

Informational Robustness of Common Belief in Rationality

Gabriel Ziegler*

August 18, 2021

ABSTRACT

I explore the implications of informational robustness under the assumptions of common belief in rationality. That is, predictions for incomplete-information games which are valid across all possible information structures. First, I address this question from a global perspective and then generalize the analysis to allow for localized informational robustness.

KEYWORDS: informational robustness, rationalizability, incomplete information, Bayesian game

JEL CLASSIFICATION: C72, D82, D83.

Enrico de Magistris, Marciano Siniscalchi, and Peio Zuazo-Garin provided very helpful comments, which I am thankful for.

1 INTRODUCTION

For Bayesian games [Dekel et al. \(2007\)](#) introduce the solution concept of *interim-correlated rationalizability (ICR)* and show that it captures the behavioral implications of common belief in rationality within the Bayesian game.¹ A crucial ingredient of a Bayesian game is the Harsanyi type space, which models player's information about the exogenous uncertainty and in addition implicitly determines the players' hierarchy of beliefs about this uncertainty. Changing the Harsanyi type space will change the predictions of ICR usually and therefore this solution concept is not informationally robust. In this note, I explore the robust behavioral implications when the analyst does not want to make the strong assumption about the exact information (and higher-order beliefs) players have about the exogenous uncertainty.

Early pioneers in the area of informational robustness include [Aumann \(1987\)](#), [Brandenburger and Dekel \(1987\)](#), and [Forges \(1993, 2006\)](#). [Bergemann and Morris \(2013, 2016\)](#) recently exploited the full power of informational robustness to provide robust predictions in economic environments with uncertainty.² The main analysis here is closest to that of [Bergemann and Morris \(2017\)](#). However, there is major conceptual difference: their starting point is that play in a Bayesian game is governed by Bayes Nash equilibrium, while here I start from the primitive assumptions of common belief in rationality. I will discuss a natural connection between these two approaches along the way of the analysis.

2 MAIN ANALYSIS

In this section, I will first introduce the relevant notation and definitions in [Subsection 2.1](#). [Subsection 2.2](#) establishes the main robustness result. A more general informational robustness question is addressed in [Subsection 2.3](#).

¹To be precise, it should be called common *correct* belief in rationality, but I will use the shorter wording throughout.

²Some of these ideas are fruitfully applied to the theory of robust mechanism design as initiated by [Bergemann and Morris \(2005, 2009, 2011\)](#). Other papers dealing with related ideas about robustness include [Battigalli \(1999, 2003\)](#), [Battigalli and Siniscalchi \(2003\)](#), [Dekel et al. \(2007\)](#), [Liu \(2015\)](#), [Tang \(2015\)](#), and [Germano and Zuazo-Garin \(2017\)](#).

2.1 THE ECONOMIC ENVIRONMENT, INFORMATION STRUCTURES, AND SOLUTION CONCEPTS

An *economic environment* consists of a tuple $\mathcal{E} = \langle I, \Theta_0, (A_i, \Theta_i, u_i)_{i \in I} \rangle$ where $I = \{1, 2\}$ is set of *players*³ and Θ_0 is a finite set of *states of nature*. Moreover, for each player i there is (i) a finite set of (pure) *actions* A_i , (ii) a finite set of *payoff types*,⁴ and (iii) a *utility function* $u_i : A \times \Theta \rightarrow \mathbb{R}$, where $A := \prod_{i \in I} A_i$ and $\Theta := \prod_{i \in I \cup \{0\}} \Theta_i$ denote the set of action *profiles* and *payoff states*, respectively. For each player i a randomization of own strategies $\alpha_i \in \Delta(A_i)$ is referred to as a *mixed strategy*,⁵ and a probability measure $\mu_i \in \Delta(\Theta_0 \times \Theta_{-i} \times A_{-i})$, where $\Theta_{-i} := \Theta_{3-i}$ and $A_{-i} := A_{3-i}$,⁶ as a *conjecture*. When necessary, with some abuse of notation, a_i refers to the degenerate mixed strategy that assigns probability one to pure action a_i . For each payoff type θ_i , each conjecture μ_i and possibly mixed action α_i naturally induce *expected utility* $U_i(\mu_i; \alpha_i, \theta_i)$ and based on this, each player i 's *best-reply* correspondence for payoff type θ_i is defined by assigning to each conjecture μ_i the subset of pure actions $BR_i(\mu_i; \theta_i)$ that maximize its corresponding expected utility.⁷ For the rest of this note, I consider the economic environment \mathcal{E} to be fixed and therefore drop most explicit mentions to it.

Belief-free rationalizability (BFR) is a solution concept due to Battigalli (1999, 2003) that requires only the specification of an economic environment.⁸ Action a_i is *belief-free rationalizable* for payoff type θ_i if it is iteratively a best-reply to a belief

³To simplify notation, I will consider two players throughout. All results can be extended to any finite number of players

⁴Magistris (2021) extends Proposition 1 to allow for more general action and type spaces.

⁵Throughout this chapter, for any topological space X , as usual, $\Delta(X)$ denotes the set of probability measures on the Borel σ -algebra of X .

⁶Similar notation will be used for indexing throughout.

⁷That is, given conjecture μ_i and payoff type θ_i the expected utility is

$$U_i(\mu_i; \alpha_i, \theta_i) := \sum_{(a_i, a_{-i}) \in A} \sum_{(\theta_0, \theta_{-i}) \in \Theta_0 \times \Theta_{-i}} \mu_i[\theta_0, \theta_{-i}, a_{-i}] \cdot \alpha_i[a_i] \cdot u_i(a_i, a_{-i}, \theta_0, \theta_i, \theta_{-i})$$

for each possibly mixed action α_i , and the set of best-replies is $BR_i(\mu_i; \theta_i) := \arg \max_{a_i \in A_i} U_i(\mu_i; a_i, \theta_i)$.

⁸For a more recent discussion of the relationship of BFR to other solution concepts see Battigalli et al. (2011). Bergemann and Morris (2017) call this solution concept ex-post rationalizability because it is equivalent to the iterative deletion of ex-post dominated actions. Bergemann and Morris also define a slightly stronger solution concept which they call belief-free rationalizability. In their version there is a belief restriction in place constraining the supports of the beliefs. After Corollary 2, I discuss their solution concept in more detail.

that assigns positive probability only to actions of the other player that survived the previous round. Formally, action a_i is belief-free rationalizable for payoff type θ_i if $a_i \in BFR_i^\infty(\theta_i) := \bigcap_{n \geq 0} BFR_i^n(\theta_i)$, where $BFR_i^0(\theta_i) := A_i$ and inductively for any $n \in \mathbb{N}$,

$$BFR_i^n(\theta_i) := \left\{ a_i \in BFR_i^{n-1}(\theta_i) \left| \begin{array}{l} \text{There exists } \mu_i \in \Delta(\Theta_0 \times \Theta_{-i} \times A_{-i}) \text{ s.t.:} \\ (i) \quad \text{supp } \mu_i \subseteq \Theta_0 \times \text{graph}(BFR_{-i}^{n-1}), \\ (ii) \quad a_i \in BR_i(\mu_i; \theta_i) \end{array} \right. \right\}. \quad (BFR^n)$$

Battigalli and Siniscalchi (1999, 2002) show that BFR corresponds to the behavioral implications of common belief in rationality.⁹ Usual arguments can be used to give a fixed-point definition of rationalizability:¹⁰ for every player i and every payoff type θ_i consider a set of actions $F_i(\theta_i)$ with the following fixed-point property

$$F_i(\theta_i) := \left\{ a_i \in A_i \left| \begin{array}{l} \text{There exists } \mu_i \in \Delta(\Theta_0 \times \Theta_{-i} \times A_{-i}) \text{ s.t.:} \\ (i) \quad \text{supp } \mu_i \subseteq \Theta_0 \times \text{graph}(F_{-i}), \\ (ii) \quad a_i \in BR_i(\mu_i; \theta_i) \end{array} \right. \right\}. \quad (BFR_{FP})$$

Then the pair $(BFR_i^\infty)_{i \in I}$ understood as correspondences is equal to the pair of correspondences $(F_i)_{i \in I}$ satisfying the fixed-point property and are largest by set inclusion.

Harsanyi's (1967) approach differs from the previous approach by appending a type structure to the economic environment. For the purpose of this chapter, we will call such a type structure an *information structure*.¹¹ An information structure is a tuple $\mathcal{Y} = \langle (Y_i, \pi_i)_{i \in I} \rangle$, where for each player i Y_i is a finite set of *signal realizations* and thus $X_i := \Theta_i \times Y_i$ is the set of *information types* describing the private information of player i . Moreover, $\pi_i : X_i \rightarrow \Delta(\Theta_0 \times X_{-i})$ specifies the beliefs about the

⁹Their result is actually more general; see Battigalli et al. (2011).

¹⁰Battigalli (2003, Proposition 8.1) establishes this equivalence in a more general setting.

¹¹Formally, there is no difference, but the interpretation changes. In this chapter we want to model hard information, whereas Harsanyi's type structures are only a modeling device to represent *hierarchies of beliefs* about $(\theta_0, \theta_1, \theta_2)$. Dekel and Siniscalchi (2015, Section 1.1) discuss the conceptual difference.

opponent's information and state of nature.¹² An economic environment \mathcal{E} together with an information structure \mathcal{Y} constitutes a *Bayesian game* $\mathcal{B} = \langle \mathcal{E}, \mathcal{Y} \rangle$.

Dekel et al. (2007) show that common belief in rationality within a Bayesian game is behaviorally characterized by *interim correlated rationalizability*. Action a_i is interim correlated rationalizable for information type $x_i = (\theta_i, y_i)$ if it survives an iterated elimination procedure similar to above, but where the beliefs about opponent's information and state of nature have to coincide with the information prescribed by $\pi_i(\theta_i, y_i)$. Formally, action a_i is interim correlated rationalizable for information type $x_i = (\theta_i, y_i)$ if $a_i \in ICR_i^{\infty, \mathcal{Y}}(\theta_i, y_i) := \bigcap_{n \geq 0} ICR_i^{n, \mathcal{Y}}(\theta_i, y_i)$, where $ICR_i^{0, \mathcal{Y}}(\theta_i, y_i) := A_i$ and inductively for any $n \in \mathbb{N}$,

$$ICR_i^{n, \mathcal{Y}}(\theta_i, y_i) := \left\{ a_i \in ICR_i^{n-1, \mathcal{Y}}(\theta_i, y_i) \left| \begin{array}{l} \text{There exists } \mu_i \in \Delta(\Theta_0 \times \Theta_{-i} \times Y_{-i} \times A_{-i}) \text{ s.t.:} \\ (i) \quad \text{supp } \mu_i \subseteq \Theta_0 \times \text{graph}(ICR_{-i}^{n-1, \mathcal{Y}}), \\ (ii) \quad a_i \in BR_i(\text{marg}_{\Theta_0 \times \Theta_{-i} \times A_{-i}} \mu_i; \theta_i), \\ (iii) \quad \text{marg}_{\Theta_0 \times \Theta_{-i} \times Y_{-i}} \mu_i = \pi(\theta_i, y_i) \end{array} \right. \right\}. \quad (ICR^n)$$

Again, this can be equivalently stated as fixed-point. Dekel et al. (2007, Claim 3) establish this characterization:¹³ for every player i and every information type (θ_i, y_i) consider a set of actions $F_i(\theta_i, y_i)$ with the following fixed-point property

$$F_i(\theta_i, y_i) := \left\{ a_i \in A_i \left| \begin{array}{l} \text{There exists } \mu_i \in \Delta(\Theta_0 \times \Theta_{-i} \times Y_{-i} \times A_{-i}) \text{ s.t.:} \\ (i) \quad \text{supp } \mu_i \subseteq \Theta_0 \times \text{graph}(F_{-i}), \\ (ii) \quad a_i \in BR_i(\text{marg}_{\Theta_0 \times \Theta_{-i} \times A_{-i}} \mu_i; \theta_i), \\ (iii) \quad \text{marg}_{\Theta_0 \times \Theta_{-i} \times Y_{-i}} \mu_i = \pi(\theta_i, y_i) \end{array} \right. \right\}. \quad (ICR_{FP})$$

Then the pair $(ICR_i^{\infty, \mathcal{Y}})_{i \in I}$ understood as correspondences is equal to the pair of correspondences $(F_i)_{i \in I}$ satisfying the fixed-point property and are largest by set inclusion.

Remark 1. *The notation might suggest that interim correlated rationalizability depends on the information structure \mathcal{Y} , but not on the economic environment \mathcal{E} . Obvi-*

¹²This definition of information structure is stated from an interim perspective. Up to measure-zero events, there is an equivalent formalization from an ex-ante perspective.

¹³Their setting slightly differs from the setting here, but their argument can easily be adapted.

ously this is not case, but since \mathcal{E} will be fixed throughout this notation simplifies the exposition.

Although most of this note will focus on the behavioral implications of common belief in rationality, it will be useful to define the appropriate version of *Bayes-Nash equilibrium* for a Bayesian game as introduced by Harsanyi (1967).¹⁴ For a given Bayesian game \mathcal{B} , define a *strategy* of player i by $s_i : \Theta_i \times Y_i \rightarrow A_i$.¹⁵ Then a strategy profile $s = (s_1, s_2)$ constitutes a Bayes-Nash equilibrium if for every player i and every $(\theta_i, y_i) \in \Theta_i \times Y_i$

$$s_i(\theta_i, y_i) \in BR_i(s_{-i} \circ \pi_i(\theta_i, y_i); \theta_i), \quad (\text{BNE})$$

where $s_{-i} \circ \pi_i(\theta_i, y_i)[\theta_0, \theta_{-i}, a_{-i}] := \sum_{y_{-i} \in Y_{-i} : s_{-i}(\theta_{-i}, y_{-i}) = a_{-i}} \pi_i(\theta_i, y_i)[\theta_0, \theta_{-i}, y_{-i}]$. Let $BNE^{\mathcal{Y}} = (BNE_i^{\mathcal{Y}})_{i \in I}$ denote the set of Bayes-Nash equilibrium strategy profiles for information structure \mathcal{Y} .¹⁶

2.2 INFORMATIONAL ROBUSTNESS

Bergemann and Morris (2013, 2016, 2017) study the question of informational robust predictions in Bayesian games if the analyst (or any outside observer) does not know the information structure of the Bayesian game. Their starting point is Bayes-Nash equilibrium, whereas I take common belief in rationality as the starting point. Thus, the outside observer wants to characterize the set of all actions that are interim-correlated rationalizability for *any* information structure. The following proposition formally relates this information robustness question to belief-free rationalizability.

Proposition 1. *Let \mathcal{E} be an economic environment. For every player i and every payoff type θ_i , $a_i \in BFR_i^\infty(\theta_i)$ if and only if there exists an information structure \mathcal{Y}*

¹⁴The epistemic foundation of Bayes-Nash equilibrium is still an open question. Dekel and Siniscalchi (2015, Theorem 15) provide demanding sufficient conditions (beyond common belief in rationality) if there are two players.

¹⁵I consider only pure strategies here in this note for simplicity and ease of notation. The analysis extends to mixed strategies.

¹⁶Remark 1 applies here as well.

and a signal y_i such that $a_i \in ICR_i^{\infty, \mathcal{Y}}(\theta_i, y_i)$. That is,

$$BFR_i^{\infty}(\theta_i) = \bigcup_{\mathcal{Y}} \bigcup_{y_i \in Y_i} ICR_i^{\infty, \mathcal{Y}}(\theta_i, y_i).$$

Proof. Follows as a direct application of [Proposition 2](#) with informational restrictions $\Delta_{i, \theta_i} = \Delta(\Theta_0 \times \Theta_{-i})$. ■

[Brandenburger and Dekel \(1987\)](#) establish an informational robustness interpretation similar to above for (complete information) rationalizability starting from Nash equilibrium. [Battigalli and Siniscalchi \(2003, Propositions 4.2 and 4.3\)](#) extend this robustness interpretation to Bayes-Nash equilibrium allowing for belief restrictions,¹⁷ whereas [Bergemann and Morris \(2017, Section 4.5\)](#) mention a similar interpretation for belief-free rationalizability, in particular. The following corollary establishes the formal result as conjectured in [Bergemann and Morris \(2017\)](#)—it follows directly as a corollary from [Proposition 1](#) and [Dekel et al. \(2007, Remark 2\)](#):

Corollary 1. *Let \mathcal{E} be an economic environment. For every player i and every payoff type θ_i , $a_i \in BFR_i^{\infty}(\theta_i)$ if and only if there exists an information structure \mathcal{Y} and a Bayes-Nash equilibrium strategy profile s such that for every player i and every payoff type θ_i there exists some signal $y_i^* \in Y_i$ such that $a_i = s_i(\theta_i, y_i^*)$. That is,*

$$BFR_i^{\infty}(\theta_i) = \bigcup_{\mathcal{Y}} \bigcup_{s_i \in BNE_i^{\mathcal{Y}}} \bigcup_{y_i \in Y_i} s_i(\theta_i, y_i).$$

2.3 LOCALIZED INFORMATIONAL ROBUSTNESS

The previous section captured in a sense the robustest prediction to informational assumptions: the analyst does not want to make any assumptions about information (and higher-order beliefs about this assumption). Therefore, the previous results can be seen as *global* informational robustness. However, in some instances this might be a too demanding robustness questions; maybe the analyst is willing to make some informational assumptions. For example, that every player assigns positive probability to all of the opponent's payoff types and this itself is commonly believed among the players. In such a case taking the union across *all* information structures (and all

¹⁷See [Corollary 2](#) below.

signal realizations) is too permissive: the analyst wants to consider all information structures which are consistent with the baseline informational assumptions.

Following Battigalli (1999, 2003) and Battigalli and Siniscalchi (2003), I formalize the baseline informational assumptions via belief restrictions for each player.¹⁸ Informally, the analyst is willing to make the assumption that player’s beliefs about the payoff state lies within a pre-specified set of beliefs. Formally, an *informational restriction* is a pair $\Delta := (\Delta_1, \Delta_2) := ((\Delta_{1,\theta_1})_{\theta_1 \in \Theta_1}, (\Delta_{2,\theta_2})_{\theta_2 \in \Theta_2})$, where for each player i and each payoff type θ_i , $\Delta_{i,\theta_i} \subseteq \Delta(\Theta_0 \times \Theta_{-i})$ is a set of beliefs about the unknown parts of the the payoff state, i.e. $\Theta_0 \times \Theta_{-i}$. The interpretation is that players (and payoff types) received some information about the overall payoff state, but the analyst is only willing to assume the resulting beliefs are within Δ_i . If $\Delta_{i,\theta_i} = \Delta(\Theta_0 \times \Theta_{-i})$ for every θ_i and every player i then there are no restrictions, which corresponds to the case analyzed in the previous part.

If the analyst is not concerned about robustness, she would—as before—model the strategic situation with a Bayesian game, but now she would make sure that the information structure is consistent with the hypothesized informational restrictions.

Definition 1. For a given economic environment \mathcal{E} and an informational restriction Δ , an information structure \mathcal{Y} is consistent with Δ when $\text{marg}_{\Theta_0 \times \Theta_{-i}} \pi_i(\theta_i, y_i) \in \Delta_{i,\theta_i}$ for every information type $(\theta_i, y_i) \in \Theta_i \times Y_i$ and every player i . Let $\mathbb{Y}(\Delta)$ denote the collection of all information structures consistent with Δ .

The localized informational robustness question for a given informational restriction Δ is to characterize the set of all interim-correlated actions across all information structures consistent with Δ . Unless Δ does not impose any restrictions it is obvious that the resulting set of actions will be a refinement of belief-free rationalizability. Indeed, as shown below the relevant robust solution concept is given by Δ -rationalizability as introduced by Battigalli (1999, 2003) and Battigalli and Siniscalchi (2003). As before the definition is given inductively: action a_i is Δ -rationalizable for payoff type θ_i if it is iteratively a best-reply to a belief that (i) is inside the allowed

¹⁸Battigalli (1999, 2003) and Battigalli and Siniscalchi (2003) consider more general belief restrictions; potentially also restricting beliefs about opponent’s actions. To highlight the difference, I will refer to the belief restrictions in this informational setting as *informational restrictions*. Artemov et al. (2013) and Ollár and Penta (2017) study robust mechanism design with belief restrictions via informational restrictions as considered here.

beliefs Δ_{i,θ_i} and (ii) assigns positive probability to actions of the other player that survived the previous round. Formally, action a_i is Δ -rationalizable for payoff type θ_i if $a_i \in \Delta R_i^\infty(\theta_i) := \bigcap_{n \geq 0} \Delta R_i^n(\theta_i)$, where $\Delta R_i^0(\theta_i) := A_i$ and inductively for any $n \in \mathbb{N}$,

$$\Delta R_i^n(\theta_i) := \left\{ a_i \in \Delta R_i^{n-1}(\theta_i) \left| \begin{array}{l} \text{There exists } \mu_i \in \Delta(\Theta_0 \times \Theta_{-i} \times A_{-i}) \text{ s.t.:} \\ (i) \quad \text{marg}_{\Theta_0 \times \Theta_{-i}} \mu_i \in \Delta_{i,\theta_i}, \\ (ii) \quad \text{supp } \mu_i \subseteq \Theta_0 \times \text{graph}(\Delta R_{-i}^{n-1}), \\ (iii) \quad a_i \in BR_i(\mu_i; \theta_i) \end{array} \right. \right\}. \quad (\Delta R^n)$$

As before a fixed-point definition of Δ -rationalizability comes in handy: for every player i and every payoff type θ_i consider a set of actions $F_i(\theta_i)$ with the following fixed-point property:

$$F_i(\theta_i) := \left\{ a_i \in A_i \left| \begin{array}{l} \text{There exists some } \mu_i \in \Delta(\Theta_0 \times \Theta_{-i} \times A_{-i}) \text{ such that:} \\ (i) \quad \text{marg}_{\Theta_0 \times \Theta_{-i}} \mu_i \in \Delta_{i,\theta_i}, \\ (ii) \quad \text{supp } \mu_i \subseteq \Theta_0 \times \text{graph}(F_{-i}), \\ (iii) \quad a_i \in BR_i(\mu_i; \theta_i) \end{array} \right. \right\}. \quad (\Delta R_{FP})$$

Then the pair $(\Delta R_i^\infty)_{i \in I}$ understood as correspondences is equal to the pair of correspondences $(F_i)_{i \in I}$ satisfying the fixed-point property and are largest by set inclusion.

With this definition in hand, the main result can be stated formally:

Proposition 2. *Let \mathcal{E} be an economic environment and fix belief restrictions Δ . For every player i and every payoff type θ_i , $a_i \in \Delta R_i^\infty(\theta_i)$ if and only if there exists an information structure \mathcal{Y} consistent with Δ such that for every player i and every payoff type θ_i there exists some signal $y_i^* \in Y_i$ such that $a_i \in ICR_i^{\infty, \mathcal{Y}}(\theta_i, y_i^*)$. That is,*

$$\Delta R_i^\infty(\theta_i) = \bigcup_{\mathcal{Y} \in \mathbb{Y}(\Delta)} \bigcup_{y_i^* \in Y_i} ICR_i^{\infty, \mathcal{Y}}(\theta_i, y_i^*).$$

Proof. For a given information structure \mathcal{Y} such that $\text{marg}_{\Theta_0 \times \Theta_{-i}} \pi_i(\theta_i, \theta_i) \in \Delta_{i,\theta_i}$ for every player i and every payoff type θ_i , consider a signal y_i such that $a_i \in ICR_i^{\infty, \mathcal{Y}}(\theta_i, y_i)$. I show that $a_i \in \Delta R_i^\infty(\theta_i)$ by induction, i.e. $a_i \in \Delta R_i^n(\theta_i)$ for every n . The statement is trivial for $n = 0$. So assume the statement is true

for $n \geq 0$. Since $a_i \in ICR_i^{\infty, \mathcal{Y}}(\theta_i, y_i)$ and using [Equation \$ICR_{FP}\$](#) there is a belief $\mu_i \in \Delta(\Theta_0 \times \Theta_{-i} \times Y_{-i} \times A_{-i})$ such that

- (1) $\text{supp } \mu_i \subseteq \Theta_0 \times \left\{ (\theta_{-i}, y_{-i}, a_{-i}) \in \Theta_{-i} \times Y_{-i} \times A_{-i} \mid a_{-i} \in ICR_{-i}^{\infty, \mathcal{Y}}(\theta_{-i}, y_{-i}) \right\}$
- (2) $BR_i \left(\text{marg}_{\Theta_0 \times \Theta_{-i} \times A_{-i}} \mu_i; \theta_i \right)$
- (3) $\text{marg}_{\Theta_0 \times \Theta_{-i} \times Y_{-i}} \mu_i = \pi(\theta_i, y_i)$

Let $\hat{\mu}_i = \text{marg}_{\Theta_0 \times \Theta_{-i} \times A_{-i}} \mu_i$ then (3) implies $\text{marg}_{\Theta_0 \times \Theta_{-i}} \hat{\mu}_i \in \Delta_{i, \theta_i}$. Furthermore, for any $(\theta_0, \theta_{-i}, a_{-i})$ with $\hat{\mu}_i[\theta_0, \theta_{-i}, a_{-i}] > 0$, we know that $\mu_i[\theta_0, \theta_{-i}, y_{-i}, a_{-i}] > 0$ for some y_{-i} . Thus, by (1) $a_{-i} \in ICR_{-i}^{\infty, \mathcal{Y}}(\theta_{-i}, y_{-i})$ and using the induction hypothesis $a_{-i} \in \Delta R_{-i}^n(\theta_{-i})$. Now, by (2) a_i is also a maximizer for $\hat{\mu}_i$, so that $a_i \in \Delta R_i^{n+1}(\theta_i)$.

Conversely, if $\Delta R_i^\infty(\theta_i) = \emptyset$ the statement is trivial. If not, then for every $a_i \in \Delta R_i^\infty(\theta_i)$, there is a justifying belief $\mu_i^{a_i, \theta_i} \in \Delta(\Theta_0 \times \Theta_{-i} \times A_{-i})$ satisfying (i)–(iii) from [Equation \$\Delta R_{FP}\$](#) . Consider the following information structure: For every player i set $Y_i = A_i$ and assign $\pi_i(\theta_i, a_i) = \mu_i^{a_i, \theta_i}$ for every information type (θ_i, a_i) . For every payoff type θ_i , note that $\text{marg}_{\Theta_0 \times \Theta_{-i}} \pi_i(\theta_i, y_i) \in \Delta_{i, \theta_i}$ for every $y_i \in Y_i$ by (i). Now, fix $a_i \in \Delta R_i^\infty(\theta_i)$ and I will prove by induction that $a_i \in ICR_i^{\infty, \mathcal{Y}}(\theta_i, a_i)$. The statement is trivial for $n = 0$, so assume the statement is true for $n \geq 0$. To see it holds for $n + 1$, define $\mu_i \in \Delta(\Theta_0 \times \Theta_{-i} \times Y_{-i} \times A_{-i})$ by

$$\mu_i[\theta_0, \theta_{-i}, y_{-i}, a_{-i}] = \mu_i^{a_i, \theta_i}[\theta_0, \theta_{-i}, a_{-i}]$$

if $y_{-i} = a_{-i}$ and zero otherwise. By construction (ii) and (iii) of [Equation \$ICR^n\$](#) are satisfied. For (i), consider $(\theta_0, \theta_{-i}, y_{-i}, a_{-i})$ such that $\mu_i[\theta_0, \theta_{-i}, y_{-i}, a_{-i}] > 0$, then by construction $y_{-i} = a_{-i}$ and $\mu_i^{a_i, \theta_i}[\theta_0, \theta_{-i}, a_{-i}] > 0$. Thus, by (ii) of [Equation \$\Delta R_{FP}\$](#) we have $a_{-i} \in \Delta R_{-i}^\infty(\theta_{-i}) \subseteq ICR_{-i}^{n, \mathcal{Y}}(\theta_{-i}, a_{-i})$, where the inclusion holds due to the induction hypothesis. Thus, we conclude that $a_i \in ICR_i^{n+1, \mathcal{Y}}(\theta_i, a_i)$. \blacksquare

As before, exploiting the relationship of ICR with Bayes-Nash equilibrium gives local informational robustness with equilibrium as baseline assumption as a corollary.

Corollary 2 (Battigalli, 2003; Battigalli and Siniscalchi, 2003). *Let \mathcal{E} be an economic environment and fix belief restrictions Δ . For every player i and every payoff type θ_i , $a_i \in \Delta R_i^\infty(\theta_i)$ if and only if there exists an information structure \mathcal{Y} consistent with Δ and a Bayes-Nash equilibrium strategy profile s such that for every player i and every payoff type θ_i there exists some signal $y_i^* \in Y_i$ such that $a_i = s_i(\theta_i, y_i^*)$. That is,*

$$\Delta R_i^\infty(\theta_i) = \bigcup_{\mathcal{Y} \in \mathbb{Y}(\Delta)} \bigcup_{s_i \in BNE_i^{\mathcal{Y}}} \bigcup_{y_i^* \in Y_i} s_i(\theta_i, y_i^*).$$

The main result about informational robustness of Bergemann and Morris (2017, Proposition 8) can be seen as a special case of Corollary 2. In their model, there are no private payoff types. In my setting this corresponds to assuming that the utility functions u_i depend only on θ_0 (and on the action profile). With this assumption, θ_i is directly payoff irrelevant, but could potentially serve as a payoff-relevant signal (i.e. about θ_0). Indeed, Bergemann and Morris (2017) start with a baseline information structure with beliefs given by $\varphi_i : \Theta_i \rightarrow \Delta(\Theta_0 \times \Theta_{-i})$. Defining corresponding informational restrictions as $\Delta_{i,\theta_i} = \{\mu \in \Delta(\Theta_0 \times \Theta_{-i}) : \text{supp } \mu \subseteq \text{supp } \varphi_i(\theta_i)\}$ then yields Bergemann and Morris’s solution concept as Δ -rationalizability using the definition in this note. Bergemann and Morris are interested in when players might have more information than the baseline information embodied in φ . More information might render some states irrelevant by Bayesian updating, but it cannot make states probable when they were impossible according to the baseline information. With this consideration in mind, an analyst is only willing to make the informational assumptions given by the support of φ . Whereas Corollary 2 reduces to Proposition 8 of Bergemann and Morris (2017), Proposition 2 shows that their informational robustness question has the same answer when the starting point of the analysis is common belief rationality instead of Bayes-Nash equilibrium.
