{ind}}{\sim} \mathcal{N}(\mu_i, \sigma^2), i = 1, \ldots, p \), the MLE \( \hat{\mu}_{\text{MLE}} = X = (X_1, \ldots, X_p) \) of \( \mu = (\mu_1, \ldots, \mu_p) \) is dominated by \( \hat{\mu}_{\text{S}} = (\hat{\mu}_1^S, \ldots, \hat{\mu}_p^S) \) where 
\[
\hat{\mu}_i^S = X_i \exp(-\frac{c(S)}{S}(X))
\]
for some suitable \( c: \mathbb{R} \to \mathbb{R} \) and \( S = \sum_{i=1}^p d^2(X_i, e) \). We also provide concrete examples of \( c(S) \) and compare their performance in Section 5.

### 1.3 Literature Review

Since the publication of the seminal work by James and Stein (1961), researchers in Statistics and related disciplines have been trying to generalize the James-Stein estimator to a variety of parameter estimation problems. For example, shrinkage estimators for simultaneous estimation have been proposed for: means of independent Poisson random variables (Clevenson and Zidek, 1975; Tsui, 1981; Tsui and Press, 1982), scale parameters of independent Gamma random variables (Berger, 1980; Gupta, 1986), and location parameters of spherically symmetric distributions (Brandwein and Strawderman, 1990, 1991). The key technique used in these works is to reduce the problem to the study a particular differential inequality, i.e. the difference between the risks of a proposed shrinkage estimator and the
MLE. This is also the technique we adopt in our work. On the other hand, Efron and Morris (1973) provided an empirical Bayes interpretation for the James-Stein estimator and also proposed several competing empirical Bayes estimators. Following this approach, Xie et al. (2012) proposed an empirical Bayes shrinkage estimator for a heteroscedastic hierarchical model by minimizing Stein’s unbiased risk estimate (SURE) (Stein, 1981). Note that the idea of minimizing SURE had already been applied to a variety of problems, e.g. Li (1985) and Donoho and Johnstone (1995). By the nature of SURE, the shrinkage estimator derived using this technique possesses certain asymptotic optimality properties amongst the class of shrinkage estimators. Hence, this technique has been applied to derive shrinkage estimators for different models (Jing et al., 2016; Xie et al., 2016).

The study of shrinkage estimation in non-Euclidean spaces has however been mainly limited to the case of covariance matrices in literature. For the estimation of covariance matrix of a normal distribution, Stein (1975) proposed to shrink the eigenvalues of the sample covariance matrix and Ledoit and Wolf (2004) proposed to shrink the sample covariance matrix to the identity. There is vast literature on this topic and we refer the interested readers to Donoho et al. (2018) and the references therein. When estimating multiple covariance matrices (or symmetric positive definite (SPD) matrices) in the context of medical imaging applications, specifically the analysis of diffusion tensor images, shrinkage estimation was shown to yield improvement over the MLE in (Yang and Vemuri, 2019; Yang et al., 2020). In directional statistics, Sengupta and Maitra (1998) showed that the MLE is admissible and is the best equivariant estimator for simultaneously estimating the location parameters of several von Mises-Fisher (or Langevin) distributions. Hendriks (2005) also showed that for matrix von Mises-Fisher family, the empirical mean location is admissible. The matrix von Mises-Fisher family is defined on the Steifel manifolds, which include the hypersphere and the orthogonal group as special cases. To the best of our knowledge, we are not aware of any other work on shrinkage estimation in non-Euclidean spaces thus motivating our study of this problem on Lie groups including SO($N$) and the torus as examples. We would like to point out that the manifold of $N \times N$ SPD matrices can be endowed with a Lie group structure (Arsigny et al., 2007), although it is not a subgroup of GL($N$). This was the assumed structure on the manifold of SPD matrices in the work of Yang and Vemuri (2019)
and Yang et al. (2020).

1.4 Organization

The rest of this paper is organized as follows. In Section 2, we present some essential and relevant background material on Lie groups. In Section 3, we present the proofs of Theorem 1, Theorem 3, and Theorem 4. Section 4 contains the example of SO(3) along with all the relevant computations. In Section 5, we present simulation studies to validate our theory. We also apply our proposed shrinkage estimator to the problem of multiple-robot localization and show that the proposed shrinkage estimators can further sharpen the estimates over the current state-of-the-art estimates using the Unscented Kalman Filter on Lie Groups (Brossard et al., 2017). Finally, we draw conclusions in Section 6.

2 Lie Groups and Its Riemannian Geometry

In this section, we review some material on Riemannian geometry and Lie groups that are essential for our work presented in this paper. For more details, we refer the interested readers to Lee (2018) for Riemannian Geometry and Sepanski (2007) for compact Lie Groups respectively.

Let $M$ be a smooth manifold. For $p \in M$, the tangent space of $M$ at $p$ is denoted by $T_p M$ which is a vector space. Its dual space, denoted by $T^*_p M$, is called the cotangent space. The disjoint union of all tangent spaces is called the tangent bundle $TM = \bigsqcup_{p \in M} T_p M$. Similarly, the cotangent bundle is the disjoint union of the cotangent spaces $T^*M = \bigsqcup_{p \in M} T^*_p M$. A smooth section of the tangent bundle, i.e. $X : M \to TM$ and $X_p := X(p) \in T_p M$, is called a vector field, while a smooth section on the cotangent bundle i.e. $\omega : M \to T^*M$ and $\omega_p := \omega(p) \in T^*_p M$, is called a covector field or a differential 1-form. The space of all vector fields is denoted by $\mathfrak{X}(M)$ and the space of all differential 1-form is denoted by $\Omega^1(M)$. For a smooth function $f \in C^\infty(M)$, the differential of $f$ is a differential 1-form $df$ such that $(df)_p(X_p) = X_p f$ for $X \in \mathfrak{X}(M)$.
2.1 Lie Groups

A Lie Group $G$ is a smooth manifold whose group multiplication and group inverse are smooth. A Lie algebra $\mathfrak{g}$ is a vector space with a bilinear and anti-symmetric map $[\cdot, \cdot] : \mathfrak{g} \times \mathfrak{g} \to \mathfrak{g}$, called a Lie bracket, satisfying the Jacobi identity: $[x, [y, z]] + [y, [z, x]] + [z, [x, y]] = 0$ for $x, y, z \in \mathfrak{g}$. For each Lie group $G$, there is an associated Lie algebra $\mathfrak{g} \cong T_eG$ where $e$ is the identity element of $G$. Common examples of Lie groups are $\text{GL}(N)$ (the group of $N \times N$ real invertible matrices) and $\text{SO}(N)$ (the group of $N \times N$ orthogonal matrices with determinant 1) whose Lie algebras are $\mathfrak{gl}(N)$ (the vector space of all $N \times N$ real matrices) and $\mathfrak{so}(N)$ (the vector space of all real skew-symmetric matrices), respectively. The Lie bracket in the examples above is the matrix commutator $[x, y] = xy - yx$.

The relationship between a Lie group $G$ and its Lie algebra $\mathfrak{g}$ can be characterized by the (Lie group) exponential map $\exp : \mathfrak{g} \to G$ defined by $V \mapsto \exp(tV)$ for $V \in \mathfrak{g}$ and $t \in \mathbb{R}$. In a neighborhood of $0 \in \mathfrak{g}$, the exponential map is invertible, and we denote this inverse by log. For matrix Lie groups (the examples above), the exponential map and its inverse are simply the matrix exponential and the principal logarithm of the matrix. Since this work focuses on connected Lie groups that are either (i) abelian or (ii) compact, we assume $G$ to be one of these cases from here on for the rest of the paper.

Haar measure A left-invariant (resp. right-invariant) Haar measure is a measure that is invariant to left-translation (resp. right-translation). However, a left-invariant Haar measure is not right-invariant in general. A Lie group is called unimodular if its left-invariant Haar measure is also right-invariant. Abelian Lie groups and compact Lie groups are unimodular (see Knapp (2002, Corollary 8.31)). Whenever the Lie group is compact, we assume that the Haar measure is normalized, i.e. $\int_G dx = 1$.

Lie derivative Let $f$ be a real-valued function defined on $G$ and $V \in \mathfrak{X}(G)$. The Lie derivative of $f$ along $V$ is defined by

$$\mathcal{L}_V f = \left. \frac{d}{dt} f(x \exp(tV_e)) \right|_{t=0}.$$
Since $L_V f$ depends only on $V_e \in \mathfrak{g}$, with a slight abuse of notation, we write $L_V f$ for $V \in \mathfrak{g}$.

The integration by parts formula (with respect to the Haar measure) is given by

$$
\int_G (L_V f_1)(x)f_2(x)dx = -\int_G f_1(x)(L_V f_2)(x)dx
$$

where $f_i : G \to \mathbb{R}$ and $V \in \mathfrak{g}$ (see Chirikjian (2012, Ch. 12.2.1)).

**Adjoint representation** The adjoint representation of $G$ on $\mathfrak{g}$, denoted by $\text{Ad} : G \to \text{GL}(\mathfrak{g})$, is defined by $\text{Ad}_g(x) := \text{Ad}(g)(x) = gxg^{-1}$ where $g \in G$, $x \in \mathfrak{g}$ and $\text{GL}(\mathfrak{g})$ is the space of all invertible linear transformations on $\mathfrak{g}$. The adjoint representation of $\mathfrak{g}$ on $\mathfrak{g}$, denoted by $\text{ad} : \mathfrak{g} \to \text{End}(\mathfrak{g})$, is defined by $\text{ad}_x(y) := \text{ad}(x)(y) = [x,y]$ for $x,y \in \mathfrak{g}$. An important relationship between $\text{Ad}$ and $\text{ad}$ is that $\text{Ad}_{\exp(x)} = \exp(\text{ad}_x)$ for $x \in \mathfrak{g}$. This formula is interpreted as

$$
\text{Ad}_{\exp(x)}(y) = \exp(\text{ad}_x)(y) = \sum_{k=0}^{\infty} \frac{\text{ad}_x^k(y)}{k!}
$$

where $\text{ad}_x^k(y) = [x,[x,\ldots,[x,y]]]$ and $x,y \in \mathfrak{g}$.

**Baker-Campbell-Hausdorff formula** Since a Lie algebra is in general not abelian, i.e. $[x,y] \neq 0$, $\log(\exp(x) \exp(y)) \neq \log(\exp(x+y)) = x+y$. The Baker-Campbell-Hausdorff (BCH) formula provides an expression for $\log(\exp(x) \exp(y))$ as a series in terms of $x$, $y$, and their Lie brackets

$$
\log(\exp(x) \exp(y)) = x + y + \frac{1}{2}[x,y] + \frac{1}{12}([x,[x,y]] + [y,[y,x]]) + \ldots
$$

where $x,y \in \mathfrak{g}$. There are different expressions for this formula. One that we use in this work is,

$$
\log(\exp(x) \exp(y)) = x + T_x(y) + O(y^2)
$$

where $T_x$ is an operator from $\mathfrak{g}$ to $\mathfrak{g}$ defined by

$$
T_x(y) = \frac{\text{ad}_x}{I - \exp(-\text{ad}_x)}(y)
$$

(see Sepanski (2007, Ch. 5.2) or Hall (2015, Theorem 5.3)). Note that when $\mathfrak{g}$ is abelian, i.e. $\text{ad}_x = 0$ for $x \in \mathfrak{g}$, $T_x$ is defined to be the identity map. A series expansion for $T_x$ is given
by,
\[ T_x(y) = \left( \sum_{k=0}^{\infty} \frac{B_k^+}{k!} \text{ad}_x^k \right)(y) = \sum_{k=0}^{\infty} \frac{B_k^+}{k!} \text{ad}_x^k(y) \]
where the $B_k^+$'s are the Bernoulli numbers.

2.2 Riemannian Geometry

For a smooth manifold, a *Riemannian metric* is a smooth assignment of inner products $g_p(\cdot, \cdot) = \langle \cdot, \cdot \rangle_p$ on $T_pM$. The pair $(M, g)$ denotes a Riemannian manifold. Note that all smooth manifolds admit a Riemannian metric. For $v \in T_pM$, the norm induced by the inner product is denoted by $\|v\|_p = \sqrt{\langle v, v \rangle_p}$. For a Riemannian manifold $(M, g)$, we can define a distance metric on $M$ by
\[
d(p, q) = \inf_{\gamma} \left\{ L(\gamma) = \int_0^1 \| \gamma'(t) \|_{\gamma(t)} dt; \gamma : [0, 1] \to M, \gamma(0) = p, \gamma(1) = q \right\}
\]
for $p, q \in M$ and the curve $\gamma$ that attains the infimum is called a minimizing curve.

For $p \in M$ and $v \in T_pM$, denote the geodesic emanating from $p$ with tangent vector $v$ by $\gamma_{p,v} : [0, 1] \to M$ such that $\gamma(0) = p$ and $\gamma'(0) = v$. Then the (Riemannian) exponential map at $p$, $\text{Exp}_p : T_pM \to M$, is given by $\text{Exp}_p(v) = \gamma_{p,v}(1)$ and it is a diffeomorphism on a small neighborhood of 0 in $T_pM$. Its inverse is denoted by $\text{Log}_p : M \to T_pM$. In this case, the distance between $p, q \in M$ can be expressed as $d(p, q) = \| \text{Log}_p(q) \|_p$.

**Riemannian metric on $G$** Since $G$ is a smooth manifold, it admits a Riemannian metric. For a compact or an abelian Lie group, a natural choice of Riemannian metric that respects the group structure is a bi-invariant Riemannian metric, i.e. a metric that is invariant to both left-translation and right-translation. In this case, the Riemannian exponential map coincides with the Lie group exponential map, i.e. $\text{Exp}_e = \exp : \mathfrak{g} \to G$ and $\text{Exp}_p(v) = p \exp(p^{-1}v)$ for $v \in T_pG$. As a consequence of the Riemannian metric being bi-invariant, the induced distance is also invariant to the left and right translation. For the rest of this paper, we use $\langle \cdot, \cdot \rangle$ to denote the inner product on $\mathfrak{g}$ and $\| \cdot \|$ to denote the norm induced by the inner product. The intrinsic distance can be expressed as $d(x, y) = \| \text{Log}_x(y) \|_x = \sqrt{\langle x \log(x^{-1}y), x \log(x^{-1}y) \rangle_x = \sqrt{\langle \log(x^{-1}y), \log(x^{-1}y) \rangle} = \| \log x \|}$.
3 Shrinkage Estimators for the Fréchet Means

In this section, we first present the normal distribution defined on a Riemannian manifold introduced by Pennec (2006). This normal distribution is derived using the maximum entropy principle, i.e. the distribution which maximizes the entropy given that the FM and the covariance of the distribution are known.

**Definition 1** Let $X$ be a random variable taking value on a Lie group $G$. We say that $X$ follows a *Gaussian distribution* with location $\mu \in G$ and standard deviation $\sigma > 0$, denoted $X \sim \mathcal{N}(\mu, \sigma^2)$, if the density of $X$ with respect to the Haar measure is

$$f(x) = C(\mu, \sigma) \exp \left( - \frac{d^2(x, \mu)}{2\sigma^2} \right)$$

where $C(\mu, \sigma)$ is the normalizing constant such that $\int_G f(x) \, dx = 1$.

Note that this definition of Gaussian distribution is different from the one defined by the solution of the heat equation on Lie groups (see, for example, Applebaum (2014, Ch. 5.6)) for which closed form of the density function is not available in general. The Gaussian distribution in Definition 1, however, shares some nice properties with the Gaussian distribution on $\mathbb{R}$ as stated below. Hence, we choose to work with this definition instead. The proofs of the following propositions can be found in Cheng and Vemuri (2013), Fletcher (2013), and Chakraborty and Vemuri (2019).

**Proposition 1** The normalizing constant for the Gaussian distribution on Lie group $G$ is independent of $\mu$. Hence we write $C(\mu, \sigma) = C(\sigma)$.

**Proposition 2** Given $X_1, \ldots, X_n \overset{iid}{\sim} \mathcal{N}(\mu, \sigma^2)$, the MLE of $\mu$ is given by

$$\hat{\mu}^{MLE} = \arg \min_{m \in G} \sum_{i=1}^{n} d^2(X_i, m)$$

which is the Fréchet mean of $X_1, \ldots, X_n$.

The main problem we focus on in this work is the following: Suppose $X \sim \mathcal{N}(\mu, \sigma^2)$ where $\sigma^2 > 0$ is known and $\mu \in G$. By Proposition 2, the MLE of $\mu$ is $\hat{\mu}^{MLE} = X$. Motivated by the James-Stein estimator, we consider the shrinkage estimator

$$\hat{\mu}^{JS} = X \exp \left( - \frac{c(S)}{S} \log X \right)$$ (1)
where \( S = \sum_{i=1}^{p} d^2(X_i, e) \). Let the loss function be \( L(\hat{\mu}, \mu) = d^2(\hat{\mu}, \mu) \) and the risk function be the expected value of the loss function \( R(\hat{\mu}, \mu) = \mathbb{E}L(\hat{\mu}(X), \mu) \). We show that under certain conditions the proposed shrinkage estimator dominates the MLE in the sense that

\[
R(\hat{\mu}^{JS}, \mu) < R(\hat{\mu}^{MLE}, \mu), \quad \text{for all } \mu \in G.
\]

(2)

As in the proof of the dominance of the classical James-Stein estimator in \( \mathbb{R}^n \), we need a generalized version of Stein’s lemma that is valid for Lie groups, which we will state and prove now.

### 3.1 Generalization of Stein’s Lemma to Lie Groups

The original Stein’s lemma is obtained via integration by parts. We apply the integration by parts formula on Lie groups to the normal distribution and we have the following lemma.

**Lemma 1** Let \( X \sim \mathcal{N}(\mu, \sigma^2) \) and \( h : G \to \mathbb{R} \) be any bounded differentiable function such that \( \mathbb{E}|L_V h(X)| < \infty \) for all \( V \in \mathfrak{g} \). Then for all \( V \in \mathfrak{g} \)

\[
\mathbb{E}\left[h(X) \langle \log \mu^{-1} X, T_{\log \mu^{-1} X}(V) \rangle \right] = \sigma^2 \mathbb{E}(L_V h(X)).
\]

**Proof.** Let \( f(x) = C(\sigma) \exp \left(-\frac{d^2(x, \mu)}{2\sigma^2}\right) \) where \( x \in G, \mu \in G, \) and \( \sigma > 0 \). By definition,

\[
D_V f(x) = \frac{d}{dt} C(\sigma) \exp \left(-\frac{d^2(x \exp(tV), \mu)}{2\sigma^2}\right) \bigg|_{t=0} = -\frac{1}{2\sigma^2} C(\sigma) \exp \left(-\frac{d^2(x \exp(tV), \mu)}{2\sigma^2}\right) \frac{d}{dt} \frac{d^2(x \exp(tV), \mu)}{dt} \bigg|_{t=0} = h(x; \mu, \sigma) \left[ \frac{d}{dt} \frac{d^2(x \exp(tV), \mu)}{dt} \bigg|_{t=0} \right].
\]

Write \( d^2(x \exp(tV), \mu) = \| \log \mu^{-1} x \exp(tV) \|^2 = \|A(t)\|^2 \) and

\[
\frac{d}{dt} A(t) \bigg|_{t=0} = \frac{d}{dt} \left( \log \mu^{-1} x \exp(tV) \right) \bigg|_{t=0} = \frac{d}{dt} \left( \log \mu^{-1} x + T_{\log \mu^{-1} x}(tV) + O((tV)^2) \right) \bigg|_{t=0} = T_{\log \mu^{-1} x}(V).
\]

Then

\[
\frac{d}{dt} \|A(t)\|^2 \bigg|_{t=0} = 2\langle A(t), \frac{d}{dt} A(t) \rangle \bigg|_{t=0} = 2\langle \log \mu^{-1} x, T_{\log \mu^{-1} x}(V) \rangle.
\]
Thus for \( V \in \mathfrak{g} \)
\[
\mathcal{L}_V f(x) = -\sigma^{-2} f(x; \mu, \sigma) \langle \log \mu^{-1} x, \mathcal{T}_{\log \mu^{-1} x}(V) \rangle.
\]

Using the integration by parts formula, we have
\[
E \left[ h(X) \langle \log \mu^{-1} X, \mathcal{T}_{\log \mu^{-1} X}(V) \rangle \right] = -\sigma^2 \int_G h(x) \mathcal{L}_V f(x) \, dx
= \sigma^2 \int (\mathcal{L}_V h(x)) f(x) \, dx
= \sigma^2 E(\mathcal{L}_V h(X))
\]
which concludes the proof.

The following theorem shows that the equality in Lemma 1 is a characterization of the Gaussian distribution in Definition 1.

**Theorem 1** Let \( X \) be a \( \mathcal{G} \)-valued random variable. Then \( X \sim \mathcal{N}(\mu, \sigma^2) \) if and only if
\[
E \left[ h(X) \langle \log \mu^{-1} X, \mathcal{T}_{\log \mu^{-1} X}(V) \rangle \right] = \sigma^2 E\mathcal{L}_V h(X) \tag{3}
\]
for all bounded differentiable \( h : G \to \mathbb{R} \) and \( V \in \mathfrak{g} \).

**Proof.** The necessary condition follows from Lemma 1. Let \( f(x) = C(\sigma) \exp(-d^2(x, \mu)/(2\sigma^2)) \). We first show that for a fixed \( V \in \mathfrak{g} \) there exists a bounded differentiable function \( \tilde{h}_A : G \to \mathbb{R} \) such that
\[
\tilde{h}_A(x) \langle \log \mu^{-1} x, \mathcal{T}_{\log \mu^{-1} x}(V) \rangle - \sigma^2 \mathcal{L}_V \tilde{h}_A(x) = I_A(x) - F(A)
\]
where \( I_A(\cdot) \) is the indicator function, \( F(A) = \int_A f(x) \, dx \) is the Gaussian measure, and \( A \in \mathcal{B}(G) \) is a Borel set. Multiplying \(-\sigma^{-2} f(x)\) on both side of the equation above, we get
\[
\mathcal{L}_V(f \tilde{h}_A)(x) = -\sigma^2 f(x)(I_A(x) - F(A)).
\]
Then \( \tilde{h}_A \) is given by
\[
\tilde{h}_A(x) = \begin{cases} 
-\frac{\sigma^2}{f(x)} \tilde{f}_V(x)(1 - F(A)) & x \in A \\
\frac{\sigma^2}{f(x)} \tilde{f}_V(x) F(A) & x \notin A
\end{cases}
\]
where \( \tilde{f}_V : G \to \mathbb{R} \) is such that \( \mathcal{L}_V \tilde{f}_V(x) = f(x) \). The existence of \( \tilde{f}_V \) is guaranteed by the fundamental theorem of differential equations. Suppose that \( X \) is a \( \mathcal{G} \)-valued random
variable with probability measure $P_X$ and satisfies Eq. (3) for all differentiable $h$ and $V \in \mathfrak{g}$. Since $\tilde{h}_A$ is differentiable, we have
\[
0 = E\left[\tilde{h}_A(X)\langle \log \mu^{-1}X, \mathcal{T}_{\log \mu^{-1}x}(V) \rangle - \sigma^2 \mathcal{L}_V \tilde{h}_A(X)\right] \\
= E[I_A(x) - F(A)] \\
= P_X(A) - F(A).
\]
The choice of $A \in \mathcal{B}(G)$ is arbitrary and hence $P_X = F$, i.e. $X \sim \mathcal{N}(\mu, \sigma^2)$. This concludes the proof. \hfill \square

Theorem 1 is a generalization of Stein’s characterization of Gaussian distribution (Stein, 1986, Lemma II.1) to compact Lie groups and the proof follows the idea of the original proof. Note that when $G$ is abelian, $\mathcal{T}_x$ is the identity map and $\log \mu^{-1}x = \log x - \log \mu$. Thus, Lemma 1 simplifies to
\[
E\left[h(X)\langle \log X - \log \mu, V \rangle \right] = \sigma^2 E(\mathcal{L}_V h(X)).
\]

### 3.2 Shrinkage Estimation on Abelian Lie Groups

In this subsection, we tackle the case when $G$ is abelian. We note that abelian Lie groups only consist a tiny portion of the entire class of Lie groups. However, they are commonly encountered in applications, for example the Euclidean space and the circle $S^1 \subset \mathbb{R}^2$. In fact, if $G$ is a $p$-dimensional connected abelian Lie group, then $G \cong \mathbb{R}^k \times (\text{SO}(2))^{p-k}$ (Procesi, 2007, Ch. 4, Sec. 4.2) and hence $\mathfrak{g} \cong \mathbb{R}^p$. Since the case of $G = \mathbb{R}^p$ is already handled by the classical James-Stein estimator, we first focus on the case of $G = (\text{SO}(2))^p$ which is also called a torus. In this case, a point on $x \in G \cong (\text{SO}(2))^p$ can be written as $x = (r_1, \ldots, r_p)$ where
\[
gr_i = \begin{bmatrix}
\cos \theta_i & -\sin \theta_i \\
\sin \theta_i & \cos \theta_i
\end{bmatrix} \in \text{SO}(2)
\]
and $v \in \mathfrak{g} \cong \mathbb{R}^p$ can be written as $v = (\theta_1, \ldots, \theta_p)$.

The canonical bi-invariant Riemannian metric for $\text{SO}(N)$ is $\langle U, V \rangle = \frac{1}{2} \text{tr}(U^TV) = -\frac{1}{2} \text{tr}(UV)$ for $U, V \in \text{so}(N)$ and hence the induced norm on $\text{so}(N)$ is $\|V\| = \sqrt{-\frac{1}{2} \text{tr}(V^2)}$. For $V \in \text{so}(2)$ and $X \in \text{SO}(2)$, via direct computation, we have $\exp(V) = (\cos \|V\|)I +
$\|V\|^{-1}\sin\|V\|V$ and $\log X = (\|A\|^{-1}\sin^{-1}\|A\|)A$ where $A = \frac{1}{2}(X - X^T)$. Since $\mathfrak{so}(2)$ is abelian, $\mathcal{T}_V = I$ for $V \in \mathfrak{so}(2)$.

Endowed with the bi-invariant Riemannian metric, the induced distance is given by $d(x_1, x_2) = \|\log x_1^T x_2\| = \min(|\theta_1 - \theta_2|, 2\pi - |\theta_1 - \theta_2|)$ where $x_1, x_2 \in \text{SO}(2)$ and $\theta_i \in [-\pi, \pi)$ is the corresponding angle of $x_i$. The normalized Haar measure is given by $dx = (2\pi)^{-1}d\theta$ (Chirikjian, 2012, Ch. 12.4.3) and the Gaussian distribution with respect to the normalized Haar measure is given by

$$f(x; \mu, \sigma) = \frac{1}{C(\sigma)}\exp\left(-\frac{\|\log x^T \mu\|^2}{2\sigma^2}\right) = (2\pi)^{-1}C(\sigma)\exp\left(-\min\left\{\frac{(\theta - \nu)^2}{2\sigma^2}, \frac{(2\pi - |\theta - \nu|)^2}{2\sigma^2}\right\}\right) = (2\pi)^{-1}C(\sigma)\exp\left(-\frac{(\theta - \nu)^2}{2\sigma^2}\right)$$

which is simply the truncated normal, where $\nu \in [-\pi, \pi)$ and $\theta \in [\nu - \pi, \nu + \pi)$ are the angles corresponding to $\mu$ and $x$, and

$$C(\sigma) = 2\pi\sigma(\Phi(\pi/\sigma) - \Phi(-\pi/\sigma)), \quad \Phi(x) = \int_{-\infty}^{x} \frac{1}{\sqrt{2\pi}}e^{-x^2/2}dx.$$ 

The equality in Lemma 1 simplifies to $Eh(\theta)(\theta - \nu) = \sigma^2 Eh'(\theta)$ for differentiable and bounded $h : [\nu - \pi, \nu + \pi) \to \mathbb{R}$ and $h(\nu - \pi) = h(\nu + \pi)$.

**Theorem 2** Let $G = (\text{SO}(2))^p$ and $X \sim N(\mu, \sigma^2)$ where $\sigma > 0$ is known and $\mu \in G$. If (i) $0 < c(\cdot) < 2(p - 2)\sigma^2$, $p > 2$, (ii) $c(S)$ is non-decreasing, and (iii) the expectations of $c(S)^2/S$, $c(S)/S$, and $c'(S)$ exist, then Eq. (2) holds.

**Proof.** Write $X = [X_1, \ldots, X_p] \in G$ and $\mu = [\mu_1, \ldots, \mu_p]$ where $X_i, \mu_i \in \text{SO}(2)$. Recall that $S = d^2(X, e) = \sum_{i=1}^{p} d^2(X_i, e) = \sum_{i=1}^{p} \|\log X_i\|^2$. Write $b(S) = c(S)/S$. By definition,

$$R(\hat{\mu}_{\text{MLE}}, \mu) = Ed^2(X, \mu) = \sum_{i=1}^{p} Ed^2(X_i, \mu_i) = \sum_{i=1}^{p} E\|\log \mu_i^{-1}X_i\|^2$$

14
and

\[
R(\hat{\mu}^{JS}, \mu) = \sum_{i=1}^{p} E d^2 (X_i \exp(-b(S) \log X_i), \mu_i)
\]

\[
= \sum_{i=1}^{p} E \| \log \mu_i^{-1} X_i - b(S) \log X_i \|^2
\]

\[
= \sum_{i=1}^{p} E \| \log \mu_i^{-1} X_i \|^2 + Eb(S)^2 \| \log X_i \|^2
\]

\[
- 2 \sum_{i=1}^{p} Eb(S) \langle \log X_i, E \rangle \langle \log \mu_i^{-1} X_i, E \rangle
\]

\[
= R(\hat{\mu}^{MLE}, \mu) + E \left[ \frac{c(S)^2}{S} \right] - 2 \sum_{i=1}^{p} \sigma^2 E \mathcal{L}_E^{(i)} b(S) \langle \log X_i, E \rangle
\]

where the last equality is from Lemma 1. Note that

\[
\mathcal{L}_E^{(i)} b(S) \langle \log X_i, E \rangle = c'(S) S^{-1} \langle \log X_i, E_1 \rangle \mathcal{L}_E^{(i)} S + c(S) S^{-1} (\mathcal{L}_E^{(i)} \log X_i, E_1)
\]

\[
- c(S) S^{-2} \langle \log X_i, E_1 \rangle \mathcal{L}_E^{(i)} S
\]

\[
= (c'(S) S^{-1} - c(S) S^{-2}) \langle \log X_i, E_1 \rangle \mathcal{L}_E^{(i)} S
\]

\[
+ c(S) S^{-1} (\mathcal{L}_E^{(i)} \log X_i, E_1)
\]

and \( \mathcal{L}_E \log X_i = \frac{d}{dt} \log(X_i \exp(tE_1))|_{t=0} = E_1 \) and \( \mathcal{L}_E^{(i)} S = 2 \langle \log X_i, E_1 \rangle \). Thus

\[
R(\hat{\mu}^{JS}, \mu) - R(\hat{\mu}^{MLE}, \mu)
\]

\[
= E \left[ \frac{c(S)^2}{S} \right] - 2 \sigma^2 \sum_{i=1}^{p} E \mathcal{L}_E^{(i)} b(S) \langle \log X_i, E \rangle
\]

\[
= E \left[ \frac{c(S)^2}{S} \right] - 2 \sigma^2 \sum_{i=1}^{p} E [2(c'(S) S^{-1} - c(S) S^{-2}) d^2(X_i, e) + c(S) S^{-1}]
\]

\[
= E \left[ \frac{c(S)^2}{S} \right] - 2(p - 2) \sigma^2 E c(S) S^{-1} - 4 \sigma^2 E c'(S)
\]

\[
= E \left[ \frac{c(S)^2 - 2 \sigma^2(p - 2)c(S)}{S} \right] - 4 \sigma^2 E c'(S)
\]

which is negative by assumptions (i), (ii), and (iii). This concludes the proof. \(\square\)

Theorem 2 provides a large class of shrinkage estimators. Two examples of \(c(S)\) are given in the following corollaries. The proofs are straightforward and omitted here.
Corollary 1  Let $c(S) = \alpha S^\beta$. If $0 < \alpha < \frac{2(p-2)\sigma^2}{p^22^\beta}$ and $\beta \geq 1$, then Eq. (2) holds. In this case, the difference between the risks is given by

$$\alpha^2 ES^{2\beta-1} - 2\alpha\sigma^2(p - 2 + 2\beta) ES^{\beta-1}.$$

Corollary 2  Let $c(S) = \exp(\alpha S + \beta)$. If $0 < \alpha < \frac{\log 2(p-2)\sigma^2 - \beta}{p\sigma^2}$ and $\beta < \log 2(p-2)\sigma^2$, then Eq. (2) holds.

As we can see, the proof of Theorem 2 doesn’t deviate much from the case in Euclidean space. In particular, the proof relies only on Lemma 1 as in the case of $\mathbb{R}^p$. However, due to the compactness, the behavior of proposed shrinkage estimator on $(SO(2))^p$ is quite different from the Euclidean case. This will be demonstrated and discussed in detail in Section 5. Combining Theorem 2 and the result in Euclidean space, we have the following theorem for general abelian Lie groups.

**Theorem 3**  Let $G$ be a $p$-dimensional connected abelian Lie group, i.e. $G \cong \mathbb{R}^k \times (SO(2))^{p-k}$, and $X \sim \mathcal{N}(\mu, \sigma^2)$ where $\sigma > 0$ is known and $\mu \in G$. If (i) $0 < c(\cdot) < 2(p-2)\sigma^2$, $p > 2$, (ii) $c(S)$ is non-decreasing, and (iii) the expectations of $c(S)^2/S$, $c(S)/S$, and $c'(S)$ exist, then Eq. (2) holds.

Theorem 3 completes the generalization of the James-Stein estimator to abelian Lie groups. We now turn to the more complicated case: compact Lie groups.

### 3.3 Shrinkage Estimation on Compact Lie Groups

Now we tackle the case of compact Lie groups. Due to the non-commutativity, inevitably the result becomes more complicated. Unlike the abelian Lie groups which can always be written as a direct product of one-dimensional abelian Lie groups $\mathbb{R}$ or $SO(2)$, the factorization of compact Lie groups is more involved (see for instance Sepanski (2007, Theorem 5.22)). Hence, instead of estimating the FM on a compact Lie group, we consider the following simultaneous estimation problem. Let $G$ be an $m$-dimensional compact Lie group. Given $X_i \overset{\text{ind}}{\sim} \mathcal{N}(\mu_i, \sigma^2)$, $i = 1, \ldots, p$, where $\sigma^2 > 0$ is known and $\mu_i \in G$, we would like to estimate $\mu = (\mu_1, \ldots, \mu_p) \in G^p$, where $G^p$ is the direct product of $p$ copies of $G$. Denote $X = (X_1, \ldots, X_p) \in G^p$. The loss
function for an estimator $\hat{\mu} = (\hat{\mu}_1, \ldots, \hat{\mu}_p)$ is $L(\hat{\mu}, \mu) = \sum_{i=1}^p d^2(\hat{\mu}_i, \mu_i)$ and the risk function is the expectation of the loss function $R(\hat{\mu}, \mu) = EL(\hat{\mu}(X), \mu) = \sum_{i=1}^p Ed^2(\hat{\mu}_i(X), \mu_i)$.

From Proposition 2, the MLE for $\mu$ would be $\hat{\mu}_{MLE}^{} = X$. Motivated by the James-Stein estimator, we consider a shrinkage estimator $\hat{\mu}_{JS} = (\hat{\mu}_{JS1}, \ldots, \hat{\mu}_{JSp})$ where $\hat{\mu}_{JSi} = X_i \exp(- \frac{c(S)}{S} \log X_i)$ and $S = \sum_{i=1}^p d^2(X_i, e)$. Note that $c(S) = \frac{c(S)}{S} \log X_i$’s are bounded and differentiable. It’s easy to see that this class of estimator includes the MLE by setting $h_{ij}(X) \equiv 0$.

The next theorem shows that a subclass of these estimators asymptotically dominates the MLE in the sense that the risk function is uniformly smaller.

**Theorem 4** Let $X_i \overset{ind}{\sim} \mathcal{N}(\mu_i, \sigma^2)$ where $\sigma > 0$ is known, $i = 1, \ldots, p$. Suppose that $\| [x,y] \| < B\|x\|\|y\|$ for some $0 < B < 2$, $x, y \in \mathfrak{g}$ and $d(x, y) \leq M \leq \pi$ for $x, y \in G$. Let $\hat{\mu}_{JS}^i = X_i \exp(- \frac{c(S)}{S} \log X_i) = X_i \exp(- \sum_{j=1}^m h_{ij}(X)E_j)$. If

(i) $0 < c(\cdot) < 2\sigma^2 \left(2 + \frac{BM}{2} \left(1 - \cot \frac{BM}{2}\right)\right)^2 (\sum_{i=1}^p \text{tr} \log X_i - 2)$,

(ii) $\sum_{i=1}^p \text{tr} \log X_i - 2 > 0$ almost surely,

(iii) $c(\cdot)$ is non-decreasing, and

(iv) the expectations of $c(S)^2/S$, $c(S)/S$, and $c'(S)$ exist,

then,

$$R(\hat{\mu}_{JS}, \mu) - R(\hat{\mu}_{MLE}, \mu) \leq 0$$

for all $\mu \in G^p$.

Note that the assumption of $d(x, y) \leq M \leq \pi$ for $x, y \in G$ might seem restrictive at first sight. However, for compact Lie groups, this can always be achieved by scaling the Riemannian metric. Before presenting the proof of Theorem 4, we need the following lemma.

**Lemma 2** Let $G$ be a compact Lie group endowed with a bi-invariant Riemannian metric and its Lie algebra be $\mathfrak{g}$. Suppose $\| [x,y] \| \leq B\|x\|\|y\|$ for some $B > 0$, $x, y \in \mathfrak{g}$. Then $\|T_x\|_{op} \leq 2 + \frac{B\|x\|}{2} \left(1 - \cot \frac{B\|x\|}{2}\right)$. 

17
Proof. Since \( \|x, y\| \leq B \|x\| \|y\| \), \( \|\text{ad}_x^k(y)\| \leq B^k \|x\|^k \|y\| \). Then for \( x, y \in \mathfrak{g} \)

\[
\|T_x(y)\| \leq \sum_{k=0}^{\infty} \frac{|B_k^+|}{k!} \|\text{ad}_x^k(y)\| \leq \left( \sum_{k=0}^{\infty} \frac{|B_k^+|}{k!} (B \|x\|^k) \right) \|y\|.
\]

Since \( B_0^+ = 1 \), \( B_1^+ = \frac{1}{2} \), \( B_k^+ = 0 \) for odd \( k > 1 \), and \( B_k^+ < 0 \) when \( k \) is divisible by 4, we have

\[
\sum_{k=0}^{\infty} \frac{|B_k^+|}{k!} (B \|x\|^k)^k = 1 + \frac{1}{2} B \|x\| + \sum_{k=2}^{\infty} \frac{|B_k^+|}{k!} (B \|x\|^k)^k
\]

\[
= 1 + \frac{1}{2} B \|x\| + \sum_{k=2}^{\infty} \frac{|B_k^+|}{k!} (B \|x\|^k)^k i^{k-2}
\]

\[
= 1 + \frac{1}{2} B \|x\| - \left( \frac{B \|x\| i}{1 - \exp(-B \|x\| i)} - 1 - \frac{1}{2} B \|x\| i \right)
\]

\[
= 2 + \frac{B \|x\|}{2} \left( 1 - \cot \frac{B \|x\|}{2} \right)
\]

which concludes the proof. \( \square \)

Proof of Theorem 4. By definition,

\[
R(\hat{\mu}^{\text{MLE}}, \mu) = \sum_{i=1}^{p} E d^2(X_i, \mu_i) = \sum_{i=1}^{p} E \| \log \mu_i^{-1} X_i \|^2
\]

and

\[
R(\hat{\mu}^S, \mu) = \sum_{i=1}^{p} E d^2(X_i \exp(-\sum_{j=1}^{m} h_{ij}(X) E_j), \mu_i)
\]

\[
= \sum_{i=1}^{p} E \| \log \mu_i^{-1} X_i \exp \left( - \sum_{j=1}^{m} h_{ij}(X) E_j \right) \|^2
\]

\[
= \sum_{i=1}^{p} E \| \log \mu_i^{-1} X_i - \sum_{j=1}^{m} h_{ij}(X) T_{\log \mu_i^{-1} X_i}(E_j) + O \left( \frac{c(S)^2}{S^2} (\log X_i)^2 \right) \|^2
\]

\[
= \sum_{i=1}^{m} E \| \log \mu_i^{-1} X_i \|^2 + \sum_{j=1}^{m} E h_{ij}(X)^2 \| T_{\log \mu_i^{-1} X_i}(E_j) \|^2
\]

\[
- 2 \sum_{j=1}^{m} E h_{ij}(X) (\log \mu_i^{-1} X_i, T_{\log \mu_i^{-1} X_i}(E_j)) + O \left( E \frac{c(S)^2}{S^2} \| \log X_i \|^2 \right)
\]

\[
= \sum_{i=1}^{p} E \| \log \mu_i^{-1} X_i \|^2 + E \| T_{\log \mu_i^{-1} X_i} \left( \frac{c(S)}{S} \log X_i \right) \|^2
\]

\[
- 2\sigma^2 \sum_{j=1}^{m} E \mathcal{L}^{(i)}_{E_j} h_{ij}(X) + O \left( E \frac{c(S)^2}{S^2} \| \log X_i \|^2 \right)
\]
where the last equality is from Lemma 1. By Lemma 2 and $B\|\log \mu_i^{-1}X_i\| = Bd(\mu_i, X_i) \leq 2\pi,$

$$E\left\| T_{\log \mu_i^{-1}X_i} \left( \frac{c(S)}{S} \log X_i \right) \right\|^2 \leq E \left[ \frac{c(S)}{S} \| \log X_i \| \left( 2 + \frac{B\|\log \mu_i^{-1}X_i\|}{2} \left( 1 - \cot \frac{B\|\log \mu_i^{-1}X_i\|}{2} \right) \right) \right]^2 \leq \left( 2 + \frac{BM}{2} \left( 1 - \cot \frac{BM}{2} \right) \right)^2 E \left[ \frac{c(S)^2}{S^2} \| \log X_i \|^2 \right].$$

From the proof of Theorem 2, we know that

$$\mathcal{L}_{E_j}^{(i)} \frac{c(S)}{S} \langle \log X_i, E \rangle = c(S)S^{-1} \langle \mathcal{L}_{E_j} \log X_i, E_j \rangle$$

$$+ 2(c'(S)S^{-1} - c(S)S^{-2})\langle \log X_i, T_{\log X_i} \log X_i \rangle \langle \log X_i, T_{\log X_i}(E_j) \rangle.$$ 

Thus by the linearity of $T_{\log X_i},$ we have

$$\sum_{j=1}^{m} \mathcal{L}_{E_j}^{(i)} h_{ij}(X) = c(S)S^{-1} \sum_{j=1}^{m} \langle \mathcal{L}_{E_j} \log X_i, E_j \rangle$$

$$+ 2(c'(S)S^{-1} - c(S)S^{-2})\langle \log X_i, T_{\log X_i} \log X_i \rangle$$

$$= c(S)S^{-1} \sum_{j=1}^{m} \langle T_{\log X_i} (E_j), E_j \rangle$$

$$+ 2(c'(S)S^{-1} - c(S)S^{-2})d^2(X_i, e)$$

$$= c(S)S^{-1} \text{tr} T_{\log X_i} + 2(c'(S)S^{-1} - c(S)S^{-2})d^2(X_i, e).$$

The second equality follows from the fact that $T_x(x) = x$ and $\mathcal{L}_{E_j} \log X_i = \frac{d}{dt} \log(X_i \exp(TE_j))|_{t=0} = T_{\log X_i}(E_j).$ Thus

$$R(\hat{\mu}^S, \mu) - R(\hat{\mu}^{MLE}, \mu) \leq \sum_{i=1}^{p} \left( 2 + \frac{BM}{2} \left( 1 - \cot \frac{BM}{2} \right) \right)^2 E \left[ \frac{c(S)^2}{S^2} \| \log X_i \|^2 \right] - 2\sigma^2 c(S)S^{-1} \text{tr} T_{\log X_i}$$

$$- 4\sigma^2 (c'(S)S^{-1} - c(S)S^{-2})d^2(X_i, e) + O \left( E \frac{c(S)^2}{S^2} \| \log X_i \|^2 \right)$$

$$= E \left[ \frac{2 + \frac{BM}{2} \left( 1 - \cot \frac{BM}{2} \right) }{S} \right] c(S)^2 \left[ 2 - 2\sigma^2(\sum_{i=1}^{p} \text{tr} T_{\log X_i} - 2)c(S) \right]$$

$$- 4\sigma^2 Ec'(S) + O \left( E \frac{c(S)^2}{S^2} \| \log X_i \|^2 \right)$$

which is negative by the assumptions. This concludes the proof.
We end this section with two examples of \(c(S)\) in the following corollaries.

**Corollary 3** Let \(c(S) = \alpha S^\beta\). If \(0 < \alpha < \frac{m}{p^2 + m}\pi^2\) and \(\beta \geq 1\) where \(m = 2\sigma^2 \left(2 + \frac{BM}{2}(1 - \cot \frac{BM}{2})\right)^2 \left(\sum_{i=1}^{p} \text{tr} \log X_i - 2\right)\), then Eq. (2) holds.

**Corollary 4** Let \(c(S) = \exp(\alpha S + \beta)\). If \(0 < \alpha < \frac{\log m - \beta}{p^2 + \beta^2}\) and \(\beta < \log m\) where \(m = 2\sigma^2 \left(2 + \frac{BM}{2}(1 - \cot \frac{BM}{2})\right)^2 \left(\sum_{i=1}^{p} \text{tr} \log X_i - 2\right)\), then Eq. (2) holds.

### 4 Examples

In this section, we apply the results from the previous section to the rotation group in \(\mathbb{R}^3\). Examples of abelian Lie groups were already presented in Section 3.2.

The Lie group \(\text{SO}(3)\) is a compact 3-dimensional Lie group containing all rotation in \(\mathbb{R}^3\). It is ubiquitous in modelling the pose of an object in the 3-dimensional space (see, for example, Grenander et al. (1998) and Srivastava et al. (2002)). The Lie algebra of \(\text{SO}(3)\) is \(\mathfrak{so}(3)\) which consists of all the \(3 \times 3\) skew-symmetric matrices and we fix an orthonormal basis \(\{E_i\}_{i=1}^{3}\) for \(\mathfrak{so}(3)\) where,

\[
E_1 = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & -1 \\ 0 & 1 & 0 \end{bmatrix}, \quad E_2 = \begin{bmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ -1 & 0 & 0 \end{bmatrix}, \quad E_3 = \begin{bmatrix} 0 & -1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}.
\]

The exponential map and the log map are given by the Rodrigues’ formula \(\exp(V) = I + \frac{\sin \|V\|}{\|V\|} V + \frac{1 - \cos \|V\|}{\|V\|^2} V^2\) for \(V \in \mathfrak{so}(3)\) and \(\log R = \frac{\theta}{2\sin \theta} (R - R^T)\) where \(\theta = \cos^{-1} \left(\frac{1}{2}(\text{tr}(R) - 1)\right)\) for \(R \in \text{SO}(3)\). Therefore \(\|\log R\| = \sqrt{-\text{tr}((\log R)^2)/2} = \theta \leq \pi\).

In this example, we consider the exponential coordinates of \(\text{SO}(3)\) defined as follows. Let \(\omega = [\omega_1, \omega_2, \omega_3]^T \in \mathbb{R}^3\) and \(\omega_\times = \sum_{i=1}^{3} \omega_i E_i \in \mathfrak{so}(3)\). Then \(\|\omega_\times\|^2 = \|\omega\|^2 = \omega_1^2 + \omega_2^2 + \omega_3^2\) and \(\text{ad}_{\omega_\times} = \omega_\times\) (i.e. \(\text{ad}_{\omega_\times}(\tilde{\omega}) = [\omega_\times, \tilde{\omega}] = (\omega_\times \tilde{\omega})_\times\) for \(\tilde{\omega} \in \mathbb{R}^3\) and \(\tilde{\omega}_\times \in \mathfrak{so}(3)\)). Note that all elements of \(\Omega \in \text{SO}(3)\), except for a set of measure 0, can be parametrized by a \(\omega \in B_\pi(0) \subset \mathbb{R}^3\) where \(B_r(y) = \{x \in \mathbb{R}^3 : \|x - y\| < r\}\). Thus we assume that \(\omega \in B_\pi(0)\) in the rest of this work. Under this coordinate system, Engø (2001) provided a closed form expression for the BCH formula

\[
\log(\exp(u_\times) \exp(v_\times)) = \alpha u_\times + \beta v_\times + \gamma [u_\times, v_\times]
\]
where
\[ \alpha = \frac{\sin^{-1}(d) \ a}{d \ ||u||}, \quad \beta = \frac{\sin^{-1}(d) \ b}{d \ ||v||}, \quad \gamma = \frac{\sin^{-1}(d) \ c}{d \ ||u|| \ ||v||} \]

and
\[ a = \sin ||u|| \cos^2(||v||/2) - \sin ||v|| \sin^2(||u||/2) \ \frac{u^Tv}{||u|| \ ||v||} \]
\[ b = \sin ||v|| \cos^2(||u||/2) - \sin ||u|| \sin^2(||v||/2) \ \frac{u^Tv}{||u|| \ ||v||} \]
\[ c = \frac{1}{2} \sin ||u|| \sin ||v|| - 2 \sin^2(||u||/2) \sin^2(||v||/2) \ \frac{u^Tv}{||u|| \ ||v||} \]
\[ d = \sqrt{a^2 + b^2 + 2ab \ \frac{u^Tv}{||u|| \ ||v||} + c^2 \left(1 - \frac{(u^Tv)^2}{||u||^2 \ ||v||^2}\right)} \]

for nonzero \( u, v \in B_\pi(0) \). Thus the distance is \( d(\exp(-u \times), \exp(v \times)) = ||\log(\exp(u \times) \exp(v \times))|| = \sin^{-1}(d) \). The density function of the normal distribution when \( \mu = I \) can be simplified to
\[ f(x; I, \sigma^2) = C(\sigma) \exp \left( -\frac{d^2(x, I)}{2\sigma^2} \right) \]
\[ = C(\sigma) \frac{2(1 - \cos ||u||)}{||u||^2} \exp \left( -\frac{||u||^2}{2\sigma^2} \right) \]
\[ = f(u; 0, \sigma^2) \]

where \( u \in B_\pi(0) \) is such that \( x = \exp(u \times) \), and the Jacobian of the exponential coordinates on SO(3) can be found in Chirikjian (2012, Ch. 10.6.6).

**Sampling** \( X \sim \mathcal{N}(\mu, \sigma^2) \) By the left-invariance of the density function, generating a random sample \( X \sim \mathcal{N}(\mu, \sigma^2) \) amounts to generating a random sample from \( U \sim f(u; 0, \sigma^2) \) and letting \( X = \mu \exp(U \times) \). The sampling from \( f(u; 0, \sigma^2) \) can be further simplified as follows. Let \( u = (r, \theta, \phi) \) be the spherical coordinate where \( r = ||u|| \in [0, \pi), \theta \in [0, \pi] \), and \( \phi \in [0, 2\pi) \). Therefore
\[ f(r, \theta, \phi; 0, \sigma^2) = C(\sigma) 2(1 - \cos r) \exp \left( -\frac{r^2}{2\sigma^2} \right) \sin \theta, \]
that is, we generate \( r, \theta, \) and \( \phi \) independently from \( f_R(r) \propto (1 - \cos r) \exp(-\frac{r^2}{2\sigma^2}) \mathbb{I}_{[0, \pi]}, \)
\( f_\theta(\theta) \propto \sin \theta \mathbb{I}_{[0, \pi]}, \) and \( f_\phi(\phi) \propto \mathbb{I}_{[0, 2\pi]} \). Standard Metropolis-Hastings algorithms can be applied directly for sampling.
For $G = \text{SO}(3)$, Ge (2014, Lemma 2.5) showed that $\| [x,y] \| \leq \frac{1}{2} \| x \| \| y \|$ for $x, y \in \mathfrak{so}(3)$. Thus we set $B = \frac{1}{2}$ in this case. The operator $\mathcal{T}_{\omega_x}$ is given by

$$
\mathcal{T}_{\omega_x} = \sum_{k=0}^{\infty} \frac{B_k^+}{k!} \text{ad}_{\omega_x}^k = \sum_{k=0}^{\infty} \frac{B_k^+}{k!} \omega_x^k
$$

$$
= I + \frac{1}{2} \omega_x + \left( \sum_{k=2}^{\infty} \frac{B_k^+}{k!} (\| \omega \| i)^{k-2} \right) \omega_x^2
$$

$$
= I + \frac{1}{2} \omega_x + \left( \frac{\| \omega \| i}{1 - \exp(-\| \omega \| i)} - 1 - \frac{1}{2} \| \omega \| i \right) \frac{\omega_x^2}{-\| \omega \|^2}
$$

$$
= I + \frac{1}{2} \omega_x + \left( \frac{\| \omega \| \sin \| \omega \|}{2(1 - \cos \| \omega \|)} - 1 \right) \frac{\omega_x^2}{-\| \omega \|^2}
$$

where the third equality follows from the fact that $\omega_x^3 = -\| \omega \|^2 \omega_x$ and $B_k^+ = 0$ for odd $k$. Since $\text{tr} \omega_x = 0$ and $\text{tr} \omega_x^2 = -2\| \omega \|^2$, we have

$$
\text{tr} \mathcal{T}_{\omega_x} = 1 + \frac{\| \omega \| \sin \| \omega \|}{1 - \cos \| \omega \|} = 1 + \| \omega \| \cot \| \omega \| \frac{1}{2}.
$$

Note that for $X \sim \mathcal{N}(\mu, \sigma^2)$, $d(X, e) = \| \log X \| < \pi$ almost surely. Therefore $\sum_{i=1}^{p} \text{tr} \mathcal{T}_{\log X_i} - 2 = (p - 2) + \sum_{i=1}^{p} \| \log X_i \| \cot \frac{\| \log X_i \|}{2} > 0$ almost surely if $p > 2$. Hence Theorem 4 is applicable.

5 Experiments

In this section, we present simulation studies (in Section 5.1) as well as an application to state estimation (in Section 5.2) on the Lie groups $\text{SO}(2)$ and $\text{SO}(3)$ to demonstrate that the proposed shrinkage estimator dominates the MLE asymptotically. State estimation in the context here refers to the estimation of the location and orientation of an object in motion from noisy measurements.

5.1 Simulation Studies

The setup for the simulation studies is as follows: First we generate $\mu_i \overset{\text{iid}}{\sim} \mathcal{N}(I, \tau^2)$ and $X_i \sim \mathcal{N}(\mu_i, \sigma^2)$ for $i = 1, \ldots, p$. Then, we compute the MLE and the shrinkage estimates and the loss for these estimates. We repeat the above procedure for $m = 10,000$ times and
obtain the estimated risk for each estimators by averaging their corresponding loss over the repetitions. We then compare their performance for different values of $\tau$, $\sigma$, and $p$.

For $G = \text{SO}(2)$, we compare the four estimators from Corollary 1 and 2

\[
\hat{\mu}_{\text{MLE}}^i = X_i \\
\hat{\mu}_{\text{Linear}}^i = X_i \exp \left( -\frac{(p - 2)\sigma^2}{p\pi^2} \log X_i \right) \\
\hat{\mu}_{\text{Quad}}^i = X_i \exp \left( -\frac{(p - 2)\sigma^2}{p^2\pi^4} S \log X_i \right) \\
\hat{\mu}_{\text{Exp}}^i = X_i \exp \left( -S^{-1} \exp \left( \frac{\log 2(p - 2)\sigma^2}{2p\pi^2} S \right) \log X_i \right)
\]

where $S = \sum_{i=1}^{p} d^2(X_i, I)$. The results are shown in Figure 1. In this case, the risk of MLE can be computed analytically

\[
R(\hat{\mu}_{\text{MLE}}, \mu) = \sum_{i=1}^{p} d^2(X_i, \mu_i) = \sigma^2 - \frac{2\pi\sigma\phi(\pi/\sigma)}{\Phi(\pi/\sigma) - \Phi(-\pi/\sigma)}
\]

where $\phi(x)$ and $\Phi(x)$ are the pdf and cumulative distribution function (cdf) of the standard normal distribution respectively. Note that in Figure 1, we divide all the risks by $p$ for better visual comparison.

</tbody>
</table>

It is evident from the Figure 1 that all the three shrinkage estimators outperform the MLE although each of them behave differently. The improvement of linear and quadratic shrinkage estimators does not depend on $p$ while the exponential shrinkage estimator improves less significantly for larger $p$. The improvement is also more significant when $\tau$ is small, which is concomitant with our expectation since, for small $\tau$, the $\mu_i$’s are clustered and shrinkage is beneficial. On the other hand, for large $\sigma$, the $X_i$ is not an accurate estimate of $\mu_i$ which can thus be improved via shrinkage. For numerical comparison, we compute the percentage reduction in average loss (PRIAL) for each estimator defined by $\frac{\hat{R}(\hat{\mu}^{MLE}, \mu) - \hat{R}(\hat{\mu}, \mu)}{\hat{R}(\hat{\mu}^{MLE}, \mu)} \times 100\%$ reported in Table 1. Note that we averaged the PRIAL over $p$ to make the table more compact. This table indeed confirms the observations from Figure 1.

For $G = SO(3)$, we compare the following estimators from Corollary 3 and 4

\[
\begin{align*}
\hat{\mu}_i^{MLE} &= X_i \\
\hat{\mu}_i^{Linear} &= X_i \exp \left( - \frac{m}{2p\pi^2} \log X_i \right) \\
\hat{\mu}_i^{Quad} &= X_i \exp \left( - \frac{m}{2p^2\pi^4} S \log X_i \right) \\
\hat{\mu}_i^{Exp} &= X_i \exp \left( - S^{-1} \exp \left( \frac{\log m}{2p\pi^2} S \right) \log X_i \right)
\end{align*}
\]
where \( S = \sum_{i=1}^{p} d^2(X_i, I) \) and

\[
m = 2\sigma^2 \left( 2 + \frac{BM}{2} \left( 1 - \cot \frac{BM}{2} \right) \right)^2 \left( \sum_{i=1}^{p} \text{tr} \log X_i - 2 \right)
\]

\[
= 2\sigma^2 \left( 2 + \frac{\pi}{4} \left( 1 - \cot \frac{\pi}{4} \right) \right)^2 \left( p - 2 + \sum_{i=1}^{p} \| \log X_i \| \cot \frac{\| \log X_i \|}{2} \right)
\]

\[
= 8\sigma^2 \left( p - 2 + \sum_{i=1}^{p} \| \log X_i \| \cot \frac{\| \log X_i \|}{2} \right).
\]

These comparison results are depicted in Figure 2 and summarized in Table 2. As evident, the behavior of the proposed shrinkage estimators are similar to the case of \text{SO}(2).

### 5.2 Multi-Object Tracking

We now present an application of shrinkage estimation to multiple robot/object tracking. Recently, the well-known Unscented Kalman Filter (UKF) was extended to cope with data in Lie groups, called \text{UKFLG} (Brossard et al., 2017; Barrau and Bonnabel, 2018). In Brossard et al. (2017), the observations/measurements are assumed to follow the model:

\[
y = h(X) + v
\]
Table 2: The PRIAL for the synthetic experiment in SO(3). Note that the PRIAL is averaged over $p$.

where $X \in G$ is the underlying state variable taking values in a Lie group $G$, $h : G \to \mathbb{R}^k$ is the observation function, and $v \sim N(\bar{v}, R)$ is the Gaussian random noise in $\mathbb{R}^k$. For example, in 2D robot localization, the observation is the location of the monitored robot, the underlying state variable is assumed to be an element in SE(2), i.e.

$$X = \begin{bmatrix} A & b \\ 0 & 1 \end{bmatrix}$$

and the observation function is $h(X) = b \in \mathbb{R}^2$. At time $t$, the state propagation from time $t - 1$ is given by $X_t = X_{t-1} \exp(\omega_t)$ where $\omega_t$ taking its values in the Lie algebra, $\mathfrak{g}$, of $G$, contains the parameters characterizing the propagation. In the 2D robot localization example, $V_t$ is the velocity (angular velocity) measured at time $t$. The goal is to estimate $X_{t+1}$ given $X_t$, $\omega_{t+1}$ and $y_{t+1}$. In the 2D robot localization example, with the estimated $X_{t+1}$, we can estimate the true location of the robot since the observed location $y_{t+1}$ is contaminated by noise. The algorithm to solve this problem is omitted here and we refer the reader to Brossard et al. (2017). Their algorithm however is designed to localize a single robot. When there are multiple robots to be localized, one can apply the UKFLG algorithm to each robot independently. As seen from the synthetic data experiments presented in Section 5.1, when simultaneously estimating multiple parameters, shrinking the original estimates proves to be beneficial. Hence, in this work, we propose to shrink the UKFLG estimates to obtain more accurate results.

In this case the state space SE(2) is neither compact nor abelian. In order to apply the proposed shrinkage estimation, we consider a slightly different space $\text{SO}(2) \times \mathbb{R}^2$. Note that
SE(2) and SO(2) × R² are diffeomorphic as differentiable manifolds but not isomorphic as Lie groups since SE(2) = SO(2) ⋊ R² where ⋊ is the semidirect product. Hence, we can apply the results in Section 3.2 to derive shrinkage estimators.

Figure 3: Two example trajectories; Solid lines represent the ground truth and dashed lines represent the estimates.

In this experiment, we generated T = 10 independent trajectories (see Figure 3 for example) with n = 20 observations from each trajectory, ground truth states \( \{X_{ij}^n\}_{i=1}^T \), and noise variance \( \sigma^2 \). Then, we applied UKFLG to each trajectory independently and obtained the estimated states \( \{\hat{X}_{ij}^n\}_{i=1}^T \). For each \( i = 1, \ldots, n \), the shrinkage estimates are computed using \( \{X_{ij}\}_{j=1}^T \). The improvement of the shrinkage estimators is measured by the PRIAL. With 10,000 Monte Carlo simulations, the mean square errors (MSE) and PRIAL values for different \( \sigma^2 \) are summarized in Table 3. As evident from these results, it is clear that the shrinkage estimator dominates the UKFLG in localization of multiple robots.

6 Conclusion

In this work, we generalized Stein’s characterization of normal distributions from \( \mathbb{R}^n \) to connected Lie groups, specifically the compact and abelian Lie groups. Based on this result, we proposed a class of shrinkage estimators for the FM of normal distribution on the aforementioned Lie groups and proved that this class of shrinkage estimators dominates the MLE, i.e. having smaller mean squared error than the MLE. Finally, we presented simulation
Table 3: The PRIAL and the MSE for multiple-robot localization.

studies to demonstrate the superior performance of the proposed shrinkage estimators over the MLE in estimating the FM of the normal distribution defined on the aforementioned Lie groups. For applications, we considered the problem of multiple-object tracking and applied the shrinkage estimator in conjunction with the unscented Kalman filter on Lie Groups (UKFLG) algorithm yielding much improved object localization estimates over the UKFLG when used in isolation.
