Abstract

We introduce a new class \mathcal{G} of plane bipartite graphs and prove that each graph in \mathcal{G} admits a proper square contact representation. A contact between two squares is *proper* if they intersect in a line segment of positive length. The class \mathcal{G} is the family of quadrangulations obtained from the 4-cycle C_4 by successively inserting a single vertex or a 4-cycle of vertices into a face.

1 Introduction

Geometric representations of graphs have many applications and yield intriguing problems [9]. Koebe's celebrated *circle packing theorem* [8], for example, states that every planar graph is a contact graph of interior-disjoint disks in the plane. Schramm [10] proved that this theorem holds even if we replace the disks with homothets of an arbitrary smooth strictly convex body in the plane. The result extends to non-smooth convex bodies in a weaker form (where a homothet may degenerate to a point, and three or more homothets may have a common point of intersection), and every planar graph is only a *subgraph* of such a contact graph.

In this paper, we consider *strong* contact representations with interior-disjoint convex bodies where no three convex bodies have a point in common. It is an open problem to classify graphs that admit a strong contact representation with homothets of a triangle or a square. It is known that every partial 3-tree [1] and every 4-connected planar graph admits a strong contact representation with homothetic triangles, see [5, 6]; but there are 3-connected planar graphs which do not admit such a representation. We note here that every planar graph admits a strong contact representation with (non-homothetic) triangles [3]; see also [6].

Strong contact representations with homothetic squares have been considered only recently. Da Lozzo et al. [2] proved that every $K_{3,1,1}$ -free partial 2-tree admits a proper contact representation with homothetic squares, where a contact between two squares is *proper* if they intersect in a line segment of positive length (in particular, proper contacts yield a strong contact representation). Eppstein [4] indicated that another family of graphs, defined recursively, can also be represented as a proper contact graph of squares. We remark that Klawitter et al. [7] proved that every triangle-free planar graph is the proper contact graph of (non-homothetic) axis-aligned rectangles.

Contribution. Let \mathcal{G} be a family of plane bipartite graphs defined recursively as follows. (i) \mathcal{G} contains the 4-cycle C_4 . (ii) If $G \in \mathcal{G}$ and $f = (v_1, v_2, v_3, v_4)$ is a bounded 4-face of G , then \mathcal{G} also contains the graphs G_a and G_b obtained by the following two operations: (a) insert a vertex u into f and connect it to v_1 and v_3 ; (b) insert four vertices u_1, \dots, u_4 into f , add the cycle (u_1, u_2, u_3, u_4) and the edges $u_i v_i$ for $i = 1, \dots, 4$; see Fig. 1.

Every 2-degenerate bipartite plane graph can be constructed by operation (a); and the 1-skeleton of every polycube whose dual graph is a tree [4] can be constructed by operation

37th European Workshop on Computational Geometry, St. Petersburg, Russia, April 7–9, 2021. This is an extended abstract of a presentation given at EuroCG'21. It has been made public for the benefit of the community and should be considered a preprint rather than a formally reviewed paper. Thus, this work is expected to appear eventually in more final form at a conference with formal proceedings and/or in a journal.

60:2 Axis-Aligned Square Contact Representations

■ **Figure 1** The two operations used to obtain a graph in \mathcal{G}

(b). However, the two operations jointly produce a larger class \mathcal{G} , which belongs to the class of 3-degenerate bipartite plane graphs. The following is main result of this paper.

► **Theorem 1.1.** *Every graph in \mathcal{G} admits a proper square contact representation.*

Terminology. Let $G = (V, E)$ be an edge-maximal plane bipartite graph. In a square contact representation, every vertex v_i corresponds to an axis-aligned square $s(v_i)$, and every face to an axis-aligned rectangle $g(f_i)$, which is also called the *gap* corresponding to f_i . The aspect ratio of an axis-aligned rectangle r is $\text{height}(r)/\text{width}(r)$. The side length of a square s is denoted by $\text{len}(s)$. Scaling up a square from a corner by (or to) x means to increase the width and height of the square by x (or to x) in such a way that the position of the specified corner remains fixed.

2 Maintaining a Square Contact Representation

In this section, we show how to maintain a square contact representation of a graph in \mathcal{G} under operations (a) and (b). Specifically, we show that one can insert one or four new squares corresponding to these operations in a rectangular gap of suitable size.

► **Lemma 2.1.** *For every $\alpha, \beta > 0$, there exists an axis-aligned rectangle that can be subdivided by two horizontal (resp., vertical) lines into three rectangles of aspect ratios α , 1, and β , respectively.*

Proof. Let R be a rectangle of aspect ratio $\alpha + \beta + 1$, with width x and height $(\alpha + \beta + 1)x$. Two horizontal lines at distance αx and βx from the top and bottom side of R , resp., subdivide R into rectangles of aspect ratios α , 1, and β , as required; see Fig. 2. ◀

■ **Figure 2** Constructing an outer rectangle given two inner rectangle aspect ratios.

To establish Theorem 1.1, we need a stronger version of Lemma 2.1 that allows the aspect ratios to vary within a small threshold.

► **Lemma 2.2.** *For every $\alpha, \beta, \varepsilon > 0$, there exists a $\delta > 0$ such that any rectangle of aspect ratio γ with $|\gamma - (\alpha + \beta + 1)| < \delta$ can be subdivided by two horizontal lines into rectangles of aspect ratios α' , 1, and β' such that $|\alpha' - \alpha| < \varepsilon$ and $|\beta' - \beta| < \varepsilon$.*

Proof. Let $\delta = \min\{\alpha, \beta, 1, \varepsilon\}$. Let R be a rectangle of aspect ratio γ , where $|\gamma - (\alpha + \beta + 1)| < \delta$, width x and height γx . Two horizontal lines at distance αx and $(1 + \alpha)x$, resp., from the top side of R , subdivide R into rectangles of aspect ratios α , 1, and $\beta' = \gamma - \alpha - 1$. Note that $\beta' > 0$ and $|\beta' - \beta| = |\gamma - (\alpha + \beta + 1)| < \delta \leq \varepsilon$. ◀

► **Lemma 2.3.** *For every $\alpha_1, \dots, \alpha_5 > 0$, there exists an axis-aligned rectangle R that can be subdivided into four squares and five rectangular gaps of aspect ratios $\alpha_1, \dots, \alpha_5$ such that (refer to Figs. 1b and 5)*

- *the four squares are each in contact with a side of R , and their contact graph is a 4-cycle (but the contacts along the 4-cycle are not necessarily proper);*
- *the first four gaps are each incident to the upper-left, lower-left, lower-right, and upper-right corner of R , respectively, and the fifth gap lies in the interior of R .*

The proof of Lemma 2.3 requires some preparation, and is presented later in this section. The following lemma shows that all improper contacts can be replaced by proper contacts at the expense of allowing the five aspect ratios to vary within a given threshold. Using exact values of the aspect ratios, Lemma 2.3 can only guarantee single-point contacts. Figure 3 shows an example of aspect ratios which cannot be realized with proper contacts.

■ **Figure 3** If all the gaps have aspect ratio 1, then scaling any of the squares to changing the point contacts into proper contacts would change the aspect ratios of the outer gaps.

► **Lemma 2.4.** *For every $\alpha_1, \dots, \alpha_5 > 0$ and $\varepsilon > 0$, there exists a $\lambda > 0$ and a $\delta > 0$ such that every axis-aligned rectangle R of aspect ratio λ' , $|\lambda - \lambda'| < \delta$, can be subdivided into four squares and five gaps of aspect ratios α'_i , with $|\alpha'_i - \alpha_i| < \varepsilon$, for $i = 1, \dots, 5$ such that*

- *the four squares are each in contact with a side of R , and their contact graph is a 4-cycle, and all contacts are proper;*
- *the first four gaps are each incident to the upper-left, lower-left, lower-right, and upper-right corner of R , respectively, and the fifth gap lies in the interior of R .*

For convenience, we will rename $\alpha_1, \dots, \alpha_5$ respectively based on the positions of the gaps to which they correspond as α_c (center), α_{tl} (top-left), α_{tr} (top-right), α_{br} (bottom-right), α_{bl} (bottom-left). Also, name the squares incident to the top, bottom, right, and left side of R as $s_t, s_b, s_r,$ and s_ℓ , respectively.

We will prove Lemma 2.3 by starting with an initial configuration (Fig. 4), where the aspect ratio of the center gap is already α_c , and there are improper contacts between adjacent squares of the cycle. Then we incrementally modify the configuration, while the center gap remains fixed, until all remaining gaps have the target aspect ratios $\alpha_{tl}, \alpha_{tr}, \alpha_{br},$ and

60:4 Axis-Aligned Square Contact Representations

α_{bl} . We denote the current aspect ratios of these gaps by g_{tl} , g_{tr} , g_{br} , and g_{bl} in the same fashion as α_{tl} , \dots , α_{bl} . We next define the initial configuration and four additional special configurations that play a role in intermediate steps of the incremental construction.

Initial configuration. To create the initial configuration, we start by drawing the interior gap and placing s_t, \dots, s_ℓ incident to it, with each of their side lengths equal to the side of the interior gap to which they are incident (see Fig. 4). Note that the aspect ratios of every outer gap is α_c^{-1} in this configuration.

■ **Figure 4** The initial configuration, with squares and gap aspect ratios labeled.

Pinwheel configuration. A *clockwise* pinwheel configuration is defined as follows (see Fig. 5a):

- the lower-right corner of s_t lies on the left side of s_r ,
- the lower-left corner of s_r lies on the top side of s_b ,
- the top-left corner of s_b lies on the right side of s_ℓ ,
- the top-right corner of s_ℓ lies on the bottom side of s_t .

A *counterclockwise* pinwheel can be obtained by a reflection.

Stacked configuration. We define a *vertical* stacked configuration as follows (see Fig. 5b):

- the top-right corner of s_b lies on the left side of s_r ,
- the top-left corner of s_b lies on the right side of s_ℓ ,
- the lower-right corner of s_t lies on the left side of s_r ,
- the lower-left corner of s_t lies on the right side of s_ℓ .

A *horizontal* stacked configuration can be obtained by rotation.

Arrow configuration. We define a *downward* arrow configuration as follows (see Fig. 5c):

- the top-right corner of s_b lies on the bottom side of s_r ,
- the top-left corner of s_b lies on the bottom side of s_ℓ ,
- the lower-right corner of s_t lies on the left side of s_r ,
- the lower-left corner of s_t lies on the right side of s_ℓ .

upward, *leftward*, and *rightward* arrow configurations can be obtained by rotation. We also define the *directional* square of the arrow configuration to be the one furthest in the direction after which the configuration is named (e.g., s_b for a downward arrow configuration).

Figure 5 Examples of four special configurations.

Near-pinwheel configuration. We define a *clockwise* near-pinwheel configuration as a configuration which would be a clockwise pinwheel configuration if one of the contacts between squares was changed from vertical to horizontal, or vice-versa (see Fig. 5d). This contact is called the *reversed* contact of the near-pinwheel configuration. A *counterclockwise* near-pinwheel configuration can be obtained by reflection.

Lemmas 2.5–2.9 below concern transformations of these special configurations, and are used in the proof of Lemma 2.3.

► **Lemma 2.5.** *Assume that the top-left corner of s_r is on the right side of s_t and the bottom-left corner of s_r is on the right side of s_b , and let $\alpha_{tr} > g_{tr}$ be given. There exists a $d > 0$ such that if we slide s_r upward by d and scale it up by a factor of d/g_{br} from its bottom-left corner, then no aspect ratio other than g_{tr} changes, and after the transformation we have $\alpha_{tr} = g_{tr}$, or $\alpha_{tr} > g_{tr}$ and s_r and s_b have a point contact. Similar statements hold after reflections and rotations of the configuration.*

Proof. Let the bottom-right gap have height h_1 and width w prior to the transformation. Assume that we slide s_r upward by some amount $d > 0$ and scale it up by a factor of d/g_{br} from its bottom-left corner. After the transformation, it has height $h_1 + d$ and width $w + \frac{dw}{h_1}$. As

$$\frac{h_1}{w} = \frac{h_1 + d}{w + \frac{dw}{h_1}},$$

the aspect ratio of the bottom-right gap has not changed. Let the height of top-right gap be h_2 prior to the transformation, and note that its width is also w . After the transformation, it has height $h_2 - d$ and width $w + \frac{d}{g_{br}}$. Thus, its height monotonically decreases in d , and its width monotonically increases in d , so g_{tr} monotonically decreases in d . We can choose $d = \min(d_1, d_2)$, where $d_1 \geq 0$ is the value which would reduce the contact between s_r and s_b to a single point after the transformation, and $d_2 \geq 0$ is the value which would achieve $\alpha_{tr} = g_{tr}$. ◀

► **Lemma 2.6.** *A clockwise (resp., counterclockwise) pinwheel configuration can be transformed such that g_{br} or g_{tl} (resp., g_{tr} or g_{bl}) increases to, or such that g_{tr} or g_{bl} (resp., g_{br} or g_{tl}) decreases to any amount $\gamma > 0$, while all other aspect ratios remain the same.*

60:6 Axis-Aligned Square Contact Representations

Proof. Assume w.l.o.g. that we are given a *clockwise* pinwheel configuration, and we wish to increase the aspect ratio g_{br} to $\gamma > g_{br}$. If we scale up s_b from its top-left corner by some amount d_1 , then $g_{b\ell}$ will increase. To account for this change, though, we can scale up s_ℓ as well so that $g_{b\ell}$ remains constant. Let h be the height of the central gap. Then,

$$g_{d\ell} = \frac{\text{len}(s_b) - \text{len}(s_\ell) + h}{\text{len}(s_\ell)}.$$

After increasing the length of s_b by d_1 , we must then increase the length of s_ℓ by some amount d_2 such that

$$\frac{\text{len}(s_b) - \text{len}(s_\ell) + h}{\text{len}(s_\ell)} = \frac{(\text{len}(s_b) + d_1) - (\text{len}(s_\ell) + d_2) + h}{\text{len}(s_\ell) + d_2}$$

so that $g_{b\ell}$ does not change. Solving this equation for d_2 yields

$$d_2 = d_1 \frac{\text{len}(s_\ell)}{\text{len}(s_b) + h}.$$

Because s_ℓ is not in contact with the bottom of R , $\text{len}(s_\ell) < \text{len}(s_d) + h$. Thus, $d_2 < d_1$.

Let w be the width of the central gap. Then,

$$g_{u\ell} = \frac{\text{len}(s_t)}{\text{len}(s_\ell) - \text{len}(s_t) + w}.$$

After increasing the length of s_ℓ by d_2 , to maintain $g_{t\ell}$, we must increase the length of s_t by some amount d_3 such that

$$\frac{\text{len}(s_t)}{\text{len}(s_\ell) - \text{len}(s_t) + w} = \frac{\text{len}(s_t) + d_3}{(\text{len}(s_\ell) + d_2) - (\text{len}(s_t) + d_3) + w}.$$

Solving for d_3 gives

$$d_3 = d_2 \frac{\text{len}(s_t)}{\text{len}(s_\ell) + w}.$$

Because s_t is not in contact with the left side of R , $\text{len}(s_u) < \text{len}(s_\ell) + w$. Thus, $d_3 < d_2$.

After increasing the length of s_t by d_3 , we must increase the length of s_r by some amount d_4 to maintain g_{tr} . Similarly to the argument above, we obtain $d_4 < d_3$, and thus, $d_4 < d_1$.

So, this series of transformations, preserving g_{tr} , $g_{t\ell}$, $g_{b\ell}$, and the central gap, increases the length of s_b by d_1 , which is more than the amount it increases the length of s_r , d_4 . Specifically,

$$d_4 = \frac{d_1 \text{len}(s_\ell) \text{len}(s_t) \text{len}(s_r)}{(\text{len}(s_b) + h)(\text{len}(s_\ell) + w)(\text{len}(s_t) + h)} < d_1.$$

Before the transformations, the top of s_b overlapped the bottom of s_r by some amount x . After the transformations, it overlaps by $x + d_1$, because s_b has been scaled up from its upper-left corner. The length of the common boundary of s_r and s_b has decreased by

$$d_1 \left(1 - \frac{\text{len}(s_\ell) \text{len}(s_t) \text{len}(s_r)}{(\text{len}(s_b) + h)(\text{len}(s_\ell) + w)(\text{len}(s_t) + h)} \right).$$

The width of the bottom-right gap equals $\text{len}(s_b)$ minus the length of the common boundary between s_r and s_b . Consequently, the width of the bottom-right gap decreases and its height increases linearly in d_1 . Overall, g_{br} monotonically increases in d_1 . We have constructed a series of transformations that can increase g_{br} to any $\gamma > g_{br}$ with a suitable d_1 . \blacktriangleleft

► **Lemma 2.7.** *A vertical (resp., horizontal) stacked configuration with a point contact between two of the squares can be transformed such that the aspect ratio of the outer gap between those squares increases (resp., decreases) to any amount $\gamma > 0$ while all other aspect ratios remain the same.*

Proof. Assume w.l.o.g. that we are given a vertical stacked configuration in which s_r and s_b have a point contact, and we wish to increase the aspect ratio g_{br} to $\gamma > g_{br}$.

If there is not a point contact between s_ℓ and s_t , then the following transformation can be applied. Scale up s_b from its top-left corner to increase g_{br} . To account for the resulting change in $g_{b\ell}$, scale up s_ℓ and translate it downward while maintaining $g_{t\ell}$, as described in Lemma 2.5. This transformation will either increase g_{br} to γ , or it will result in a point contact between s_ℓ and s_t .

If there is a point contact between s_ℓ and s_t , then the squares are arranged in a pinwheel configuration, and by Lemma 2.6 we can increase g_{br} to γ while maintaining all other aspect ratios. ◀

► **Lemma 2.8.** *An upward or downward (resp., rightward or leftward) arrow configuration, with a point contact between the directional square and one of its neighbors, can be transformed such that the aspect ratio of the outer gap between those squares increases (resp., decreases) to any amount $\gamma > 0$ while all other aspect ratios remain the same.*

Proof. Assume w.l.o.g. that we are given a downward arrow configuration in which s_r and s_b have a point contact, and we wish to increase the aspect ratio g_{br} to γ .

If s_b and s_ℓ do not have a point contact, translate s_b to the right while scaling it up in order to maintain $g_{b\ell}$ (as described in Lemma 2.5) while increasing g_{br} until $g_{br} = \gamma$, or until there is a point contact between s_b and s_ℓ .

If s_b and s_ℓ have a point contact, then scale up s_b from its top-left corner to increase g_{br} . To account for the corresponding change in $g_{b\ell}$, translate s_ℓ downward while scaling it up to maintain $g_{t\ell}$ (as described in Lemma 2.5) until $g_{br} = \gamma$, or until there is a point contact between s_ℓ and s_t .

If s_ℓ and s_t have a point contact, then the squares are arranged in a pinwheel configuration, and by Lemma 2.6 we can increase g_{br} to γ while maintaining all other aspect ratios. ◀

► **Lemma 2.9.** *A near-pinwheel configuration can be transformed such that the aspect ratio of the outer gap in the direction of the near-pinwheel (clockwise or counterclockwise) from the reversed contact increases to any amount $\gamma > 0$ if its left side is the side of a square, or decreases to any amount $\gamma > 0$ if its top side is the side of a square, while all other aspect ratios remain the same.*

Proof. Assume w.l.o.g. that we are given a clockwise near-pinwheel with an reversed top-right contact, and we wish to increase the aspect ratio g_{br} to γ .

Perform the following transformation until s_t and s_r have a point-contact or until g_{br} has been increased to γ . Scale up s_b from its top-left corner to increase g_{br} by some portion of the difference between g_{br} and γ . To account for the corresponding change in $g_{b\ell}$, scale up s_ℓ from its top-right corner. To account for the corresponding change in $g_{t\ell}$, scale up s_t and translate it to the left while maintaining g_{tr} as described in Lemma 2.5.

Once s_t and s_r have a point contact, then the configuration is a pinwheel, and by Lemma 2.6 we can increase g_{br} to γ . ◀

Proof of Lemma 2.3. Let α_c , $\alpha_{t\ell}$, α_{tr} , α_{br} , and $\alpha_{b\ell}$ be given. Start with the initial configuration (cf. Fig. 4). If the target aspect ratios of all four outer gaps are α_c^{-1} , then R can be

drawn now with aspect ratio α_c . Otherwise, one or more of the outer gaps must have their aspect ratios changed, either by increasing or decreasing them.

Rotate and reflect the initial configuration if necessary such that at least one gap needs to be made wider (i.e., $\alpha < g$), and the ratio g/α is maximal for the upper-right gap. In order to change g_{tr} to α_{tr} , we can scale up s_r from its lower-left corner until $g_{tr} = \alpha_{tr}$. This scaling will not affect g_{tl} or g_{bl} , but it will decrease g_{br} . After the scaling, the bottom-right gap will either have the target aspect ratio already, need to be wider yet, or need to be narrower. From now on, we will not mention the case where a gap has reached its target aspect ratio already, because it just means that the next step can be skipped.

If the bottom-right gap needs to be wider yet, then by Lemma 2.5 we can scale up s_r and translate it downward until $g_{br} = \alpha_{br}$ without changing g_{tr} . As g/α is assumed to be maximal for the upper-right gap, if this transformation results in a point contact between s_r and s_t , it also achieves $g_{br} = \alpha_{br}$ (because otherwise, $g_{br} > g_{tr} = \alpha_{tr}$).

If the bottom-right gap needs to be narrower, then we can scale up s_b from its top-left corner until $g_{br} = \alpha_{br}$. This will increase g_{bl} .

Now, we can assume that $g_{tr} = \alpha_{tr}$ and $g_{br} = \alpha_{br}$. We distinguish between four cases:

1. s_b has not been scaled, and either $\alpha_{bl} \leq \alpha_c^{-1}$ or $\alpha_{tl} \leq \alpha_c^{-1}$.
2. s_b has been scaled up from its top-left corner, $\alpha_{bl} \leq \alpha_{tl}$, and $\alpha_{bl} \leq \alpha_c^{-1}$.
3. s_b has been scaled up from its top-left corner, $\alpha_{tl} \leq \alpha_{bl}$, and $\alpha_{tl} \leq \alpha_c^{-1}$.
4. $\alpha_{tl} > \alpha_c^{-1}$ and $\alpha_{bl} > \alpha_c^{-1}$.

Case 1: s_b has not been scaled, and either $\alpha_{bl} \leq \alpha_c^{-1}$ or $\alpha_{tl} \leq \alpha_c^{-1}$. Reflect the configuration such that $\alpha_{bl} \leq \alpha_{tl}$. Scale up s_ℓ from its top-right corner until $g_{bl} = \alpha_{bl}$ (making the top-left gap wider). Then, if g_{tl} needs to decrease further, by Lemma 2.5 we can scale up and translate s_ℓ until $g_{tl} = \alpha_{tl}$ to achieve all target aspect ratios (once again, this transformation guarantees $g_{tl} = \alpha_{tl}$ even if it results in a point contact, because we assume $\alpha_{bl} \leq \alpha_{tl}$). Otherwise, the top-left gap needs to be narrower. Since the configuration is a horizontal stacked configuration, and by Lemma 2.7 we can apply a series of transformations to achieve all target aspect ratios.

Case 2: s_b has been scaled up from its top-left corner, $\alpha_{bl} \leq \alpha_{tl}$, and $\alpha_{bl} \leq \alpha_c^{-1}$. Scale up s_ℓ from its top-right corner until $g_{bl} = \alpha_{bl}$. This transformation decreases g_{tl} . Then, if g_{tl} needs to decrease further, by Lemma 2.5 we can scale up and translate s_ℓ until $g_{tl} = \alpha_{tl}$ to achieve all target aspect ratios (once again guaranteed because $\alpha_{bl} \leq \alpha_{tl}$). Otherwise the top-left gap needs to be narrower. Since the squares are arranged in a pinwheel configuration, Lemma 2.6 completes the proof.

Case 3: s_b has been scaled up from its top-left corner, $\alpha_{tl} \leq \alpha_{bl}$, and $\alpha_{tl} \leq \alpha_c^{-1}$. Scale up s_ℓ from its bottom-right corner until $g_{tl} = \alpha_{tl}$. This transformation decreases g_{bl} . Then, if g_{bl} needs to decrease further, by Lemma 2.5 we can scale up s_ℓ and translate it downward, maintaining all other aspect ratios, until $g_{bl} = \alpha_{bl}$ or s_ℓ and s_t have a point contact. If s_ℓ and s_t have a point contact, then the squares are arranged in a pinwheel configuration, and Lemma 2.6 completes the proof. Otherwise, g_{bl} needs to increase. Since the squares form a downward arrow configuration in this case, with a point contact between s_b and s_ℓ , Lemma 2.8 completes the proof.

Case 4: $\alpha_{tl} > \alpha_c^{-1}$ and $\alpha_{bl} > \alpha_c^{-1}$. We distinguish between two subcases.

Case 4.1: If the top-right corner of s_b lies on the bottom side of s_r , then by Lemma 2.5, we can translate s_b to the left while scaling it up until $g_{bl} = \alpha_{bl}$ or s_b and s_r have a point-contact, while maintaining all other aspect ratios. If $g_{bl} = \alpha_{bl}$, then the configuration is a near-pinwheel and Lemma 2.9 completes the proof. Otherwise, if s_b and s_r have a point-contact, then the conditions of Case 4.2 below are satisfied and we proceed as follows.

Case 4.2: If the top-right corner of s_b lies on the left side of s_r , then scale up s_t from its bottom-right corner until $g_{t\ell} = \alpha_{t\ell}$ and scale up s_b from its top-right corner until $g_{b\ell} = \alpha_{b\ell}$. Now, g_{tr} and g_{br} (which were previously at their target values) both need to decrease. Reflect the configuration if necessary so that the width of the bottom-right gap needs to be increased by a larger amount than the top-right gap. Scale up s_r from its lower-left corner until $g_{tr} = \alpha_{tr}$. Then, because the width of the lower-right gap needed to be increased by a larger amount of the two, it still needs to be wider. The configuration is a rightward arrow, so by Lemma 2.8, we can decrease g_{br} arbitrarily while maintaining the other aspect ratios. ◀

It is easy to extend Lemma 2.3 to Lemma 2.4 by changing any improper contacts among adjacent squares in the 4-cycle into proper contacts.

Proof of Lemma 2.4. Let $\alpha_c, \alpha_{t\ell}, \alpha_{tr}, \alpha_{br}, \alpha_{b\ell}$, and $\varepsilon > 0$ be given. By Lemma 2.3, there is a rectangle R with some aspect ratio λ that can be subdivided into five gaps and four squares s_b, s_t, s_ℓ , and s_r whose contact graph is a cycle.

Case 1. Assume first that all four contacts in the cycle are proper. Then the Lemma 2.4 holds with the same λ . In each case, there exists a square that can be scaled up or down while maintaining proper contacts in the cycle. When scaling a single square, the aspect ratio of the bounding box R and some of the gaps change continuously. By continuity, there exists a $\delta > 0$ such that if the aspect ratios of the bounding box is λ' with $|\lambda' - \lambda| < \delta$, then all five gaps are at most ε from their target values.

Case 2. Next assume that one or more contacts in the cycle are improper, i.e., two squares intersect in a common corner. For each improper contact, we can successively scale up one of the two squares to establish a proper contact. We scale up each square by a sufficiently small amount such that the aspect ratios of the five gaps change by less than $\varepsilon/2$. Let λ' be the aspect ratio of the new bounding box. We can show, similarly to Case 1, that Lemma 2.4 holds with $\lambda = \lambda'$ and some $\delta > 0$ by continuity. ◀

3 Proof of Theorem 1.1

Finally, we have all the tools needed to prove Theorem 1.1. We prove Theorem 1.1, by induction, in the following stronger form.

► **Theorem 1.** *Let $G \in \mathcal{G}$ be a graph with n vertices and $n - 3$ bounded faces f_1, \dots, f_{n-3} . For all $\alpha_1, \dots, \alpha_{n-3} > 0$ and for all $\varepsilon > 0$, the graph G admits a proper square contact representation such that the aspect ratio of the gap corresponding to f_i is α'_i , with $|\alpha_i - \alpha'_i| < \varepsilon$, for all $i = 1, \dots, n - 3$.*

Proof. We proceed by induction on n , the number of vertices of G .

Basis step. Assume that $G = C_4$ is a 4-cycle with a single bounded face f_1 . It is clear that for any $\alpha_1 > 0$, C_4 has a proper square contact representation as a pinwheel configuration in which the gap corresponding to f_1 has aspect ratio α_1 .

Induction step. Let $G \in \mathcal{G}$ be a graph with $n \geq 5$ vertices, and assume that the claim holds for all graphs in \mathcal{G} with fewer than n vertices. Then G was constructed from a graph $G_0 \in \mathcal{G}$ with operation (a) or (b) that inserts one or four vertices into a 4-face $f_0 = (v_1, \dots, v_4)$. We may assume w.l.o.g. that v_1 and v_3 correspond to squares that lie on the vertical sides of the gap corresponding to f in any square contact representation. We distinguish between two cases.

Case (a). Assume that G was obtained from G_0 by inserting a vertex u into f_0 and connecting it to v_1 and v_3 . This operation subdivides f_0 into f_1 and f_2 ; and all other faces

are present in both G and G_0 . Let $\alpha_0 = \alpha_1 + \alpha_2 + 1$. By Lemma 2.2, there exists a $\delta > 0$ such that any rectangle of aspect ratio α'_0 with $|\alpha'_0 - \alpha_0| < \delta$ can be subdivided by two horizontal lines into rectangles of aspect ratios α'_1 , 1, and α'_2 such that $|\alpha'_1 - \alpha_1| < \varepsilon$ and $|\alpha'_2 - \alpha_2| < \varepsilon$. The induction hypothesis with $\varepsilon_0 = \min\{\varepsilon, \delta\}$, implies that G_0 admits a proper square contact representation such that the gap corresponding to f_0 has aspect ratio α'_0 , where $|\alpha'_0 - \alpha_0| < \delta$, and all other gaps are at most ε off from their target aspect ratios. Lemma 2.2 now yields a subdivision of the gap corresponding to f_0 into a square in proper contact with the squares corresponding to v_1 and v_3 , and two gaps of aspect ratios α'_1 and α'_2 with $|\alpha'_1 - \alpha_1| < \varepsilon$ and $|\alpha'_2 - \alpha_2| < \varepsilon$.

Case (b). Assume that G was obtained from G_0 by inserting a 4-cycle (u_1, u_2, u_3, u_4) into f_0 and adding the edges $u_i v_i$ for $i = 1, \dots, 4$. This operation subdivides f_0 into five faces f_1, \dots, f_5 of G ; and all other faces are present in both G and G_0 .

By Lemma 2.4, there exists a $\alpha_0 > 0$ and a $\delta > 0$ such that any rectangle of aspect ratio α'_0 with $|\alpha'_0 - \alpha_0| < \delta$ can be subdivided into four squares and five gaps corresponding to f_1, \dots, f_5 , of aspect ratios $\alpha'_1, \dots, \alpha'_5$, respectively, such that $|\alpha'_i - \alpha_i| < \varepsilon$ for $i = 1, \dots, 5$. The induction hypothesis with $\varepsilon_0 = \min\{\varepsilon, \delta\}$ implies that G_0 admits a proper square contact representation such that the gap corresponding to f_0 has aspect ratio α'_0 , where $|\alpha'_0 - \alpha_0| < \delta$, and all other gaps are at most ε off from their target aspect ratios. Lemma 2.4 now yields a subdivision of the gap corresponding to f_0 into four squares, each in contact with a unique one of v_1, \dots, v_4 and cyclically in contact with one another, and five gaps of aspect ratios $\alpha_1, \dots, \alpha_5$ with $|\alpha'_i - \alpha_i| < \varepsilon$ for $i = 1, \dots, 5$. ◀
