(ACHIRAL) LEFSCHETZ FIBRATION EMBEDDINGS OF 4-MANIFOLDS

SUHAS PANDIT AND SELVAKUMAR A

Abstract. In this paper, we prove Lefschetz fibration embeddings of achiral as well as simplified broken (achiral) Lefschetz fibrations of compact, connected, orientable 4–manifolds over $D^2$ into the trivial Lefschetz fibration of $\mathbb{CP}^2 \times D^2$ over $D^2$. These results can be easily extended to achiral as well as simplified broken (achiral) Lefschetz fibrations over $\mathbb{CP}^1$. From this, it follows that every closed, connected, orientable 4–manifold admits a smooth (simplified broken) Lefschetz fibration embedding in $\mathbb{CP}^2 \times \mathbb{CP}^1$. We provide a huge collection of bordered Lefschetz fibration which admit bordered Lefschetz fibration embeddings into a trivial Lefschetz fibration $\tilde{\pi}: D^4 \times D^2 \to D^2$. We also show that every closed, connected, orientable 4–manifold $X$ admits a smooth embedding into $S^4 \times S^2$ as well as into $S^4 \times S^2$. From this, we get another proof of a theorem of Hirsch which states that every closed, connected, orientable 4–manifold smoothly embeds in $\mathbb{R}^7$. We also discuss Lefschetz fibration embedding of non-orientable 4–manifolds $X$, where $X$ does not admit 3– and 4–handles in the handle decomposition, into the trivial Lefschetz fibration of $\mathbb{CP}^2 \times D^2$ over $D^2$.

1. INTRODUCTION

In this note, we work with Lefschetz fibration $\pi: X^4 \to D^2$, where $X^4$ is a compact, connected, orientable 4–manifold with non-empty boundary. We shall show that given a Lefschetz fibration $\pi: X^4 \to D^2$, it admits a Lefschetz fibration embedding into a trivial Lefschetz fibration $\mathbb{CP}^2 \times D^2$ over $D^2$, see Section 3, Theorem 6.

In Section 4, we show that given an achiral Lefschetz fibration $\pi: X \to D^2$ on a 4–manifold $X$ with regular fiber, a closed, connected, orientable surface $\Sigma_g$ of genus $g \geq 1$ such that the vanishing cycle corresponding to each achiral singularity is a non-separating simple closed curve on $\Sigma_g$, then there exists a Lefschetz fibration embedding of $X$ into a trivial Lefschetz fibration $\tilde{\pi}: \mathbb{CP}^2 \times D^2 \to D^2$, see Theorem 13.

Also, we show that given an achiral Lefschetz fibration $\pi: X \to D^2$ on a 4–manifold $X$ with regular fiber $a$ closed, connected, orientable surface $\Sigma_g$ of genus $g \geq 1$, there exists a Lefschetz fibration embedding of $X$ into a trivial Lefschetz fibration $\tilde{\pi}: (\mathbb{CP}^2 \# \mathbb{CP}^2) \times D^2 \to D^2$ as well as into a trivial Lefschetz fibration $\tilde{\pi}: (\mathbb{CP}^2 \# \mathbb{CP}^2) \times D^2 \to D^2$, see Theorem 15.

We also discuss similar results for simplified broken achiral Lefschetz fibration and bordered Lefschetz fibrations, refer Sections 5 and 6, see Theorems 20 and 27.

Also, in Section 6, we provide a huge collection of bordered Lefschetz fibration which...
admit bordered Lefschetz fibration embeddings into a trivial Lefschetz fibration $\tilde{\pi}: D^4 \times D^2 \to D^2$, see Theorem 29 and 32.

Our results can be easily extended to the closed, connected, oriented 4–manifolds $X$ with Lefschetz fibration $\pi: X \to \mathbb{C}P^1$, see Subsection 4.1, Theorem 16. Moreover, if $\pi: X^4 \to \mathbb{C}P^1$ is a simplified broken achiral Lefschetz fibration, where $X$ is a closed connected orientable 4–manifold such that each regular fiber in the higher genus piece is a closed, connected, orientable genus $g > 2$ surface $\Sigma_g$ and if the vanishing cycle corresponding to each achiral singularity is non-separating on $\Sigma_g$, then there exists a Lefschetz fibration embedding of $\pi: X^4 \to \mathbb{C}P^1$ into a trivial Lefschetz fibration $\tilde{\pi}: \mathbb{C}P^2 \times \mathbb{C}P^1 \to \mathbb{C}P^1$, see Section 5, Theorem 23.

It is known that every closed, connected, oriented 4–manifold admits a simplified broken Lefschetz fibration over $\mathbb{C}P^1$. From this, it follows that every closed, connected, orientable 4–manifold admits a smooth embedding in $\mathbb{C}P^2 \times \mathbb{C}P^1$, see Section 5, Corollary 24.

We also show that every closed, connected, orientable 4-manifold $X$ admits a smooth embedding into $S^4 \times S^2$ as well as into $S^4 \times S^2$, see Section 5, Theorem 36. From this, we get another proof of a theorem of Hirsch which states that every closed, connected, orientable 4–manifold smoothly embeds in $\mathbb{R}^7$, see Corollary 37.

Finally in Section 7, we have Lefschetz fibration embedding results for non-orientable manifolds $X$ over $D^2$ such that the handle decomposition of $X$ does not admit 3– and 4–handles, see Theorems 39 and 40.

In [5], Ghanwat and Pancholi have proved that every closed, oriented smooth 4–manifold admits a smooth embedding in $\mathbb{C}P^3$.

2. Preliminaries

In this section, we will recall the necessary notions for this article.

2.1. Mapping class group.

**Definition 1.** (The mapping class group of a manifold) The mapping class group of a manifold $M$ is the group of isotopy classes of diffeomorphisms of $M$, where the group operation is induced by the composition of diffeomorphisms. When $M$ is an orientable manifold, we consider the diffeomorphisms and the isotopies preserving the orientation of $M$. In case if $M$ has non-empty boundary $\partial M$, we assume that all the diffeomorphisms and the isotopies are the identity in a collar neighborhood of the boundary. We will denote the mapping class group of $M$ by $\text{MCG}(M)$.

Lickorish in [12] proved that every element of the mapping class group of a closed orientable surface is a product of isotopy classes of the Dehn twists along the simple closed curves on the surface. Let us recall the definition of a Dehn twist.

**Definition 2.** (Dehn twist)

A Dehn twist along a circle $S^1 \times \{\frac{1}{2}\}$ in $S^1 \times [0, 3]$ is a diffeomorphism of $S^1 \times [0, 3]$ given by $(e^{i\theta}, t) \to (e^{i(\theta + 2\pi f(t))}, t)$, where $f: [0, 3] \to [0, 3]$ is a smooth function that is identically 0 on the interval $[0, 1]$, on the interval $[1, 2]$ it increases monotonically from 0 to 1 and $f$ is identically 1 on the interval $[2, 3]$. Note that the Dehn twist fixes a collar of both the boundary components of $S^1 \times [0, 3]$, see Figure 1. Hence, given an embedded circle $c$ in a surface $\Sigma$, we can define the Dehn twist of an annular neighborhood $N(c) = S^1 \times [0, 3]$ of $c = S^1 \times \{\frac{1}{2}\}$ in $\Sigma$ which is the identity when restricted to the boundary of this annular neighborhood. Clearly, we can extend this...
A Dehn twist along the centre curve \( c \) of an annulus.

The orientable closed surface of genus \( g \) with the Lickorish generating curves.

diffeomorphism by the identity in the complement of the annular neighborhood to produce a diffeomorphism of \( \Sigma \). This diffeomorphism is called a Dehn twist \( d_c \) along the embedded circle \( c \) in the surface \( \Sigma \).

Thus, the right (respectively left) handed Dehn twist \( d_c \) on \( \Sigma \) is given by removing an annular neighbourhood of \( c \) and regluing it after giving a full \( 2\pi \) twist to the right (respectively left). The right handed Dehn twist \( d_c \) is determined up to the isotopy class of \( c \) and is independent of the orientation on \( c \).

Lickorish [12], proved that the mapping class group of a closed orientable surface is generated by the Dehn twists along non-separating simple closed curves on the surface as shown in Figure 2. For a compact orientable surface with non-empty boundary the mapping class group is generated by the curves given in Figure 3. We call the curves shown in Figure 2 and 3 the Lickorish generating curves. In [10], Humphries provided a minimal set of generators for mapping class group of orientable surfaces.

Lickorish in [13], also showed that to generate the mapping class group of a non-orientable surface, the Dehn twists are not enough, in addition, we require homeomorphisms which are known as \( Y \)-homeomorphisms. Consider a Möbius band \( M_D \) with interior \( \bar{D} \) of a disc \( D \) removed. We attach a Möbius band \( M \) along \( \partial D \) to get a Klein bottle \( K \) with a hole, which we call a \( Y \)-space. Now, move \( M \) once along the core of \( M_D \) to get a homeomorphism called the \( Y \)-homeomorphism.
of \( K \) which fixes the boundary of \( K \). We can consider an embedding of \( K \) in a non-orientable surface \( N \) and extend this homeomorphism by the identity on \( N \setminus K \), to a \( Y \)-homeomorphism of \( N \) about \( K \).

Recall that a closed non-orientable surface is a connected sum of the real projective planes, \( \mathbb{R}P^2 \)‘s. The number of \( \mathbb{R}P^2 \)‘s occurring in the connected sum is called the \textit{genus} of the non-orientable surface.

In [8], Hirose showed that Szepietowski’s system of generators, given in [18], for the mapping class group of a non-orientable surface is a minimal generating set by Dehn twists and a \( Y \)-homeomorphism, see Figure 4.

2.2. \textbf{Lefschetz fibration}. Now, we discuss the notion of Lefschetz fibration.

\textbf{Definition 3.} (Lefschetz fibration on \( 2n \)-manifold) \textit{Let} \( X \) \textit{be a compact, connected, orientable smooth} \( 2n \)-\textit{manifold with non-empty boundary. A proper smooth map} \( \pi : X \to D^2 \) \textit{is said to be a Lefschetz fibration if}

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figure3.png}
\caption{The orientable surface of genus \( g \) with \( n \) boundary components along with the Lickorish generating curves. Here, \( \sigma_{ij} \) is a curve which is a boundary component of a planar subsurface of \( F \) whose boundary components are precisely \( \sigma_1, \sigma_j \) and \( \sigma_{ij} \).}
\end{figure}

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figure4.png}
\caption{The Szepietowski generating set for the mapping class group of a closed non-orientable genus \( g \) surface.}
\end{figure}
(1) the map $\pi$ has finitely many critical (or singular) points $q_i$, all lie in the interior of $X$ with critical (or singular) values $f(q_i) = p_i$, $1 \leq i \leq n$ and $p_i \neq p_j$, for $i \neq j$.

(2) for each critical point $q_i$ and its corresponding critical value $p_i$, there exist coordinate charts $U_{q_i} = \mathbb{C}^n$ around $q_i = (0, \ldots, 0)$ and $V_{p_i} = \mathbb{C}$ around $p_i = 0$ in $X$ and $D^2$, respectively which agree with the orientations of $X$ and $D^2$, such that the restriction of $\pi$ on $U_{q_i}$ is the map $\pi : U_{q_i} \to V_{p_i}$ defined as $\pi(z_1, \ldots, z_2) = z_1^2 + z_2^2 + \ldots + z_n^2$. Such a singularity is called a Lefschetz singularity.

(3) for a regular value $p$, the fiber is a closed, connected, oriented co-dimension 2-submanifold of $X^{2n}$.

We call the fiber $\pi^{-1}(p_i)$ corresponding to a singular point $p_i$ a singular fiber and the fiber $\pi^{-1}(p)$ corresponding to a regular point $p$ a regular fiber.

2.3. Topology of Lefschetz fibration. Consider a Lefschetz fibration $\pi : X^4 \to D^2$ on a 4-manifold $X$ with non-empty boundary. Suppose that $q_1, q_2, \ldots, q_n$ and $p_1, p_2, \ldots, p_n$ are the critical points and the critical values of $\pi$ respectively, such that $\pi(q_i) = p_i$. Now, we have a corresponding handle decomposition of $X$ as follows: Fix a regular value $p$ in the interior of $D^2$ and an identification of the fiber $\pi^{-1}(p)$ with a compact surface $\Sigma_g$ possibly with non-empty boundary. Consider an arc $\alpha_i$ in the interior of $D^2$ connecting $p$ to the singular value $p_i$ for each $i$ such that $\alpha_i \cap \alpha_j = \{p\}$, $i \neq j$. The labels $p_i$’s for the singular values and the arcs $\alpha_i$’s can be chosen in a cyclic order with respect to a small circle around $p$ with the anticlockwise orientation on the circle.

For each critical value $p_i$ and the regular value $p$, we choose small open disc $D_{p_i}$ centered at $p_i$ and $D_p$ centered at $p$ respectively, such that the discs $D_{p_i}, D_p$ are disjoint from each other in $D^2$, see Figure 5. In the complement of the critical values, the map

$$\pi|_{X \setminus (\bigcup_{i=1}^n \pi^{-1}(p_i))} : X \setminus (\bigcup_{i=1}^n \pi^{-1}(p_i)) \to D^2 \setminus \{p_1, p_2, \ldots, p_n\}$$

is a locally trivial fiber bundle. Note that $\pi^{-1}(D_p) = D_p \times \Sigma_g$ as $D_p$ is contractible. Let $\nu(\alpha_i)$ be a regular neighborhood of the arc $\alpha_i$. Then, $\pi^{-1}(D_p \cup \nu(\alpha_i) \cup D_{p_i})$ is diffeomorphic to $D^2 \times \Sigma_g$ with a 2-handle $H_{p_i}$ attached along a closed curve $\gamma_1$ in a fiber $\{pt\} \times \Sigma_g \subset \partial D^2 \times \Sigma_g$ with the framing $-1$ with respect to the surface framing. We describe the handle attachment as follows:

Choose the coordinate charts $U_{q_1} = \mathbb{C} \times \mathbb{C}$ around $q_1 = (0, 0)$ and $V_{p_1} = \mathbb{C}$ around $p_1$ in $X$ and $D^2$ respectively, such that the restriction of $\pi$ on $U_{q_1}$ is the maps $\pi(z_1, z_2) = z_1^2 + z_2^2$. Hence, near the critical point $q_1$, the regular fiber is given by $z_1^2 + z_2^2 = t$, and after multiplying $\pi$ by a unit complex number, we can assume that $t > 0$. Consider the plane $\mathbb{R}^2 = \{(z_1, z_2) \in \mathbb{C}^2 : z_1 = x_1 + 0i, z_2 = x_2 + 0i\}$ in $\mathbb{C}^2$. The intersection of the fibers with this plane are the circles $x_1^2 + x_2^2 = t$ in $\mathbb{R}^2$. We assume $\partial D_1 = \Sigma_g^1 \cap \mathbb{R}^2$ is the curve $\gamma_1$. Note that each circle $x_1^2 + x_2^2 = t$ bounds a disc $D_t \subset \mathbb{R}^2$ and as $t$ approaches to 0, the disc $D_t$ shrinks to a point in $\mathbb{R}^2$. Note that $\partial D_1 = \Sigma_g^1 \cap \mathbb{R}^2$ and the singular fiber $\Sigma_g^1$ being created from $\Sigma_g^1$ by the collapse of $D_1$. We call the circle $\partial D_1 = \gamma_1$ the vanishing cycle of the critical point $q_1$. A regular neighborhood $\nu(\Sigma_g^0)$ of the singular fiber is obtained from the neighbourhood $\Sigma_g^1$ by adding a regular neighbourhood of $D_1$. The later
neighbourhood is a 2–handle $H_{p_i}$ attached to $\nu(\Sigma_g^1)$. For more details regarding framing of the handle attachments refer [13] and [15].

Note that if $\Sigma_g$ is closed, $\pi^{-1}(D_p \cup \nu(\alpha_1) \cup D_{p_1})$ is diffeomorphic to $D^2 \times \Sigma_g \cup H_{p_1}$ and $\partial(\pi^{-1}(D_p \cup \nu(\alpha_1) \cup D_{p_1})) = \partial(D^2 \times \Sigma_g \cup H_{p_1})$ is diffeomorphic to a $\Sigma_g$–bundle over $S^1$. If we continue in the anticlockwise direction around $p$ and include other critical values in the similar way, we get

$$X_0 = \pi^{-1}(D_p \cup (\cup_{i=1}^n \nu(\alpha_i)) \cup (\cup_{i=1}^n D_{p_i}))$$

which is diffeomorphic to $(D^2 \times \Sigma_g) \cup (\cup_{i=1}^n H_{p_i})$, where $H_i$ is a 2–handle attached along the vanishing cycle $\gamma_i$ in the distinct fibers of $\partial D^2 \times \Sigma_g \to \partial D^2$ with the framing $-1$ with respect to the surface framing. Also, the boundary of $X_0$ is

$$\partial X_0 = \partial((D^2 \times \Sigma_g) \cup (\cup_{i=1}^n H_{p_i})),$$

which is a $\Sigma_g$–bundle over $S^1$ with the monodromy the product of right handed Dehn twist along the vanishing cycles.

In case if $\Sigma_g$ has non-empty boundary, the boundary of $X_0$ is a closed 3–manifold with an open book structure on it. More precisely,

$$\partial X_0 = \partial((D^2 \times \Sigma_g) \cup (\cup_{i=1}^n H_{p_i})) \cup D^2 \times \partial \Sigma_g.$$ 

Recall that an open book decomposition of a manifold $M$ is a pair $(B, \pi)$, where $B$ is a co-dimension 2 submanifold with a trivial normal bundle in $M$ and $\pi : M \backslash B \to S^1$ is a locally trivial fibration such that the fibration in a neighborhood of $B$ looks like the trivial fibration of $(B \times D^2) \backslash B \times \{0\} \to S^1$ sending $(x, r, \theta)$ to $\theta$, where $x \in B$.
and \((r, \theta)\) are polar coordinates on \(D^2\). For each \(\theta \in S^1\), the closure of \(\pi^{-1}(\theta)\) is called a page and the monodromy of the fibration is called the monodromy of the open book. Thus, given a Lefschetz fibration \(\pi : X^4 \to D^2\) and a radial projection \(\theta : D^2 \setminus \{0\} \to \partial D^2\), we get an open book decomposition on \(\partial X\) by the map \(\theta \circ \pi : (\partial X \setminus \pi^{-1}(0)) \to S^1\) with binding \(\pi^{-1}(0) \cap \partial X\), where 0 is a base point with regular fiber.

Note that any locally trivial fiber bundle over \(S^1\) with fibers \(\Sigma\), a closed manifold, is canonically isomorphic to the fiber bundle

\[
\Sigma \times [0, 1] \cong (\phi(x), 1),
\]

for some diffeomorphism \(\phi\) of \(\Sigma\). Let us recall the definition of mapping torus:

**Definition 4.** (Mapping torus) Let \(\Sigma\) be a manifold with non-empty boundary \(\partial \Sigma\) and \(\varphi\) be a diffeomorphism of \(\Sigma\) which is the identity in a collar neighborhood of \(\partial \Sigma\). Then, we define the mapping torus \(MT(\Sigma, \partial \Sigma, \varphi)\) of \(\Sigma\) as

\[
\Sigma \times [0, 1] / \sim,
\]

where \(\sim\) is the equivalence relation identifying \((x, 0)\) with \((\varphi(x), 1)\).

### 3. Co-dimension 2 Lefschetz Fibration embeddings

In this section, we will discuss Lefschetz fibration embeddings of 4–dimensional Lefschetz fibrations into a 6–dimensional Lefschetz fibration. First, recall the definition of the Lefschetz fibration embedding.

**Definition 5.** Let \(\pi_1 : X \to D^2\) and \(\pi_2 : Y \to D^2\) be two Lefschetz fibrations on \(X\) and \(Y\) respectively. A proper embedding \(f : X \to Y\) is said to be a Lefschetz fibration embedding if \(\pi_2 \circ f = \pi_1\).

**Theorem 6.** Let \(\pi : X \to D^2\) be a Lefschetz fibration, where \(X\) is a compact, connected, orientable 4–manifold with non-empty boundary such that for each regular value, the fiber is a closed, connected, orientable surface of genus \(g \geq 0\). Then, there exists a Lefschetz fibration embedding of \(X\) into a trivial Lefschetz fibration \(\tilde{\pi} : \mathbb{C}P^2 \times D^2 \to D^2\).

The key idea in establishing this result is flexible embeddings of surfaces \(\Sigma_g\) in \(\mathbb{C}P^2\). The notion of flexibility of surfaces in 4-dimensional manifolds is studied in [7]. The idea of flexible embeddings is used to produce open book embeddings of closed 3–manifolds in 5–manifolds for orientable case in [10] and for non-orientable case in [3]. In [17], the flexibility of surfaces is used to study spinal open book embeddings of closed orientable 3–manifolds in 5–manifolds. In [5], flexibility is used to obtain Lefschetz fibration embedding of closed oriented 4–dimensional Lefschetz fibration over \(\mathbb{C}P^1\) into a trivial Lefschetz fibration \(\mathbb{C}P^2 \times \mathbb{C}P^1\) over \(\mathbb{C}P^1\), where fibration is given by the projection on \(\mathbb{C}P^1\). They also establish the embeddings of closed orientable 4–manifolds in \(\mathbb{C}P^3\) as well as in \(\mathbb{R}^7\).

#### 3.1. Flexibility of surfaces in \(\mathbb{C}P^2\)

**Definition 7.** (Flexible mapping class) We call a diffeomorphism \(\phi\) of a surface \(F\) a flexible diffeomorphism in a 4–manifold \(X\) if there exists an embedding \(f\) of \(F\) in \(X\) and a diffeomorphism \(\Phi\) of \(X\) isotopic to the identity map of \(X\) such that \(\phi = f^{-1} \circ \Phi \circ f\).
**Definition 8.** An embedding of a surface $\Sigma$ in $X$ is said to be flexible if every diffeomorphism of $\Sigma$ is flexible in $X$ with respect to $f$.

We recall the following result from [7] (also in [16]). For the sake of completeness, we will give this construction here again as we use it concretely.

![Diagram of twisted bands](image)

**Figure 6.** The right and left twisted bands.

**Lemma 9.** Let $\Sigma_g$ be a closed, connected, orientable genus of $g$ surface. Then, there exists a flexible embedding of $\Sigma_g$ into $\mathbb{C}P^2$.

**Proof.** Recall that every diffeomorphism of the surface $\Sigma_g$ is isotopic to a product of the Dehn twists along the Lickorish generating curves as described in Figure 2. So, in order to establish the lemma, it is enough to show that there exists an embedding of $\Sigma_g$ in $\mathbb{C}P^2$ such that each Dehn twist along the Lickorish generating curve is flexible in $\mathbb{C}P^2$.

Each Dehn twist $d_c$ along a simple closed curve $c$ in $\Sigma_g$ is supported in an annular neighbourhood of $c$ in $\Sigma_g$. In [7] (Also in [3] and [10]), it is shown that there exists a flexible embedding of an annulus $A = S^1 \times [0,1]$ in $D^4$ and hence in $\mathbb{C}P^2$ as $\mathbb{C}P^2$ has handle decomposition with a $0$–handle, a $2$–handle and a $4$–handle. The proof of this is based on the fact that the $3$–sphere $S^3$ admits an open book decomposition with pages a Hopf annulus and monodromy a Dehn twist along the central curve of the Hopf annulus. By a Hopf annulus, we mean an embedding of an annulus into $S^3$ such that the boundary of the embedded annulus is a Hopf link, i.e., the linking number of the boundary components of the embedded annulus is $\pm 1$. This implies that there exists a flow $\phi_1$ on $S^3$ whose time $1$ map $\phi_1$ induces the Dehn twist along the central curve on each page—which is a Hopf annulus—of the open book of $S^3$. We can choose any Hopf annulus page $A$ as an embedding of the annulus $A$ in $S^3$.

Using the flow $\phi_s$ on $S^3$, we can define a level preserving diffeomorphism $\Psi : S^3 \times [0,2] \to S^3 \times [0,2]$ such that $\Psi$ is the identity near both the boundary components of $S^3 \times [0,2]$ and $\Psi$ induces $\phi_1$ on $S^3 \times 1$, i.e. it will induce the Dehn twist along the central curve in the embedded annulus $A$ which is a positive Hopf annulus page $A$ of the open book decomposition of $S^3 \times 1$. By considering $S^3 \times [0,2]$ as a collar of the boundary $\partial D^4 = S^3 \times 0$ of $D^4$, we can extend the diffeomorphism $\Psi$ to a diffeomorphism of $D^4$ which is isotopic to the identity map of $D^4$ and the identity near the boundary. Hence, it can be extended to a diffeomorphism of $\mathbb{C}P^2$ which is isotopic to the identity map of $\mathbb{C}P^2$. In fact, it can be chosen to be the identity on the $2$–handle of $\mathbb{C}P^2$ attached to $D^4$ along an unknot with framing $+1$ in the boundary of $D^4$ as well as the $4$–handle of $\mathbb{C}P^2$. Thus, the Dehn twist
along the central curve of the annulus $A$ is flexible in $\mathbb{C}P^2$. This implies that this embedding of the annulus $A$ in $S^3 \times 1$ is a flexible embedding of $A$ in $\mathbb{C}P^2$ as every diffeomorphism of $A$ is isotopic to a power of the Dehn twist along the central curve of $A$.

In the light of above discussion, we construct an embedding of $\Sigma_g$ in $\mathbb{C}P^2$ such that each Lickorish generating curve on $\Sigma_g$ admits a Hopf annulus regular neighbourhood in the embedded $\Sigma_g$ so that each Dehn twist along the Lickorish generating curve is flexible in $\mathbb{C}P^2$ and hence the embedding of $\Sigma_g$ is flexible in $\mathbb{C}P^2$.

Figure 7. A Flexible embedding of $\Sigma_g$ in $\mathbb{C}P^2$ with an isotopy of the curve $\gamma_2$ which has a positive Hopf annulus regular neighbourhood

To construct such an embedding, we shall proceed as follows: Consider a collar neighbourhood $S^3 \times [0, 2]$ of the boundary $\partial D^4 = S^3 \times 0$ in a 4–ball $D^4$. Consider a standardly embedded closed orientable surface $S$ of genus $g$ which bounds an unknotted untwisted handlebody of genus $g$ – see Figure 2. Remove the interior of a disc $D$ from $S$ and attach a positive full-twisted band to the $\partial D$ in $S^3 \times 1$ refer Figure 3. Thus, we get a new compact connected orientable surface $S_1$ of genus $g$ with boundaries $l_1$ and $l_2$ such that $l_1 \cup l_2$ is a positive Hopf link in $S^3 \times 1$ refer Figure 3. We attach tubes $l_1 \times [0, 1]$ and $l_2 \times [0, 1]$ to get a proper embedding of $S_1$ in $D^4$. Now, we attach a 2–handle $H$ to $D^3$ along the boundary component $l_2$ of $S_1$ with framing +1 and then attach a 4–handle on the resulting boundary to obtain $\mathbb{C}P^2$. The component $l_2$ of the surface $S_1$ bounds a 2–disc $D'$ in the 2–handle $H$, namely the core of the 2–handle and the boundary component $l_1$ of $S_1$ bounds a disc $D''$ in the 4–handle of $\mathbb{C}P^2$. Thus, we get an embedding of the surface $\Sigma_g = S_1 \cup D' \cup D''$ in $\mathbb{C}P^2$ such that $\Sigma_g$ contains an embedded positive Hopf annulus $A$ with boundary components $l_1$ and $l_2$, refer Figure 4.

Now, we can use this disc $D'$ (or $D''$) to isotope each Lickorish generating curve $c$ to another curve $c'$ in $\Sigma_g$ so that $c'$ travels over the Hopf annulus $A$ exactly once and it admits a Hopf annulus regular neighbourhood of $\Sigma_g$ in $S^3 \times 1$ of the collar of the boundary of the 0–handle $D^4$ of $\mathbb{C}P^2$. In order to get the isotopy of the flexibility of $c'$, we push the neighborhood of $c'$ slightly towards $S^3 \times 2$ in such a way that at a fixed level between 1 and $s_0$ the intersection of this pushed regular neighborhood $\nu(c')$ is a positive Hopf link and regular neighborhood $\nu(c') \cap S^3 \times s_0$.
is a positive Hopf annulus in $S^3 \times s_0$, $s_0 \in (1, 2)$ containing the curve $c'$ as its central curve. We now perform an isotopy to induce a Dehn twist along the pushed curve $c'$ in such a way that this isotopy is supported in a small neighborhood of $S^3 \times s_0$ not intersecting $S^3 \times 1$. After performing this isotopy, we further isotope the pushed neighborhood $\nu(c')$ back to its original place in $S^3 \times 1$.

From this, one can then easily observe that each Dehn twist $d_{c'}$ is flexible in $\mathbb{C}P^2$. Moreover, the diffeomorphism of $\mathbb{C}P^2$ which induces the Dehn twist $d_{c'}$ on $\Sigma_g$ can be chosen so that it is isotopic to the identity map of $\mathbb{C}P^2$ and the identity on the 2- and 4-handle of $\mathbb{C}P^2$. Thus, we obtain a flexible embedding of $\Sigma_g$ in $\mathbb{C}P^2$ as required. For more details, refer [10] and [17].

Observe that we have constructed an embedding $f$ of $\Sigma_g$ in $\mathbb{C}P^2$ such that for every Lickorish generating curve $\gamma$, the curve $f(\gamma)$ can be isotoped to a curve $\gamma'$ such that

1. the curve $\gamma'$ admits a regular neighbourhood $\nu(\gamma)$ in $f(\Sigma_g)$ which is positive Hopf annulus in $S^3 \times 1$,
2. $\gamma'$ bounds the disc $D$ in $\mathbb{C}P^2$ which intersects $f(\Sigma_g)$ only in $\gamma'$,
3. a tubular neighbourhood $\mathcal{N}(D) = D^2 \times D^2$ intersects $f(\Sigma_g)$ in the regular neighbourhood $\nu(\gamma')$ of $\gamma'$ in $f(\Sigma_g)$,
4. we can choose coordinates $(z_1, z_2)$ on $\mathcal{N}(D)$ such that $\nu(\gamma') = g^{-1}(1) \cap f(\Sigma_g)$, where $g : \mathbb{C}^2 \to \mathbb{C}$ is the map defined by $g(z_1, z_2) = z_1^2 + z_2^2$ and the plane $\mathbb{R}^2 = \{(z_1, z_2) \in \mathbb{C}^2 : z_1 = x_1 + i0, z_2 = x_2 + i0\}$ in $\mathbb{C}^2$ intersects $\mathcal{N}(D)$ in the disc $D$. Note that $\gamma'$ is the circle $x_1^2 + x_2^2 = 1$ and the disc $D$ is $x_1^2 + x_2^2 \leq 1$ in $\mathbb{R}^2$.

Any simple closed curve $\gamma$ in $\Sigma_g$ is said to be in the standard position with respect to the embedding $f_{pr}$ if $f_{pr}(\gamma)$ can be isotoped to a curve $\gamma'$ in $f_{pr}(\Sigma_g) \cap S^3 \times 1$ such that $\gamma'$ admits a regular neighbourhood $\nu(\gamma')$ in $f_{pr}(\Sigma_g)$ which is a positive Hopf annulus in $S^3 \times 1$. Any such curve will satisfy the conditions (1), (2), (3) and (4) satisfied by the Lickorish generating curves as described above.

We call the flexible embedding of $\Sigma_g$ in $\mathbb{C}P^2$ constructed in the proof of Lemma 9 the preferred embedding of $\Sigma_g$ in $\mathbb{C}P^2$. We denote this embedding by $f_{pr} : \Sigma_g \to \mathbb{C}P^2$ and the embedded surface $\Sigma_g$ by $\Sigma_{pr}$. We call the pair $(\mathbb{C}P^2, \Sigma_{pr})$ the preferred $\mathbb{C}P^2$ and we denote it by $\mathbb{C}P^2_{pr}$.

**Remark 10.** Note that the simple closed curves shown by red color in Figure 8 are separating curves and they are in the standard position with respect to $f_{pr}$.

**Remark 11.**

1. The monodromy of the singular fibration $g : \mathcal{N}(D) = \mathbb{C}^2 \to \mathbb{C} = D^2$ with the singular point $(0, 0)$ is the positive Dehn twist $d_{\gamma'}$ along the curve $\gamma'$ which lies in the regular fiber $g^{-1}(1) \cap \Sigma_{pr} = \nu(\gamma')$.
2. The isotopy of $\mathcal{N}(D)$ which produces the positive Dehn twist $d_{\gamma'}$ on $g^{-1}(1) \cap \Sigma_{pr}$ can be extended to an isotopy $\Psi_s$, $s \in [0, 1]$, of $\mathbb{C}P^2$ such that the isotopy is supported in the tubular neighbourhood $\mathcal{N}(D)$. Then, we have $f_{pr}^{-1} \circ \Psi_s \circ f_{pr} = d_{\gamma'}$ up to isotopy. Thus, we have isotopy of $\mathbb{C}P^2$ supported in the tubular neighbourhood $\mathcal{N}(D)$ of $D$ which produces Dehn twist $d_{\gamma'}$ on $\Sigma_{pr}$.
3.2. Proof of Theorem 6 (Lefschetz fibration embedding). Consider a Lefschetz fibration \( \pi : X^4 \to D^2 \) on a compact, connected, oriented 4-manifold \( X \) with non-empty boundary. Suppose that \( q_1, q_2, \ldots, q_n \) and \( p_1, p_2, \ldots, p_n \) are the critical points and the critical values of \( \pi \) respectively, such that \( \pi(q_i) = p_i \). Fix a regular value \( p \) in the interior of \( D^2 \) and an identification of a fiber \( \pi^{-1}(p) \) with a closed surface \( \Sigma_g \). For each \( i = 1, 2, \ldots, n \), choose a small open disc \( D_{p_i} \) centered at the critical value \( p_i \) and a disc \( D_p \) centered at \( p \) in \( D^2 \) such that these discs are disjoint from each other. Consider an arc \( \alpha_i \) in the interior of \( D^2 \) connecting \( p \) to a point \( p_i' \) on \( \partial D_{p_i} \) for each \( i \) such that \( \alpha_i \)'s meet only at the point \( p \). The labels \( p_i \)'s for the singular values and the arcs \( \alpha_i \)'s can be chosen in a cyclic order with respect to a small circle around \( p \) with the anticlockwise orientation on the circle. Note that

\[
D_p \cup (\cup_{i=1}^n \nu(\alpha_i)) \cup (\cup_{i=1}^n D_{p_i})
\]

is a 2-disc. Let \( \gamma_i \) be the vanishing cycle corresponding to the critical value \( p_i \) on \( \Sigma_g \). Note that there is a unique lift of \( \gamma_i \) in the fiber on \( p_i' \).

Firstly, we will construct Lefschetz fibration embedding of the Lefschetz fibration of \( X \) restricted to the Lefschetz fibration over \( D_{p_i} \) into the trivial Lefschetz fibration \( \tilde{\pi} : \mathbb{C}P^2 \times D_{p_i} \to D_{p_i} \) for each singular value \( p_i \). Then, we will construct Lefschetz fibration embedding of the Lefschetz fibration of \( X \) restricted to the Lefschetz fibration over \( \tilde{D} = D_{p} \cup (\cup_{i=1}^n \nu(\alpha_i)) \) into the trivial Lefschetz fibration \( \tilde{\pi} : \mathbb{C}P^2 \times \tilde{D} \to \tilde{D} \). Finally, we will glue these Lefschetz fibration embeddings to get the required Lefschetz fibration embedding of \( \pi : X \to D^2 \) into the trivial Lefschetz fibration embedding \( \tilde{\pi} : \mathbb{C}P^2 \times D^2 \to D^2 \).

Case -(I): When the vanishing cycle \( \gamma_i \) is in the standard position with respect to the preferred embedding of \( \Sigma_g \):

As the vanishing cycle \( \gamma_i \) on \( \Sigma_g \) is in the standard position with respect to \( \tilde{\pi} \), \( f_{pr} (\gamma_i) \) can be isotope to \( \gamma_i' \) in \( \Sigma_{pr} \) such that the regular neighbourhood of \( \gamma_i' \) in \( \Sigma_{pr} \cap S^3 \times 1 \) is a positive Hopf annulus \( S^3 \times 1 \). The curve \( \gamma_i' \) bounds a disc \( D^2 \) in \( \mathbb{C}P^2 \) such that \( \partial D^2 = \gamma_i' \) and \( D^2 \) intersects \( \Sigma_{pr} \) only in \( \gamma_i' \). Also, we have a tubular neighbourhood \( \mathcal{N}(D^2) = D^2 \times D^2 \) intersects \( \Sigma_{pr} \) in a regular neighbourhood \( \nu(\gamma_i') \) of \( \gamma_i' \). The tubular neighbourhood \( \mathcal{N}(D^2) \) admits the coordinates \((z_1, z_2)\) on \( \mathcal{N}(D^2) \) such that \( \nu(\gamma_i') = g^{-1}(1) \cap \Sigma_{pr} \), where \( g : \mathbb{C}^2 \to \mathbb{C} \) is a map defined by \( g(z_1, z_2) = z_1^2 + z_2^2 \) and the plane \( \mathbb{R}^2 = \{(z_1, z_2) : z_1 = x_1 + i0, z_2 = x_2 + i0\} \) in \( \mathbb{C}^2 \) intersect \( \Sigma_{pr} \) in the disc \( D^1 = \{(x_1, 0, x_2, 0) : x_1^2 + x_2^2 \leq 1\} \subset \mathbb{R}^2 \).

Recall that the Dehn twist \( d_{\gamma_i} \) is flexible in \( \mathbb{C}P^2 \). Therefore, as described in Remark 11 there exists an isotopy \( \Psi_i : \mathbb{C}P^2 \to \mathbb{C}P^2 \) such that \( f_{pr}^{-1} \circ \Psi_i \circ f_{pr} = d_{\gamma_i} \) (up to isotopy) and this isotopy is supported in the tubular neighbourhood of \( D^2 \).

In other words, \( \Psi_i \) induces the Dehn twist \( d_{\gamma_i} \) on \( \Sigma_{pr} \).

The map \( \pi_{|_{p_i^{-1}(D_{p_i})}} : \pi^{-1}(D_{p_i}) \to D_{p_i} \) is a Lefschetz fibration with \( p_i \) is the only critical value. We shall construct a Lefschetz fibration embedding of the Lefschetz fibration \( \pi_{|_{p_i^{-1}(D_{p_i})}} : \pi^{-1}(D_{p_i}) \to D_{p_i} \) into a trivial Lefschetz fibration \( \tilde{\pi} : \mathbb{C}P^2 \times D_{p_i} \to D_{p_i} \).

We identify the disc \( D_{p_i} \) as well as the disc \( D^1 \) as \( \{te^{2\pi is}|s, t \in [0, 1]\} \). The point \( p_i' \) is \((0, 1) = 1.e^{2\pi i0} \in \partial D^1 \). For each \((s, t) \in [0, 1] \times [0, 1]\), we shall define a flexible embedding \( f_{s,t}^i \) of \( \Sigma_g \) in \( \mathbb{C}P^2 \) as follows: We shall denote the image of \( \Sigma_g \) under the embedding \( f_{s,t}^i \) by \( \Sigma_{s,t}^i \).
We consider $f_{0,1}$ as the preferred embedding $f_{pr}$. Note that $\Sigma_{0,1} = \Sigma_{pr}$.

We consider a smooth family $f_{i,t}$, $t \in (0,1]$ of the flexible embeddings of $\Sigma_g$ in $CP^2$ such that:

1. there exists an isotopy $\{\Psi_{i,t}\}_{t \in (0,1]}$ of $CP^2$ supported in $N(D^i) = N(D_{0,1}^i)$ such that the embedding $f_{i,t} = \Psi_{0,t} \circ f_{pr}$.

2. the simple closed curve $\gamma_{0,t}^i = f_{0,t}^i(\gamma_i)$ bounds the disc $D_{0,t}^i$ which is the image of the disc $D_{0,1}^i$ under the isotopy. The disc $D_{0,t}^i$ intersects $\Sigma_{0,t}$ only in $\gamma_{0,t}^i$. Here, $\gamma_{0,t}^i = g^{-1}(t) \cap \mathbb{R}^2 = \{(x_1, 0, x_2, 0) : x_1^2 + x_2^2 = t\}$ and $D_{0,t}^i = \{(x_1, 0, x_2, 0) : x_1^2 + x_2^2 \leq t\}$ is a subset of $\mathbb{R}^2$.

3. we have a tubular neighbourhood $N(D_{0,1}^i) \subset N(D_{0,1})$ intersects $\Sigma_{0,t}$ in the regular neighbourhood $\nu(\gamma_{0,t}^i) = g^{-1}(t) \cap \Sigma_{0,t}$ of $\gamma_{0,t}^i$ in $\Sigma_{0,t}$.

Note that each embedding $f_{0,t}^i$, $t \in (0,1]$ is flexible. For $h : \Sigma \to \Sigma$ is a diffeomorphism then, there exists $\Phi_{pr} : CP^2 \to CP^2$ such that $f_{pr}^i \circ \Phi_{pr} \circ f_{pr} = h$ as the embedding $f_{pr}$ is a flexible embedding in $CP^2$.

Let $\Phi = \Psi_{0,t} \circ f_{pr} \circ \Psi_{0,t}^{-1}$. Then, $f_{0,t}^i \circ \Phi \circ f_{0,t}^i = h$.

We define the embedding $f_{s,t}^i$ as the map $\Psi_{s,t} \circ f_{0,t}^i$, where $\Psi_{s,t} = \Psi_{s} \circ \Psi_{0,t}^{-1}$ with the isotopy $\Psi_{s}$ of the flexibility of $d_{\gamma_i}$ described as above as well as in Remark 11. Note that $\gamma_{s,t}^i = \Psi_{s,t}(\gamma_i)$ bounds the disc $D_{s,t}^i = \Psi_{s,t}(D^i(t))$ in $CP^2$. The disc $D_{s,t}^i$ intersects $\Sigma_{s,t}$ only in $\gamma_{s,t}^i$ and the tubular neighbourhood $N(D_{s,t}^i) = \Psi_{s,t}(N(D^i))$ intersects $\Sigma_{s,t}$ in a regular neighbourhood $\nu(\gamma_{s,t}^i) = g^{-1}(t) \cap \Sigma_{s,t}$ of $\gamma_{s,t}^i$ in $\Sigma_{s,t}$. Note the restriction of $\Psi_{s,t}^i$ to $\Sigma_{s,t}^i$ induces the Dehn twist $d_{\gamma_i}$ on $\Sigma_{s,t}^i$.

Note that for each $t$, $\Sigma_{0,t}^i = \Sigma_{1,t}^i$. From this, we can observe that the mapping torus $MT(\Sigma_{0,t}^i, d_{\gamma_i}^i)$ is embedded fiberwise in the mapping torus $MT(CP^2, \Psi_{1,t}^i)$. The mapping torus $MT(CP^2, \Psi_{1,t}^i)$ is a trivial fiber bundle over the circle $\{e^{2\pi i s}, s \in [0,1]\}$ with fiber $CP^2$ containing the fiber $\Sigma_{0,t}^i$ of the locally trivial fiber bundle $MT(\Sigma_{0,t}^i, d_{\gamma_i}^i)$ over the same circle.

For each $s \in [0,1]$, if we travel through the family $\Psi_{s,1-t}$, $t \in [0,1)$ of diffeomorphisms of $CP^2$, the disc $D_{s,1}^i$ shrinks through the discs $D_{s,1-t}^i$ to the origin of $D_{0,1}^i$. Thus, the embedded surface $\Sigma_{s,1}$ can be collapsed through $\Sigma_{s,t}$ to get a singular surface $\Sigma_0$ which is obtained by pinching the vanishing cycle $\gamma_{s,1}$ to the origin of the disc $D_{0,1}^i$. The vanishing cycle $\gamma_{s,1}$ in $\Sigma_{s,1}$ corresponds to the vanishing cycle $\gamma_i \subset \Sigma_g$ of the critical value $p_i$ of the Lefschetz fibration $\pi : X^4 \to D^2$. The singular surface $\Sigma_0$ gives an embedding of the singular fiber $\pi^{-1}(p_i)$ in $CP^2$.

From this, one can see that we get a Lefschetz fibration embedding of the Lefschetz fibration $\pi_{i-1} : (D_{p_i}) \to D_{p_i}$ into the trivial Lefschetz fibration $\tilde{\pi} : CP^2 \times D_{p_i} \to D_{p_i}$.

Case -(II): When the vanishing cycle $\gamma_j$ is not in the standard position with respect to the preferred embedding of $\Sigma_g$:

Now, we consider the case where the vanishing cycle $\gamma_j$ in $\Sigma_g$ corresponding to the critical value $p_j$ of the Lefschetz fibration $\pi : X^4 \to D^2$ has the property that $f_{pr}(\gamma_j)$ can not be isotoped in $\Sigma_{pr}$ to a closed curve which admits a positive Hopf annulus neighbourhood in $\Sigma_{pr}$.
Recall the following fact that given any two simple closed non-separating curves in $\Sigma_g$, there exists a diffeomorphism of $\Sigma_g$ taking one to another. Also, given any two separating simple closed curves in $\Sigma_g$, there exists a diffeomorphism of $\Sigma_g$ taking one to another, provided they separate the surface $\Sigma_g$ into the surfaces of the same genera.

Hence, if $\gamma_j$ is non-separating, then there exists a diffeomorphism $\phi$ of $\Sigma_g$ which maps $\gamma_j$ to one of the Lickorish generators and if it is separating, then there exists a diffeomorphism of surface $\Sigma_g$ which maps $\gamma_j$ to one of the red colored separating closed curve shown in Figure 8 provided they separate the surface $\Sigma_g$ into the surfaces of the same genera, refer Remark 10. Since $f_{pr}$ is a flexible embedding, there exists an isotopy $\{\Phi_r\}_{r \in [0,1]}$ of diffeomorphisms of $\mathbb{C}P^2$ such that $f_{pr}^{-1} \circ \Phi_1 \circ f_{pr} = \phi$.

We consider a family of embeddings $\{f_r\}_{r \in [0,1]}$, where $f_r = \Phi_r \circ f_{pr}$ and we denote the image of embeddings $f_r$ by $\Sigma^r$, where $\Sigma^0 = \Sigma_{pr}$. Note that $f_{pr}$ and $f_1$ have the same image $\Sigma_{pr}$ but $f_{pr} \neq f_1$. Now, the curve $f_1(\gamma_j)$ can be isotoped to a simple closed curve $\gamma'_j$ in $\Sigma^1$ so that $\gamma_j$ is in the standard position with respect to $f_1$.

Now, we can construct a Lefschetz fibration embedding of the local Lefschetz fibration $\pi_{|\Sigma_g \setminus D_{p_j}}^{-1}(D_{p_j}) \to D_{p_j}$ into a trivial Lefschetz fibration of $\mathbb{C}P^2 \times D_{p_j}$ over $D_{p_j}$ by constructing smooth family of diffeomorphism $\Psi_{s,t}$ of $\mathbb{C}P^2$ and embeddings $f_{s,t}$ of $\Sigma_g$ as described above with the properties that $\Psi_{0,1}^j = Id_{\mathbb{C}P^2}$ and $f_{0,1}^j = f_1$ from the family $\{f_r\}_{r \in [0,1]}$ described above.

Thus, we have a Lefschetz fibration embedding of the local Lefschetz fibration $\pi_{|\Sigma_g \setminus D_{p_k}}^{-1}(D_{p_k}) \to D_{p_k}$ into a trivial Lefschetz fibration of $\mathbb{C}P^2 \times D_{p_k}$ over $D_{p_k}$ for each critical value $p_k$.

Hence, we have a Lefschetz fibration embedding of the Lefschetz fibration $\pi : \pi^{-1}(\bigcup_{i=1}^n D_{p_i}) \to \bigcup_{i=1}^n D_{p_i}$ into a trivial Lefschetz fibration $\tilde{\pi} : \mathbb{C}P^2 \times \bigcup_{i=1}^n D_{p_i} \to \bigcup_{i=1}^n D_{p_i}$.
Let $\tilde{D} = \bigcup_{i=1}^{n} \nu(\alpha_i) \cup D_p$. We construct a Lefschetz fibration embedding of the Lefschetz fibration

$$\pi : \pi^{-1}(\tilde{D}) \to \hat{D}$$

into a trivial Lefschetz fibration

$$\tilde{\pi} : \mathbb{C}P^2 \times \hat{D} \to \hat{D}.$$ 

Then, we glue all Lefschetz fibration embeddings constructed above to get the Lefschetz fibration embedding of the Lefschetz fibration $\pi : \pi^{-1}(D_0) \to D_0$ into the Lefschetz fibration $\tilde{\pi} : \mathbb{C}P^2 \times D_0 \to D_0$, where $D_0 = \hat{D} \cup (\bigcup_{i=1}^{n} D_{p_i})$.

**Lefschetz fibration embedding over $D_0$:**

Consider the region $B$ as shown in Figure 9 which is the union of the disc $D_p$ with the strips $S_1, S_2, ..., S_n$, where $S_i = [0, \epsilon] \times [0, 1]$ identified with $D_p$ along $[0, \epsilon] \times \{1\}$. We consider the trivial Lefschetz fibration $\tilde{\pi} : \mathbb{C}P^2 \times B \to B$, where the fibers are $\mathbb{C}P^2_{pr}$, i.e., $\mathbb{C}P^2$ together with the preferred embedding $f_{pr}$ of $\Sigma_g$.

Now, for the critical point $p_i$ whose vanishing cycle $\gamma_i$ in $\Sigma_g$ is in the standard position with respect to the embedding $f_{pr}$, we consider the strip $R_{\gamma_i} = [0, \epsilon] \times [0, 1]$ as shown in Figure 9. The edge $[0, \epsilon] \times \{1\} \subset R_{\gamma_i}$ is identified with the arc $[0, \epsilon] \subset \partial D_{p_i}$ of the disc $D_{p_i}$, and the edge $[0, \epsilon] \times \{0\} \subset R_{\gamma_i}$ is identified with the edge $[0, \epsilon] \times \{0\} \subset S_i$. Note that one of the boundary component of $S_i \cup R_{\gamma_i}$ is a part arc $\alpha_i$.

Now, we consider the trivial Lefschetz fibration $\tilde{\pi} : \mathbb{C}P^2 \times R_{\gamma_i} \to R_{\gamma_i}$ with the fibers $\Psi_{ts,1}(\mathbb{C}P^2)$ for $(s, t) \in R_{\gamma_i} = [0, \epsilon] \times [0, 1]$. One can observe that when
When \( t = 0 \), the fibers \( \Psi_{t,1}^{i}(CP^2) \) are \( CP^2_{pr} \) which coincide with the fibers on the edge \([0, \epsilon] \times \{0\} \subset S_1\), and when \( t = 1 \), the fibers \( \Psi_{t,1}^{i}(CP^2) \) coincide with the fibers on the arc \([0, \epsilon] \subset \partial D_p\). This gives a Lefschetz fibration embedding of

\[
\pi|_{s-1(R_{\gamma_j})} : \pi^{-1}(R_{\gamma_j}) \to R_{\gamma_i}
\]

into the trivial Lefschetz fibration

\[
\tilde{\pi} : CP^2 \times R_{\gamma_i} \to R_{\gamma_i}
\]

with fibers \( \Psi_{t,1}^{i}(CP^2) \).

For the critical point \( p_j \) whose vanishing cycle \( \gamma_j \) in \( \Sigma_0 \) is not in the standard position with respect to the embedding \( f_{pr} \), we consider the strips \( R_{\gamma_j} = [0, \epsilon] \times [0, 1] \) and \( R_{\gamma'_j} = [0, \epsilon] \times [0, 1] \) as shown in Figure 9. The edge \([0, \epsilon] \times \{1\} \subset R_{\gamma_j} \) is identified with the arc \([0, \epsilon] \subset \partial D_{\gamma_j} \) of the disc \( D_{\gamma_j} \). The edge \([0, \epsilon] \times \{0\} \subset R_{\gamma_i} \) is identified with the edge \([0, \epsilon] \times \{1\} \subset R_{\gamma'_j} \) and the edge \([0, \epsilon] \times \{0\} \subset R_{\gamma'_j} \) is identified with the edge \([0, \epsilon] \times \{0\} \subset S_j \). Note that one of the boundary components of \( S_j \cup R_{\gamma_j} \cup R_{\gamma'_j} \) is a part of the arc \( \alpha_j \).

Now, we consider the trivial Lefschetz fibration \( \tilde{\pi} : CP^2 \times R_{\gamma_j} \to R_{\gamma_j} \) with fibers \( \Phi_{1}(\mathcal{C}P^2_{pr}), \) for \((s, t) \in R_{\gamma_j} = [0, \epsilon] \times [0, 1] \) and the trivial Lefschetz fibration \( \tilde{\pi} : CP^2 \times R_{\gamma_j} \to R_{\gamma_j} \) with the fibers \( \Psi_{t,1}^{i}(\Phi_{1}(\mathcal{C}P^2_{pr})), \) for \((s, t) \in R_{\gamma_j} = [0, \epsilon] \times [0, 1] \).

One can observe that when \( t = 0 \), the fiber \( \Phi_{1}(\mathcal{C}P^2_{pr}) \) of \([0, \epsilon] \times \{0\} \subset R_{\gamma_j} \) are \( CP^2_{pr} \), which coincide with the fibers on the edge \([0, \epsilon] \times \{0\} \subset S_j \) for each \( s \in [0, \epsilon] \). The fiber \( \Psi_{t,1}^{i}(\Phi_{1}(\mathcal{C}P^2)) \) of the edge \([0, \epsilon] \times \{0\} \subset R_{\gamma_j} \) is \( \Phi_{1}(\mathcal{C}P^2) \) coincides with the fiber on the edge \([0, \epsilon] \times \{1\} \subset R_{\gamma'_j} \) for each \( s \). Finally, when \( t = 1 \), the fiber \( \Psi_{t,1}^{i}(\Phi_{1}(\mathcal{C}P^2_{pr})) \) of \([0, \epsilon] \times \{1\} \subset R_{\gamma_j} \) coincide with the fiber on the arc \([0, \epsilon] \subset \partial D_p, \) for each \( s \). This gives a Lefschetz fibration embedding of

\[
\pi|_{s-1(R_{\gamma_j} \cup R_{\gamma'_j})} : \pi^{-1}(R_{\gamma_j} \cup R_{\gamma'_j}) \to R_{\gamma_i} \cup R_{\gamma'_j}
\]

into the trivial Lefschetz fibration

\[
\tilde{\pi} : CP^2 \times (R_{\gamma_j} \cup R_{\gamma'_j}) \to R_{\gamma_i} \cup R_{\gamma'_j}
\]

with fibers described on \( R_{\gamma_j} \) and \( R_{\gamma'_j} \) as above.

Now, we can glue all the Lefschetz fibration embeddings constructed above to get a required Lefschetz fibration embedding of

\[
\pi|_{s-1(D_0)} : \pi^{-1}(D_0) \to D_0
\]

into the trivial Lefschetz fibration \( \tilde{\pi} : CP^2 \times D_0 \to D_0 \), where

\[
D_0 = D_p \cup (\cup_{i=1}^{n}\nu(\alpha_i)) \cup (\cup_{i=1}^{n}\partial D_0).
\]

Note that \( D^2 \setminus D_0 \) is just the collar \( S^1 \times [0, 1] \) of the boundary of \( D^2 \) with \( S^1 \times \{0\} = \partial D^2 \), one can easily extend both the Lefschetz fibrations \( \pi|_{s-1(D_0)} : \pi^{-1}(D_0) \to D_0 \) and \( \tilde{\pi} : CP^2 \times D_0 \to D_0 \) to the Lefschetz fibration \( \pi : X \to D^2 \) and the trivial Lefschetz fibration \( \tilde{\pi} : CP^2 \times D^2 \to D^2 \) in such a way that we will get the Lefschetz fibration embedding of the Lefschetz fibration \( \pi : X \to D^2 \) to the trivial Lefschetz fibration \( \tilde{\pi} : CP^2 \times D^2 \to D^2 \). This completes the arguments of Theorem 6.
4. **Achiral Lefschetz fibration**

In this section, we shall discuss Lefschetz fibration embeddings of 4–dimensional achiral Lefschetz fibration into the trivial Lefschetz fibration \( \pi : \mathbb{C}P^2 \times D^2 \to D^2 \). Recall the definition of an achiral Lefschetz fibration on 4–manifolds.

**Definition 12.** (Achiral Lefschetz fibration on 4–manifold) Let \( X \) be a compact, connected, orientable smooth 4–manifold with non-empty boundary. A proper smooth map \( \pi : X \to D^2 \) is said to be an achiral Lefschetz fibration if

1. the map \( \pi \) has finitely many critical (or singular) points \( q_i \), all lie in the interior of \( X \) with critical (or singular) values \( f(q_i) = p_i, 1 \leq i \leq n \) and \( p_i \neq p_j \), for \( i \neq j \).
2. for each critical point \( q_i \) and its corresponding critical value \( p_i \), there exist coordinate charts \( U_{q_i} = \mathbb{C}^n \) around \( q_i = (0, \ldots, 0) \) and \( V_{p_i} = \mathbb{C} \) around \( p_i = 0 \) in \( X \) and \( D^2 \) respectively, such that the restriction of \( \pi \) in \( U_{q_i} \), \( \pi : U_{q_i} \to V_{p_i} \), defined as either \( \pi(z_1, z_2) = z_1^2 + z_2^2 \) or \( \pi(z_1, z_2) = z_1^2 + z_2^2 \).
3. for a regular value \( p \), the fiber is a closed, connected, oriented surface of \( X \).

Note that an achiral Lefschetz fibration is a Lefschetz fibration which satisfies the conditions (1) and (2) of Definition 8 without requiring the coincidence of the canonical orientation determined by \((z_1, z_2)\) and the orientation of \( X \). For a critical value \( p_i \) which has the coordinate map \( \pi(z_1, z_2) = z_1^2 + z_2^2 \) defined in the above definition corresponds to attaching a 2–handle to a near by regular fiber along the vanishing cycle \( \gamma \) with framing +1. From the handle decomposition of a 4–manifold associated to a Lefschetz fibration given in Subsection 2.3 one can see that the critical value \( p_i \) contributes a negative Dehn twist along the vanishing cycle \( \gamma \) to the boundary monodromy of the Lefschetz fibration. Such a singularity, we call an achiral singularity. For more details, see [6] and [15].

Any simple closed curve \( \gamma \) in \( \Sigma_g \) is said to be in the achiral standard position with respect to the embedding \( f_{pr} \) if \( f_{pr}(\gamma) \) can be isotoped to a curve \( \gamma' \) in \( f_{pr}(\Sigma_g) \cap S^3 \times 1 \) such that \( \gamma' \) admits a regular neighbourhood \( \nu(\gamma') \) in \( f_{pr}(\Sigma_g) \) which is a negative Hopf annulus in \( S^3 \times 1 \). Any such curve will satisfy the following conditions.

- the curve \( \gamma' \) admits a regular neighbourhood \( \nu(\gamma) \) in \( f_{pr}(\Sigma_g) \) which is a negative Hopf annulus in \( S^3 \times 1 \)
- \( \gamma' \) bounds a disc \( D \) in \( \mathbb{C}P^2 \) which intersects \( f_{pr}(\Sigma_g) \) only in \( \gamma' \)
- a tubular neighbourhood \( \mathcal{N}(D) = D^2 \times D^2 \) intersects \( f_{pr}(\Sigma_g) \) in a regular neighbourhood \( \nu(\gamma') \) of \( \gamma' \) in \( f_{pr}(\Sigma_g) \),
- we can choose coordinates \((z_1, z_2)\) on \( \mathcal{N}(D) \) such that \( \nu(\gamma') = g^{-1}(1) \cap f_{pr}(\Sigma_g) \), where \( g : \mathbb{C}^2 \to \mathbb{C} \) is a map defined by \( g(z_1, z_2) = z_1^4 + z_2^4 \) and the plane \( \mathbb{R}^2 = \{(z_1, z_2) \in \mathbb{C}^2 : z_1 = x_1 + i0, z_2 = x_2 + i0\} \) in \( \mathbb{C}^2 \) intersects \( \mathcal{N}(D) \) in the disc \( D \). Note that \( \gamma' \) is the circle \( x_1^2 + x_2^2 = 1 \) and the disc \( D \) is \( x_1^2 + x_2^2 \leq 1 \) in \( \mathbb{R}^2 \).

The monodromy of the achiral singular fibration \( g : \mathcal{N}(D) = \mathbb{C}^2 \to \mathbb{C} = D^2 \) with the achiral singular point \((0,0)\) is the negative Dehn twist \( d_{\gamma'}^{-1} \) along the curve \( \gamma' \) which lies in the regular fiber \( g^{-1}(1) \cap \Sigma_{pr} = \nu(\gamma') \). The isotopy of \( \mathcal{N}(D) \) which produces the negative Dehn twist \( d_{\gamma'}^{-1} \) on \( g^{-1}(1) \cap \Sigma_{pr} \) can be extended to an isotopy \( \Psi_s, s \in [0,1] \), of \( \mathbb{C}P^2 \) such that the isotopy is supported in the tubular neighbourhood \( \mathcal{N}(D) \). Then, we have \( f_{pr}^{-1} \circ \Psi_1 \circ f_{pr} = d_{\gamma'}^{-1} \) up to isotopy. Thus, we have isotopy of \( \mathbb{C}P^2 \) supported in the tubular neighbourhood \( \mathcal{N}(D) \) of \( D \) which
produces Dehn twist $d_{\gamma_j}^{-1}$ on $\Sigma_{pr}$.

Now, we have the following theorem.

**Theorem 13.** Let $\pi : X \to D^2$ be an achiral Lefschetz fibration, where $X$ is a compact, connected, orientable 4–manifold with non-empty boundary such that for each regular value, the fiber is a closed, connected, orientable surface $\Sigma_g$ of genus $g \geq 1$. If the vanishing cycle corresponding to each achiral singularity is non-separating in $\Sigma_g$. Then, there exists a Lefschetz fibration embedding of $X$ into a trivial Lefschetz fibration $\tilde{\pi} : \mathbb{C}P^2 \times D^2 \to D^2$.

**Proof.** We use the preferred embedding $f_{pr}$ of $\Sigma_g$ into $\mathbb{C}P^2$ the same as the one used in Theorem 6.

For a non-achiral Lefschetz singularity $p_i$ with a neighbourhood $D_{p_i}$, not containing any other singularity, we can produce local Lefschetz fibration embedding of the Lefschetz fibration $\pi_{|\pi^{-1}(D_{p_i})} : \pi^{-1}(D_{p_i}) \to D_{p_i}$ into the trivial Lefschetz fibration $\tilde{\pi} : \mathbb{C}P^2 \times D_{p_i} \to D_{p_i}$, as described in Subsection 3.2.

Now, we consider the case of an achiral singular point $p_j$ with corresponding vanishing cycle $\gamma_j$ which is non-separating. Suppose $f_{pr}(\gamma_j)$ is in the achiral standard position. Then, using the arguments given in the proof of Theorem 6 and replacing positive Hopf annulus regular neighbourhood by negative Hopf annulus regular neighbourhood in the arguments, we get the local Lefschetz fibration embedding of the Lefschetz fibration $\pi_{|\pi^{-1}(D_{p_j})} : \pi^{-1}(D_{p_j}) \to D_{p_j}$ into the trivial Lefschetz fibration $\tilde{\pi} : \mathbb{C}P^2 \times D_{p_j} \to D_{p_j}$ as described in Subsection 3.2.

![Figure 10](image.png)

**Figure 10.** The curve $\beta$ in the surface $\Sigma_g$ of genus $g > 0$ admits a negative Hopf annulus regular neighbourhood in $\Sigma_g$.

Suppose $\gamma_j$ is not in the achiral standard position with respect to $f_{pr}$. We consider the simple closed curve $\beta$ shown in Figure 10. The curve $\beta$ is non-separating in $\Sigma_g$. Note that $\beta$ is in the achiral standard position with respect to the embedding $f_{pr}$. As we know that given any two non-separating simple closed curve there exists a diffeomorphism mapping one to another, we choose a diffeomorphism $\phi$ which maps $\gamma_j$ to $\beta$ in $\Sigma_g$. As the embedding $f_{pr} : \Sigma_g \to \mathbb{C}P^2$ is flexible, there exists an isotopy $\{\Gamma_r\}_{r \in [0,1]}$ such that $f_{pr}^{-1} \circ \Gamma_1 \circ f_{pr} = \phi$.

We consider a family of embeddings $\{f_r\}_{r \in [0,1]}$, where $f_r = \Gamma_r \circ f_{pr}$ and we denote the image of embeddings $f_r$ by $\Sigma^r$, where $\Sigma^0 = \Sigma_{pr}$. Note that $f_{pr}$ and $f_1$ have the same image $\Sigma_{pr}$. Now, the curve $\gamma_j$ is in the achiral standard position with respect to the embedding $f_1$. 
In this way, given any vanishing cycle $\gamma_j$, we can find a flexible embedding of $\Sigma_g$ ambient isotopic to $f_{pr}$ in $\mathbb{C}P^2$ such that $\gamma_j$ either in the standard position or in the achiral standard position with respect to that embedding.

Now, using the arguments given in Theorem 6, we obtain the Lefschetz fibration embedding of the achiral Lefschetz fibration $\pi : X \to D^2$ to the trivial Lefschetz fibration $\tilde{\pi} : (\mathbb{C}P^2 \# \mathbb{C}P^2) \times D^2 \to D^2$.

We call a Lefschetz fibration allowable if none of its vanishing cycle is null-homologous in the regular fiber.

**Remark 14.** Thus, given an allowable achiral Lefschetz fibration over $D^2$ it admits a Lefschetz fibration embedding into a trivial Lefschetz fibration $\tilde{\pi} : (\mathbb{C}P^2 \# \mathbb{C}P^2) \times D^2 \to D^2$.

**Theorem 15.** Let $\pi : X \to D^2$ be an achiral Lefschetz fibration, where $X$ is a compact, connected, orientable 4-manifold with non-empty boundary such that for each regular value, the fiber is a closed, connected, orientable surface $\Sigma_g$ of genus $g \geq 0$. Then, there exists a Lefschetz fibration embedding of $X$ into a trivial Lefschetz fibration $\tilde{\pi} : (\mathbb{C}P^2 \# \mathbb{C}P^2) \times D^2 \to D^2$ as well into a trivial Lefschetz fibration $\tilde{\pi} : (\mathbb{C}P^2 \# \mathbb{C}P^2) \times D^2 \to D^2$.

**Proof.** In this case, we construct a preferred embedding of $\Sigma_g$ in $\mathbb{C}P^2$ as described in Lemma 9 with following modification:

Consider a collar neighbourhood $S^3 \times [0, 2]$ of the boundary $\partial D^4 = S^3 \times 0$ in a 4-ball $D^4$. Consider a standardly embedded closed orientable surface $S$ of genus $g$ which bounds an unknotted untwisted handlebody of genus $g$ – see Figure 2 – in $S^3 \times 1$. Remove the interiors of two disjoint discs $D_1$ and $D_2$ from $S$ and attach one positive full-twisted band and one negative full-twisted band to $\partial D_1$ and $\partial D_2$ respectively, in $S^3 \times 1$, refer Figure 11. Thus, we get a new compact, connected,
orientable surface $S_1$ of genus $g$ with boundaries $l_1, l_2, l_3$ and $l_4$ such that $l_1 \cup l_2$ is a positive Hopf link and $l_3 \cup l_4$ is a negative Hopf link in $S^3 \times 1$, refer Figure [11]. We attach tubes $l_i \times [0, 1]$, $i = 1, 2, 3, 4$ to get a proper embedding of $S_1$ in $D^4$. Now, we attach 2–handles $H_2$ and $H_4$ to $D^4$ along the boundary components $l_2$ and $l_4$ of $S_1$ with the framing $+1$ and $+1$ (respectively $-1$) respectively, and then attach a 4–handle on the resulting boundary to obtain $\mathbb{CP}^2 \# \mathbb{CP}^2$ (respectively, $\mathbb{CP}^2 \# \overline{\mathbb{CP}^2}$). The components $l_i$ of the surface $S_1$ bounds a 2–disc $D_i'$ in the 2–handle $H_i$ for $i = 2, 4$, namely the core of the 2–handle and the boundary component $l_i$, $i = 1, 3$ of $S_1$ bounds a disc $D_i''$ in the 4–handle of $\mathbb{CP}^2 \# \mathbb{CP}^2$ (respectively, $\mathbb{CP}^2 \# \overline{\mathbb{CP}^2}$). Thus, we get an embedding of the surface $\Sigma_g = S_1 \cup D_1' \cup D_2'' \cup D_3' \cup D_4''$ in $\mathbb{CP}^2 \# \mathbb{CP}^2$ (respectively, $\mathbb{CP}^2 \# \overline{\mathbb{CP}^2}$) such that $\Sigma_g$ contains an embedded positive Hopf annulus $A$ and negative Hopf annulus $A'$ with boundary components $l_1 \cup l_2$ and $l_3 \cup l_4$, refer Figure [11]. We consider this embedding as our preferred embedding $f_{pr}$ of $\Sigma_g$.

Then, using the arguments given in Theorem [6], we obtain the Lefschetz fibration embedding of the achiral Lefschetz fibration $\pi : X \to D^2$ to the trivial Lefschetz fibration $\tilde{\pi} : (\mathbb{CP}^2 \# \overline{\mathbb{CP}^2}) \times D^2 \to D^2$ (respectively, $\tilde{\pi} : \mathbb{CP}^2 \# \overline{\mathbb{CP}^2} \times D^2 \to D^2$).

4.1. Achiral Lefschetz fibration over $\mathbb{CP}^1$. Let $X^4$ be a closed connected orientable 4–manifold. A smooth map $\pi : X^4 \to S^2 = \mathbb{CP}^1$ is said to be a Lefschetz fibration if the conditions (1), (2) and (3) of Definition [4] are satisfied. Similarly, we have the notion of an achiral Lefschetz fibration $\pi : X^4 \to S^2 = \mathbb{CP}^1$.

If we consider a disc $D^2$ in $\mathbb{CP}^1$ containing all the critical values of $\pi$, then we can construct a Lefschetz fibration embedding of the Lefschetz fibration $\tilde{\pi}_{|_{\mathbb{CP}^2 \times D^2}} : \pi^{-1}(D^2) \to D^2$ in a trivial Lefschetz fibration $\tilde{\pi} : \mathbb{CP}^2 \times D^2 \to D^2$.

Now, $\pi$ is a Lefschetz fibration over $\mathbb{CP}^1$, the product of the Dehn twist along the vanishing cycles taken in the same way the corresponding critical values lie on a small counter clockwise oriented circle around the preferred regular value in $D^2$ as described in Subsection [5.2], is isotopic to the identity map of $\Sigma_g$, i.e., the monodromy of the $\Sigma_g$ fiber bundle over $\partial D^2$ is isotopic to the identity of $\Sigma_g$. This implies that we get a trivial $\Sigma_g$ fiber bundle over $\partial D^2$. As the embedding $f_{pr} : \Sigma_g \to \mathbb{CP}^2$ is flexible in $\mathbb{CP}^2$ and the monodromy of the $\Sigma_g$ bundle over $\partial D^2$ is flexible in $\mathbb{CP}^2$, we get a trivial $\mathbb{CP}^2$ bundle $\partial D^2$. Using the isotopy of the monodromy of $\Sigma_g$ with the identity map of $\Sigma_g$ and the flexibility of the preferred embedding, we can extend the Lefschetz fibration embedding of $\pi_{|_{\mathbb{CP}^2 \times D^2}} : \pi^{-1}(D^2 \cup A) \to D^2 \cup A$ into $\tilde{\pi}_{|_{\mathbb{CP}^2 \times (D^2 \cup A)}} : \mathbb{CP}^2 \times (D^2 \cup A) \to D^2 \cup A$, where $A$ is the collar of $\partial(\mathbb{CP}^1 \setminus D^2)$. Finally, we can extend this bundle trivially to the removed disc of $\mathbb{CP}^2$ over $\mathbb{CP}^1$. Therefore, both $\Sigma_g$ bundle over $\partial D^2$ and $\mathbb{CP}^2$ bundle over $\partial D^2$ can be extended to a trivial Lefschetz fibrations over $\mathbb{CP}^1 \setminus D^2$ so that we get a Lefschetz fibration embedding of Lefschetz fibration $\pi : X^4 \to S^2 = \mathbb{CP}^1$ into a trivial $\pi : \mathbb{CP}^2 \times \mathbb{CP}^1 \to S^2 = \mathbb{CP}^1$.

Thus, we have the following theorems:

**Theorem 16.** Let $\pi : X^4 \to \mathbb{CP}^1$ be an achiral Lefschetz fibration, where $X$ is a closed, connected, orientable 4–manifold such that for each regular value, the fiber is a closed, connected, orientable surface $\Sigma_g$ of genus $g \geq 2$. If the vanishing cycle corresponding to each achiral singularity is non-separating on $\Sigma_g$, then there exists a Lefschetz fibration embedding of $\pi : X^4 \to \mathbb{CP}^1$ into a trivial Lefschetz fibration $\tilde{\pi} : \mathbb{CP}^2 \times \mathbb{CP}^1 \to \mathbb{CP}^1$. 

Theorem 17. Let \( \pi : X^4 \to \mathbb{C}P^1 \) be an achiral Lefschetz fibration, where \( X \) is a closed, connected, orientable 4-manifold such that for each regular value, the fiber is a closed, connected, orientable surface \( \Sigma_g \) of genus \( g \geq 2 \). Then, there exists a Lefschetz fibration embedding of \( X \) into a trivial Lefschetz fibration \( \tilde{\pi} : (\mathbb{C}P^2 \# \mathbb{C}P^2) \times \mathbb{C}P^1 \to \mathbb{C}P^1 \) as well as into a trivial Lefschetz fibration \( \tilde{\pi} : (\mathbb{C}P^2 \# \mathbb{C}P^2) \times \mathbb{C}P^1 \to \mathbb{C}P^1 \).

5. Broken Lefschetz fibration

In this section, we shall discuss Lefschetz fibration embeddings of broken Lefschetz fibrations.

Definition 18. Let \( X \) be a compact, connected, oriented 4-manifold with non-empty boundary. A proper smooth surjective map \( \pi : X \to D^2 \) is said have a round singularity along an embedded 1-manifold \( Z \subset \text{int}(X) \setminus C \), where \( C \) is the set of Lefschetz singularities of \( \pi \), if around every \( q \in Z \), there are coordinates \((t, x_1, x_2, x_3)\) with \( t \) a local coordinate on \( Z \) such that \( \pi \) is given by the map \((t, x_1, x_2, x_3) \mapsto (t, x_1^1 + x_2^2 - x_3^2) \). We call the image \( \pi(Z) \subset \text{int}(D^2) \) the round image.

Definition 19. A proper smooth surjective map \( \pi : X \to D^2 \) defined on a compact, connected, oriented 4-manifold \( X \) with non-empty boundary is said to be a broken Lefschetz fibration (BLF) if \( \pi \) has both Lefschetz and round singularities.

A broken Lefschetz fibration is said to be a simplified broken Lefschetz fibration (SBLF) if

- the round singular set \( Z \) is connected and its image on \( D^2 \) is a boundary parallel circle,
- the regular fibers of \( \pi \) are connected,
- the disc containing all the Lefschetz singular value is contained in the interior of the disc bounded by \( \pi(Z) \).

Thus, we get the decomposition of the SBLF into 3 pieces which are

1. a genus \( g - 1 \) Lefschetz fibration over an annulus, we call this piece a lower genus piece,
2. a genus \( g \) Lefschetz fibration over a 2-disc, we call this piece the higher genus piece and
3. a round cobordism between the boundaries of the the higher genus piece and the lower genus piece containing the round singular set in the interior.

A handle description of a SBLF is the higher genus Lefschetz fibration together with a round 2-handle attached to it. A round 2-handle is a fiberwise 2-handle attachment parameterized along \( Z \). Thus, a (untwisted) round 2-handle is \( S^1 \times D^2 \times D^1 = S^1 \times D^3 \). Note that the (untwisted) round 2-handle \( S^1 \times D^3 \) can be regarded as the union of a 0-handle and a 1-handle. So, we can express a (untwisted) round 2-handle in the 4-manifold as attaching a 4-dimensional 2-handle and a 3-handle. The attaching circle of the 2-handle of a round 2-handle is a simple closed curve \( \gamma \) on a regular fiber, which is preserved under the monodromy of this fibration up to isotopy. Since this attachment comes from the fiberwise handle attachments, the 2-handle should have the fiber framing zero. Hence, the framing of the handle attachments are trivial. Here, we will consider attaching untwisted 2-handle, hence
the monodromy \( \phi \) maps \( \gamma \) to \( \gamma \), i.e., we assume \( \phi(\gamma) = \gamma \). For more details, refer [1] and [2].

Now, we prove the following theorem.

**Theorem 20.** Let \( \pi : X \to D^2 \) be a simplified broken Lefschetz fibration, where \( X \) is a compact, connected, orientable 4–manifold with non-empty boundary such that each regular fiber in the higher genus piece is a closed, connected, orientable surface of genus \( g > 2 \), then there exists a Lefschetz fibration embedding of \( X \) into a trivial Lefschetz fibration \( \tilde{\pi} : \mathbb{C}P^2 \times D^2 \to D^2 \).

**Proof.** Consider a SBLF \( \pi : X \to D^2 \). Let \( q_1, ..., q_n \) denote the Lefschetz singularities in the interior of \( X \) and \( p_1, ..., p_n \) be the corresponding singular values of \( q_i \)'s. Let \( Z \) be the round singular circle in the interior of \( X \) and \( Z' = \pi(Z) \) be the image of \( Z \) in \( D^2 \). The circle \( Z' \) encloses all the singular values and is boundary parallel. Let \( D \) be the disc containing all the singular values and contained in the disc bounded by \( Z' \), see Figure 12.

![Figure 12](image_url)

**Figure 12.** In the figure the circle \( Z' \) is a round singular image of broken Lefschetz fibration.

Now, as shown in Theorem 6 we have a Lefschetz fibration embedding of the Lefschetz fibration \( \pi_{|_{\pi^{-1}(D)}} : \pi^{-1}(D) \to D \) into a trivial Lefschetz fibration \( \tilde{\pi} : \mathbb{C}P^2 \times D \to D \). Let \( \phi \) be the boundary monodromy of the Lefschetz fibration \( \pi_{|_{\pi^{-1}(D)}} : \pi^{-1}(D) \to D \) and let \( \Psi \) be the boundary monodromy of the Lefschetz fibration \( \tilde{\pi} : \mathbb{C}P^2 \times D \to D \). Then, \( f_{pr}^{-1} \circ \psi \circ f_{pr} = \phi \).

Consider the annulus \( A = D^2 \setminus D = S^1 \times [-1, 1] = \{((e^{i\theta}, t) : \theta \in [0, 2\pi], t \in [-1, 1]\} \) with \( S_1 \times -1 = \partial D^2, S_1 \times 1 = \partial D \) and \( S_1 \times 0 = Z' \). Suppose \( \pi^{-1}((0, 1)) \) is \( \mathbb{C}P^2 \), i.e., \( \mathbb{C}P^2 \) with preferred embedding \( f_{pr} \) of \( \Sigma_g \).

Let \( \gamma \) be a simple closed curve on \( \Sigma_g \) preserved by the monodromy \( \phi \) of \( \pi_{|_{\pi^{-1}(D)}} \). Suppose that \( \gamma' = f_{pr}(\gamma) \) up to isotopy in \( \Sigma_{pr} \) has following properties:
We call such a simple closed curve $\gamma$ to the embedding $f$.

First, we consider the case where $\gamma$ to the embedding $\gamma$ follows: We will consider isotopy $\Psi_{t}$ in $D(\gamma, 1)$.

We can consider $[0, 1] \times D^{2}$ of $D^{2}$ intersects $\Sigma_{pr}$ in the annulus $\nu(\gamma') = \gamma' \times [-1, 1]$ and $\gamma' \times 0$ and $\gamma' \times 1$ are unknots and unlinked in $S^{3} \times -1$ as described in the construction in the Lemma.

Moreover, $D'(\gamma') \subset \mathcal{N}(D')$ with $\partial D'(\gamma') = \gamma' \times [-1, 1]$.

We can choose coordinates $(\theta, x_{1}, x_{2}, x_{3})$ on $\mathcal{N}(D')$ such that $\Sigma_{pr} \cap g^{-1}(0, 1) = \nu(\gamma')$ with $D'(\gamma') = \{(0, x_{1}, x_{2}, x_{3}) : x_{1}^{2} + x_{2}^{2} \leq 1, x_{3} \in [-1, 1]\}$, where $g : \mathbb{R}^{4} \to \mathbb{R}^{2}$ is a map defined by $(\theta, x_{1}, x_{2}, x_{3}) \mapsto (\theta, x_{1}^{2} + x_{2}^{2} - x_{3}^{2})$ and the plane $\mathbb{R}^{2} = \{(0, x_{1}, x_{2}, 0) \in \mathbb{R}^{4} : x_{1}, x_{2} \in \mathbb{R}\}$ in $\mathbb{R}^{4}$ intersect $\mathcal{N}(D')$ in the disc $D'$.

We call such a simple closed curve $\gamma$ is in the SBLF standard position with respect to the embedding $f_{pr}$.

We can consider $[0, 2\pi] \times D^{2} \times [-1, 1] \subset \mathcal{N}(D')$. Note that all the Lickorish generating curves admit this property with respect to the preferred embedding. First, we consider the case where $\gamma$ is in the SBLF standard position with respect to the embedding $f_{pr}$.

![Figure 13. Flexible embedding of $\Sigma_{g-1}$ from $\Sigma_{g}$.](image)

Now, we consider the flexible embeddings $f_{0,t}$, $t \in (0, 1]$ with $f_{0,1} = f_{pr}$ as follows: We will consider isotopy $\Psi_{t}$, $t \in (0, 1]$ of diffeomorphism of $\mathbb{C}P^{2}$ supported in $\mathcal{N}(D')$ with $\Psi_{1} = id$ such that

- the embeddings $f_{0,t} = \Psi_{t} \circ f_{pr}$.
- the curve $f_{0,t}(\gamma)$ bounds a disc $\Psi_{t}(D') = D'_{t} \subset D'$ in $\mathbb{C}P^{2}$ which intersect the surface $f_{0,t}(\Sigma_{pr})$ only in $f_{0,t}(\gamma')$.
- the tubular neighbourhood $\Psi_{t}(\mathcal{N}(D'_{t}))$ of $D'_{t}$ intersect $f_{0,t}(\Sigma_{pr})$ in the annulus $f_{0,t}(\nu(\gamma')) = \gamma' \times [-1, 1]$.
- moreover, $\Psi_{t}(D' \times [-1, 1]) \subset \mathcal{N}(D'_{t})$ with $\partial D'_{t} \times [-1, 1] = \gamma' \times [-1, 1]$.
- we have $f_{0,t}(\Sigma_{pr}) \cap g^{-1}(0, t) = \nu(\gamma')$ with $D'_{t} \times [-1, 1] = \{(0, x_{1}, x_{2}, x_{3}) : x_{1}^{2} + x_{2}^{2} \leq t, x_{3} \in [-1, 1]\}$, see Figure 13.

For each $t \in (0, 1]$, if we travel through the family $\Psi_{t}$ of diffeomorphisms of $\mathbb{C}P^{2}$, the disc $D' = D'_{t}$ shrinks through the discs $D'_{t}$ to the origin of $D'$. Thus, the
embedded surface $f_{0,1}(\Sigma_{pr})$ can be collapsed through $f_{0,t}(\Sigma_{pr})$ to get a singular surface $\Sigma'$ which is obtained by pinching the circle $\gamma'$ to the origin of the disc $D'$. The singular surface $\Sigma_0$ gives a flexible embedding of the singular fiber $\pi^{-1}(0,0)$ in $\mathbb{C}P^2$, where $(0,0) \in Z' \subset A$ as the monodromy preserves $\gamma'$ up to isotopy. Hence, the isotopy $\{\Psi_t\}_{t \in [0,1]}$ clearly extends to the isotopy $\{\Psi_t\}_{t \in [0,1]}$.

Now, we construct flexible embeddings of the lower genus surface $\Sigma_{g-1}$ from the preferred embedding $f_{pr} : \Sigma_g \to \mathbb{C}P^2$. Consider the surface $\Sigma_{pr} \setminus (\gamma' \times (-1,1))$ and cap off by the discs $D' \times -1$ and $D' \times 1$ to get the preferred embedding $f_{pr}^{-1} : \Sigma_{g-1} \to \mathbb{C}P^2$ of the surface $\Sigma_{g-1}$ and we denote the image $f_{pr}^{-1}(\Sigma_{g-1})$ by $\Sigma_{g-1}$. Now, consider $\Sigma_{pr}^{-1} \cup D' \times [-1,1]$ and consider the isotopy $\Psi_t$, $t \in [-1,0]$, where $\Psi_t = \Psi_{-t}$. Consider the embeddings $f_{0,t}^{-1} = \Psi_t \circ f_{pr}^{-1}$, $t \in [-1,0]$ of $\Sigma_{g-1}$. Note that by construction these embeddings are flexible.

Now, we can construct flexible embeddings of $f_{n,t}$, $t \in (0,1)$, $f_{n,0}$ and $f_{n,t}^{-1}$, $t \in [-1,0]$ as well as the family $\Psi_{n,t}$, $t \in [-1,1]$ as discussed in proof of Theorem 0. From this, we can see that the mapping tori

- $MT(f_{0,1}(\Sigma_{pr}), \phi)$, $t \in (0,1]$ is embedded fiberwise in $MT(\mathbb{C}P^2, \Psi_0, \phi \circ \Psi_0^{-1}), t \in (0,1]$.
- $MT(\Sigma_0, \phi)$ is embedded fiberwise in $MT(\mathbb{C}P^2, \Psi_0, \phi \circ \Psi_0^{-1})$ and
- $MT(f_{0,1}(\Sigma_{pr}^{-1}), \phi)$, $t \in [-1,0)$ is embedded fiberwise in $MT(\mathbb{C}P^2, \Psi_0, t \circ \Psi \circ \Psi_0^{-1}), t \in [-1,0)$.

From this, we can see that the Lefschetz fibration embedding of the Lefschetz fibration $\pi_{|_{\pi^{-1}(D)}} : \pi^{-1}(D) \to D$ to the trivial Lefschetz fibration $\tilde{\pi} : \mathbb{C}P^2 \times D \to D$ which we constructed extends into the Lefschetz fibration embedding of the Lefschetz fibration $\pi : X \to D^2$ into a trivial Lefschetz fibration $\tilde{\pi} : \mathbb{C}P^2 \times D^2 \to D^2$.

If $\gamma$ is not in the SBLF standard position with respect to the embedding $f_{pr}$, then we can choose a diffeomorphism $h$ of the surface $\Sigma_g$ such that $h$ maps $\gamma$ to one of the Lickorish generating curves. Since $f_{pr}$ is a flexible embedding, there exists an isotopy $\{\Phi_r\}_{r \in [0,1]}$ of diffeomorphisms of $\mathbb{C}P^2$ such that $f_{pr}^{-1} \circ \Phi_1 \circ f_{pr} = h$. We consider a family of embeddings $\{f_r\}_{r \in [0,1]}$, where $f_r = \Phi_r \circ f_{pr}$ and we denote the image of embeddings $f_r$ by $\Sigma_r$, where $\Sigma_0 = \Sigma_{pr}$. Now, $f_1(\gamma)$ has the required property with respect to embedding $f_{1,1}$, i.e., $\gamma$ is in the SBLF standard position with respect to $f_1$. As $\gamma$ preserved by $\phi$, $h(\gamma)$ is preserved by $h \circ \phi \circ h^{-1}$. Hence, we have fiberwise embedding of $MT(\Sigma_r, h \circ \phi \circ h^{-1})$ into $MT(\mathbb{C}P^2, \Phi_r \circ \Phi \circ \Phi^{-1})$, for every $r$.

From this, we can see that the Lefschetz fibration embedding of the Lefschetz fibration $\pi_{|_{\pi^{-1}(D)}} : \pi^{-1}(D) \to D$ to the trivial Lefschetz fibration $\tilde{\pi} : \mathbb{C}P^2 \times D \to D$ which we constructed extends into the Lefschetz fibration embedding of the Lefschetz fibration $\pi_{|_{\pi^{-1}(D \cup C_0)}} : \pi^{-1}(D \cup C_0) \to D \cup C_0$ into the trivial Lefschetz fibration $\tilde{\pi} : \mathbb{C}P^2 \times (D \cup C_0) \to D \cup C_0$, where $C_0$ is a small collar of the boundary $S^1 \times 1$ of the annulus $A$. Note that the boundary monodromy of the Lefschetz fibration $\pi_{|_{\pi^{-1}(D \cup C_0)}} : \pi^{-1}(D \cup C_0) \to D \cup C_0$ is $h \circ \phi \circ h^{-1}$ and the boundary monodromy of the Lefschetz fibration $\tilde{\pi} : \mathbb{C}P^2 \times (D \cup C_0) \to D \cup C_0$ is $\Phi_1 \circ \Phi \circ \Phi^{-1}$ which is isotopic to the identity of $\mathbb{C}P^2$.

Finally, using the similar argument given above, we can extend this embedding into the Lefschetz fibration embedding of the Lefschetz fibration $\pi : X \to D^2$ into
a trivial Lefschetz fibration \( \tilde{\pi} : \mathbb{C}P^2 \times D^2 \to D^2 \). This completes the arguments of Theorem \[20\].

Using the arguments in Theorem \[18\, 15\, \text{and} \, 20\] we have the following theorems.

**Theorem 21.** Let \( \pi : X \to D^2 \) be a simplified broken achiral Lefschetz fibration, where \( X \) is a compact, connected, orientable 4–manifold with non-empty boundary such that each regular fiber in the higher genus piece is a closed, connected, orientable surface of genus \( g \geq 1 \). If the vanishing cycles corresponding to each achiral singularity is non-separating on \( \Sigma \), then there exists a Lefschetz fibration embedding of \( X \) into a trivial Lefschetz fibration \( \tilde{\pi} : \mathbb{C}P^2 \times D^2 \to D^2 \).

**Theorem 22.** Let \( \pi : X \to D^2 \) be a simplified broken achiral Lefschetz fibration, where \( X \) is a compact, connected, orientable 4–manifold with non-empty boundary such that each regular fiber in the higher genus piece is a closed, connected, orientable surface \( \Sigma \) of genus \( g \geq 1 \). Then, there exists a Lefschetz fibration embedding of \( X \) into a trivial Lefschetz fibration \( \tilde{\pi} : (\mathbb{C}P^2 \# \mathbb{C}P^2) \times D^2 \to D^2 \) as well as into a trivial Lefschetz fibration \( \tilde{\pi} : (\mathbb{C}P^2 \# \mathbb{C}P^2) \times D^2 \to D^2 \).

For a simplified broken achiral Lefschetz fibration \( \pi : X^4 \to \mathbb{C}P^1 \), we can easily obtain the following results using arguments given in the proof of Theorems \[16\, 17\].

**Theorem 23.** Let \( \pi : X^4 \to \mathbb{C}P^1 \) be a simplified broken achiral Lefschetz fibration, where \( X \) is a closed, connected, orientable 4–manifold such that each regular fiber in the higher genus piece is a closed, connected, orientable surface \( \Sigma_g \) of genus \( g > 2 \). If the vanishing cycle corresponding to each achiral singularity is non-separating on \( \Sigma_g \), then there exists a Lefschetz fibration embedding of \( \pi : X^4 \to \mathbb{C}P^1 \) into a trivial Lefschetz fibration \( \tilde{\pi} : \mathbb{C}P^2 \times \mathbb{C}P^1 \to \mathbb{C}P^1 \).

As every closed, connected, oriented 4–manifold admits a simplified broken Lefschetz fibration over \( \mathbb{C}P^1 \) with the higher genus regular fiber, a surface \( \Sigma_g \) of genus \( g > 2 \), we have the following result.

**Corollary 24.** Every closed, connected, orientable 4–manifold admits a smooth embedding in \( \mathbb{C}P^2 \times \mathbb{C}P^1 \).

**Theorem 25.** Let \( \pi : X^4 \to \mathbb{C}P^1 \) be a simplified broken achiral Lefschetz fibration, where \( X \) is a closed, connected, orientable 4–manifold such that each regular fiber in the higher genus piece is a closed, connected, orientable surface \( \Sigma_g \) of genus \( g > 2 \). Then, there exists a Lefschetz fibration embedding of \( X \) into a trivial Lefschetz fibration \( \tilde{\pi} : (\mathbb{C}P^2 \# \mathbb{C}P^2) \times \mathbb{C}P^1 \to \mathbb{C}P^1 \) as well into a trivial Lefschetz fibration \( \tilde{\pi} : (\mathbb{C}P^2 \# \mathbb{C}P^2) \times \mathbb{C}P^1 \to \mathbb{C}P^1 \).

6. **Bordered Lefschetz fibration**

In this section, we discuss the notion of bordered Lefschetz fibration.

**Definition 26.** (Bordered Lefschetz fibration on 4–manifold) Let \( X \) be a compact, connected, orientable smooth 4–manifold with non-empty boundary. A smooth map \( \pi : X \to D^2 \) is said to be a bordered Lefschetz fibration if

1. the map \( \pi \) has finitely many critical (or singular) points \( q_i \), all lie in the interior of \( X \) with critical (or singular) values \( f(q_i) = p_i, 1 \leq i \leq n \) and \( p_i \neq p_j \), for \( i \neq j \),
Theorem 27. Let $\Sigma$ be a compact, connected, orientable 4–manifold with non-empty boundary.

(2) for each critical point $q_i$ and its corresponding critical value $p_i$, there exist coordinate charts $U_{q_i} = \mathbb{C}^2$ around $q_i = (0,0)$ and $V_{p_i} = \mathbb{C}$ around $p_i = 0$ in $X$ and $D^2$ respectively, which agree with the orientations of $X$ and $D^2$, such that the restriction of $\pi$ on $U_{q_i}$ is the map $\pi : U_{q_i} \to V_{p_i}$ defined as $\pi(z_1, z_2) = z_1^2 + z_2^2$.

(3) for a regular value $p$, the fiber is a compact, connected, oriented proper surface of $X$ with non-empty boundary.

Note that the bordered (achiral) Lefschetz fibration gives an open book structure on its boundary.

Note that using the construction given in Lemma 3 one can obtain a proper flexible embeddings of a surface $\Sigma_{g,n}$ of genus $g$ with $n$ boundary components in $DE(m)$ as well as in $DE(m)\#DE(m)$, where $DE(m)$ is the $D^2$ bundle over $S^2$ with the Euler number an integer $m$, for more details refer [16], [3] and [17].

Now, the following are the consequences of the arguments given in Theorem 6. First, consider a collar neighbourhood $S^3 \times [0, 2]$ of the boundary $\partial D^4 = S^3 \times 0$ in a 4–ball $D^4$. Consider a standardly embedded closed orientable surface $S$ of genus $g$ which bounds an unknotted untwisted handlebody of genus $g$ – see Figure 2. Remove the interior of $n$ disjointly embedded discs $D_1, ..., D_n$ with $\partial D_i = l_i$ from $S$ to get a surface $\Sigma_{g,n}$ of genus $g$ with $n$ boundary components and attach tubes $l_1 \times [0, 1], ..., l_n \times [0, 1]$ to get a proper embedding of the surface $\Sigma_{g,n}$ of genus $g$ with $n$ boundary components in $D^4$. We consider this embedding as the preferred embedding $f_{\pi}$ of $\Sigma_{g,n}$ in $D^4$.

Consider a collection $\mathcal{A} = \{a_i\}$ and $\mathcal{B} = \{b_i\}$ of simple closed curves in $\Sigma_{g,n}$ such that each $a_i$ admit a regular neighbourhood in $\Sigma_{g,n}$ which is a positive Hopf annulus in $S^3 \times 1$ and each $b_i$ admit a regular neighbourhood in $\Sigma_{g,n}$ which is a negative Hopf annulus in $S^3 \times 1$. For example, see Figure 3. Note that all the Dehn twists $d_{a_i}, d_{a_i}^{-1}, d_{b_i}$ and $d_{b_i}^{-1}$ are flexible in $D^4$. The curves $a_i$’s are in the standard position and the curves $b_i$’s are in the achiral standard position with respect to the preferred embedding $f_{\pi}$ in $D^4$.

Consider a collections $\mathcal{C}$ of curves $\gamma$ such that $h(\gamma) = a_j$ for some $a_j \in \mathcal{A}$ and for some diffeomorphism $h$ of $\Sigma_{g,n}$ which is a product of positive as well as negative powers of the Dehn twists $d_{a_i}$ and $d_{b_i}$, i.e., $h$ belongs to the subgroup of generated by the Dehn twists $d_{a_i}$ and $d_{b_i}$. Similarly, we consider a collections $\mathcal{C}'$ of curves $\gamma$
such that $h(\gamma) = b_j$ for some $b_j \in B$ and for some diffeomorphism $h$ of $\Sigma_{g,n}$ which is a product of positive as well as negative powers of the Dehn twists $d_{a_i}$ and $d_{b_i}$. Note that such a $h$ is flexible in $D^4$.

**Theorem 29.** Suppose that $\pi : X \to D^2$ is a bordered achiral Lefschetz fibration with the property that

- the regular fiber of $\pi$ is the surface $\Sigma_{g,n}$ of genus $g$ with $n$ boundary components,
- the vanishing cycle corresponding to each Lefschetz singularity is in the collection $C$,
- the vanishing cycle corresponding to each achiral Lefschetz singularity is in the collection $C'$.

Then, $\pi : X \to D^2$ admits a Lefschetz fibration embedding into the trivial Lefschetz fibration $\tilde{\pi} : D^4 \times D^2 \to D^2$.

**Proof.** Even though the preferred embedding $f_{pr} : \Sigma_{g,n} \to D^4$ is not a flexible embedding, we can use the flexibility of Dehn twists $d_{a_i}, d^{-1}_{a_i}, d_{b_i}, d^{-1}_{b_i}$ and any $h$ which is product of positive and negative powers of the Dehn twists $d_{a_i}$ and $d_{b_i}$ together with the arguments given in the proof of Theorem 6 and 13 to obtain the required embedding.

□

**Remark 30.** Similar result to Theorem 29 can be proved when $\pi : X \to D^2$ is an achiral Lefschetz fibration with closed fibers.

Using the arguments given for Theorem 29 we can show the following result.

**Theorem 31.** Suppose that $\pi : X \to S^2$ is an achiral Lefschetz fibration with the property that

- the vanishing cycle corresponding to each Lefschetz singularity is in the collection $C$,
- the vanishing cycle corresponding to each achiral Lefschetz singularity is in the collection $C'$.

Then, $\pi : X \to S^2$ admits a Lefschetz fibration embedding into the trivial Lefschetz fibration $\tilde{\pi} : D^4 \times S^2 \to S^2$ and into $\tilde{\pi} : S^4 \times S^2 \to S^2$.

Recall that the mapping class group of a compact orientable surface $\Sigma_{g,1}$ of genus $g$ with connected boundary is generated by the Humphries generating curves $\gamma_1, \gamma_2, \alpha_1, \ldots, \alpha_g, \beta_1, \ldots, \beta_{g-1}$
given in Figure 15. Let \( K = \{ \gamma_1, \alpha_1, \ldots, \alpha_g, \beta_1, \ldots, \beta_{g-1} \} \). Consider a collections \( \mathcal{H} \) of curves \( \gamma \) such that \( h(\gamma) = c \) for some \( c \in K \) and for some diffeomorphism \( h \) of \( \Sigma_{g,n} \), which is a product of positive as well as negative powers of the Dehn twists along the curves in \( K \). Now, we have the following theorem.

**Theorem 32.** Let \( \pi : X \to D^2 \) be a bordered Lefschetz fibration, where \( X \) is a compact, connected, orientable 4–manifold with non-empty boundary such that for each regular value, the fiber is a compact, connected, orientable surface \( \Sigma_{g,1} \) of genus \( g \geq 1 \) with connected boundary. Suppose that all the vanishing cycles corresponding to the Lefschetz fibration are in the set \( \mathcal{H} \), then there exists a Lefschetz fibration embedding of \( X \) into a trivial Lefschetz fibration \( \tilde{\pi} : D^4 \times D^2 \to D^2 \).

\[
\begin{align*}
\alpha_1 & \quad \alpha_2 & \quad \alpha_3 & \quad \alpha_g \\
\beta_1 & \quad \beta_2 & \quad \beta_3 & \quad \beta_{g-1}
\end{align*}
\]

**Figure 15.** A surface of genus \( g \) having connected boundary with the Humphries generating curves \( \gamma_1, \gamma_2, \alpha_1, \ldots, \alpha_g, \beta_1, \ldots, \beta_{g-1} \).

\[
\begin{align*}
\gamma_1 & \quad \alpha_1 & \quad \beta_1 & \quad \alpha_2 & \quad \beta_2 & \quad \beta_{g-1} & \quad \alpha_g
\end{align*}
\]

**Figure 16.** An embedding of a surface of genus \( g > 0 \) having connected boundary with the Humphries generating curves \( \gamma_1, \alpha_1, \ldots, \alpha_g, \beta_1, \ldots, \beta_{g-1} \).

**Proof.** This construction is from [17]. We can construct an embedding of the surface \( \Sigma_{g,1} \) in \( S^3 \) as follow: Consider \( 2g \) mutually disjoint and unlinked standardly
embedded annuli $A_1, A_2, \ldots, A_{2g}$ in $S^3$, i.e. the boundary components of each $A_i$ are unknots and unlinked. Let $A_i = C_i \times [-1, 1]$, where $C_i = S^1$, for each $i$. Consider two properly embedded disjoint arcs $a_i = \theta_i \times [-1, 1]$ and $a'_i = \theta'_i \times [-1, 1]$ in $A_i$, for each $i$. Let $R_i = a_i \times [-1, 1]$ and $R'_i = a'_i \times [-1, 1]$ be two disjoint rectangular neighborhoods of $a_i$ and $a'_i$ in $A_i$. Now, we glue $A_i$ to $A_{i+1}$ along $R'_i$ and $R_i+1$ so that $a'_i \times \{-1,1\} = \partial a_{i+1} \times [-1, 1]$ to get an embedding of a surface $\Sigma_{g,1}$ of genus $g$ with connected boundary, see Figure 16. One can observe that the Humphries generating curves $\alpha_i$'s, $\beta_j$'s and $\gamma_1$ correspond to the central curves of the distinct annuli $A_j$'s as shown in Figure 16. In the above construction, we replace all the annuli $A_i$ by the positive Hopf annuli $H_i^+$ see Figure 17. Thus, we get an embedding $f$ of $\Sigma_{g,1}$ in $S^3$ such that each of the Humphries generating curves $\alpha_i$'s, $\beta_j$'s and $\gamma_1$ admit a positive Hopf annulus regular neighbourhood. We can consider this $S^3$ as $S^3 \times \frac{1}{2}$, where $S^3 \times [0, 1]$ is a collar of the boundary $\partial D^4 = S^3 \times 0$ in $D^4$. We can see that this embedding can be made a proper embedding $f_{pr}$ in $D^4$ such that the curves $\gamma_1, \alpha_1, \ldots, \alpha_g, \beta_1, \ldots, \beta_{g-1}$ given in Figure 15 are in the standard position with respect to the embedding $f_{pr}$. Note that the embedding $f_{pr}$ of $\Sigma_{g,1}$ in $D^4$ is not flexible in $D^4$ but the Dehn twists along the curves $\gamma_1, \alpha_1, \ldots, \alpha_g, \beta_1, \ldots, \beta_{g-1}$ are flexible in $D^4$.

Now, we can use the flexibility of Dehn twists $d_c, d_{c^{-1}}$ where $c \in K$ and any $h$ which is product of positive and negative powers of the Dehn twists $d_c, c' \in K$ together with the arguments given in the proof of Theorem 6 and 13, to obtain the required embedding.

\[ \square \]

Remark 33. Note that by plumbing a negative Hopf annuli instead of a positive Hopf annuli in the proof of Theorem 32 for appropriate vanishing cycle,s we can produce embeddings of certain bordered achiral Lefschetz fibration into a trivial Lefschetz fibration $\tilde{\pi} : D^4 \times D^2 \to D^2$. In fact, one can consider various cases.
6.2. Embedding of closed orientable 4–manifolds in $S^4 \times S^2$ and $S^4 \times S^2$.

Now, we shall show that every closed, connected, orientable 4–manifold admits a smooth embedding in $S^4 \times S^2$ as well as in $S^4 \times S^2$. We recall the following result from [4].

**Theorem 34** (Etnyre–Fuller). Let $X$ be a closed, connected, orientable 4–manifold. Then, we may write $X = Y_1 \cup Y_2$, where each $Y_i$ is a 2–handlebody which admits an achiral Lefschetz fibration over $D^2$ with bounded fibers of the same genus, and with the induced open books on $\partial Y_1 = -\partial Y_2$ coinciding.

**Remark 35.** We can assume that vanishing cycles of each Lefschetz fibration described in the above result to be non-nullhomologous.

Let $f_1 : Y_1 \to D^2$ and $f_2 : Y_2 \to D^2$ be two achiral Lefschetz fibrations with bounded fibers such that each $f_i$ induces an open book structure on the common boundary $\partial Y_1 = -\partial Y_2$ and the open book structures on $\partial Y_1 = -\partial Y_2$ coincide. We can stabilize the achiral Lefschetz fibrations so that each has fibers with connected boundary. We can reconstruct $X$ from the pieces $Y_1$ and $Y_2$ as follows: We first glue along the pages of the open books, by forming

$$W = Y_1 \cup_{f^{-1}_1(\partial D^2)} f^{-1}_2(\partial D^2) Y_2.$$ 

Now, we have an achiral Lefschetz fibration with bounded fibers $f_1 \cup f_2 : W \to S^2$. Note that each fiber of these achiral Lefschetz fibrations has connected boundary. Therefore, $\partial W = S^1 \times S^2 = S^1 \times D^2 \cup S^1 \times D^2$, where $S^1 \times D^2$ is $\partial Y \setminus f^{-1}_i(\partial D^2)$. Hence, if we glue $S^1 \times D^2$ to $S^1 \times D^2$ in $\partial W$, we get the 4–manifold $X$. Note that gluing an $S^1 \times D^2$ to $W$ will produce the same result as gluing $S^1 \times D^2$ to $S^1 \times D^2$. Hence, we have $X = W \cup S^1 \times D^3$.

**Theorem 36.** Every closed, connected, orientable 4–manifold $X$ admits a smooth embedding into $S^4 \times S^2$ as well as into $S^4 \times S^2$.

**Proof.** Let $X = Y_1 \cup Y_2$ be a closed, connected, orientable smooth 4–manifold, where each $Y_i$ is a 2–handlebody which admits an allowable achiral Lefschetz fibrations $f_1 : Y_1 \to D^2$ and $f_2 : Y_2 \to D^2$ with fibers $\Sigma$ having the same genus and the connected boundary, and with the induced open books on $\partial Y_1 = -\partial Y_2$ coinciding. Existence of such a decomposition follows from the Theorem [4].

Now, we construct the proper Lefschetz fibration embeddings $g_i$ of the Lefschetz fibrations $f_1 : Y_1 \to D^2$ and $f_2 : Y_2 \to D^2$ into two different copies of trivial Lefschetz fibrations $\tilde{\pi}_i : Q_i = DE(m) \times D^2 \to D^2$, $i = 1, 2$, as described in Theorem 27. The Lefschetz fibration embedding of $f_i : Y_i \to D^2$ into $\tilde{\pi}_i : DE(m) \times D^2 \to D^2$ gives an open book embedding of the open book of $M_i = \partial Y_i$ into the open book of $N_i = \partial (DE(m) \times D^2)$. Note that

$$N = \partial (DE(m) \times D^2) = \begin{cases} S^2 \times S^3 & \text{when } m \text{ is even,} \\ S^2 \times S^3 & \text{when } m \text{ is odd.} \end{cases}$$

We have $N_1 = -N_2$ and the open books on $N_1$ and $N_2$ coincides. Note that $f_i|_{M_i} : M_i \setminus (\partial \Sigma \times D^2) \to \partial D^2 = S^1 = \{ e^{i\theta} : 0 \leq \theta \leq 2\pi \}$ and $\tilde{\pi}_i|_{N_i} : N_i \setminus (\partial DE(m) \times D^2) \to S^1$ are locally trivial fiber bundle over $S^1$ such that $\tilde{\pi}_i|_{N_i} \circ g_i|_{M_i} = f_i|_{M_i}$. Let $f^{-1}_i(0) = \Sigma_0 = f_{pr}(\Sigma)$ be the page of the open book on $M_i$ and $\tilde{\pi}^{-1}_i(0) = DE(m)_{pr}$ be the page of the open book on $N_i$. Let $\phi_i$ and $\Phi_i(\sim id)$
be the monodromy on the open books of $M_i$ and $N_i$ respectively. Then, we have $f_{pr}^{-1} \circ \Phi_i \circ f_{pr} = \phi_i$. As $\Phi_i$ is isotopic to the identity map of $DE(m)$, we have $\tilde{\pi}_{i|N_i}^{-1}(\partial D^2) \to S^1$ is a trivial $DE(m)$ bundle over $S^1$.

Suppose that $h : \Sigma \to \Sigma$ is the identification of the page $\Sigma_0$ of $M_1$ and $M_2$ which gives identification on the pages of the open books on $M_1$ and $M_2$. Since $f_{pr} : \Sigma \to \DE(m)$ is a flexible embedding, there exists a diffeomorphism $\Phi : DE(m) \to DE(m)$ which is isotopic to the identity map of $DE(m)$ such that $f_{pr}^{-1} \circ \Phi \circ f_{pr} = h$. We use $\Phi$ to identify the page $\tilde{\pi}_{i|N_i}^{-1}(0) = \DE(m)_{pr}$ of the open books of $N_1$ and $N_2$ which will use to identify the pages of the open books on $N_i$.

Now, we glue $Q_1$ and $Q_2$ along the pages of open books of $N_1$ and $N_2$ using the identification $\Phi$ to get a trivial Lefschetz fibration $\tilde{\pi}_1 \cup \tilde{\pi}_2 : DE(m) \times S^2 \to S^2$. Note that $DE(m) \times S^2$ contains the proper embedding of $X \setminus S^1 \times D^3$ of $X$. Now, we glue $\partial DE(m) \times D^3$ to $DE(m) \times S^2$ such that we get an embedding of $X$ in $Y = DE(m) \times S^2 \cup \partial DE(m) \times D^3$.

Note that $Y = \partial(DE(m) \times D^3) = \partial DE(m) \times D^3 \cup DE(m) \times S^2$. But, $DE(m) \times D^3$ is a $(D^2$–bundle over $S^3) \times D^3 = DE(m) \bigoplus (S^2 \times D^3)$ which is a $D^5$–bundle over $S^2$. Hence, $Y$ is the boundary of a $D^5$–bundle over $S^2$, i.e., $Y$ is a $S^4$–bundle over $S^2$. But a $S^4$–bundle over $S^2$ is completely determined by $\pi_1(SO(5)) = Z_2$. From this one can see that,

$$Y = \begin{cases} S^4 \times S^2 & \text{when } m \text{ is even}, \\ S^4 \times S^2 & \text{when } m \text{ is odd}. \end{cases}$$

This completes the proof. \hfill $\Box$

Now, we give another proof of a theorem of Hirsch [14] which states that every closed orientable 4-manifold embeds in $\mathbb{R}^7$.

**Corollary 37.** Every closed, connected, orientable 4-manifold is smoothly embedded in $\mathbb{R}^7$.

**Proof.** By Theorem 36 every closed, connected, orientable smooth 4-manifold smoothly embeds in $S^4 \times S^2$. As $S^4$ sits inside $\mathbb{R}^7$ with the trivial normal bundle $S^3 \times D^3$, we have smooth embedding of $S^4 \times S^2$ in $\mathbb{R}^7$. Hence, every closed, connected, orientable 4-manifold smoothly embeds in $\mathbb{R}^7$. \hfill $\Box$

## 7. Lefschetz Fibration on Non-orientable 4–Manifolds

Recently, in [14] Miller and Ozbagci discuss the Lefschetz fibration on a compact non-orientable 4–manifold $X$ with non-empty boundary which is a handlebody without 3– and 4–handles. They showed that any non-orientable 4–dimensional handlebody without 3– and 4–handles admits a Lefschetz fibration over the 2–disc $D^2$ whose regular fibers are compact non-orientable surface with non-empty boundary. We will review Lefschetz fibration on non-orientable 4–manifolds.

### 7.1. Lefschetz Fibration

Now, we discuss the notion of Lefschetz fibration.

**Definition 38.** (Lefschetz fibration on non-orientable 4–manifold) Let $X$ be a compact, connected, non-orientable smooth 4–manifold with non-empty boundary. A smooth map $\pi : X \to D^2$ is said to be a Lefschetz fibration if
(1) the map $\pi$ has finitely many critical (or singular) points $q_i$, all lie in the interior of $X$ with critical (or singular) values $f(q_i) = p_i$, $1 \leq i \leq n$ and $p_i \neq p_j$, for $i \neq j$.

(2) for each critical point $q_i$ and its corresponding critical value $p_i$, there exist coordinate charts $U_{q_i} = \mathbb{C}^2$ around $q_i = (0,0)$ and $V_{p_i} = \mathbb{C}$ around $p_i = 0$ in $X$ and $D^2$ respectively such that the restriction of $\pi$ on $U_{q_i}$ is the map $\pi : U_{q_i} \to V_{p_i}$, defined as $\pi(z_1, z_2) = z_1z_2$. Such a singularity is called Lefschetz singularity.

(3) for a regular value $p$, the fiber is a compact connected non-orientable surface with non-empty boundary.

Now, let us discuss the 2–handle description near a singular point of a Lefschetz fibration $\pi : X^4 \to D^2$ of a non-orientable 4–manifold $X$. Suppose that $q_1, q_2, \ldots, q_n$ and $p_1, p_2, \ldots, p_n$ are the critical and the critical values of $\pi$ respectively, such that $\pi(q_i) = p_i$. First, consider the trivial Lefschetz fibration $\pi : D^2 \times \Sigma \to D^2$, where $\Sigma$ is a compact non-orientable surface with non-empty boundary. We attach 2–handles along the 2–sided simple closed curves $\gamma_i$ – one for each critical point $q_i$ – embedded in the distinct regular fibers along the boundary $\partial(D^2 \times \Sigma)$ of $D^2 \times \Sigma$. The framing of each 2–handle is given by the $\pm 1$ framing with respect to the surface framing. Note that there is no canonical orientation on the regular neighbourhood of the attaching curve. We will choose some orientation on the regular neighbourhood of the attaching curve $\gamma_i$ and we will consider the framing of the attaching 2–handle $\pm 1$ accordingly. The local monodromy around the critical value is a Dehn twist along attaching curve $\gamma_i$ which we call the vanishing cycle corresponding to the critical value $p_i$. The choice of the right(positive) handed Dehn twist and the left(negative) handed Dehn twist depends on the choice of the orientation on the regular neighbourhood of the vanishing cycle, i.e., for a fixed orientation of the regular neighbourhood of a 2–sided curve if we attach a 2–handle with $-1$ (respectively, $+1$) framing, then we can assume the local monodromy corresponds to the positive (respectively, the negative) Dehn twist along the vanishing cycle in the surface $\Sigma$. If a vanishing cycle $\gamma$ appears twice corresponding to two distinct critical values and if the 2–handles are attached along the vanishing cycle $\gamma$ – lying in the different regular fibers in $\partial(D^2 \times \Sigma)$ – with framing $+1$ and $-1$ with respect to the choice of the surface framing in the regular neighbourhood of $\gamma$ on $\Sigma$, then the Dehn twists $d_\gamma$ and $d_\gamma^{-1}$ will appear in the boundary monodromy description of the Lefschetz fibration. Here onwards, we will fix some orientation on the regular neighbourhood of each vanishing cycle on $\Sigma$.

Kobayashi and Omori in [11] proved that $\mathcal{MCG}(\Sigma)$ is generated by the Dehn twists along the 2–sided simple closed curves $\alpha_i$, $\beta_i$, $\alpha_{ij}$, $\rho_{ij}$, $\sigma_{ij}$, $\sigma'_{ij}$, $\sigma$ as shown in Figure and the $Y$– homeomorphism obtained by sliding $\mu_1$ along $\alpha_1$ once on the $Y$–space.

Now, we prove the following theorem.

**Theorem 39.** Let $\pi : X \to D^2$ be a bordered Lefschetz fibration, where $X$ is a compact, connected, non-orientable 4–manifold with non-empty boundary such that the handle decomposition of $X$ does not admit 3– and 4–handles. Suppose that for each regular value, the fiber is a compact, connected, non-orientable surface $\Sigma_{g,n}$ of genus $g \geq 1$ with $n$ boundary components. If the boundary monodromy is a product of only positive powers of Dehn twists along the vanishing cycles, then
there exists a Lefschetz fibration embedding of $X$ into a trivial Lefschetz fibration $\tilde{\pi}: DE(m) \times D^2 \to D^2$.

First, we define the following notion.

Any simple closed curve $\gamma$ in $\Sigma_g$ is said to be in the achiral standard position with respect to the embedding $f_{pr}$ if $f_{pr}(\gamma)$ can be isotoped to a curve $\gamma'$ in $f_{pr}(\Sigma_g) \cap S^3 \times 1$ such that $\gamma'$ admits a regular neighbourhood $\nu(\gamma')$ in $f_{pr}(\Sigma_g)$ which is a negative Hopf annulus in $S^3 \times 1$. Any such curve will satisfy the following conditions.

- the curve $\gamma'$ admits a regular neighbourhood $\nu(\gamma)$ in $f_{pr}(\Sigma_g)$ which is a Hopf annulus in $S^3 \times 1$,
- $\gamma'$ bounds the disc in $DE(m)$ which intersects $f_{pr}(\Sigma_g)$ only in $\gamma'$,
- a tubular neighbourhood $N(D) = D^2 \times D^2$ intersects $f_{pr}(\Sigma_g)$ in a regular neighbourhood $\nu(\gamma')$ of $\gamma'$ in $f_{pr}(\Sigma_g)$,
- we can choose coordinates $(z_1, z_2)$ on $N(D)$ such that $\nu(\gamma') = g^{-1}(1) \cap f_{pr}(\Sigma_g)$, where $g: \mathbb{C}^2 \to \mathbb{C}$ is a map defined by $g(z_1, z_2) = z_1 z_2$ and the plane $\mathbb{R}^2 = \{(z_1, z_2) \in \mathbb{C}^2 : z_1 = x + iy, z_2 = x - iy\}$ in $\mathbb{C}^2$ intersects $N(D)$ in the disc $D$ and the surface $\Sigma$ in $\gamma'$. Note that $\gamma'$ is the circle $x^2 + y^2 = 1$ and the disc $D$ is $x^2 + y^2 \leq 1$ in $\mathbb{R}^2$.

Note that Remark 11 also true in this setup.
Consider a 4–ball $S^3$ from for each $i$ of genus $g$ boundary components are $S^3$ with framing an integer $m$ disjointly embedded discs, say $A_1, A_2, \ldots, A_g, D_1, \ldots, D_n$. If we attach $g$ disjoint Möbius bands $\mu_1, \ldots, \mu_g$ to $\partial A_1, \ldots, \partial A_g$ respectively, then we get the non-orientable surface $\Sigma$ of genus $g$ with $n$ boundary components as shown in Figure 19. Equivalently, $\Sigma$ can obtained from $S^3$ $\Sigma$ can obtained from $S^3$ + $n$ disjointly embedded discs, say $A_1, A_2, \ldots, A_g, D_1, \ldots, D_n$ from $S^3$. We attach $g$ right-half twisted bands to $\partial A_1, \ldots, \partial A_g$ and a right (or left) full-twisted band to the $\partial D_1$ in $S^3 \times \frac{1}{2}$. We denote the new boundary components by $b_1, \ldots, b_g, l_1', l_1, l_2, \ldots, l_n$. We attach disjoint discs $D_1', \ldots, D_n'$ to $b_1, \ldots, b_g$, respectively such that $D_i' \subset S^3 \times \frac{1}{2}$ and $D_i' \cap S^3 \times \frac{1}{2} = b_i$. We denote the new surface obtained above by $S'$ whose boundary components are $l_1', l_1, \ldots, l_n$. Consider the surface $S''$ which is obtained from $S'$ by considering the union of $S'$ with $n + 1$ cylinders, namely $l_1' \times [\frac{1}{2}, 1]$ and $l_i \times [\frac{1}{2}, 1]$ for each $i = 1, 2, \ldots, n$. Now, we attach a 2–handle $H^2$ to $D^4$ along $l_1' \times 1$ with framing an integer $m$ to obtain $DE(m)$. Note that $l_1' \times 1$ bounds a disc $D$ in the 2–handle such that the interior of $D$ is disjoint from $S''$. We attach this disc to $S''$ to obtain a proper embedding $f$ of $\Sigma$ with boundary components $l_1, l_2, \ldots, l_n$ in $DE(m)$. We perturb this embedding slightly to make it into a smooth and proper embedding. For flexibility of this embedding, refer [3].

We call this embedding as the preferred embedding $f_{pr}$ of $\Sigma$ in $DE(m)$. Note that we have a preferred embedding of $\Sigma$ in $DE(m)$ such that

1. each of the curves $\alpha_1, \ldots, \alpha_g, \alpha_{ij}$'s has a Hopf annulus as a regular neighborhood and is in the standard position with respect to $f_{pr}$,
2. each of the curves $\beta_1, \ldots, \beta_n, \sigma_{ij}$'s, $\rho_{ij}$'s has a regular neighborhood a standardly embedded annulus,

Figure 19. An embedding of the non-orientable surface $\Sigma$ of genus $g$ with $n$ boundary components with the curve $\eta$ in $DE(m)$. $\alpha_1 \# b_1 \eta$ is an isotopy of $\alpha_1$ along the disc in the handle of $DE(m)$. 

7.2. Flexible embedding of a non-orientable surface in $DE(m)$. We describe the non-orientable surface $S_{g,n}$ of genus $g$ with $n$ boundary components as follows: Consider a surface $S_{g,n}$ obtained from a 2–sphere $S$ by removing the interiors of $g + n$ disjointly embedded discs, say $A_1, A_2, \ldots, A_g, D_1, \ldots, D_n$. If we attach $g$ disjoint Möbius bands $\mu_1, \ldots, \mu_g$ to $\partial A_1, \ldots, \partial A_g$ respectively, then we get the non-orientable surface $\Sigma$ of genus $g$ with $n$ boundary components as shown in Figure 19. Equivalently, $\Sigma$ can obtained from $S_{g,n}$ by antipode identification on the $\partial A_i$, for each $i$.

Now, we describe a proper flexible embedding of the non-orientable surface $\Sigma$ of genus $g$ with $n$ boundary components in $DE(m)$. This construction is from [3]. Consider a 4–ball $D^4$. Consider a 2-sphere $S$ which is the boundary of a 3–ball in $S^3 \times \frac{1}{2}$ in the collar $S^3 \times [0, 1]$ of $\partial D^4$ with $S^3 \times 1 = \partial D^4$. We remove $g + n$ disjointly embedded 2–discs, say $A_1, A_2, \ldots, A_g, D_1, \ldots, D_n$ from $S$. We attach $g$ right-half twisted bands to $\partial A_1, \ldots, \partial A_g$ and a right (or left) full-twisted band to the $\partial D_1$ in $S^3 \times \frac{1}{2}$. We denote the new boundary components by $b_1, \ldots, b_g, l_1', l_1, l_2, \ldots, l_n$. We attach disjoint discs $D_1', \ldots, D_n'$ to $b_1, \ldots, b_g$, respectively such that $D_i' \subset S^3 \times [\frac{1}{2}, \frac{3}{2}]$ and $D_i' \cap S^3 \times \frac{1}{2} = b_i$. We denote the new surface obtained above by $S'$ whose boundary components are $l_1', l_1, \ldots, l_n$. Consider the surface $S''$ which is obtained from $S'$ by considering the union of $S'$ with $n + 1$ cylinders, namely $l_1' \times [\frac{1}{2}, 1]$ and $l_i \times [\frac{1}{2}, 1]$ for each $i = 1, 2, \ldots, n$. Now, we attach a 2–handle $H^2$ to $D^4$ along $l_1' \times 1$ with framing an integer $m$ to obtain $DE(m)$. Note that $l_1' \times 1$ bounds a disc $D$ in the 2–handle such that the interior of $D$ is disjoint from $S''$. We attach this disc to $S''$ to obtain a proper embedding $f$ of $\Sigma$ with boundary components $l_1, l_2, \ldots, l_n$ in $DE(m)$. We perturb this embedding slightly to make it into a smooth and proper embedding. For flexibility of this embedding, refer [3].

We call this embedding as the preferred embedding $f_{pr}$ of $\Sigma$ in $DE(m)$. Note that we have a preferred embedding of $\Sigma$ in $DE(m)$ such that

1. each of the curves $\alpha_1, \ldots, \alpha_g, \alpha_{ij}$'s has a Hopf annulus as a regular neighborhood and is in the standard position with respect to $f_{pr}$,
2. each of the curves $\beta_1, \ldots, \beta_n, \sigma_{ij}$'s, $\rho_{ij}$'s has a regular neighborhood a standardly embedded annulus,
(3) each of the curves $\sigma_{ij}'$’s, $\sigma$ has a regular neighborhood a two full-twisted annulus.

Note that we can isotope the curve $\beta \in \{\beta_1, \ldots, \beta_{n-1}, \sigma_{ij}, \rho_{ij}\}$ to $\beta \# \eta$ so that regular neighborhood of $\beta \# \eta$ is a Hopf annulus as shown in the Figure 19. Here, $\eta$ is the curve which goes over the the full twisted band exactly once and does not meet any Möbius band $\mu_i$ and $\beta \# \eta$ denotes the band connected sum of $\beta$ and $\eta$. We will choose a band which does not meet any Möbius band $\mu_i$ of the surface. Moreover, each curve $\beta$ is in the standard position with respect to the embedding $f_{pr}$. Note that the orientations on $\nu(\beta)$ and $\nu(\eta)$ will induce an orientation on $\nu(\beta \# \eta)$.

Now, while constructing the embedding of $\Sigma$ in $DE(m)$, we can attach a left full-twisted band to the boundary component $\partial D_1$ as shown the Figure 18 so that the regular neighborhood of each of the curves $\sigma_{ij}' \# \eta$ and $\sigma \# \eta$ is a Hopf annulus. For, these regular neighborhoods will have three full-twists but two of them cancel each other to get a Hopf annulus neighborhood. Note that any 2-sided separating curve shown in Figure 18 and any curve which does not meet any Möbius band $\mu_i$ can be isotoped to be in the standard position with respect to $f_{pr}$ by considering band connected sum with the curve $\eta$.

If a 2–sided simple closed curve $\gamma$ in $\Sigma$ is not in the standard position with respect to $f_{pr}$, then we can construct an embedding of $\Sigma$ as described in the proof of Theorem 4 such that $\gamma$ is in the standard position with respect to that embedding, according to whether the given curve is separating or non-separating. The following fact is also true for non-orientable surfaces: Given any two 2-sided non-separating simple closed curves, there exists a diffeomorphism of a non-orientable surface $\Sigma$ which maps one to another and preserves the given orientations of the regular neighbourhoods. Also, for any two 2-sided separating simple closed curves, there exists a diffeomorphism of a non-orientable surface $\Sigma$ which maps one to another and preserves the given orientations of the regular neighbourhoods, provided they separate the surface $\Sigma$ into surfaces with the same genera and the same boundary components. So, if the given curve $\gamma$ is non-separating, then we shall consider a diffeomorphism of $\Sigma$ which maps $\gamma$ to say, $\alpha_1$ shown in Figure 18. If the given curve $\gamma$ is separating, then we shall consider a diffeomorphism of $\Sigma$ which maps $\gamma$ to a separating curve which does not meet any Möbius band $\mu_i$ shown in Figure 18 and separates the surface $\Sigma$ into the surfaces with the same genera and the same number of boundary components. As the embedding $f_{pr}$ is flexible, we can get a
new embedding, say $f_1$ of $\Sigma$ in $DE(m)$ such that the curve $\gamma$ is in the standard position with respect to the embedding $f_1$.

7.3. Lefschetz fibration embedding for non-orientable 4–manifolds. Suppose $q_1, q_2, ..., q_k$ be the critical points of the Lefschetz fibration $\pi: X \to D^2$ and $p_1, p_2, ..., p_k$ be the corresponding critical values in $D^2$ such that $\pi(q_i) = p_i$. Suppose that the regular fiber at $p \in D^2$ is identified with the compact, connected non-orientable surface $\Sigma = \Sigma_{g,n}$ of genus $g$ and with $n$ boundary components. Let $\gamma_1, \gamma_2, ..., \gamma_k$ be the vanishing cycles corresponding to the critical values $p_1, p_2, ..., p_k$ respectively. We shall fix the orientation of the regular neighbourhood $\nu(\gamma_i)$ of each vanishing cycle $\gamma_i$ in $\Sigma$ as well as on the regular neighbourhood $\nu(\eta)$ of the curve $\eta$.

Note that in the handle description of $X$ corresponding to the Lefschetz fibration $\pi: X \to D^2$, the 2–handles are attached to the vanishing cycle $\gamma$ with framing +1 with respect to the surface framing. This will corresponds to the Dehn twist $d_\gamma$ in the boundary monodromy of the Lefschetz fibration which is described as a product of Dehn twist along the vanishing cycles. Then, using the flexibility of $f_{pr}$ as well as the flexibility of embeddings with respect to which the vanishing cycles are in the standard position, we can proceed as the arguments given in the proof of Theorem 39 to get the Lefschetz fibration embedding of the Lefschetz fibration $\pi: X \to D^2$ into the trivial Lefschetz fibration $\tilde{\pi}: DE(m) \times D^2 \to D^2$. This proves Theorem 39.

Theorem 40. Let $\pi: X \to D^2$ be a bordered Lefschetz fibration, where $X$ is a compact connected non-orientable 4–manifold with non-empty boundary without 3– and 4–handles in the handle decomposition such that for each regular value the fiber is a compact connected non-orientable genus $g > 2$ surface $\Sigma$ with connected boundary. If the vanishing cycle corresponding to the Lefschetz singularity is not the boundary parallel, then there exists a Lefschetz fibration embedding of $X$ into a trivial Lefschetz fibration $\tilde{\pi}: DE(m) \times D^2 \to D^2$.

Proof of Theorem 40. We can consider the setup as in the last theorem. The result follows from the last theorem if in the handle description of $X$ corresponding to the Lefschetz fibration $\pi: X \to D^2$, the 2–handles are attached to the vanishing cycle $\gamma$ with framing +1 with respect to the surface framing.

Now, we shall consider the case where in the handle description of $X$ corresponding to the Lefschetz fibration $\pi: X \to D^2$, the 2–handles are attached to the vanishing cycles with framing $-1$ with respect to the surface framing. Let $\gamma$ be such a vanishing cycle in $\Sigma$. This corresponds to the Dehn twist $d^{-1}_\gamma$ in the boundary monodromy of the Lefschetz fibration. Then, we proceed as in the following two steps.

Step -I:
If $\gamma$ is non-separating, we can consider a diffeomorphism $h_1$ which maps $\gamma$ to one of the non-separating generating curve $\alpha_i$. In particular, we can send $\gamma$ to the curve $\alpha_1$. If $\gamma$ is separating, we can consider a diffeomorphism $h_1$ which maps $\gamma$ to one of the separating curve which does not meet any M"obius band $\mu_i$.

Step -II:
Figure 21. Left of the figure shows a separating curve $c$ bounding a subsurface $\Sigma'$ and a Möbius band $\mu_j$. Right of the figure shows the result of the slide diffeomorphism of $\Sigma$ which slides $\Sigma'$ along the core of the Möbius band $\mu_j$. Note that the orientation of the regular neighbourhood of $c$ changes by this slide diffeomorphism.

Now, we need to consider a diffeomorphism $h_2$ of the surface $\Sigma$ which will map $h_1(\gamma)$ to $h_2(h_1(\gamma))$ such that $h_2h_1 \circ (d_{\gamma})^{-1} \circ (h_2h_1)^{-1} = dh_1(\gamma)$. This means, we need a diffeomorphism $h_2$ such that $h_2 \circ h_1$ should change the orientation when restricted to the regular neighbourhoods of $\gamma$ and $h_2(h_1(\gamma))$ and is in the standard position with respect to $f_{pr}$. Then, using the flexibility of the diffeomorphism $h_2 \circ h_1$, we get a flexible embedding $f_2$ of $\Sigma$ such that $\gamma$ is in the standard position with respect to $f_2$.

Now, we will define the diffeomorphism $h_2$. First, we define the notion of a slide diffeomorphism $h_2$ of the surface $\Sigma$ along $\mu_j$ which slides only the subsurface $\Sigma'$ in $f_{pr}(\Sigma)$.

**Slide diffeomorphism:** Consider a Möbius band $\mu_j$ with core $\lambda$ as shown in Figure 18 and consider a connected, compact subsurface $\Sigma'$ disjoint from $\mu_j$ and bounded by a curve $C$ in $f_{pr}(\Sigma)$ which does not meet any Möbius band $\mu_i$. Let $B$ be a 3-ball in $S^3 \times \frac{1}{2}$ such that $C \subset \partial B$ and $B \cap f_{pr}(\Sigma)$ is the subsurface $\Sigma'$. Now, there is an isotopy $\rho_t$ of $S^3 \times \frac{1}{2}$ which slides $B$ along the core curve of the Möbius band $\mu_j$ and come back to its original position. Note that this isotopy of $DE(m)$ induces a diffeomorphism on $\Sigma$, for more details refer [7] and [3]. We call this diffeomorphism a slide diffeomorphism of the surface $\Sigma$ along $\mu_j$ which slides only the subsurface $\Sigma'$ in $f_{pr}(\Sigma)$.

Note that the slide diffeomorphism will not disturb the curves inside the surface $\Sigma'$ but changes the orientation on the regular neighbourhoods of the curves, for example, refer Figure 21. Also, note that the slide diffeomorphisms are flexible in $f_{pr}$.

Suppose that $h_1(\gamma)$ is separating and $h_1(\gamma)$ bounds a subsurface $\Sigma'$ which does not contain a Möbius band say, $\mu_j$ in $\Sigma$. Consider the slide diffeomorphism $h_2$ of the surface which is obtained by sliding the subsurface $\Sigma'$ once along the core curve of the Möbius band $\mu_j$, refer Figure 21. Note that the slide diffeomorphism $h_2$ preserves the curve $h_1(\gamma)$ but changes the orientation of the regular neighbourhood of $h_1(\gamma)$. Now, we can isotope $h_2(h_1(\gamma))$ along the Hopf band to get $h_2(h_1(\gamma))\#_h\eta$ which admits the required Hopf annulus regular neighbourhood. Now, using the flexibility of $h_2 \circ h_1$, we get an embedding $f_2$ of $\Sigma$ in $DE(m)$ such that $\gamma$ is in the standard position with respect to this embedding $f_2$.

Suppose that $h_1(\gamma)$ is non-separating. With out loss of generality, we can assume that $h_1(\gamma) = \alpha_1$. As the genus $g > 2$, we can use the same idea described in the last paragraph to get $h_2$. We shall consider the separating curve which bounds
the subsurface $\Sigma'$ such that $\Sigma'$ contains only the M"obius bands $\mu_1$ and $\mu_2$ and no other M"obius bands $\mu_j$. Then, we consider the diffeomorphism $h_2$ which slides $\Sigma'$ over some M"obius band $\mu_j$, $j \neq 1, 2$. This choice of $h_2$ will provide us the required orientation of the regular neighbourhood of $\alpha_1$.

Thus, corresponding to each vanishing cycle, we can construct a proper flexible embedding $f$ of $\Sigma$ in $\mathcal{D}E(m)$ such that the vanishing cycle is in the standard position with respect to $f$.

Now, we can use the arguments given in Theorem 6 to get the Lefschetz fibration embedding of the Lefschetz fibration $\pi : X \to D^2$ into the trivial Lefschetz fibration $\tilde{\pi} : \mathcal{D}E(m) \times D^2 \to D^2$. This proves Theorem 40.

**Remark 41.** Similar to Theorem 32, one can show that a huge collection of non-orientable bordered Lefschetz fibrations Lefschetz fibration embeds into the trivial Lefschetz fibration $\tilde{\pi}$.

### 7.4. Embedding of closed non-orientable 4–manifolds

In [14], Miller and Ozbagci proved that if $X$ is a closed, non-orientable, connected 4–manifold which admits a Lefschetz fibration over $S^2$ equipped with a section of square $\pm 1$, then $X$ admits a decomposition $X = W \cup_\partial V$, where both $W$ and $V$ admit bordered Lefschetz fibrations over $D^2$ such that the induced open books coincide on their common boundary $\partial W = \partial V$, refer the proof of Theorem 1.10 in [14].

We have the following result.

**Theorem 42.** Let $X$ be a closed non-orientable 4–manifold. Suppose that $X$ admits a decomposition $X = W \cup_\partial V$, where both $W$ and $V$ admit bordered Lefschetz fibrations over $D^2$ so that the induced open books coincide on their common boundary $\partial W = \partial V$. If both $V$ and $W$ satisfy the hypothesis of either Theorem 39 or Theorem 40, then $X$ admits a smooth embedding into $S^4 \times S^2$ as well as into $S^4 \times S^2$.

**Proof.** The proof follows from the similar arguments given in the proof of Theorem 36.
