Abstract

We consider solutions of the KP hierarchy which are elliptic functions of $x = t_1$. It is known that their poles as functions of t_2 move as particles of the elliptic Calogero-Moser model. We extend this correspondence to the level of hierarchies and find the Hamiltonian H_k of the elliptic Calogero-Moser model which governs the dynamics of poles with respect to the k -th hierarchical time. The Hamiltonians H_k are obtained as coefficients of the expansion of the spectral curve near the marked point in which the Baker-Akhiezer function has essential singularity.

1 Introduction

The investigation of dynamics of poles of singular solutions to nonlinear integrable equations was initiated in the seminal paper [1], where it was shown that poles of elliptic and rational solutions to the Korteweg-de Vries and Boussinesq equations move as particles of the integrable many-body Calogero-Moser system [2, 3, 4, 5] with some restrictions in the phase space. As it was proved in [6, 7], this connection becomes most natural for the more general Kadomtsev-Petviashvili (KP) equation, in which case there are no restrictions in the phase space for the Calogero-Moser dynamics of poles.

The KP equation is the first member of an infinite hierarchy of consistent integrable equations with infinitely many independent variables (times) $\mathbf{t} = \{t_1, t_2, t_3, \dots\}$ (the KP hierarchy). In [8], Shiota has shown that the correspondence between rational solutions to the KP equation and the Calogero-Moser system with rational potential can be extended to the level of hierarchies: the evolution of poles with respect to the higher times t_k of the KP hierarchy was shown to be governed by the higher Hamiltonians $H_k = \text{tr } L^k$ of the integrable Calogero-Moser system, where L is the Lax matrix. Later this correspondence was generalized to trigonometric solutions of the KP hierarchy (see [9, 10]).

A natural generalization of rational and trigonometric solutions are elliptic (double periodic in the complex plane) solutions. Elliptic solutions to the KP equation

$$3u_{t_2 t_2} = \left(4u_{t_3} - 12uu_x - u_{xxx}\right)_x \quad (1)$$

(where $x = t_1$) were studied by Krichever in [11], where it was shown that poles x_i of the elliptic solutions

$$u = - \sum_{i=1}^N \wp(x - x_i) + 2c \quad (2)$$

as functions of t_2 move according to the equations of motion

$$\ddot{x}_i = 4 \sum_{k \neq i} \wp'(x_i - x_k) \quad (3)$$

of the Calogero-Moser system of particles with the elliptic interaction potential $\wp(x_i - x_j)$ (\wp is the Weierstrass \wp -function). Here dot means derivative with respect to the time t_2 .

See also the review [12]. The Calogero-Moser system is Hamiltonian with the Hamiltonian

$$H = \sum_i p_i^2 - 2 \sum_{i < j} \wp(x_i - x_j) \quad (4)$$

and the Poisson brackets $\{x_i, p_k\} = \delta_{ik}$. Note that $\dot{x}_i = \partial H / \partial p_i = 2p_i$. It is known [13] that the elliptic Calogero-Moser system is integrable, i.e., there are N independent integrals of motion H_k in involution.

The aim of this paper is to establish the precise correspondence between the flows of the KP hierarchy parametrized by the times t_m and the Hamiltonian flows of the hierarchy of the elliptic Calogero-Moser systems. In short, the result is as follows. Let the function $\lambda(z)$ be determined from the equation of the Calogero-Moser spectral curve in the form

$$\det_{N \times N} \left((z + \zeta(\lambda))I - L(\lambda) \right) = 0, \quad (5)$$

where I is the unity matrix, $L(\lambda)$ is the Lax matrix of the Calogero-Moser system depending on the spectral parameter λ and $\zeta(\lambda)$ is the Weierstrass ζ -function. We show that the function $\lambda(z)$ expanded as $z \rightarrow \infty$ as

$$\lambda(z) = -Nz^{-1} + \sum_{m \geq 1} H_m z^{-m-1} \quad (6)$$

is the generating function for the Calogero-Moser Hamiltonians H_m corresponding to the flows t_m of the KP hierarchy. We find first few Hamiltonians explicitly. In the rational and trigonometric limit it is possible to find them for any m in terms of traces of the Lax matrix and the result coincides with what was previously known (see [8, 10]).

2 The KP hierarchy

The KP hierarchy is an infinite set of evolution equations in the times $\mathbf{t} = \{t_1, t_2, t_3, \dots\}$ for functions of a variable x . In the Lax formulation of the hierarchy, the main object is the pseudo-differential operator

$$\mathcal{L} = \partial_x + \sum_{k \geq 1} u_k \partial_x^{-k}, \quad (7)$$

where the coefficient functions u_k are functions of x and \mathbf{t} . The equations of the KP hierarchy are encoded in the Lax equations

$$\partial_{t_m} \mathcal{L} = [\mathcal{A}_m, \mathcal{L}], \quad \mathcal{A}_m = (\mathcal{L}^m)_+, \quad (8)$$

where $(\dots)_+$ means taking the purely differential part of a pseudo-differential operator. In particular, we have $\partial_{t_1} \mathcal{L} = \partial_x \mathcal{L}$, i.e., $\partial_{t_1} u_k = \partial_x u_k$ for all $k \geq 1$. This means that the evolution in t_1 is simply a shift of x : $u_k(x, \mathbf{t}) = u_k(x + t_1, t_2, t_3, \dots)$.

An equivalent formulation of the KP hierarchy is through the zero curvature (Zakharov-Shabat) equations

$$\partial_{t_n} \mathcal{A}_m - \partial_{t_m} \mathcal{A}_n + [\mathcal{A}_m, \mathcal{A}_n] = 0. \quad (9)$$

The simplest nontrivial equation (1) is obtained for $u = u_1$ at $m = 2, n = 3$.

A common solution to the KP hierarchy is provided by the tau-function $\tau = \tau(x, \mathbf{t})$. The coefficient functions u_k of the Lax operator can be expressed through the tau-function. For example,

$$u_1(x, \mathbf{t}) = u(x, \mathbf{t}) = \partial_x^2 \log \tau(x, \mathbf{t}). \quad (10)$$

The whole hierarchy is encoded in the bilinear relation [14, 15]

$$\oint_{\infty} e^{(x-x')z + \xi(\mathbf{t}, z) - \xi(\mathbf{t}', z)} (e^{-D(z)} \tau(x, \mathbf{t})) (e^{D(z)} \tau(x', \mathbf{t}')) dz = 0 \quad (11)$$

valid for all $x, x', \mathbf{t}, \mathbf{t}'$, where

$$\xi(\mathbf{t}, z) = \sum_{k \geq 1} t_k z^k$$

and $D(z)$ is the differential operator

$$D(z) = \sum_{k \geq 1} \frac{z^{-k}}{k} \partial_{t_k}. \quad (12)$$

The integration contour is a big circle around infinity separating the singularities coming from the exponential factor from those coming from the tau-functions.

Let us point out an important corollary of the bilinear relation. Applying the operator $D'(\mu) = -\sum_{k \geq 1} \mu^{-k-1} \partial_{t_k}$ to (11) and putting $x = x', \mathbf{t} = \mathbf{t}'$ after that, we obtain

$$-\sum_{k \geq 1} \oint_{\infty} \mu^{-k-1} z^k (e^{-D(z)} \tau) (e^{D(z)} \tau) dz + \oint_{\infty} D'(\mu) (e^{-D(z)} \tau) (e^{D(z)} \tau) dz = 0$$

or

$$\frac{1}{2\pi i} \oint_{\infty} \frac{z}{\mu(z - \mu)} (e^{-D(z)} \tau) (e^{D(z)} \tau) dz = D'(\mu) \partial_x \tau \tau - D'(\mu) \tau \partial_x \tau.$$

Taking the residues in the left hand side, we get the equation

$$\frac{(e^{D(\mu)} \tau) (e^{-D(\mu)} \tau)}{\tau^2} = 1 - D'(\mu) \partial_x \log \tau. \quad (13)$$

The zero curvature equations (9) are compatibility conditions of the auxiliary linear problems

$$\partial_{t_k} \psi = \mathcal{A}_k \psi \quad (14)$$

for the wave function $\psi = \psi(x, \mathbf{t}, z)$ depending on the spectral parameter z . In particular, at $k = 2$ we have the equation

$$\partial_{t_2} \psi = \partial_x^2 \psi + 2u\psi. \quad (15)$$

One can also introduce the adjoint wave function ψ^* satisfying the adjoint equation (14):

$$-\partial_{t_k} \psi^* = \mathcal{A}_k^\dagger \psi^*, \quad (16)$$

where the \dagger -operation is defined as $(f(x) \circ \partial_x^n)^\dagger = (-\partial_x)^n \circ f(x)$. In [14, 15] it is shown that the wave functions can be expressed through the tau-function in the following way:

$$\psi(x, \mathbf{t}, z) = e^{xz + \xi(\mathbf{t}, z)} \frac{e^{-D(z)} \tau(x, \mathbf{t})}{\tau(x, \mathbf{t})}, \quad (17)$$

$$\psi^*(x, \mathbf{t}, z) = e^{-xz - \xi(\mathbf{t}, z)} \frac{e^{D(z)} \tau(x, \mathbf{t})}{\tau(x, \mathbf{t})}. \quad (18)$$

Note that in terms of the wave functions the equation (13) can be written in the form

$$\partial_{t_m} \partial_{t_1} \log \tau(x, \mathbf{t}) = \operatorname{res}_{\infty} \left(z^m \psi(x, \mathbf{t}, z) \psi^*(x, \mathbf{t}, z) \right), \quad (19)$$

where $\operatorname{res}_{\infty}$ is defined as $\operatorname{res}_{\infty}(z^{-n}) = \delta_{n1}$.

3 Elliptic solutions

The ansatz for the tau-function of elliptic (double-periodic in the complex plane) solutions to the KP hierarchy is

$$\tau = e^{Q(x, \mathbf{t})} \prod_{i=1}^N \sigma(x - x_i(\mathbf{t})), \quad (20)$$

where

$$Q(x, \mathbf{t}) = c(x + t_1)^2 + (x + t_1)A(t_2, t_3, \dots) + B(t_2, t_3, \dots)$$

with a constant c , a linear function

$$A(t_2, t_3, \dots) = A_0 + \sum_{j \geq 2} a_j t_j \quad (21)$$

and some function $B(t_2, t_3, \dots)$. In (20)

$$\sigma(x) = \sigma(x | \omega, \omega') = x \prod_{s \neq 0} \left(1 - \frac{x}{s} \right) e^{\frac{x}{s} + \frac{x^2}{2s^2}}, \quad s = 2\omega m + 2\omega' m' \quad \text{with integer } m, m'$$

is the Weierstrass σ -function with quasi-periods $2\omega, 2\omega'$ such that $\operatorname{Im}(\omega'/\omega) > 0$. It is connected with the Weierstrass ζ - and \wp -functions by the formulas $\zeta(x) = \sigma'(x)/\sigma(x)$, $\wp(x) = -\zeta'(x) = -\partial_x^2 \log \sigma(x)$. The monodromy properties of the function $\sigma(x)$ are

$$\sigma(x + 2\omega) = -e^{2\eta(x+\omega)} \sigma(x), \quad \sigma(x + 2\omega') = -e^{2\eta'(x+\omega')} \sigma(x), \quad (22)$$

where the constants $\eta = \zeta(\omega)$, $\eta' = \zeta(\omega')$ are related by $\eta\omega' - \eta'\omega = \pi i/2$. The roots x_i are assumed to be all distinct. Correspondingly, the function $u = \partial_x^2 \log \tau$ is an elliptic function with double poles at the points x_i :

$$u = - \sum_{i=1}^N \wp(x - x_i) + 2c. \quad (23)$$

The poles depend on the times t_1, t_2, t_3, \dots . The dependence on t_1 is especially simple: since the solution must depend on $x + t_1$, we have $\partial_{t_1} x_i = -1$.

Let $\Delta(\mu)$ be the difference operator

$$\Delta(\mu) = e^{D(\mu)} + e^{-D(\mu)} - 2. \quad (24)$$

Substituting the ansatz (20) into equation (13), we get:

$$e^{G+(x+t_1)\Delta(\mu)A} \prod_i \frac{\sigma(x - e^{D(\mu)} x_i) \sigma(x - e^{-D(\mu)} x_i)}{\sigma^2(x - x_i)}$$

$$= 1 + 2c\mu^{-2} - D'(\mu)A - \sum_k D'(\mu)x_k \wp(x - x_k),$$

where

$$G = 2c\mu^{-2} + \mu^{-1}(e^{D(\mu)} - e^{-D(\mu)})A + \Delta(\mu)B.$$

The right hand side is an elliptic function of x with periods $2\omega, 2\omega'$. Therefore, for the left hand side be also an elliptic function of x with the same periods the following relations have to be satisfied:

$$\begin{cases} \exp\left(-2\eta\Delta(\mu) \sum_k x_k + 2\omega\Delta(\mu)A\right) = 1 \\ \exp\left(-2\eta'\Delta(\mu) \sum_k x_k + 2\omega'\Delta(\mu)A\right) = 1 \end{cases}$$

from which it follows that

$$\Delta(\mu)A = 2n'\eta - 2n\eta', \quad \Delta(\mu) \sum_k x_k = 2n'\omega - 2n\omega' \quad \text{with integer } n, n'.$$

The right hand sides do not depend on μ . Expanding the equalities in powers of μ , one sees that the left hand sides are $O(\mu^{-2})$ as $\mu \rightarrow \infty$, therefore, $n = n' = 0$ and we have

$$\Delta(\mu)A = 0, \quad \Delta(\mu) \sum_k x_k = 0. \quad (25)$$

The first equation is satisfied if A is a linear function of times as in (21). The second equation means that

$$(1 - e^{-D(\mu)}) \sum_i x_i = -(1 - e^{D(\mu)}) \sum_i x_i. \quad (26)$$

Note that the functions (17), (18) with τ as in (20) are *double-Bloch functions*, i.e., they satisfy the monodromy properties $\psi(x + 2\omega) = B\psi(x)$, $\psi(x + 2\omega') = B'\psi(x)$ with some Bloch multipliers B, B' . Any non-trivial double-Bloch function (i.e. not an exponential function) must have poles in x in the fundamental domain. The Bloch multipliers of the function (17) are

$$B = e^{2\omega(z-\alpha(z))-2\zeta(\omega)(e^{-D(z)}-1)\sum_i x_i}, \quad B' = e^{2\omega'(z-\alpha(z))-2\zeta(\omega')(e^{-D(z)}-1)\sum_i x_i}, \quad (27)$$

where

$$\alpha(z) = 2cz^{-1} + \sum_{j \geq 2} \frac{a_j}{j} z^{-j} \quad (28)$$

with the constants a_j entering (21). Equation (26) means that the Bloch multipliers of the adjoint wave function ψ^* are B^{-1} and B'^{-1} .

Let us introduce the elementary double-Bloch function $\Phi(x, \lambda)$ defined as

$$\Phi(x, \lambda) = \frac{\sigma(x + \lambda)}{\sigma(\lambda)\sigma(x)} e^{-\zeta(\lambda)x} \quad (29)$$

($\zeta(\lambda)$ is the Weierstrass ζ -function). The monodromy properties of the function Φ are

$$\Phi(x + 2\omega, \lambda) = e^{2(\zeta(\omega)\lambda - \zeta(\lambda)\omega)} \Phi(x, \lambda),$$

$$\Phi(x + 2\omega', \lambda) = e^{2(\zeta(\omega')\lambda - \zeta(\lambda)\omega')} \Phi(x, \lambda),$$

so it is indeed a double-Bloch function. The function Φ has a simple pole at $x = 0$ with residue 1:

$$\Phi(x, \lambda) = \frac{1}{x} + \alpha_1 x + \alpha_2 x^2 + \dots, \quad x \rightarrow 0,$$

where $\alpha_1 = -\frac{1}{2} \wp(\lambda)$, $\alpha_2 = -\frac{1}{6} \wp'(\lambda)$. We will often suppress the second argument of Φ writing simply $\Phi(x) = \Phi(x, \lambda)$. We will also need the x -derivative $\Phi'(x, \lambda) = \partial_x \Phi(x, \lambda)$.

Equations (17), (18) and (20) imply that the wave functions ψ , ψ^* have simple poles at the points x_i . One can expand the wave functions using the elementary double-Bloch functions as follows:

$$\psi = e^{xk + t_1(k-z) + \xi(\mathbf{t}, z)} \sum_i c_i \Phi(x - x_i, \lambda) \quad (30)$$

$$\psi^* = e^{-xk - t_1(k-z) - \xi(\mathbf{t}, z)} \sum_i c_i^* \Phi(x - x_i, -\lambda) \quad (31)$$

(this is similar to expansion of a rational function in a linear combination of simple fractions). Here c_i , c_i^* are expansion coefficients which do not depend on x and k is an additional spectral parameter. Note that the normalization of the functions (17), (18) implies that c_i and c_i^* are $O(\lambda)$ as $\lambda \rightarrow 0$. One can see that (30) is a double-Bloch function with Bloch multipliers

$$B = e^{2\omega(k - \zeta(\lambda)) + 2\zeta(\omega)\lambda}, \quad B' = e^{2\omega'(k - \zeta(\lambda)) + 2\zeta(\omega')\lambda} \quad (32)$$

and (31) has Bloch multipliers B^{-1} and B'^{-1} . These Bloch multipliers should coincide with (27).

Therefore, comparing (27) with (32), we get

$$2\omega(k - \zeta(\lambda) - z + \alpha(z)) + 2\zeta(\omega) \left(\lambda + (e^{-D(z)} - 1) \sum_i x_i \right) = 2\pi i n,$$

$$2\omega'(k - \zeta(\lambda) - z + \alpha(z)) + 2\zeta(\omega') \left(\lambda + (e^{-D(z)} - 1) \sum_i x_i \right) = 2\pi i n'$$

with some integer n, n' . Regarding these equations as a linear system, we obtain the solution

$$\begin{aligned} k - z + \alpha(z) - \zeta(\lambda) &= 2n'\zeta(\omega) - 2n\zeta(\omega'), \\ \lambda + (e^{-D(z)} - 1) \sum_i x_i &= 2n\omega' - 2n'\omega. \end{aligned}$$

Shifting λ by a suitable vector of the lattice spanned by 2ω , $2\omega'$, one gets zeros in the right hand sides of these equalities, so we can write

$$\begin{aligned} k &= z - \alpha(z) + \zeta(\lambda), \\ \lambda &= (1 - e^{-D(z)}) \sum_i x_i. \end{aligned} \quad (33)$$

These two equations for three variables k, z, λ determine the spectral curve. Below we will obtain another description of the spectral curve as the spectral curve of the Calogero-Moser system (given by the characteristic polynomial of the Lax matrix $L(\lambda)$ for the

Calogero-Moser system). It appears in the form $R(k, \lambda) = 0$, where $R(k, \lambda)$ is a polynomial in k whose coefficients are elliptic functions of λ (see below in section 5). These coefficients are integrals of motion in involution. The spectral curve in the form $R(k, \lambda) = 0$ appears if one excludes z from the equations (33). Equivalently, one can represent the spectral curve as a relation connecting two variables z and λ :

$$R(z - \alpha(z) + \zeta(\lambda), \lambda) = 0. \quad (34)$$

Let us write the second equation in (33) as the expansion in powers of z :

$$\lambda = - \sum_{m \geq 1} z^{-m} \hat{h}_m X, \quad X := \sum_i x_i, \quad (35)$$

where \hat{h}_k are differential operators of the form

$$\hat{h}_m = -\frac{1}{m} \partial_{t_m} + \text{higher order operators in } \partial_{t_1}, \partial_{t_2}, \dots, \partial_{t_{m-1}}. \quad (36)$$

For example, the first few are

$$\hat{h}_1 = -\partial_{t_1}, \quad \hat{h}_2 = \frac{1}{2} (\partial_{t_1}^2 - \partial_{t_2}), \quad \hat{h}_3 = \frac{1}{6} (-\partial_{t_1}^3 + 3\partial_{t_1} \partial_{t_2} - 2\partial_{t_3}).$$

As is explained above, the coefficients in the expansion (35) are integrals of motion, i.e., $\partial_{t_j} \hat{h}_m X = 0$ for all j, m . It then follows from the equation $\partial_{t_1} x_i = -1$ and from the explicit form of the operators \hat{h}_m that $\partial_{t_j} \partial_{t_2} X = 0$ and $\partial_{t_j} \partial_{t_3} X = 0$. A simple inductive argument then shows that $\partial_{t_j} \partial_{t_m} X = 0$ for all j, m . This means that $-\hat{h}_m X = \frac{1}{m} \partial_{t_m} X$ and X is a linear function of the times:

$$X = \sum_i x_i = X_0 - N t_1 + \sum_{m \geq 2} V_m t_m \quad (37)$$

with some constants V_m (velocities of the ‘‘center of masses’’ of the points x_i multiplied by N). Therefore, the second equation in (33) can be written as

$$\lambda = D(z) \sum_i x_i = -N z^{-1} + \sum_{j \geq 2} \frac{z^{-j}}{j} V_j. \quad (38)$$

In what follows we will show that $H_m = -\frac{1}{m+1} V_{m+1}$ are Hamiltonians for the dynamics of the poles in t_m , with H_2 being the standard Calogero-Moser Hamiltonian.

4 Dynamics of poles with respect to t_2

The coefficient u in the linear problem (15)

$$\partial_{t_2} \psi - \partial_x^2 \psi - 2u\psi = 0 \quad (39)$$

is an elliptic function of x of the form (23). Therefore, one can find solutions which are double-Bloch functions of the form (30).

The next procedure is standard after the work [11]. We substitute u in the form (23) and ψ in the form (30) into the left hand side of (39) and cancel the poles at the points $x = x_i$. The highest poles are of third order but it is easy to see that they cancel identically. It is a matter of direct calculation to see that the conditions of cancellation of second and first order poles have the form

$$c_i \dot{x}_i = -2kc_i - 2 \sum_{j \neq i} c_j \Phi(x_i - x_j), \quad (40)$$

$$\dot{c}_i = (k^2 - z^2 + 4c - 2\alpha_1)c_i - 2 \sum_{j \neq i} c_j \Phi'(x_i - x_j) - 2c_i \sum_{j \neq i} \wp(x_i - x_j), \quad (41)$$

where dot means the t_2 -derivative. Introducing $N \times N$ matrices

$$L_{ij} = -\frac{1}{2} \delta_{ij} \dot{x}_i - (1 - \delta_{ij}) \Phi(x_i - x_j), \quad (42)$$

$$M_{ij} = \delta_{ij}(k^2 - z^2 + \wp(\lambda) + 4c) - 2\delta_{ij} \sum_{k \neq i} \wp(x_i - x_k) - 2(1 - \delta_{ij}) \Phi'(x_i - x_j), \quad (43)$$

we can write the above conditions as a system of linear equations for the vector $\mathbf{c} = (c_1, \dots, c_N)^T$:

$$\begin{cases} L(\lambda)\mathbf{c} = k\mathbf{c} \\ \dot{\mathbf{c}} = M(\lambda)\mathbf{c}. \end{cases} \quad (44)$$

Differentiating the first equation in (44) with respect to t_2 , we arrive at the compatibility condition of the linear problems (44):

$$\left(\dot{L} + [L, M] \right) \mathbf{c} = 0. \quad (45)$$

The Lax equation $\dot{L} + [L, M] = 0$ is equivalent to the equations of motion of the elliptic Calogero-Moser system (see [12] for the detailed calculation). Our matrix M differs from the standard one by the term $\delta_{ij}(k^2 - z^2)$ but it does not affect the compatibility condition. It follows from the Lax representation that the time evolution is an isospectral transformation of the Lax matrix L , so all traces $\text{tr } L^m$ and the characteristic polynomial $\det(L - kI)$, where I is the unity matrix, are integrals of motion. Note that the Lax matrix is written in terms of the momenta p_i as follows:

$$L_{ij} = -\delta_{ij} p_i - (1 - \delta_{ij}) \Phi(x_i - x_j). \quad (46)$$

A similar calculation shows that the adjoint linear problem for the function (31) leads to the equations

$$\begin{cases} \mathbf{c}^{*T} L(\lambda) = k\mathbf{c}^{*T} \\ \dot{\mathbf{c}}^{*T} = -\mathbf{c}^{*T} M(\lambda) \end{cases} \quad (47)$$

with the compatibility condition $\mathbf{c}^{*T} \left(\dot{L} + [L, M] \right) = 0$.

5 The spectral curve

The first of the equations (44) determines a connection between the spectral parameters k, λ which is the equation of the spectral curve:

$$R(k, \lambda) = \det(kI - L(\lambda)) = 0. \quad (48)$$

As it was already mentioned, the spectral curve is an integral of motion. The matrix $L = L(\lambda)$, which has an essential singularity at $\lambda = 0$, can be represented in the form $L = V\tilde{L}V^{-1}$, where matrix elements of \tilde{L} do not have essential singularities and V is the diagonal matrix $V_{ij} = \delta_{ij}e^{-\zeta(\lambda)x_i}$. Therefore,

$$R(k, \lambda) = \sum_{m=0}^N R_m(\lambda)k^m,$$

where the coefficients $R_m(\lambda)$ are elliptic functions of λ with poles at $\lambda = 0$. The functions $R_m(\lambda)$ can be represented as linear combinations of the \wp -function and its derivatives. Coefficients of this expansion are integrals of motion. Fixing values of these integrals, we obtain via the equation $R(k, \lambda) = 0$ an algebraic curve Γ which is a N -sheet covering of the initial elliptic curve \mathcal{E} realized as a factor of the complex plane with respect to the lattice generated by $2\omega, 2\omega'$.

Example ($N = 2$):

$$\det_{2 \times 2}(kI - L(\lambda)) = k^2 + k(p_1 + p_2) + p_1p_2 + \wp(x_1 - x_2) - \wp(\lambda).$$

Example ($N = 3$):

$$\begin{aligned} \det_{3 \times 3}(kI - L(\lambda)) &= k^3 + k^2(p_1 + p_2 + p_3) \\ &+ k(p_1p_2 + p_1p_3 + p_2p_3 + \wp(x_{12}) + \wp(x_{13}) + \wp(x_{23}) - 3\wp(\lambda)) \\ &+ p_1p_2p_3 + p_1\wp(x_{23}) + p_2\wp(x_{13}) + p_3\wp(x_{12}) - \wp(\lambda)(p_1 + p_2 + p_3) - \wp'(\lambda), \end{aligned}$$

where $x_{ik} = x_i - x_k$.

In a neighborhood of $\lambda = 0$ the matrix \tilde{L} can be written as

$$\tilde{L} = -\lambda^{-1}(E - I) + O(1),$$

where E is the rank 1 matrix with matrix elements $E_{ij} = 1$ for all $i, j = 1, \dots, N$. The matrix E has eigenvalue 0 with multiplicity $N - 1$ and another eigenvalue equal to N . Therefore, we can write $R(k, \lambda)$ in the form

$$\begin{aligned} R(k, \lambda) &= \det(kI + \lambda^{-1}(E - I) + O(1)) \\ &= (k + (N-1)\lambda^{-1} - f_N(\lambda)) \prod_{i=1}^{N-1} (k - \lambda^{-1} - f_i(\lambda)), \end{aligned} \quad (49)$$

where f_i are regular functions of λ at $\lambda = 0$: $f_i(\lambda) = O(1)$ as $\lambda \rightarrow 0$. This means that the function k has simple poles on all sheets at the points P_j ($j = 1, \dots, N$) of the curve

Γ located above $\lambda = 0$. Its expansion in the local parameter λ on the sheets near these points is given by the multipliers in the right hand side of (49):

$$\begin{aligned} k &= \lambda^{-1} + f_j(\lambda) \quad \text{near } P_j, \quad j = 1, \dots, N-1, \\ k &= -(N-1)\lambda^{-1} + f_N(\lambda) \quad \text{near } P_N. \end{aligned} \tag{50}$$

The N -th sheet is distinguished, as it can be seen from (50). As in [11], we call it the upper sheet. Note that equations (33), (38) imply

$$k(\lambda) = -\frac{N-1}{\lambda} + O(1) \quad \text{as } \lambda \rightarrow 0,$$

so the expansion (38) is the expansion of $\lambda(z)$ on the upper sheet of the spectral curve in a neighborhood of the point P_N .

6 Dynamics in higher times

Our basic tool is equation (19). Substituting $\tau(x, \mathbf{t})$ in the form (20) and ψ, ψ^* in the form (30), (31) in it, we have:

$$\sum_i \partial_{t_m} x_i \wp(x - x_i) + C(t_2, t_3, \dots) = \text{res}_\infty \left(z^m \sum_{i,j} c_i c_j^* \Phi(x - x_i, \lambda) \Phi(x - x_j, -\lambda) \right). \tag{51}$$

Equating the coefficients in front of the second order poles at $x = x_i$, we obtain

$$\partial_{t_m} x_i = \text{res}_\infty (z^m c_i^* c_i) = \text{res}_\infty (z^m \mathbf{c}^{*T} E_i \mathbf{c}), \tag{52}$$

where E_i is the diagonal matrix with 1 at the place ii and zeros otherwise. At $m = 1$ this reads $\text{res}_\infty (z \mathbf{c}^{*T} E_i \mathbf{c}) = -1$ or

$$\text{res}_\infty (z \mathbf{c}^{*T} \mathbf{c}) = -N.$$

Summing the equations (52) over i , we get

$$\text{res}_\infty (z^m \mathbf{c}^{*T} \mathbf{c}) = \partial_{t_m} \sum_i x_i.$$

It then follows from these equations that

$$(\mathbf{c}^{*T} \mathbf{c}) = -N/z^2 + \sum_m z^{-m-1} \partial_{t_m} \sum_i x_i = -\lambda'(z). \tag{53}$$

The absence of terms with non-negative powers of z in the right hand side (which would not change the residue) follows from the above mentioned fact that \mathbf{c} and \mathbf{c}^* are $O(\lambda) = O(z^{-1})$ as $z \rightarrow \infty$. The last equality in (53) follows from (38). Equation (53) is an important non-trivial relation which will allow us to identify the Hamiltonians for the higher flows t_m .

Now let us note that according to (46) $E_i = -\partial_{p_i} L$. Therefore, we can continue the chain of equalities (52) as follows:

$$\begin{aligned}
\partial_{t_m} x_i &= \operatorname{res}_{\infty} \left(z^m \mathbf{c}^{*T} E_i \mathbf{c} \right) = -\operatorname{res}_{\infty} \left(z^m \mathbf{c}^{*T} \partial_{p_i} L \mathbf{c} \right) \\
&= -\partial_{p_i} \operatorname{res}_{\infty} \left(z^m \mathbf{c}^{*T} L \mathbf{c} \right) + \operatorname{res}_{\infty} \left(z^m \partial_{p_i} \mathbf{c}^{*T} L \mathbf{c} \right) + \operatorname{res}_{\infty} \left(z^m \mathbf{c}^{*T} L \partial_{p_i} \mathbf{c} \right) \\
&= -\partial_{p_i} \operatorname{res}_{\infty} \left(z^m \mathbf{c}^{*T} L \mathbf{c} \right) + \operatorname{res}_{\infty} \left(z^m \partial_{p_i} \mathbf{c}^{*T} k \mathbf{c} \right) + \operatorname{res}_{\infty} \left(z^m \mathbf{c}^{*T} k \partial_{p_i} \mathbf{c} \right) \\
&= -\partial_{p_i} \operatorname{res}_{\infty} \left(z^m \mathbf{c}^{*T} L \mathbf{c} \right) + \partial_{p_i} \operatorname{res}_{\infty} \left(z^m \mathbf{c}^{*T} k \mathbf{c} \right) - \operatorname{res}_{\infty} \left(z^m \partial_{p_i} k \mathbf{c}^{*T} \mathbf{c} \right) \\
&= -\partial_{p_i} \operatorname{res}_{\infty} \left(z^m \mathbf{c}^{*T} (L - kI) \mathbf{c} \right) - \operatorname{res}_{\infty} \left(z^m \partial_{p_i} k \mathbf{c}^{*T} \mathbf{c} \right) \\
&= \operatorname{res}_{\infty} \left(z^m \lambda'(z) \partial_{p_i} k \right).
\end{aligned}$$

Here $\partial_{p_i} k = \partial_{p_i} k(\lambda, \mathbf{I}) \Big|_{\lambda=\text{const}}$, where \mathbf{I} is the full set of integrals of motion. From (33) we see that

$$\partial_{p_i} k = (1 - \alpha'(z)) \partial_{p_i} z(\lambda, \mathbf{I}) \Big|_{\lambda=\text{const}}. \quad (54)$$

We consider z as an independent variable, so we can write

$$0 = \frac{dz}{dp_i} = \partial_{p_i} z \Big|_{\lambda=\text{const}} + \partial_{\lambda} z \Big|_{\mathbf{I}=\text{const}} \partial_{p_i} \lambda$$

or

$$\partial_{p_i} z = -\frac{\partial_{p_i} \lambda}{\lambda'(z)}.$$

Therefore, we have the first set of the Hamiltonian equations

$$\partial_{t_m} x_i = -\operatorname{res}_{\infty} \left(z^m (1 - \alpha'(z)) \partial_{p_i} \lambda \right) = \partial_{p_i} \mathcal{H}_m, \quad (55)$$

where the Hamiltonian

$$\mathcal{H}_m = H_m^{(\alpha)} + 2cH_{m-2}^{(\alpha)} + \sum_{j=2}^{m-1} a_j H_{m-j-1}^{(\alpha)} \quad (56)$$

is the linear combination of the Hamiltonians

$$H_m^{(\alpha)} = -\operatorname{res}_{\infty} \left(z^m \lambda(z) \right) \quad (57)$$

with constant coefficients. The latter implicitly depend on $\alpha(z)$ through the parametrization of the spectral curve (34).

In their turn, the Hamiltonians $H_m^{(\alpha)}$ are linear combinations of the basic Hamiltonians H_m defined at $\alpha(z) = 0$ by

$$H_m = -\operatorname{res}_{\infty} \left(z^m \lambda_0(z) \right), \quad (58)$$

where $\lambda_0(z)$ is defined through the equation of the spectral curve

$$R(z + \zeta(\lambda_0), \lambda_0) = \det \left((z + \zeta(\lambda_0))I - L(\lambda_0) \right) = 0. \quad (59)$$

Then

$$\lambda(z) = \lambda_0(z - \alpha(z)) = \lambda_0(z) - \alpha(z)\lambda_0'(z) + \frac{1}{2}\alpha^2(z)\lambda_0''(z) + \dots$$

and so we see that the Hamiltonians (57) are indeed linear combinations of the H_m 's with constant coefficients.

The remaining set of Hamiltonian equations can be obtained by differentiating (52) with respect to t_2 and using (44), (47):

$$2\partial_{t_m} p_i = \partial_{t_m} \dot{x}_i = \operatorname{res}_{\infty} \left(z^m \dot{\mathbf{c}}^{*T} E_i \mathbf{c} \right) + \operatorname{res}_{\infty} \left(z^m \mathbf{c}^{*T} E_i \dot{\mathbf{c}} \right) = \operatorname{res}_{\infty} \left(z^m \mathbf{c}^{*T} [E_i, M] \mathbf{c} \right)$$

Now, it is a matter of direct verification to see that

$$[E_i, M] = 2\partial_{x_i} L. \quad (60)$$

Therefore, we can write

$$\partial_{t_m} p_i = \operatorname{res}_{\infty} \left(z^m \mathbf{c}^{*T} \partial_{x_i} L \mathbf{c} \right).$$

Repeating the transformations presented above in detail, we have:

$$\partial_{t_m} p_i = \operatorname{res}_{\infty} \left(z^m \mathbf{c}^{*T} \mathbf{c} \partial_{x_i} k \right) = -\operatorname{res}_{\infty} \left(z^m \lambda'(z) \partial_{x_i} k \right)$$

The same argument as above shows that

$$\partial_{x_i} k = (1 - \alpha'(z)) \partial_{x_i} z(\lambda, \mathbf{I}) \Big|_{\lambda=\text{const}} \quad (61)$$

and

$$\partial_{x_i} z = -\frac{\partial_{x_i} \lambda}{\lambda'(z)}.$$

Therefore, we obtain the second set of Hamiltonian equations for the dynamics of poles:

$$\partial_{t_m} p_i = \operatorname{res}_{\infty} \left(z^m (1 - \alpha'(z)) \partial_{x_i} \lambda \right) = -\partial_{x_i} \mathcal{H}_m. \quad (62)$$

Let us find \mathcal{H}_m explicitly in terms of H_m for the case when $a_j = 0$, $c \neq 0$. In this case $\alpha(z) = 2cz^{-1}$ and we have

$$\lambda(z) = \lambda_0(z) - \sum_{j,n \geq 1} (2c)^n \binom{n+j-1}{n} H_{j-1} z^{-j-2n}, \quad (63)$$

$\mathcal{H}_m = H_m^{(\alpha)} + 2cH_{m-2}^{(\alpha)}$ and from (63) we see that

$$H_m^{(\alpha)} = H_m + \sum_{j=1}^{[m/2]} (2c)^j \binom{m-j}{j} H_{m-2j}.$$

Therefore,

$$\mathcal{H}_m = H_m + \sum_{j=1}^{[m/2]} (2c)^j \left[\binom{m-j}{j} + \binom{m-j+1}{j-1} \right] H_{m-2j}. \quad (64)$$

In particular, $\mathcal{H}_3 = H_3 + 6cH_1$ which agrees with the result of the paper [12].

7 Calculation of the Hamiltonians

In order to find the Hamiltonians explicitly, we use the description of the spectral curve given in the paper [16]:

$$\sum_{j=0}^N I_j T_{N-j}(k|\lambda) = 0, \quad (65)$$

where $T_j(k|\lambda)$ are polynomials in k of degree N such that

$$\partial_k T_n(k|\lambda) = n T_{n-1}(k|\lambda) \quad (66)$$

and I_j are integrals of motion. The first few are

$$\begin{aligned} I_0 &= 1, \\ I_1 &= \sum_i p_i, \\ I_2 &= \sum' \left(\frac{1}{2!} p_i p_j + \frac{1}{2!} \wp(x_{ij}) \right), \\ I_3 &= \sum' \left(\frac{1}{3!} p_i p_j p_k + \frac{1}{2!} p_i \wp(x_{jk}) \right), \\ I_4 &= \sum' \left(\frac{1}{4!} p_i p_j p_k p_l + \frac{1}{2! \cdot 2!} p_i p_j \wp(x_{kl}) + \frac{1}{2 \cdot (2!)^2} \wp(x_{ij}) \wp(x_{kl}) \right), \\ I_5 &= \sum' \left(\frac{1}{5!} p_i p_j p_k p_l p_r + \frac{1}{2! \cdot 3!} p_i p_j p_r \wp(x_{kl}) + \frac{1}{2 \cdot (2!)^2} p_r \wp(x_{ij}) \wp(x_{kl}) \right), \end{aligned} \quad (67)$$

where \sum' means summation over distinct indices. Recalling the equation of the spectral curve in terms of z and λ , let us also introduce $S_n(z|\lambda) = T_n(z + \zeta(\lambda)|\lambda)$, then

$$\partial_z S_n(z|\lambda) = n S_{n-1}(z|\lambda). \quad (68)$$

For example,

$$T_5(k|\lambda) = k^5 - 10\wp(\lambda)k^3 - 10\wp'(\lambda)k^2 - 5(\wp''(\lambda) - 3\wp^2(\lambda))k - 2\wp'(\lambda)\wp(\lambda).$$

We have

$$\zeta(\lambda) = \frac{1}{\lambda} - \frac{g_2 \lambda^3}{2^2 \cdot 3 \cdot 5} + O(z^{-5}),$$

where

$$g_2 = 60 \sum_{s \neq 0} \frac{1}{s^4}, \quad s = 2m\omega + 2m'\omega', \quad m, m' \in \mathbb{Z}.$$

Expanding $S_5(z|\lambda)$ in z using the above formula for T_5 , we get:

$$S_5(z|\lambda) = z^5 + \frac{5z^4}{\lambda} - \frac{g_2}{2} \left(\frac{1}{\lambda} + 5z + 5z^2\lambda + \frac{10}{3} z^3\lambda^2 + \frac{1}{6} z^4\lambda^3 \right) + O(z^{-1}).$$

Note that if we introduce the gradation such that $\deg z = 1$, $\deg \lambda = -1$, then $\deg g_2 = 4$, $\deg S_n = n$. Note also that in the rational limit $g_2 = 0$ and the equation of the spectral curve becomes linear in λ^{-1} (see below in the next section). This can be only in the case if $S_n(z|\lambda) = z^n - nz^{n-1}\lambda^{-1}$ in the rational limit (the coefficient is found from the condition (68)).

In the non-degenerate case we have

$$S_n(z|\lambda) = z^n - \frac{nz^{n-1}}{\lambda} + g_2 O(z^{n-4}) \quad (69)$$

or

$$S_n(z|\lambda) = z^n - \frac{nz^{n-1}}{\lambda} + g_2 A_n z^{n-4} + g_2 B_n I_1 z^{n-5} + O(z^{n-6}), \quad (70)$$

where A_n and B_n are some constant coefficients. (I_1 comes from the expansion $\lambda = -Nz^{-1} - \frac{I_1}{2}z^{-2} + O(z^{-3})$.) Therefore, we can write

$$\begin{aligned} S_N(z|\lambda) &= z^N - \frac{Nz^{N-1}}{\lambda} + g_2(A_N z^{N-4} + B_N I_1 z^{N-5}) + O(z^{N-6}), \\ S_{N-1}(z|\lambda) &= z^{N-1} - \frac{(N-1)z^{N-2}}{\lambda} + g_2 A_{N-1} z^{N-5} + O(z^{N-6}), \\ S_{N-j}(z|\lambda) &= z^{N-j} - \frac{(N-j)z^{N-j-1}}{\lambda} + O(z^{N-6}), \quad j = 2, 3, 4, 5. \end{aligned} \quad (71)$$

and the equation of the spectral curve acquires the form

$$\begin{aligned} z^N + \sum_{i=1}^5 I_i z^{N-i} + g_2 A_N z^{N-4} + g_2 (A_{N-1} + B_N) I_1 z^{N-5} + O(z^{N-6}) \\ = -\frac{1}{\lambda} \left(Nz^{N-1} + \sum_{i=1}^5 (N-i) I_i z^{N-i} \right). \end{aligned}$$

Expressing λ as a function of z from here, we have:

$$\begin{aligned} H_1 &= -I_1, \\ H_2 &= I_1^2 - 2I_2, \\ H_3 &= -I_1^3 + 3I_1 I_2 - 3I_3, \\ H_4 &= I_1^4 - 4I_1^2 I_2 + 2I_2^2 + 4I_1 I_3 - 4I_4 + \text{const}, \\ H_5 &= -I_1^5 + 5I_1^3 I_2 - 5I_1^2 I_3 + 5I_2 I_3 - 5I_1 I_2^2 + 5I_1 I_4 - 5I_5 + g_2 K I_1, \end{aligned} \quad (72)$$

where $K = (N + 1)A_N - N(A_{N-1} + B_N)$, or, explicitly,

$$\begin{aligned}
H_1 &= - \sum_i p_i, \\
H_2 &= \sum_i p_i^2 - \sum_{i \neq j} \wp(x_{ij}), \\
H_3 &= - \sum_i p_i^3 + 3 \sum_{i \neq j} p_i \wp(x_{ij}), \\
H_4 &= \sum_i p_i^4 - 2 \sum_{i \neq j} p_i p_j \wp(x_{ij}) - 4 \sum_{i \neq j} p_i^2 \wp(x_{ij}) \\
&\quad + \sum_{i \neq j} \wp^2(x_{ij}) + 2 \sum' \wp(x_{ij}) \wp(x_{jk}) + \text{const}, \\
H_5 &= - \sum_i p_i^5 + 5 \sum_{i \neq j} (p_i^3 + p_i^2 p_j) \wp(x_{ij}) - 5 \sum_{i \neq j} p_i \wp^2(x_{ij}) \\
&\quad - 5 \sum' p_i \wp(x_{ij}) \wp(x_{ik}) - 5 \sum' p_i \wp(x_{ij}) \wp(x_{jk}) + \text{const} \cdot \sum_i p_i.
\end{aligned} \tag{73}$$

These are indeed the Hamiltonians of the elliptic Calogero-Moser model. It is easy to see that they satisfy the property

$$H_{m-1} = -\frac{1}{m} \sum_i \partial_{p_i} H_m. \tag{74}$$

Indeed, we have

$$\lambda(z) = -Nz^{-1} + \sum_{m \geq 2} \frac{z^{-m}}{m} V_m = -Nz^{-1} + \sum_{m \geq 1} z^{-m-1} H_m$$

so

$$V_m = \partial_{t_m} \sum_i x_i = \sum_i \partial_{p_i} H_m = -m H_{m-1}.$$

One can see that the higher Hamiltonians will consist from the principal part and other terms as follows:

$$H_n = (-1)^n \sum_{|\mu|=n} C_\mu^n I_\mu + g_2 \sum_{|\nu|=n-4} B_\nu^n I_\nu + \dots, \tag{75}$$

where the first sum is taken over Young diagrams μ of $n = |\mu|$ boxes, $I_\mu = I_{\mu_1} I_{\mu_2} \dots I_{\ell(\mu)}$, where $\ell(\mu)$ is the number of non-empty rows of the diagram μ and C_μ^n is the matrix of the transition from the basis of elementary symmetric polynomials to the basis of power sums.

8 Rational and trigonometric limits

In the rational limit $\omega_1, \omega_2 \rightarrow \infty$, $\sigma(\lambda) = \lambda$, $\Phi(x, \lambda) = (x^{-1} + \lambda^{-1})e^{-x/\lambda}$ and the equation of the spectral curve becomes

$$\det(L_{\text{rat}} - (E - I)\lambda^{-1} - (z + \lambda^{-1})I) = 0, \tag{76}$$

where

$$(L_{\text{rat}})_{ij} = -\delta_{ij}p_i - \frac{1 - \delta_{ij}}{x_i - x_j} \quad (77)$$

is the Lax matrix of the rational Calogero-Moser model. Rewriting the equation of the spectral curve in the form

$$\det \left(I - E \frac{\lambda^{-1}}{L_{\text{rat}} - zI} \right) = 0$$

and using the property $\det(I + Y) = 1 + \text{tr} Y$ for any matrix Y of rank 1, we get

$$\lambda = -\text{tr} \left(E \frac{1}{zI - L_{\text{rat}}} \right) = -\sum_{n \geq 0} z^{-n-1} \text{tr} L_{\text{rat}}^n, \quad (78)$$

where we use the well known property $\text{tr}(EL_{\text{rat}}^n) = \text{tr}(L_{\text{rat}}^n)$. So the Hamiltonians are $H_m = \text{tr} L_{\text{rat}}^m$ which agrees with Shiota's result [8].

The trigonometric limit is more tricky. Let $\pi i/\gamma$ be period of the trigonometric (or hyperbolic) functions (the second period tends to infinity). The Weierstrass functions in this limit become

$$\sigma(x) = \gamma^{-1} e^{-\frac{1}{6}\gamma^2 x^2} \sinh(\gamma x), \quad \zeta(x) = \gamma \coth(\gamma x) - \frac{1}{3} \gamma^2 x.$$

The tau-function for trigonometric solutions is

$$\tau(x, \mathbf{t}) = \prod_{i=1}^N \left(e^{2\gamma x} - e^{2\gamma x_i(\mathbf{t})} \right), \quad (79)$$

so we should consider

$$\tau(x, \mathbf{t}) = \prod_{i=1}^N \sigma(x - x_i) e^{\frac{1}{6}\gamma^2(x-x_i)^2 + \gamma(x+x_i)}. \quad (80)$$

With this choice, equation (33) acquires the form $k = z + \zeta(\lambda) + \frac{1}{3}\gamma^2\lambda$ or

$$k = z + \gamma \coth(\gamma\lambda). \quad (81)$$

The trigonometric limit of the function $\Phi(x, \lambda)$ is

$$\Phi(x, \lambda) = \gamma \left(\coth(\gamma x) + \coth(\gamma\lambda) \right) e^{-\gamma x \coth(\gamma\lambda)}.$$

Therefore, the equation of the spectral curve can be written in the form

$$\det \left(W^{1/2} L W^{-1/2} + \gamma(1 - \coth(\gamma\lambda))(E - I) - (z + \gamma \coth(\gamma\lambda))I \right) = 0, \quad (82)$$

where $W = \text{diag}(w_1, w_2, \dots, w_N)$ and

$$L_{ij} = -\delta_{ij}p_i - \frac{(1 - \delta_{ij})\gamma}{\sinh(\gamma(x_i - x_j))} = -\delta_{ij}p_i - 2\gamma(1 - \delta_{ij}) \frac{w_i^{1/2} w_j^{1/2}}{w_i - w_j} \quad (83)$$

is the Lax matrix of the trigonometric Calogero-Moser model. Here and below we use the notation $w_i = e^{2\gamma x_i}$.

After the transformations similar to the rational case equation (82) can be brought to the form

$$\gamma(1 - \coth(\gamma\lambda))\text{tr} \left[W^{-1/2}EW^{1/2} \frac{1}{zI - (L - \gamma I)} \right] = 1$$

or

$$\lambda = \frac{1}{2\gamma} \log \left[1 - 2\gamma \text{tr} \left(W^{-1/2}EW^{1/2} \frac{1}{zI - (L - \gamma I)} \right) \right]. \quad (84)$$

Applying the formula $\det(I + Y) = 1 + \text{tr} Y$ for any matrix Y of rank 1 in the opposite direction, we have

$$\lambda = \frac{1}{2\gamma} \log \det \left[I - 2\gamma W^{-1/2}EW^{1/2} \frac{1}{zI - (L - \gamma I)} \right]. \quad (85)$$

Now we are going to use the identity

$$[L, W] = 2\gamma(W^{1/2}EW^{1/2} - W) \quad (86)$$

which can be easily checked. With the help of this identity, we can transform (85) as follows:

$$\begin{aligned} 2\gamma\lambda &= \log \det \left(I - W^{-1}LW \frac{1}{zI - (L - \gamma I)} + \frac{L}{zI - (L - \gamma I)} - \frac{2\gamma}{zI - (L - \gamma I)} \right) \\ &= \log \det \left[\left(I - \frac{2\gamma}{zI - (L - \gamma I)} \right) \frac{zI - (L - \gamma I)}{zI - (L + \gamma I)} \right. \\ &\quad \left. \times \left(I - W^{-1}LW \frac{1}{zI - (L - \gamma I)} + \frac{L}{zI - (L - \gamma I)} - \frac{2\gamma}{zI - (L - \gamma I)} \right) \right] \\ &= \log \det \left[\left(I - \frac{2\gamma}{zI - (L - \gamma I)} \right) \left(I - W^{-1}LW \frac{1}{zI - (L + \gamma I)} + \frac{L}{zI - (L + \gamma I)} \right) \right] \\ &= \log \det \left[\left(I - \frac{2\gamma}{zI - (L - \gamma I)} \right) \frac{1}{zI - (L + \gamma I)} (zI - (L + \gamma I) - W^{-1}LW + L) \right] \\ &= \log \det \frac{zI - (L + \gamma I)}{zI - (L - \gamma I)}. \end{aligned}$$

Therefore, we get

$$\begin{aligned} \lambda &= \frac{1}{2\gamma} \text{tr} \left(\log(I - z^{-1}(L + \gamma I)) - \log(I - z^{-1}(L - \gamma I)) \right) \\ &= -\frac{1}{2\gamma} \text{tr} \sum_{m \geq 1} \frac{z^{-m}}{m} \left((L + \gamma I)^m - (L - \gamma I)^m \right) \end{aligned} \quad (87)$$

and

$$H_m = \frac{1}{2\gamma(m+1)} \text{tr} \left((L + \gamma I)^{m+1} - (L - \gamma I)^{m+1} \right) \quad (88)$$

which agrees with the result of paper [10].

Acknowledgments

We thank I. Krichever for illuminating discussions. The research of A.Z. has been funded within the framework of the HSE University Basic Research Program and the Russian Academic Excellence Project '5-100'.
