Abstract

A finite quantum system S is coupled to a thermal, bosonic reservoir R . Initial SR states are possibly correlated, obtained by applying a quantum operation taken from a large class, to the uncoupled equilibrium state. We show that the full system-reservoir dynamics is given by a markovian term plus a correlation term, plus a remainder small in the coupling constant λ uniformly for all times $t \geq 0$. The correlation term decays polynomially in time, at a speed independent of λ . After this, the markovian term becomes dominant, where the system evolves according to the completely positive, trace-preserving semigroup generated by the Davies generator, while the reservoir stays stationary in equilibrium. This shows that (a) after initial SR correlations decay, the SR dynamics enters a regime where both the Born and Markov approximations are valid, and (b) the reduced system dynamics is markovian for all times, even for correlated SR initial states.

1 Introduction

Open quantum systems are most commonly described by a tensor product Hilbert space $\mathcal{H}_S \otimes \mathcal{H}_R$ (system and reservoir) and an interacting Hamiltonian

$$H_\lambda = H_S \otimes \mathbb{1}_R + \mathbb{1}_S \otimes H_R + \lambda V$$

where H_S and H_R are the system and reservoir Hamiltonians, λ is a coupling constant, which we consider to be small in a suitable sense, and V is an interaction operator. In the literature, coupled SR systems are sometimes studied when the parts S and R are of comparable size. In the current work, we focus on the situation $\dim \mathcal{H}_S = N < \infty$ and $\dim \mathcal{H}_R = \infty$, and a reservoir Hamiltonian H_R with continuous spectrum. In this sense,

the reservoir R is much larger than the system S in our considerations. The dynamics of an initial state (density matrix) ρ_{SR} is given by the Liouville–von Neumann (or Schrödinger) equation

$$\rho_{\text{SR}}^t = e^{-itH_\lambda} \rho_{\text{SR}} e^{itH_\lambda}$$

and the reduced system density matrix is obtained by taking the partial trace over the reservoir,

$$\rho_{\text{S}}^t = \text{tr}_{\text{R}} \{ e^{-itH_\lambda} \rho_{\text{SR}} e^{itH_\lambda} \}.$$

Uncorrelated initial states. In textbooks and research articles, most often the assumption is made that the initial state is uncorrelated, that is, of the product form $\rho_{\text{SR}} = \rho_{\text{S}} \otimes \omega_{\text{R}}$. Then one can define the *dynamical map* acting on system density matrices,

$$\mathcal{V}_t : \rho_{\text{S}} \mapsto \rho_{\text{S}}^t.$$

\mathcal{V}_t is the flow or propagator of the system dynamics and of course, it depends on the initial reservoir state ω_{R} . For example, if $\omega_{\text{R}} = \omega_{\text{R},\beta}$ is the reservoir equilibrium state at a given temperature $T = 1/\beta$, then of course the system dynamics, and hence \mathcal{V}_t , will depend on T . Due to the interaction of S and R, mediated by the operator V , the state ρ_{SR}^t is generically correlated (not of product form) for $t > 0$. This results in the violation of the group property,

$$\mathcal{V}_{t+t'} \neq \mathcal{V}_t \mathcal{V}_{t'}.$$

If the reservoir is not much influenced by the coupling to the system and initially in a stationary state under its own dynamics, then one might intuitively expect that $\rho_{\text{SR}}^t \approx \rho_{\text{S}}^t \otimes \omega_{\text{R}}$. This is called the *Born approximation*. If on top, one assumes that the reservoir loses its memory quickly, then one may expect the Markovian property to hold approximately,

$$\mathcal{V}_{t+t'} \approx \mathcal{V}_t \mathcal{V}_{t'} \quad \text{or} \quad \mathcal{V}_t \approx e^{t\mathcal{L}},$$

where the generator $\mathcal{L} = \mathcal{L}(\lambda)$ depends implicitly on the initial reservoir state ω_{R} and $\mathcal{L}(0) = -i[H_{\text{S}}, \cdot]$ generates the uncoupled system dynamics. It has been known since the seventies (see the founding papers [10, 11, 41]) that in some generality, the Markovian approximation is valid in the weak coupling, or van Hove limit. This means that

$$\lim_{\lambda \rightarrow 0} \sup_{0 \leq \lambda^2 t < a} \|\mathcal{V}_t - e^{t\mathcal{L}_{\text{S}}(\lambda)}\| = 0 \quad \text{for any } a > 0, \quad (1.1)$$

where the superoperator

$$\mathcal{L}_{\text{S}}(\lambda) = \mathcal{L}_{\text{S}} + \lambda^2 \mathcal{K}, \quad \mathcal{L}_{\text{S}} = -i[H_{\text{S}}, \cdot] \quad (1.2)$$

is called the *Davies generator*. It generates the CPTP semigroup $e^{t\mathcal{L}_{\text{S}}(\lambda)}$ [9, 16, 29] (completely positive trace preserving). The operator \mathcal{K} , a sum of a Hamiltonian plus a dissipative term, describes the influence of the bath to second order in perturbation [1, 7, 36]. From (1.1) we have an alternative expression for \mathcal{K} ,

$$\lim_{\lambda \rightarrow 0} \mathcal{V}_{\tau/\lambda^2} \circ e^{-\tau\mathcal{L}_{\text{S}}/\lambda^2} = e^{\tau\mathcal{K}}, \quad \forall \tau \geq 0. \quad (1.3)$$

The shortcoming of (1.1) is that it guarantees the accuracy of the Markovian approximation only for bounded values of $\lambda^2 t$. Said differently, (1.1) shows that the Markovian approximation is guaranteed to hold for $t \rightarrow \infty$ only if at the same time, one takes $\lambda \rightarrow 0$ in a way such that $\lambda^2 t$ stays finite. This deficiency of (1.1) was recently overcome in [24, 29, 30, 31], where it is proven, under suitable assumptions, that

$$\sup_{t \geq 0} \|\mathcal{V}_t - e^{t(\mathcal{L}_S + \lambda^2 \mathcal{K})}\| \leq C|\lambda|^{1/4}, \quad (1.4)$$

provided $|\lambda| \leq \lambda_0$ for some $\lambda_0 > 0$. Due to (1.4), the Markovian approximation is now guaranteed to be accurate to $O(|\lambda|^{1/4})$ *uniformly in time* $t \geq 0$, for all small, fixed λ . The error bound $|\lambda|^{1/4}$ is derived for the least amount of regularity of the interaction operator necessary for the proof – under a more stringent (analyticity) assumption, it can be improved to $|\lambda|^2$ (see [24]). In the recent work [8] it is shown that the validity of the Markovian approximation for arbitrarily large *finite* times does not imply the validity for all times. There the authors consider the zero temperature, dissipative Janes-Cummings model in the singular coupling limit. Given any time $t_0 > 0$, they explicitly design SR interactions (form factors $g(k)$) in such a way that the system (qubit) dynamics is *exactly Markovian* up to t_0 , but for $t > t_0$ the dynamics becomes non-Markovian. Even though this example uses the singular coupling limit ($g(k)$ not square integrable), the result indicates that the passage from (1.1) to (1.4) is not a mere technicality.

Correlated initial states. The assumption of initially uncorrelated SR states may not be physically realistic. It requires to bring together, at time $t = 0$, a system and a reservoir which at earlier times did not interact (or which by some measurement or dynamical fluke would happen to be in a product state). One should then ask about the dynamics of correlated initial states, that is, ones which are not of product form, see [17, 33, 37, 38, 39] and the references in there. For a given correlated initial state ρ_{SR} , the reduced system dynamics ρ_S^t is still well defined as above. However, one cannot define the dynamical map V_t any longer, as different ρ_{SR} can have the same marginal ρ_S (say, due to different SR correlations). Those different initial SR states evolve to states at time $t > 0$ which have different system marginals, which means that the initial marginal cannot be mapped consistently to the marginal at a later time. In our investigation, we *start* with a correlated initial state ρ_{SR} and describe its well defined reduced system dynamics $t \mapsto \rho_S^t$. The opposite approach is also studied in the literature, starting with an initial system state ρ_S , then mapping it to a SR state by an *assignment map* $\rho_S \mapsto \rho_{\text{SR}}$. The initial correlation is then encoded in the assignment map, whose structure can be analyzed [2, 14, 15, 35, 40].

Outline of main results. We consider a class of open systems for which the Markov approximation (1.4) for uncorrelated initial states, $\rho_S \otimes \omega_{\text{R},\beta}$, was proven in [31]. Here, $\omega_{\text{R},\beta}$ is the thermal equilibrium state of the reservoir at temperature $T = 1/\beta > 0$.¹ Our

¹This is not a necessary feature for our approach to work, one may also take non-equilibrium stationary states, as we will explain elsewhere.

main result, Theorem 2.2, gives an expansion of the full SR dynamics with correlated initial states ρ_{SR} . It can be expressed as follows – see after Theorem 2.2 for more in-depth and precise statements. We show that

$$\rho_{\text{SR}}^t = (e^{t\mathcal{L}_S(\lambda)} \text{tr}_{\text{R}}\{\rho_{\text{SR}}\}) \otimes \omega_{\text{R},\beta} + \chi(t, \lambda) + O(|\lambda|^{1/4}), \quad (1.5)$$

where $\mathcal{L}_S(\lambda)$ is the Davies generator (1.2) and $\chi(t, \lambda)$ describes the dynamics of the SR correlations. The relation (1.5) is valid for all $|\lambda| \leq \lambda_0$, some $\lambda_0 > 0$, with a remainder independent of time $t \geq 0$. It is to be interpreted in a weak sense, that is, when applied to operators from a SR observable algebra \mathcal{O} , (2.19). The initial states are taken from a class of states obtained by applying (very general) quantum operations on the uncoupled SR equilibrium state $\rho_{\text{S},\beta} \otimes \omega_{\text{R},\beta}$ (see (2.23)). We show the following results:

- For $\rho_{\text{SR}} = \rho_{\text{S}} \otimes \omega_{\text{R},\beta}$ (with ρ_{S} any system density matrix), we have $\chi(t, \lambda) = 0$. This shows that *the Born approximation holds* and recovers the Markovianity result (1.4).
- $\chi(t, \lambda)$ also vanishes when applied to observables $O_{\text{S}} \otimes \mathbb{1}_{\text{R}}$ of S alone, for any initial ρ_{SR} . This means that the initial correlations only influence the dynamics of observables which involve the reservoir. In particular, this shows that *the Markovian approximation is also valid for correlated initial states*, and for all times $t \geq 0$.
- In the presence of initial correlations, the Born approximation ($\rho_{\text{SR}}^t \approx \rho_{\text{S}}^t \otimes \omega_{\text{R},\beta}$) is obviously not correct for small times. However, we show that $\chi(t, \lambda) \sim 1/(1+t^3)$, which implies that initial correlations decay, and after that, the SR state enters a regime where the Born approximation is valid, even for correlated initial states. This is a statement about the *full* SR state dynamics. In contrast, as explained above, the *reduced* system state is approximated by the Markovian semigroup for all, even small, times.

2 Model and main results

2.1 Model

We consider an N -level system interacting with a reservoir modeled by a continuous family (field) of quantum harmonic oscillators, and we will largely follow the notation of [30]. The system and reservoir Hamiltonians are given by

$$H_{\text{S}} = \sum_{j=1}^N E_j |\phi_j\rangle\langle\phi_j| \quad \text{and} \quad H_{\text{R}} = \int_{\mathbb{R}^3} \omega(k) a^*(k) a(k) d^3k \quad (2.1)$$

respectively, acting on the Hilbert space

$$\mathcal{H}_{\text{SR}} = \mathbb{C}^N \otimes \mathcal{F}. \quad (2.2)$$

We often simply write H_S for $H_S \otimes \mathbb{1}$ and so on. The E_j are the system energies and $\omega(k) \geq 0$ is the frequency of the mode k ($\hbar = 1$), which we take for definiteness to follow the dispersion *e.g.* of photons,

$$\omega(k) = |k|. \quad (2.3)$$

The energy eigenstates ϕ_j form an orthonormal basis of the system Hilbert space \mathbb{C}^N and the (momentum representation) creation and annihilation operators satisfy the canonical commutation relations $[a(k), a(\ell)] = 0 = [a^*(k), a^*(\ell)]$ and $[a(k), a^*(\ell)] = \delta(k - \ell)$ (Dirac delta $k, \ell \in \mathbb{R}^3$). The reservoir Hilbert space is the (Bosonic) Fock space

$$\mathcal{F} = \bigoplus_{n \geq 0} L^2_{\text{sym}}(\mathbb{R}^{3n}, d^{3n}k), \quad (2.4)$$

built over the single-particle space $L^2(\mathbb{R}^3, d^3k)$, the square integrable scalar valued functions. The full, interacting Hamiltonian is given by

$$H_\lambda = H_S + H_R + \lambda G \otimes \varphi(g), \quad (2.5)$$

where $\lambda \in \mathbb{R}$ is the coupling constant, $G^* = G$ is any hermitian system matrix and

$$\varphi(g) = \frac{1}{\sqrt{2}}[a^*(g) + a(g)], \quad a^*(g) = \int_{\mathbb{R}^3} g(k)a^*(k)d^3k, \quad a(g) = [a^*(g)]^* \quad (2.6)$$

are the field, creation and annihilation operators, respectively. The function $g(k) \in L^2(\mathbb{R}^3, d^3k)$ in the interaction (2.5) is called the form factor – generally, when we consider $a^*(f)$, $a(f)$ we also call f test functions.

The above is a paradigmatic model for open quantum systems. For $N = 2$ it is called the spin-Boson model. As presented here, it is the continuous mode (or thermodynamic, infinite-volume) limit of a system described by a discrete set of oscillators with Hamiltonian

$$H'_R = \sum_k \omega_k a_k^* a_k \quad (2.7)$$

and field operator in the interaction given by $\varphi'(g) = \sum_k g_k a_k^* + \text{h.c.}$ In the theoretical physics literature, the limit of continuous values of k is often performed at the end of calculations of various expressions, such as transition probabilities. In this limit of a continuum of reservoir modes one can analyze irreversible dynamical effects (like time decay). In the present work, we start off directly with the reservoir having a continuum of frequencies, (2.1).

In contrast to the common assumption of initially uncorrelated system-reservoir states of the factorized form $\rho_S \otimes \rho_R$, we are concerned here with initial states obtained by correlating the system with the reservoir. The system Gibbs equilibrium density matrix at temperature $T = 1/\beta$,

$$\rho_{S,\beta} = Z_{S,\beta}^{-1} e^{-\beta H_S}, \quad (2.8)$$

$Z_{S,\beta} = \text{tr}_S e^{-\beta H_S}$, is a well defined density matrix. One can represent $\rho_{S,\beta}$ as a vector state $|\Omega_S\rangle\langle\Omega_S|$ in the enlarged Hilbert space $\mathbb{C}^N \otimes \mathbb{C}^N$ as follows. For any $O_S \in \mathcal{B}(\mathbb{C}^N)$ (bounded operators),

$$\text{tr}_{\mathbb{C}^N}(\rho_{S,\beta} A) = \langle\Omega_S, \pi_S(O_S)\Omega_S\rangle_{\mathbb{C}^N \otimes \mathbb{C}^N}, \quad (2.9)$$

where $\pi(O_S) = O_S \otimes \mathbb{1}_{\mathbb{C}^N}$ and $\Omega_S \in \mathbb{C}^N \otimes \mathbb{C}^N$ is a normalized vector (explicitly given in (3.7)). This purification representation is sometimes very helpful. For the continuous mode reservoir the situation is a bit more cumbersome. Its equilibrium state cannot be expressed as a density matrix acting on \mathcal{F} , because $e^{-\beta H_R}$ is not trace class (H_R has continuous spectrum). Rather, the reservoir equilibrium state is constructed as the limit of equilibrium states $\propto e^{-\beta H'_R}$, where H'_R , (2.7) is trace class. The limit state is expressed as a positive, linear functional $\omega_{R,\beta}$ on reservoir operators as follows. Let

$$L_0^2 = L^2(\mathbb{R}^3, d^3k) \cap L^2(\mathbb{R}^3, |k|^{-1} d^3k). \quad (2.10)$$

For $f, g \in L_0^2$ we have [6, 32]

$$\omega_{R,\beta}(a(f)) = \omega_{R,\beta}(a^*(f)) = 0, \quad \omega_{R,\beta}(a^*(f)a(g)) = \langle g, (e^{\beta|k|} - 1)^{-1} f \rangle, \quad (2.11)$$

where $\langle f, g \rangle = \int_{\mathbb{R}^3} \bar{f}(k)g(k)d^3k$. Expectations of arbitrary polynomials in creation and annihilation operators are calculated using Wick's theorem [6] and the expectation of a unitary Weyl operator

$$W(f) = e^{i\varphi(f)}, \quad f \in L_0^2, \quad (2.12)$$

is

$$\omega_{R,\beta}(W(f)) = e^{-\frac{1}{4}\langle f, \coth(\beta|k|/2)f \rangle}. \quad (2.13)$$

It is very convenient to use a purification of $\omega_{R,\beta}$, that is, to represent this state as a *vector state* in a new Hilbert space \mathcal{H}_R (different from \mathcal{F} , (2.4)), in which the operators $a^\sharp(f)$ (where $a^\sharp = a$ or $a^\sharp = a^*$) and $W(f)$ are represented by operators

$$a^\sharp(f) \mapsto \pi_R(a^\sharp(f)), \quad W(f) \mapsto \pi_R(W(f)). \quad (2.14)$$

Here, π_R is a linear map, sending operators on \mathcal{F} to operators on \mathcal{H}_R and satisfying $\pi_R(X^*) = \pi_R(X)^*$ and $\pi_R(XY) = \pi_R(X)\pi_R(Y)$, *i.e.*, π_R is a $*$ algebra representation. Let O_R be an arbitrary finite sum of products of creation and annihilation operators and Weyl operators acting on \mathcal{F} . Then we have

$$\omega_{R,\beta}(O_R) = \langle\Omega_R, \pi_R(O_R)\Omega_R\rangle_{\mathcal{H}_R} \quad (2.15)$$

for a normalized vector $\Omega_R \in \mathcal{H}_R$. In this sense, $\omega_{R,\beta}$ is represented by the vector Ω_R . The explicit form of \mathcal{H}_R , π_R and Ω_R is well known (Araki-Woods representation [4]), we give them in Section 3.1.

The purification of the uncoupled joint equilibrium state $\rho_{S,\beta} \otimes \omega_{R,\beta}$ is obtained by taking the tensor product: For operators O which are arbitrary finite sums of products

of bounded operators on \mathbb{C}^N , creation and annihilation operators and Weyl operators (with test functions in L_0^2), we have

$$\rho_{S,\beta} \otimes \omega_{R,\beta}(O) = \langle \Omega_{SR,\beta,0}, \pi(O)\Omega_{SR,\beta,0} \rangle_{\mathcal{H}_{\text{GNS}}}, \quad (2.16)$$

where (GNS stands for *Gelfand-Naimark-Segal*)

$$\mathcal{H}_{\text{GNS}} = \mathbb{C}^N \otimes \mathbb{C}^N \otimes \mathcal{H}_R, \quad \pi = \pi_S \otimes \pi_R \quad \text{and} \quad \Omega_{SR,\beta,0} = \Omega_S \otimes \Omega_R. \quad (2.17)$$

2.2 Observable algebra \mathcal{O} and correlation algebra \mathfrak{C}

We introduce two spaces of single reservoir particle states ('test functions').

- (a) The space of observable test functions is $L_{\text{obs}}^2 \subset L^2(\mathbb{R}^3, d^3k)$, consisting of all functions of the form

$$f(k) = \frac{|k|^p}{1 + |k|^p} (1 + |k|^2) h(k), \quad (2.18)$$

where $p = -\frac{1}{2}, \frac{1}{2}$ or $p > 1$, and $h(k)$ is a function s.t. for $j = 0, 1, 2, 3$, the derivatives $\frac{\partial^j}{\partial |k|^j} h(k)$ exist and are bounded for $|k| > 0$, and satisfy $\lim_{|k| \rightarrow 0} \frac{\partial^j}{\partial |k|^j} h(k) \neq 0$.

- (b) The test function space for correlation operators L_{cor}^2 consists of all functions $f \in L_{\text{obs}}^2$ such that $e^{\beta|k|} f \in L^2(\mathbb{R}^3, d^3k)$, where β is the inverse temperature.

In short, the functions in L_{obs}^2 are three times differentiable and have the infrared behaviour $f(k) \sim |k|^p$ (for $|k|$ small) and ultraviolet behaviour $f(k) \sim |k|^{-q}$ (for $|k|$ large), for some $q > 3$. Functions in L_{cor}^2 have to decay exponentially in the ultraviolet region. The **observable algebra** is defined as

$$\mathcal{O} = \mathcal{B}(\mathbb{C}^N) \otimes \mathfrak{W}_0(L_{\text{obs}}^2) \quad (2.19)$$

where $\mathcal{B}(\mathbb{C}^N)$ is the algebra of linear operators on \mathbb{C}^N and where $\mathfrak{W}_0(L_{\text{obs}}^2)$ is the algebra consisting of all finite sums and products of Weyl operators $W(f)$ with $f \in L_{\text{obs}}^2$.² Next, introduce the polynomial algebra

$$\mathcal{P} = \text{Span}\{B \otimes a^\sharp(f_1) \cdots a^\sharp(f_n) : B \in \mathcal{B}(\mathbb{C}^N), n \in \mathbb{N}, f_j \in L_{\text{cor}}^2\}, \quad (2.20)$$

where Span is the linear span (finitely many complex linear combinations) and a^\sharp denotes either of a or a^* , individually in each factor in the product in (2.20). The set \mathcal{P} consists of all polynomials of creation and annihilation operators with coefficients in $\mathcal{B}(\mathbb{C}^N)$. Furthermore, define the set of operators

$$\mathcal{X} = \text{Span}\{e^{i \sum_{r=1}^R B_r \otimes a^\sharp(f_r)} : R \in \mathbb{N}, B_r \in \mathcal{B}(\mathbb{C}^N), f_r \in L_{\text{cor}}^2\}. \quad (2.21)$$

²It is not hard to extend our results to the case when \mathcal{O} is the norm closure of (2.19) (i.e., for $\mathfrak{W}_0(L_{\text{obs}}^2)$ replaced by the C^* -algebra $\mathfrak{W}(L_{\text{obs}}^2)$), see the discussion after Theorem 2.2.

The **correlation algebra** is defined as

$$\mathfrak{C} = \text{Span}\{K_1 \cdots K_n : n \in \mathbb{N}, K_j \in \mathcal{X} \cup \mathcal{P}\}. \quad (2.22)$$

While the observable algebra \mathcal{O} consist of *bounded* operators on \mathcal{H}_{SR} , the elements K_j in (2.22) are generally *unbounded* operators. One must be careful about the definition of the product of such operators, showing up in (2.22). See Proposition 2.1.

2.3 Initial states

We use the notation $\rho(O) = \text{tr}(\rho O)$ for a density matrix ρ and an observable O . The initial states are of the form

$$\rho_{\text{SR}} = \sum_{\alpha=1}^{\nu} \rho_{\text{S},\beta} \otimes \omega_{\text{R},\beta}(K_{\alpha}^* \cdot K_{\alpha}), \quad (2.23)$$

where $\nu \in \mathbb{N}$ and the *Kraus operators* K_{α} belong to an algebra of (possibly unbounded) operators \mathfrak{C} acting on \mathcal{H}_{SR} . One may extend the results to $\nu = \infty$, see the remarks after Theorem 2.2. The definition (2.23) gives ρ_{SR} as a state in the algebraic sense, as a functional on observables of SR observables $O \in \mathcal{O}$,

$$\rho_{\text{SR}}(O) = \sum_{\alpha=1}^{\nu} \rho_{\text{S},\beta} \otimes \omega_{\text{R},\beta}(K_{\alpha}^* O K_{\alpha}). \quad (2.24)$$

The Kraus operators satisfy

$$\sum_{\alpha=1}^{\nu} K_{\alpha}^* K_{\alpha} = \mathbb{1}, \quad (2.25)$$

so that $\rho_{\text{SR}}(\mathbb{1}) = 1$ is properly normalized. The initial reduced system state is defined by the relation

$$\rho_{\text{S}}(O_{\text{S}}) = \rho_{\text{SR}}(O_{\text{S}} \otimes \mathbb{1}_{\text{R}}), \quad \forall O_{\text{S}} \in \mathcal{B}(\mathbb{C}^N). \quad (2.26)$$

The state at time t is given by

$$\rho_{\text{SR}}(e^{itH_{\lambda}} \cdot e^{-itH_{\lambda}}) = \sum_{\alpha=1}^{\nu} \rho_{\text{S},\beta} \otimes \omega_{\text{R},\beta}(K_{\alpha}^* e^{itH_{\lambda}} \cdot e^{-itH_{\lambda}} K_{\alpha}). \quad (2.27)$$

Technically, it is defined in a standard way as follows (see Section 3.2). Use the Dyson series to define the dynamics $e^{itH_{\lambda}} \cdot e^{-itH_{\lambda}}$ starting from the uncoupled dynamics $e^{itH_0} \cdot e^{-itH_0}$. Then apply the representation map π (2.17) to the Dyson series. One shows that the resulting series converges, and moreover, that the limit equals $e^{itL_{\lambda}} \pi(\cdot) e^{-itL_{\lambda}}$, where L_{λ} is a self-adjoint operator on \mathcal{H}_{GNS} , called the *Liouville operator*. The term in the sum (2.27) is defined as

$$\rho_{\text{S},\beta} \otimes \omega_{\text{R},\beta}(K_{\alpha}^* e^{itH_{\lambda}} \cdot e^{-itH_{\lambda}} K_{\alpha}) = \langle \Omega_{\text{SR},\beta,0}, \pi(K_{\alpha}^*) e^{itL_{\lambda}} \pi(\cdot) e^{-itL_{\lambda}} \pi(K_{\alpha}) \Omega_{\text{SR},\beta,0} \rangle_{\mathcal{H}_{\text{GNS}}}. \quad (2.28)$$

We prove the following result in Section 3.4:

Proposition 2.1 *The functional $\rho_{\text{SR}}(e^{itH_\lambda} \cdot e^{-itH_\lambda})$ given by (2.27) is a well defined state (positive, linear, normalized functional) on \mathcal{O} , for any choice of the $K_j \in \mathfrak{C}$.*

One can show that ρ_{SR} is also defined (finite) on observables O which are products of polynomials $B \otimes a^\dagger(f_1) \cdots a^\dagger(f_n)$ and operators $e^{i\sum_{r=1}^R B_r \otimes a^\dagger(f_r)}$ with test functions $f_j \in L^2_{\text{obs}}$. This is a larger class than \mathcal{O} . However, it will be more difficult to give a proof of our main result, Theorem 2.2, for unbounded observables. In the proof, we use the time uniform estimate $\|e^{itH_\lambda} O e^{-itH_\lambda}\| = \|O\|$, valid for *bounded* observables O . For unbounded O (say a product of creation and annihilation operators) one has to find time uniform bounds of $e^{itH_\lambda} O e^{-itH_\lambda}$ in a weak sense (on suitable functionals). This complicates the analysis and we do not address it here.

The collection of initial states does not depend the state $\rho_{\text{S},\beta}$ in the definition (2.23). Indeed, suppose we had put an arbitrary system density matrix σ_{S} in the place of $\rho_{\text{S},\beta}$ in (2.23). Then, since $\sigma_{\text{S}} = K \rho_{\text{S},\beta} K^*$ for $K = \sqrt{\sigma_{\text{S}}} (\rho_{\text{S},\beta})^{-1/2}$, we obtain the same class of initial states because changing the system reference state simply amounts to a change in the Kraus operators. The same is not true for the role of $\omega_{\text{R},\beta}$ in (2.23). If we replace there $\omega_{\text{R},\beta}$ by $\omega_{\text{R},\beta}(K^* \cdot K)$ for some reservoir operator $K \in \mathfrak{C}$ (bounded or unbounded), then we still obtain the same class of initial states. The set of such states $\omega_{\text{R},\beta}(K^* \cdot K)$ are called *normal states* w.r.t. $\omega_{\text{R},\beta}$, they form the *folium* of $\omega_{\text{R},\beta}$. However, not all states of the reservoir are of this form; for instance, $\omega_{\text{R},\beta'}$ is not normal w.r.t. $\omega_{\text{R},\beta}$ unless $\beta = \beta'$. Normal states differ from each other only ‘quasilocally’. We refer to [6, 19] for a more precise discussion of this point.

Example. An admissible initial state is for instance

$$\rho_{\text{SR}} = \Lambda(\rho_{\text{S},\beta} \otimes \omega_{\text{R},\beta}) = \frac{1}{Z} e^{\mathcal{E}} (\rho_{\text{S},\beta} \otimes \omega_{\text{R},\beta}) e^{\mathcal{E}^*},$$

where Z is a normalization factor and $\mathcal{E} = \sum_j B_j \otimes a^*(f_j) + \sum_k D_k \otimes a(f_k)$ is an arbitrary expression linear in the creation and annihilation operators. This is a state in which S and R are entangled, *c.f.* [39].

2.4 The main result

Assumptions.

(A1) *Smoothness of the form factor.* We assume that the form factor $g(k)$ in the interaction (2.5) satisfies

$$g(k) = \frac{|k|^p}{1 + |k|^{p+q}} h(k), \quad (2.29)$$

for some values $p = -\frac{1}{2}, \frac{1}{2}, \frac{3}{2}$ or $p > 2$ and $q > 2$, and where $h(k)$ is a function four times differentiable with respect to $|k|$ for $|k| > 0$, such that h and its derivatives are bounded and $\lim_{|k| \rightarrow 0} \partial_{|k|}^j h(k) \neq 0$, $j = 0, \dots, 4$.

(A2) (a) *Fermi Golden Rule Condition*: The reservoir spectral density is defined as

$$J(\omega) = \frac{1}{2}\pi\omega^2 \int_{S^2} |g(\omega, \Sigma)|^2 d\Sigma, \quad \omega \geq 0, \quad (2.30)$$

where $g(k)$ is the form factor in the interaction (2.5) and the integral is over the (polar and azimuthal) angles. We assume that

$$\langle \phi_m, G\phi_n \rangle J(|E_m - E_n|) \neq 0 \quad \text{for all system energies } E_m \neq E_n, \quad (2.31)$$

and where $\langle \phi_m, G\phi_n \rangle$ are the matrix elements of the coupling operator G (2.5) in the system energy basis.

(b) *Simplicity of resonance energies*. We assume that the so-called *level shift operators* Λ_e , $e \in \mathcal{E}_0 = \{E_m - E_n : m, n = 1, \dots, N\}$, have simple eigenvalues. The Λ_e are explicit matrices describing the second order (λ^2) corrections to the energy differences $e \in \mathcal{E}_0$, given in Section 3.6.

The assumption (A1) on the form factor is more restrictive than $g \in L_{\text{obs}}^2$ (c.f. (2.18)) in that it requires a more stringent infrared behaviour (values of p) and the existence of one more derivative, relative to functions in L_{obs}^2 . The condition (2.31) ensures that the interaction does not suppress second order (λ^2) transition processes in S due to the coupling with R. The reservoir spectral density (2.30) governs these transitions since the coupling (2.5) is linear in the field operator. This linear form of the interaction is not necessary for our method to work – other interactions will lead to explicit conditions of effective coupling but are not expressed in terms of $J(\omega)$. The assumptions (A1) together with (A2a) guarantee that the coupled system-reservoir complex has a unique stationary state, the coupled equilibrium state, for small nonzero λ , see [27]. (A2b) is a simplifying assumption that can be quite easily removed by a slightly more cumbersome analysis.

Here is our main result.

Theorem 2.2 (SR dynamics for correlated initial states) *There is a constant $\lambda_0 > 0$ such that if $|\lambda| < \lambda_0$, then the following holds. Let ρ_{SR} be an initial system-reservoir state of the form (2.24) and let ρ_{S} be its reduction to S (2.26). Then for all $t \geq 0$, $O \in \mathcal{O}$,*

$$\rho_{\text{SR}}(e^{itH_\lambda} O e^{-itH_\lambda}) = (e^{t\mathcal{L}_{\text{S}}(\lambda)} \rho_{\text{S}} \otimes \omega_{\text{R},\beta})(O) + \chi(\lambda, t, O) + R(\lambda, t, O), \quad (2.32)$$

where $\mathcal{L}_{\text{S}}(\lambda)$ is the Davies generator (1.2) and the remainder $R(\lambda, t, O)$ satisfies

$$|R(\lambda, t, O)| \leq C(O)|\lambda|^{1/4}. \quad (2.33)$$

The dispersive term satisfies

$$\chi(\lambda, t, O) = 0 \quad \text{if } \rho_{\text{SR}} = \rho_{\text{S}} \otimes \omega_{\text{R},\beta} \quad (2.34)$$

$$\chi(\lambda, t, O_{\text{S}} \otimes \mathbb{1}_{\text{R}}) = 0 \quad (2.35)$$

$$|\chi(\lambda, t, O)| \leq \frac{C(O)}{1 + t^3}, \quad (2.36)$$

and moreover,

$$|\chi(\lambda, t, O) - (\rho_{\text{SR}} - \rho_{\text{S}} \otimes \omega_{\text{R},\beta})(e^{itH_0} O e^{-itH_0})| \leq C(O) |\lambda|. \quad (2.37)$$

The constants $C(O)$ depend on O as well as the initial state ρ_{SR} (but are independent of t, λ). For $O = O_{\text{S}} \otimes \mathbb{1}_{\text{R}}$ we have $C(O_{\text{S}} \otimes \mathbb{1}_{\text{R}}) \leq c \|O_{\text{S}}\|$ with c independent of O_{S} .

2.5 Implications

Theorem 2.2 has the following consequences.

(1) Validity of the Born approximation for initially factorized states

For initial states $\rho_{\text{SR}} = \rho_{\text{S}} \otimes \omega_{\text{R},\beta}$, where ρ_{S} is any system density matrix, and for all $t \geq 0$, $O \in \mathcal{O}$, we have

$$\rho_{\text{SR}}(e^{itH_\lambda} O e^{-itH_\lambda}) = (e^{t\mathcal{L}_{\text{S}}(\lambda)} \rho_{\text{S}} \otimes \omega_{\text{R},\beta})(O) + \mathbf{O}(|\lambda|^{1/4}). \quad (2.38)$$

This shows that if the system and reservoir are initially in a product state with the reservoir in equilibrium, then the total state stays (up to $\mathbf{O}(|\lambda|^{1/4})$) of product form for all times, and the reservoir stays in its equilibrium state.

(2) Validity of the Markov approximation for initially correlated states

Taking in (2.32) observables of the form $O = O_{\text{S}} \otimes \mathbb{1}_{\text{R}}$ shows the validity of the Markovian approximation, (1.4), *even for initially correlated SR states*. Namely, denoting by ρ_{S}^t the reduction of the full state $\rho_{\text{SR}} = \rho_{\text{SR}}(e^{itH_\lambda} \cdot e^{-itH_\lambda})$ at time t , and $\rho_{\text{S}} = \rho_{\text{S}}^{t=0}$, we have

$$\sup_{t \geq 0} \|\rho_{\text{S}}^t - e^{t\mathcal{L}_{\text{S}}(\lambda)} \rho_{\text{S}}\| \leq C |\lambda|^{1/4}, \quad (2.39)$$

for a constant C independent of λ , but generally depending on the initial state ρ_{SR} . (As ρ_{S}^t is a finite-dimensional density matrix, it is not necessary to specify which norm we take in (2.39). We may take the trace norm.)

(3) Decay of correlations and emergence of the Born approximation regime

The term χ in (2.32) describes the evolution of the correlation between the system and reservoir. According to (2.36) it decays as t^{-3} . At $t = 0$, (2.32) gives $\chi(\lambda, t, O) = \rho_{\text{SR}}(O) - \text{tr}_{\text{R}}\{\rho_{\text{SR}}\} \otimes \omega_{\text{R},\beta} + \mathbf{O}(|\lambda|^{1/4})$, so if the initial state ρ_{SR} differs from $\text{tr}\{\rho_{\text{SR}}\} \otimes \omega_{\text{R},\beta}$ then for small times, the correlation term $\chi(\lambda, t, O)$ can dominate the Markovian term $(e^{t\mathcal{L}_{\text{S}}(\lambda)} \rho_{\text{S}} \otimes \omega_{\text{R},\beta})(O)$ in (2.32). Whether and by how much this happens depends on the observable O – as explained in the previous point, for $O = O_{\text{S}} \otimes \mathbb{1}_{\text{R}}$ we always have $\chi(\lambda, t, O) = 0$. To see which one of the Markovian or the correlation contributions are dominant, we use the spectral decomposition [29]

$$e^{t\mathcal{L}_{\text{S}}(\lambda)} = \sum_j e^{it(e_j + \lambda^2 a_j)} P_j, \quad (2.40)$$

where the P_j are spectral projections, the $e_j \in \mathbb{R}$ are the Bohr energies of the system (differences of eigenvalues of H_S) and $a_j \in \mathbb{C}$, $\text{Im} a_j \geq 0$ are the complex energy corrections (resonances) induced by the interaction with the reservoir. The Markovian dynamics exhibits exponential time decay $\sim e^{-\lambda^2 \gamma t}$ in all directions P_j but one, which represents the projection onto the system equilibrium state at temperature β (and for which $e_j = a_j = 0$). The decay (approach to equilibrium) is exponential and very slow for small coupling λ . On the other hand, the polynomial decay of the correlation term, t^{-3} , happens at a rate which is independent of λ , meaning that the constant in (2.36) does not depend on λ . (Indeed, that constant encodes the fact that the reservoir dynamics alone is dispersive away from the projection onto the reservoir equilibrium state.) It follows that for small coupling, the correlation term χ can be dominant for small times, but as time increases, the Markovian term becomes dominant. Then a long time later (λ small), the exponentially decaying functions lie below the power decay function, and the correlation term is leading once again, even though by that time, both those terms are smaller than the remainder $\mathbf{O}(|\lambda|^4)$.

Further remarks.

- (a) The power of the decay in (2.36) depends on the smoothness of the form factor g , (2.5), which in turn determines the decay speed of the reservoir correlation function [30, 31]. We get higher powers $\sim t^{-n}$ assuming that g is $(n+1)$ times differentiable and that the test functions in L^2_{obs} are n times differentiable. Under a certain analyticity condition on g (see [29]) and on the test functions in L^2_{obs} , one can show that the time decay in (2.36) is exponential, with a λ -independent decay rate.
- (b) We cannot ascertain in general that the constant $C(O)$ in Theorem 2.2 are bounded in the values of $t > 0$ for time-dependent observables of the form $O = e^{itH_0} O' e^{-itH_0}$. This is so since the constant will depend on ‘Sobolev norms’ of test functions appearing in the observables, that is, on their smoothness (the $L^2(\mathbb{R}^3, d^3k)$ norm of their derivatives w.r.t. $|k|$). But $e^{itH_R} W(f) e^{-itH_R} = W(e^{i|k|t} f)$ has a test function $e^{i|k|t} f(k)$ that is rough (large $|k|$ -derivative) for large t . Nevertheless, if $O = O_S \otimes \mathbb{1}_R$, then $C(e^{itH_S} O_S e^{-iH_S t} \otimes \mathbb{1}_R) \leq c \|O_S\|$ is bounded uniformly in time.
- (c) In the weak coupling regime one takes simultaneously $\lambda \rightarrow 0$ and $t \rightarrow \infty$, keeping $\tau = \lambda^2 t \in \mathbb{R}$ fixed. By (2.33), (2.36) and the previous discussion point,

$$\begin{aligned} \lim_{\lambda \rightarrow 0} R\left(\lambda, \frac{\tau}{\lambda^2}, (e^{-i\frac{\tau}{\lambda^2} H_S} \otimes \mathbb{1}_R) O (e^{i\frac{\tau}{\lambda^2} H_S} \otimes \mathbb{1}_R)\right) &= 0 \\ \lim_{\lambda \rightarrow 0} (\rho_{\text{SR}} - \rho_S \otimes \omega_{R,\beta}) \left(e^{i\frac{\tau}{\lambda^2} H_0} (e^{-i\frac{\tau}{\lambda^2} H_S} \otimes \mathbb{1}_R) O (e^{i\frac{\tau}{\lambda^2} H_S} \otimes \mathbb{1}_R) e^{-i\frac{\tau}{\lambda^2} H_0} \right) &= 0. \end{aligned}$$

Thus (2.32) gives for all $\tau > 0$, $O \in \mathcal{O}$

$$\lim_{\lambda \rightarrow 0} \rho_{\text{SR}} \left(e^{i\frac{\tau}{\lambda^2} H_\lambda} (e^{-i\frac{\tau}{\lambda^2} H_S} \otimes \mathbb{1}_R) O (e^{i\frac{\tau}{\lambda^2} H_S} \otimes \mathbb{1}_R) e^{-i\frac{\tau}{\lambda^2} H_\lambda} \right) = (e^{\tau \mathcal{K}} \rho_S \otimes \omega_{R,\beta})(O).$$

This shows that in the weak coupling scaling limit, the total system-reservoir state (in the interaction picture when the system dynamics is removed) is of the product form $(e^{\tau\mathcal{K}}\rho_S) \otimes \omega_{R,\beta}$ for all $\tau > 0$. This fact was already observed in [38].

- (d) If O belongs to the norm closure of \mathcal{O} , then take an arbitrary $\epsilon > 0$ and $O_\epsilon \in \mathcal{O}$ such that $\|O - O_\epsilon\| < \epsilon$. The quantity $\rho_{\text{SR}}(e^{itH_\lambda} O e^{-itH_\lambda})$ is still well defined and we have $\rho_{\text{SR}}(e^{itH_\lambda} O e^{-itH_\lambda}) - \rho_{\text{SR}}(e^{itH_\lambda} O_\epsilon e^{-itH_\lambda}) = O(\epsilon)$, uniformly in t . Theorem (2.2) then gives the expansion (2.32) for $\rho_{\text{SR}}(e^{itH_\lambda} O_\epsilon e^{-itH_\lambda})$, with constants $C(O_\epsilon)$ depending on ϵ . In the main term, $(e^{t\mathcal{L}_S(\lambda)}\rho_S \otimes \omega_{R,\beta})(O_\epsilon) + \chi(\lambda, t, O_\epsilon)$, we can replace O_ϵ again by O , making an error of $O(\epsilon)$, uniformly in λ and t (see also (3.49)). This shows that (2.32) remains valid for any O in the norm closure of \mathcal{O} , modulo adding an arbitrarily small term $O(\epsilon)$ and allowing the constants $C(O)$ to depend also on ϵ . One may use a similar argument to extend the result of Theorem 2.2 to $\nu = \infty$ in (2.23).

Connections. The mathematical method we are using is based on [30, 31]. To our knowledge, this is the only approach able to handle perturbation theory in small λ valid for all times $t \geq 0$. On the physics side, our work is close to [38, 39], where the authors show that the master equation is valid for correlated initial states in the weak coupling limit (see the Remark (c) above). Their technique is based on the Nakajima-Zwanzig projection method and does not extend beyond the weak coupling scaling regime. In some aspects, the setup in [38, 39] is more general (allowing to treat NESS for example – an extension of our methods to include this is planned) and in some aspects it is less general (their Kraus operators have to be bounded for the main result in [38] – even though unbounded ones are used in applications given in [39]).

One of our main conclusions is that initial correlations do not invalidate the Markovian approximation. This means that the distinguishability (trace distance) of reduced system states cannot increase during the evolution (by more than $\mathbf{O}(|\lambda|^{1/4})$). An important feature responsible for this is that the reservoir dynamics is dispersive, meaning that the evolution converges to the stationary (equilibrium) state. This is built into the model by taking the infinite volume limit (continuous reservoir mode frequencies) and by the continuity of the spectrum of H_R (see also [30, 31, 29]). In contrast, if R is *finite*, an M -level system with discrete energy levels, then different effects appear. Those are studied in a variety of papers. It is shown in [25, 13] that for finite-dimensional S and R , the backflow of information $R \rightarrow S$ can lead to an *increase* in the distinguishability if the SR state is initially correlated, an effect which cannot happen for initial product states. The increase is a measure for non-Markovianity of the dynamics. In this situation, initial correlations lead to non-Markovianity of the system dynamics. A related question is whether and how the system dynamics can be represented by completely positive, Kraus representation maps. In [20], the authors consider finite-dimensional S and R and show that a Kraus representation is valid for all times and for general initial correlations if and only if the joint dynamics is local unitary (no SR coupling). It is shown in [34] that the

dynamics of an open N -level system can be described by at most N^2 completely positive trace preserving maps. The result is built on a decomposition of the (correlated) initial state using a so-called bath-positive decomposition.

In [3], a new correlation picture approach is used to show that the reduced system dynamics satisfies a Lindblad-like master equation, in which the jump operators depend on the initial SR correlation, yielding a nonlinear evolution equation. The philosophy there is to build a weak correlation, rather than a weak coupling, perturbation theory. The corresponding perturbation series does not converge uniformly in time, but allows to analyze a strongly interacting SR dynamics for finite times.

3 Proof of Theorem 2.2

3.1 Purification of ρ_{SR}

Our approach follows the works [30, 31] (see also [23]) and we adopt the notation of [31]. The first step is to work with a purification of the initial state ρ_{SR} . Consider $\rho_{\text{S}} \otimes \omega_{\text{R},\beta}$, where ρ_{S} is an arbitrary density matrix acting on \mathbb{C}^N and $\omega_{\text{R},\beta}$ is the reservoir equilibrium state (2.13). The state $\rho_{\text{S}} \otimes \omega_{\text{R},\beta}$ is represented by a *vector*

$$\Psi_0 = \Psi_{\text{S}} \otimes \Omega_{\text{R}} \in \mathcal{H}_{\text{GNS}} \quad (3.1)$$

in the new ‘purification’ Hilbert space

$$\mathcal{H}_{\text{GNS}} = \mathcal{H}_{\text{S}} \otimes \mathcal{H}_{\text{R}} \quad (3.2)$$

where

$$\mathcal{H}_{\text{S}} = \mathbb{C}^N \otimes \mathbb{C}^N \quad \text{and} \quad \mathcal{H}_{\text{R}} = \bigoplus_{n \geq 0} L^2_{\text{sym}}((\mathbb{R} \times S^2)^n, (du \times d\Sigma)^n) \quad (3.3)$$

is the (symmetric) Fock space over the one-particle space

$$L^2(\mathbb{R} \times S^2, du \times d\Sigma) \equiv L^2(\mathbb{R} \times S^2). \quad (3.4)$$

Here, $d\Sigma$ is the uniform measure over the unit sphere $S^2 \subset \mathbb{R}^3$. The link between $\rho_{\text{S}} \otimes \omega_{\text{R},\beta}$ and (3.1) is given by a representation map

$$\pi = \pi_{\text{S}} \otimes \pi_{\text{R}} : \mathcal{O} \rightarrow \mathcal{L}(\mathcal{H}), \quad (3.5)$$

mapping observables O acting on $\mathbb{C}^N \otimes \mathcal{F}$ (before purification (2.2)) to operators on \mathcal{H}_{GNS} (after purification (3.2)), in such a way that

$$(\rho_{\text{S}} \otimes \omega_{\text{R},\beta})(O) = \langle \Psi_0, \pi(O)\Psi_0 \rangle_{\mathcal{H}_{\text{GNS}}}. \quad (3.6)$$

The vector Ω_{R} in (3.1) is the vacuum vector in the Fock space \mathcal{H}_{R} (3.3). It is the purification of the reservoir thermal equilibrium. The vector $\Psi_{\text{S}} \in \mathbb{C}^N \otimes \mathbb{C}^N$ is the

purification of the system density matrix ρ_S . For example, the purification of the system Gibbs state $\rho_{S,\beta}$ (2.8) is given by

$$\Omega_{S,\beta} = Z_{S,\beta}^{-1/2} \sum_{j=1}^N e^{-\beta E_j/2} \phi_j \otimes \phi_j \in \mathbb{C}^N \otimes \mathbb{C}^N, \quad (3.7)$$

where $Z_{S,\beta} = \text{tr}_S e^{-\beta H_S}$. The representation map π , (3.5) is explicitly given by

$$\pi_S(A) = A \otimes \mathbb{1}_S, \quad (3.8)$$

$$\pi_R(W(f)) = W_\beta(\tau_\beta f), \quad (3.9)$$

where

$$\tau_\beta : L^2(\mathbb{R}^3, d^3k) \rightarrow L^2(\mathbb{R} \times S^2, du \times d\Sigma) \quad (3.10)$$

takes a function $f(k)$, $k \in \mathbb{R}^3$, into the function $(\tau_\beta f)(u, \Sigma)$, $u \in \mathbb{R}$, $\Sigma \in S^2$, defined by

$$(\tau_\beta f)(u, \Sigma) = \sqrt{\frac{u}{1 - e^{-\beta u}}} |u|^{1/2} \begin{cases} f(u, \Sigma), & u \geq 0 \\ -\bar{f}(-u, \Sigma) & u < 0 \end{cases}. \quad (3.11)$$

On the right side of (3.11), g is represented in spherical coordinates, $u = |k| \geq 0$, $\Sigma \in S^2$. The Weyl operator $W(f)$ on the left side of (3.9) is given by (2.12) and is defined for $f \in L^2(\mathbb{R}^3, d^3k)$. The Weyl operator on the right side is defined for functions $f \in L^2(\mathbb{R} \times S^2, du \times d\Sigma)$, as $W_\beta(f) = e^{i\varphi_\beta(f)}$, where $\varphi_\beta(f) = \frac{1}{\sqrt{2}}[a_\beta^*(f) + a_\beta(f)]$ is the field operator in the Fock space \mathcal{H}_R , (3.3), smoothed out with f . The representation map π_R is also defined on creation operators, by the explicit formula

$$\pi_\beta(a^*(f)) = a_\beta^* \left(\sqrt{\frac{u}{1 - e^{-\beta u}}} |u|^{1/2} f(u, \Sigma) \chi_+(u) \right) - a_\beta \left(\sqrt{\frac{u}{1 - e^{-\beta u}}} |u|^{1/2} \bar{f}(-u, \Sigma) \chi_-(u) \right), \quad (3.12)$$

where $\chi_+(u) = 1$ if $u \geq 0$ and $\chi_+(u) = 0$ for $u < 0$ (and $\chi_-(u) = 1 - \chi_+(u)$). We refer to [6, 29, 31, 32] for more detail. The purification of the initial state ρ_{SR} (2.24) is given by

$$\sum_{\alpha=1}^{\nu} \rho_{S,\beta} \otimes \omega_{R,\beta}(K_\alpha^* O K_\alpha) = \sum_{\alpha=1}^{\nu} \langle \Omega_{SR,\beta,0}, \pi(K_\alpha^*) \pi(O) \pi(K_\alpha) \Omega_{SR,\beta,0} \rangle, \quad (3.13)$$

where the inner product is that of \mathcal{H}_{GNS} (3.2) and

$$\Omega_{SR,\beta,0} = \Omega_{S,\beta} \otimes \Omega_R \quad (3.14)$$

is the uncoupled equilibrium (KMS) state. We note that π is well defined on polynomials in creation and annihilation operators (and limits thereof), see (2.11), and $\pi(\mathfrak{C})$ is a well defined set of unbounded operators on \mathcal{H}_{GNS} . We prove in Lemma 3.4 below that $\pi(K) \Omega_{SR,\beta,0}$ is well defined for any $K \in \mathfrak{C}$. This guarantees that (3.13) is well defined. One can see the right hand side of (3.13) as the *definition* of our state ρ_{SR} .

3.2 Coupled dynamics and Liouville operator

The uncoupled Heisenberg dynamics $\alpha_0^t(O) = e^{itH_0} O e^{-itH_0}$ leaves \mathcal{O} invariant (see (2.19)), but the interacting dynamics $e^{itH_\lambda} O e^{-itH_\lambda}$ does not. It is thus not *a priori* clear how to represent $e^{itH_\lambda} O e^{-itH_\lambda}$ as an operator in \mathcal{H}_{GNS} . However, we can extend the domain of π and define a self-adjoint *Liouville operator* on \mathcal{H}_{GNS} , such that for $O \in \mathcal{O}$,

$$\pi(e^{itH_\lambda} O e^{-itH_\lambda}) = e^{itL_\lambda} \pi(O) e^{-itL_\lambda}. \quad (3.15)$$

To do this we proceed in a standard way using the Dyson expansion

$$e^{itH_\lambda} O e^{-itH_\lambda} = \alpha_0^t(O) + \sum_{n \geq 1} (i\lambda)^n \int_{0 \leq t_1 \leq \dots \leq t_n \leq t} dt_1 \cdots dt_n T_{t_1, \dots, t_n}(O), \quad (3.16)$$

where

$$T_{t_1, \dots, t_n}(O) = [\alpha_0^{t_n}(V), [\alpha_0^{t_{n-1}}(V), \dots, [\alpha_0^{t_1}(V), \alpha_0^t(O)] \dots]] \quad (3.17)$$

is the multiple commutator and $V = G \otimes \varphi(g)$ is the interaction operator (2.5). The series (3.16) converges in the strong sense on suitable states. It is easy to check that

$$\pi(e^{itH_0} O e^{-itH_0}) = e^{itL_0} \pi(O) e^{-itL_0}, \quad (3.18)$$

where the uncoupled Liouville operator is (not writing obvious factors $\mathbb{1}$)

$$L_0 = L_S + L_R, \quad L_S = H_S \otimes \mathbb{1}_S - \mathbb{1}_S \otimes H_S, \quad L_R = d\Gamma(u). \quad (3.19)$$

Here, $d\Gamma(u)$ is the second quantization of multiplication by the radial variable $u \in \mathbb{R}$, acting on the Fock space \mathcal{H}_R (3.3). In particular, $e^{itL_R} a_\beta(f) e^{-itL_R} = a_\beta(e^{itu} f)$ is a Bogoliubov transformation. We now apply π to the right side of (3.16). More precisely, one shows that π applied to the truncated series $\sum_{n=1}^N \dots$ has a strong limit as $N \rightarrow \infty$. Due to the structure of the sum, the limit operator has again the form of a Dyson series and equals $e^{itL_\lambda} \pi(O) e^{-itL_\lambda}$ (see for instance Section 2.1.3 of [18] for details). The self-adjoint operator L_λ is called the *Liouville operator* and has the form

$$L_\lambda = L_0 + \lambda I, \quad (3.20)$$

where the interaction operator I in (3.20) is given by $I = \pi(G \otimes \varphi(g)) - J\pi(G \otimes \varphi(g))J$ (compare with (2.5)), where J is the modular conjugation. The explicit form of J is well known, see *e.g.* (1.21) of [22]. One then gets the expression [22, 29]

$$I = G \otimes \mathbb{1}_S \otimes \varphi_\beta(\tau_\beta g) - \mathbb{1}_S \otimes \mathcal{C}G\mathcal{C} \otimes \varphi_\beta(e^{-\beta u/2} \tau_\beta g), \quad (3.21)$$

where \mathcal{C} is the operator taking complex conjugation of components of vectors in \mathbb{C}^N written in the eigenbasis of H_S . The construction of L_λ associated to H_λ is well understood [21, 5, 12, 29]. The upshot is that the right side of (3.15) defines the dynamics of the infinitely extended system.

From perturbation theory of equilibrium (KMS) states [12, 6] we know that the interacting system-reservoir complex has a unique equilibrium state, represented by a normalized vector $\Omega_{\text{SR},\beta,\lambda} \in \mathcal{H}$, satisfying

$$L_\lambda \Omega_{\text{SR},\beta,\lambda} = 0. \quad (3.22)$$

The vector $\Omega_{\text{SR},\beta,\lambda}$ is analytic in λ at the origin, with (c.f. (3.14))

$$\|\Omega_{\text{SR},\beta,\lambda} - \Omega_{\text{SR},\beta,0}\| \leq C|\lambda|. \quad (3.23)$$

3.3 Resonance expansion and proof of Theorem 2.2

The expectation of a system-reservoir observable $O \in \mathcal{O}$ in the state ρ_{SR} at time t is

$$\rho_{\text{SR}}(e^{itH_\lambda} O e^{-itH_\lambda}) = \sum_{\alpha=1}^{\nu} \rho_{\text{S},\beta} \otimes \omega_{\text{R},\beta}(K_\alpha^* e^{itH_\lambda} O e^{-itH_\lambda} K_\alpha). \quad (3.24)$$

We now analyze one of the terms in the sum, for a fixed α , writing simply K for K_α , and we will restore the sum over the α at the end. According to (3.13), (3.15) we have

$$\rho_{\text{S},\beta} \otimes \omega_{\text{R},\beta}(K^* e^{itH_\lambda} O e^{-itH_\lambda} K) = \langle \Omega_{\text{SR},\beta,0}, \pi(K^*) e^{itL_\lambda} \pi(O) e^{-itL_\lambda} \pi(K) \Omega_{\text{SR},\beta,0} \rangle, \quad (3.25)$$

where $\Omega_{\text{SR},\beta,0}$ is the uncoupled KMS state (3.14). The representation $\pi'(\cdot) = J\pi(\cdot)J$ has the property that $\pi'(X)$ and $\pi(Y)$ commute for all operators X, Y (Tomita-Takesaki, [6, 29]); for unbounded X, Y the commutation is understood in the strong (or weak) sense on suitable vectors. We now use the identity

$$\pi(X) \Omega_{\text{SR},\beta,0} = \pi'(e^{-\beta H_0/2} X^* e^{\beta H_0/2}) \Omega_{\text{SR},\beta,0}, \quad (3.26)$$

which holds provided the operator $e^{-\beta H_0/2} X^* e^{\beta H_0/2}$ is well defined (note that $e^{\beta H_0/2}$ is unbounded). The relation (3.26) is derived as follows. We have

$$\begin{aligned} \pi(X) \Omega_{\text{SR},\beta,0} &= J \Delta^{1/2} \pi(X^*) J \Delta^{1/2} \Omega_{\text{SR},\beta,0} \\ &= J \Delta^{1/2} \pi(X^*) \Delta^{-1/2} J \Omega_{\text{SR},\beta,0}. \end{aligned} \quad (3.27)$$

The first equality in (3.27) is the defining property of J and Δ and the modular operator is $\Delta = e^{-\beta L_0}$. The second equality in (3.27) follows from $JL_0 = -L_0J$ [6, 12, 5, 29]. Next,

$$\begin{aligned} \Delta^{1/2} \pi(X^*) \Delta^{-1/2} &= e^{itL_0} \pi(X^*) e^{-itL_0} \Big|_{t=i\beta/2} \\ &= \pi(e^{itH_0} X^* e^{-itH_0}) \Big|_{t=i\beta/2} \\ &= \pi(e^{-\beta H_0/2} X^* e^{\beta H_0/2}). \end{aligned} \quad (3.28)$$

Using that $J\pi(\cdot)J = \pi'(\cdot)$ and combining (3.28) with (3.27) yields (3.26). Due to (3.26) we may replace, in (3.25), $\pi(K)$ by $\pi'(e^{-\beta H_0/2} K^* e^{\beta H_0/2})$ and use that the latter operator commutes with $e^{itL_\lambda} \pi(O) e^{-itL_\lambda}$,

$$\begin{aligned} &\rho_{\text{S},\beta} \otimes \omega_{\text{R},\beta}(K^* e^{itH_\lambda} O e^{-itH_\lambda} K) \\ &= \langle \Omega_{\text{SR},\beta,0}, \pi(K^*) \pi'(e^{-\beta H_0/2} K^* e^{\beta H_0/2}) e^{itL_\lambda} \pi(O) e^{-itL_\lambda} \Omega_{\text{SR},\beta,0} \rangle. \end{aligned} \quad (3.29)$$

By (3.22) we have $e^{-itL_\lambda}\Omega_{\text{SR},\beta,\lambda} = \Omega_{\text{SR},\beta,\lambda}$ and so

$$e^{itL_\lambda}\pi(O)e^{-itL_\lambda}\Omega_{\text{SR},\beta,0} = e^{itL_\lambda}\pi(O)\Omega_{\text{SR},\beta,\lambda} + e^{itL_\lambda}\pi(O)(\Omega_{\text{SR},\beta,0} - \Omega_{\text{SR},\beta,\lambda}), \quad (3.30)$$

where the uncoupled equilibrium state $\Omega_{\text{SR},\beta,0}$ is given in (3.14). We combine (3.29), (3.30) and (3.23) into

$$\rho_{\text{S},\beta} \otimes \omega_{\text{R},\beta}(K^* e^{itH_\lambda} O e^{-itH_\lambda} K) = \langle \phi, e^{itL_\lambda} \psi \rangle + R_1(t, \lambda), \quad (3.31)$$

where

$$\begin{aligned} \phi &= \pi(K)\pi'(e^{\beta H_0/2} K e^{-\beta H_0/2})\Omega_{\text{SR},\beta,0} \\ \psi &= \pi(O)\Omega_{\text{SR},\beta,0} \end{aligned} \quad (3.32)$$

and

$$|R_1(\lambda, t)| \leq C|\lambda| \|O\| \|\pi(K)\pi'(e^{\beta H_0/2} K e^{-\beta H_0/2})\Omega_{\text{SR},\beta,0}\|, \quad (3.33)$$

uniformly in $t \in \mathbb{R}$. Now we apply the results of [30] to the main term on the right side of (3.31). That work gives an expansion of $\langle \phi, e^{itL_\lambda} \psi \rangle$ for vectors ϕ, ψ satisfying

$$\phi, \psi \in \mathcal{D}, \quad \bar{L}_\lambda \phi, \bar{L}_\lambda \psi \in \mathcal{D}, \quad (3.34)$$

where $\bar{L}_\lambda = P_{\text{R}}^\perp L_\lambda P_{\text{R}}^\perp|_{\text{Ran}P_{\text{R}}^\perp}$ and where $\mathcal{D} \subset \mathcal{H}_{\text{GNS}}$ is a suitable sense set which we present in (3.89) below. The orthogonal projection P_{R} is defined as

$$P_{\text{R}} = \mathbb{1}_{\text{S}} \otimes |\Omega_{\text{R}}\rangle\langle\Omega_{\text{R}}|, \quad P_{\text{R}}^\perp = \mathbb{1} - P_{\text{R}}. \quad (3.35)$$

We show that (3.34) holds in Section 3.5 and continue here the analysis using the result of Theorem 2.1 of [30],

$$\langle \phi, e^{itL_\lambda} \psi \rangle = \langle \phi, (e^{it(M(\lambda))} \otimes P_{\text{R}})\psi \rangle + \langle \phi, P_{\text{R}}^\perp e^{itP_{\text{R}}^\perp L_\lambda P_{\text{R}}^\perp} P_{\text{R}}^\perp \psi \rangle + R(\lambda, t), \quad (3.36)$$

with a remainder satisfying

$$|R(\lambda, t)| \leq C|\lambda|^{1/4} \mathcal{A}(\phi, \psi), \quad (3.37)$$

for constants C and \mathcal{A} independent of λ and $t \geq 0$. We now explain the operator $M(\lambda)$ in (3.36). Denote by \mathcal{E}_0 the set of all differences of eigenvalues of H_{S} (*i.e.*, the spectrum of L_{S} , (3.19)). Denote the eigenprojection of L_0 associated to $e \in \mathcal{E}_0$ by $P_e = P_{\text{S},e} \otimes P_{\text{R}}$, where $P_{\text{S},e}$ is the eigenprojection of L_{S} and define the *level shift operator*

$$\Lambda_e = -P_e I P_e^\perp (L_0 - e + i0_+)^{-1} I P_e, \quad (3.38)$$

where $i0_+$ is the limit of $i\epsilon$ as $\epsilon \rightarrow 0_+$ (the limit in (3.38) exists in operator norm, see [30, 31]). The operator Λ_e acts on $\text{ran}P_e$. It is explained in detail in [30] how Λ_e determines

the eigenvalues of L_λ close to e . Under the Fermi Golden Rule and simplicity conditions (A2a), (A2b), the operator $M(\lambda)$ in (3.36) is given by

$$M(\lambda) = L_S + \lambda^2 \Lambda, \quad \Lambda = \bigoplus_{e \in \mathcal{E}_0} \Lambda_e. \quad (3.39)$$

The operators L_S and Λ commute. Now that we have explained the objects defining the dynamics ‘along P_R ’ in (3.36) we can analyze it further. Writing

$$\pi(O) = \sum_j \pi(O_S^j \otimes O_R^j) = \sum_j \pi_S(O_S^j) \otimes \pi_R(O_R^j) \quad (3.40)$$

and taking into account (3.32) and (3.35), it follows that

$$\begin{aligned} \langle \phi, (e^{itM(\lambda)} \otimes P_R) \psi \rangle &= \sum_j \omega_{R,\beta}(O_R^j) \langle \phi, (e^{itM(\lambda)} \pi_S(O_S^j) \Omega_{S,\beta}) \otimes \Omega_R \rangle \\ &= \sum_j \omega_{R,\beta}(O_R^j) \langle \phi, (\pi_S(e^{t\mathcal{L}_*} O_S^j) \Omega_{S,\beta}) \otimes \Omega_R \rangle, \end{aligned} \quad (3.41)$$

where the operator \mathcal{L}_* is uniquely defined by (see also [29, 30, 31])

$$e^{itM(\lambda)} \pi_S(X) \Omega_{S,\beta} = \pi_S(e^{t\mathcal{L}_*} X) \Omega_{S,\beta}, \quad \text{for all system operators } X \in \mathcal{B}(\mathbb{C}^N). \quad (3.42)$$

The second factor of the summand of (3.41) is (*c.f.* (3.32))

$$\begin{aligned} &\langle \phi, (\pi_S(e^{t\mathcal{L}_*} O_S^j) \Omega_{S,\beta}) \otimes \Omega_R \rangle \\ &= \langle \pi(K) \Omega_{SR,\beta,0}, \pi(e^{t\mathcal{L}_*} O_S^j \otimes \mathbb{1}_R) \pi'(e^{-\beta H_0/2} K^* e^{\beta H_0/2}) \Omega_{SR,\beta,0} \rangle \\ &= \rho_{S,\beta} \otimes \omega_{R,\beta}(K^*(e^{t\mathcal{L}_*} O_S^j \otimes \mathbb{1}_R) K), \end{aligned} \quad (3.43)$$

where we used (3.24), (3.26) in the last step. Now we remember that we wrote K for K_α , and summing over α , as per (3.24), we obtain from (3.31), (3.36),

$$\begin{aligned} \rho_{SR}(e^{itH_\lambda} O e^{-itH_\lambda}) &= \sum_\alpha \sum_j \omega_{R,\beta}(O_R^j) \rho_{S,\beta} \otimes \omega_{R,\beta}(K_\alpha^*(e^{t\mathcal{L}_*} O_S^j \otimes \mathbb{1}_R) K_\alpha) \\ &\quad + \langle \Phi, P_R^\perp e^{itP_R^\perp L_\lambda P_R^\perp} P_R^\perp \pi(O) \Omega_{SR,\beta,0} \rangle + R_2(\lambda, t), \end{aligned} \quad (3.44)$$

where

$$\Phi = \sum_{\alpha=1}^\nu \pi(K_\alpha) \pi'(e^{\beta H_0/2} K_\alpha e^{-\beta H_0/2}) \Omega_{SR,\beta,0} \quad (3.45)$$

and the remainder is the sum of (3.33) and (3.37),

$$\begin{aligned} |R_2(\lambda, t)| &\leq C |\lambda|^{1/4} \sum_{\alpha=1}^\nu \mathcal{A} \left(\pi(K_\alpha) \pi'(e^{\beta H_0/2} K_\alpha e^{-\beta H_0/2}) \Omega_{SR,\beta,0}, \pi(O) \Omega_{SR,\beta,0} \right) \\ &\quad + C |\lambda| \|O\| \sum_{\alpha=1}^\nu \left\| \pi(K_\alpha) \pi'(e^{\beta H_0/2} K_\alpha e^{-\beta H_0/2}) \Omega_{SR,\beta,0} \right\|. \end{aligned} \quad (3.46)$$

In terms of the reduced initial state ρ_S , defined in (2.26), the first term on the right side of (3.44) is simply

$$\begin{aligned}
& \sum_{\alpha} \sum_j \omega_{R,\beta}(O_R^j) \rho_{S,\beta} \otimes \omega_{R,\beta}(K_{\alpha}^*(e^{t\mathcal{L}^*} O_S^j \otimes \mathbb{1}_R) K_{\alpha}) \\
&= \sum_j \rho_S(e^{t\mathcal{L}^*} O_S^j) \omega_{R,\beta}(O_R^j) \\
&= \sum_j ((e^{t\mathcal{L}} \rho_S) \otimes \omega_{R,\beta})(O_S^j \otimes O_R^j) = ((e^{t\mathcal{L}} \rho_S) \otimes \omega_{R,\beta})(O), \tag{3.47}
\end{aligned}$$

where \mathcal{L} is the adjoint of \mathcal{L}_* with respect to the inner product $(X, Y) = \text{tr}_S X^* Y$ of the space of system operators. It is shown in the Appendix of [29] that \mathcal{L} is the Davies generator. Combine (3.47) and (3.44),

$$\rho_{SR}(e^{itH_{\lambda}} O e^{-itH_{\lambda}}) = ((e^{t\mathcal{L}} \rho_S) \otimes \omega_{R,\beta})(O) + \chi(\lambda, t, O) + R_2(\lambda, t), \tag{3.48}$$

where (recall Φ is given in (3.45))

$$\chi(\lambda, t, O) = \langle \Phi, P_R^{\perp} e^{itP_R^{\perp} L_{\lambda} P_R^{\perp}} P_R^{\perp} \pi(O) \Omega_{SR,\beta,0} \rangle. \tag{3.49}$$

This is the expansion (2.32) of Theorem 2.2. The decay (2.36) follows from the regularity of the resolvent, as explained in (1.10) of [30] (see also the related Lemma 3.1 below). Note that $P_R^{\perp} \pi(O_S \otimes \mathbb{1}_R) \Omega_{SR,\beta,0} = 0$. Using this in (3.49) shows (2.35). Furthermore, for initial states $\rho_{RS} = \rho_S \otimes \omega_{R,\beta}$ the Kraus operators are of the form $K_{\alpha} = K'_{\alpha} \otimes \mathbb{1}_R$ and thus $P_R^{\perp} \Phi = 0$, see (3.45). Using this information in (3.49) shows (2.34). We now prove (2.37). From (3.49),

$$\chi(\lambda, t, O) = \langle \Phi, P_R^{\perp} e^{itL_0} \pi(O) \Omega_{SR,\beta,0} \rangle + T(\lambda, t, O) \tag{3.50}$$

where, writing \bar{X} for $P_R^{\perp} X P_R^{\perp}|_{\text{Ran} P_R^{\perp}}$,

$$T(\lambda, t, O) = i\lambda \int_0^t \langle \Phi, P_R^{\perp} e^{is\bar{L}_{\lambda}} \bar{I} e^{-i(s-t)L_0} P_R^{\perp} \pi(O) \Omega_{SR,\beta,0} \rangle ds. \tag{3.51}$$

Using that $P_R^{\perp} = \mathbb{1} - P_R$ one readily sees that

$$\langle \Phi, P_R^{\perp} e^{itL_0} \pi(O) \Omega_{SR,0} \rangle = \rho_{SR}(e^{itH_0} O e^{-itH_0}) - (\rho_S \otimes \omega_{R,\beta})(e^{itH_0} O e^{-itH_0}). \tag{3.52}$$

In order to show the bound (2.37) it suffices to prove that for all $t \geq 0$,

$$|T(\lambda, t, O)| \leq C|\lambda|. \tag{3.53}$$

The clue in this bound is that the integrand of (3.51) decays in s sufficiently quickly to be integrable. Let $A = d\Gamma(i\partial_u)$, acting on \mathcal{H}_S (3.3). Denote the j -fold commutator of \bar{X} with \bar{A} by $\text{ad}_{\bar{A}}^j(\bar{X}) = [\dots [[\bar{X}, \bar{A}], \bar{A}] \dots]$.

Lemma 3.1 *Suppose the form factor g satisfies $\|\partial_u^j \tau_\beta g\|_{L^2(\mathbb{R} \times S^2)} < \infty$ for $j = 0, \dots, 4$ and suppose X is an operator such that $\|\mathcal{N}^{-1/2} \text{ad}_A^j(\bar{X}) \mathcal{N}^{-1/2}\| < \infty$ for $j = 1, 2, 3$, where $\mathcal{N} = d\Gamma(\mathbb{1}_{\mathcal{H}_R})$ is the number operator in the Fock space \mathcal{H}_R (see (3.3) and also (3.80)). Then we have*

$$\max_{1 \leq r \leq 3} \left| \langle \Phi, (\bar{L}_\lambda - z)^{-1} \bar{X} (\bar{L}_0 - \zeta)^{-r} \Psi \rangle \right| \leq C_{\bar{X}} \|\Phi\|_3 \|\Psi\|_3, \quad (3.54)$$

uniformly in z, ζ with $\text{Im}z, \text{Im}\zeta < 0$. Here, $\|\cdot\|_j$ is the norm (3.88) and $C_{\bar{X}}$ is a constant depending on \bar{X} .

We give a proof of Lemma 3.1 below. For now we apply it to estimate the term (3.51). We write the propagator $e^{-i(s-t)L_0}$ in its resolvent representations (Fourier-Laplace transform, see also equation (1.30) in [30]), for $w > 0$,

$$\begin{aligned} & \langle \Phi, P_R^\perp e^{is\bar{L}_\lambda} \bar{I} e^{-i(s-t)L_0} P_R^\perp \pi(O) \Omega_{\text{SR}, \beta, 0} \rangle \\ &= \frac{-1}{2\pi i} \int_{\mathbb{R}-iw} \frac{e^{i(t-s)\zeta}}{(\zeta + i)^2} \langle \Phi, P_R^\perp e^{is\bar{L}_\lambda} \bar{I} (\bar{L}_0 - \zeta)^{-1} P_R^\perp \Psi \rangle d\zeta, \end{aligned} \quad (3.55)$$

where $\Psi = (\bar{L}_0 + i)^2 \pi(O) \Omega_{\text{SR}, \beta, 0}$. Next we proceed analogously for $e^{is\bar{L}_\lambda}$ to obtain (set $\tau = t - s$)

$$\begin{aligned} T(\lambda, t, O) &= i\lambda \left(\frac{-1}{2\pi i}\right)^2 \int_0^t d\tau \int_{\mathbb{R}-iw} dz \frac{e^{i(t-\tau)z}}{(z+i)^2} \int_{\mathbb{R}-iw} d\zeta \frac{e^{i\tau\zeta}}{(\zeta+i)^2} \\ &\quad \times \langle \Phi', (\bar{L}_\lambda - z)^{-1} \bar{I} (\bar{L}_0 - \zeta)^{-1} \Psi \rangle, \end{aligned} \quad (3.56)$$

with $\Phi' = (\bar{L}_\lambda + i)^2 \Phi$. One shows that Ψ and Φ' are well defined and $\|\Phi'\|_3, \|\Psi\|_3 < \infty$ by the arguments of Section 3.5. We divide the τ integral into $\tau \in [0, 1]$ and $\tau \in [1, t]$, so

$$T(\lambda, t, O) = T_1(\lambda, t, O) + T_2(\lambda, t, O), \quad (3.57)$$

where T_1 is given by (3.56) with \int_0^t replaced by \int_1^t and $|T_2(\lambda, t, O)| \leq C|\lambda|$. To analyze T_1 , we use (twice) that $e^{i\tau\zeta} = \frac{1}{i\tau} \partial_\zeta e^{i\tau\zeta}$ and integrate by parts in ζ , to arrive at

$$\begin{aligned} T_1(\lambda, t, O) &= i\lambda \left(\frac{-1}{2\pi i}\right)^2 \int_1^t d\tau \frac{-1}{\tau^2} \int_{\mathbb{R}-iw} dz \frac{e^{i(t-\tau)z}}{(z+i)^2} \int_{\mathbb{R}-iw} d\zeta e^{i\tau\zeta} \\ &\quad \times \partial_\zeta^2 \{ (\zeta + i)^{-2} \langle \Phi', (\bar{L}_\lambda - z)^{-1} \bar{I} (\bar{L}_0 - \zeta)^{-1} \Psi \rangle \}. \end{aligned} \quad (3.58)$$

We now use Lemma 3.1 to bound the term $\partial_\zeta^2 \{ (\zeta + i)^{-2} \langle \Phi', (\bar{L}_\lambda - z)^{-1} \bar{I} (\bar{L}_0 - \zeta)^{-1} \Psi \rangle \}$, and we arrive at

$$|T_1(\lambda, t, O)| \leq C|\lambda| \int_1^t \frac{d\tau}{\tau^2} \leq C|\lambda|, \quad \forall t \geq 1. \quad (3.59)$$

Note that in the application of Lemma 3.1, we took $\bar{X} = \bar{I}$, and $\|\mathcal{N}^{-1/2} \text{ad}_A^j(\bar{I}) \mathcal{N}^{-1/2}\| < \infty$ is guaranteed by the condition 2.29 on the form factor g . This shows the relation (3.53)

and hence (2.37). The proof of Theorem 2.2 is complete, modulo a proof of Lemma (3.1), which we now present.

Proof of Lemma 3.1. As in the proof of Theorem 3.1 in [31], one considers the regularization $\bar{L}_\lambda(\alpha) = \bar{L}_0 + i\alpha\bar{\mathcal{N}} + \lambda\bar{I}(\alpha)$, $\alpha > 0$, where

$$\bar{I}(\alpha) = \frac{1}{\sqrt{2\pi}} \int_{\mathbb{R}} \widehat{f}(s) e^{i\alpha s \bar{A}} \bar{I} e^{-i\alpha s \bar{A}} ds, \quad A = d\Gamma(i\partial_u) \quad (3.60)$$

and \widehat{f} is the Fourier transform of a Schwartz function f satisfying $f^{(k)}(0) = 1$, $k = 0, 1, 2, \dots$. The bound (3.54) follows if the same (α independent) bound can be shown with $\bar{L}_\lambda, \bar{L}_0$ replaced by $\bar{L}_\lambda(\alpha), \bar{L}_0(\alpha)$, see Section 3.1.1 of [31]. Let us write for short $R_z = (\bar{L}_\lambda(\alpha) - z)^{-1}$ and $S_\zeta = (\bar{L}_0(\alpha) - \zeta)^{-1}$. We also write X instead of \bar{X} in the remainder of the proof, and A for \bar{A} , I for \bar{I} . Note that $S_\zeta = e^{\alpha A} (L_0 - \zeta)^{-1} e^{-\alpha A}$. Using that $\partial_\alpha (S_\zeta)^k = A S_\zeta^k - S_\zeta^k A$ and $\partial_\alpha R_z = A R_z - R_z A + \lambda R_z Y R_z$, where

$$Y = \partial_\alpha I(\alpha) - [A, I(\alpha)] = \frac{1}{\sqrt{2\pi}} \int_{\mathbb{R}} (is - 1) \widehat{f}(s) e^{i\alpha s A} [A, I] e^{-i\alpha s A} ds, \quad (3.61)$$

we get

$$\begin{aligned} \partial_\alpha \langle \Phi, R_z X S_\zeta^3 \Psi \rangle &= \langle \Phi, A R_z X S_\zeta^3 \Psi \rangle - \langle \Phi, R_z X S_\zeta^3 A \Psi \rangle \\ &\quad + \langle \Phi, R_z [X, A] S_\zeta^3 \Psi \rangle + \lambda \langle \Phi, R_z Y R_z X S_\zeta^3 \Psi \rangle. \end{aligned} \quad (3.62)$$

Using that $\|\mathcal{N}^{1/2} R_z A \Phi\| \leq C\alpha^{-1/2} \|\Phi\|_2$ (see Proposition 3.4(2) of [31]) and $\|R_z\|, \|S_\zeta\| \leq C/\alpha$ (see Proposition 3.3(1) of [31]), together with the fact that $\|\mathcal{N}^{-1/2} Y \mathcal{N}^{-1/2}\| \leq C\alpha^\ell$, for any $\ell = 1, 2, \dots$ provided $\|\partial_u^j \tau_\beta g\|_{L^2} < \infty$ ($j = 0, \dots, \ell + 1$, see Proposition 3.4(1) of [31]³), we estimate $|\langle \Phi, A R_z X S_\zeta^3 \Psi \rangle| \leq C\alpha^{-3} \|\mathcal{N}^{-1/2} X \mathcal{N}^{-1/2}\| \|\Phi\|_2 \|\Psi\|_2$ and the same upper bound for the second term on the right side of (3.62). The third one is estimated by $|\langle \Phi, R_z [X, A] S_\zeta^3 \Psi \rangle| \leq C\alpha^{-3} \|\mathcal{N}^{-1/2} [X, A] \mathcal{N}^{-1/2}\| \|\Phi\|_2 \|\Psi\|_2$. For the fourth term on the right side, we take $\ell = 1$ to get $|\langle \Phi, R_z Y R_z X S_\zeta^3 \Psi \rangle| \leq C\alpha^{-3} \|\mathcal{N}^{-1/2} X \mathcal{N}^{-1/2}\| \|\Phi\|_1 \|\Psi\|_1$ (we also use the bound $\|\mathcal{N}^{1/2} R_z \mathcal{N}^{1/2}\| \leq C$, *c.f.* Proposition 3.3(2) of [31]). All together, we obtain

$$|\partial_\alpha \langle \Phi, R_z X S_\zeta^3 \Psi \rangle| \leq C\alpha^{-3} \|\Phi\|_2 \|\Psi\|_2. \quad (3.63)$$

We integrate in α , using that $|\langle \Phi, R_z X S_\zeta^3 \Psi \rangle|_{\alpha=1} \leq C\|\Phi\| \|\Psi\|$, to obtain

$$|\langle \Phi, R_z X S_\zeta^3 \Psi \rangle| \leq C(1 + \alpha^{-2}) \|\Phi\|_2 \|\Psi\|_2. \quad (3.64)$$

Now we use the bound (3.64) to estimate the three first terms on the right side of (3.62) from above by $C(1 + \alpha^{-2}) \|\Phi\|_3 \|\Psi\|_3$, provided that $\|\mathcal{N}^{-1/2} [[X, A], A] \mathcal{N}^{-1/2}\| < \infty$. The norm is now $\|\cdot\|_3$ due to the presence of the operator A in the first two terms of the

³This convenient bound is not hard to derive by expanding $e^{i\alpha s A} [A, I] e^{-i\alpha s A}$ in (3.61) in a power series in α and using that $f^{(k)}(0) = 1$.

right side of (3.62). We use $\ell = 2$ to estimate the last term on the right side of (3.62) and hence we get (3.63) with α^{-3} replaced by α^{-2} . Thus (3.64) holds with α^{-2} replaced by α^{-1} . We now repeat the process one more time, using the latest bounds in (3.62) and integrating to obtain $|\langle \Phi, R_z X S_\zeta^3 \Psi \rangle| \leq C \|\Phi\|_3 \|\Psi\|_3$. It is assumed that $\ell = 3$ and $\|\mathcal{N}^{-1/2}[[[X, A], A], A] \mathcal{N}^{-1/2}\| < \infty$.

This concludes the proof of Lemma 3.1 and hence that of Theorem 2.2. \square

3.4 Proof of Proposition 2.1

We first show Lemma 3.2 and 3.3 detailing some representation independent bounds on polynomials of creation, annihilation and Weyl operators. Then give the proof of Proposition 2.1, starting at (3.79) below.

The number operator on the Fock space \mathcal{F} (2.4) is given by

$$\widehat{N} = d\Gamma(\mathbb{1}_{\mathcal{F}}) = \int_{\mathbb{R}^3} a^*(k)a(k)d^3k. \quad (3.65)$$

We often write \widehat{N} for $\mathbb{1}_{\mathcal{C}^N} \otimes \widehat{N}$. In order to alleviate the notation, in this section we will use the symbol N for the number operator \widehat{N} , even though N also denotes the dimension of the system Hilbert space.

Lemma 3.2 *For any $K \in \mathcal{X} \cup \mathcal{P}$ and any $\epsilon > 0$, we have $\|Ke^{-\epsilon N}\| < \infty$.*

Proof of Lemma 3.2. Let $K = a^{(\sigma_1)}(f_1) \cdots a^{(\sigma_\ell)}(f_\ell) \in \mathcal{P}$, where $\sigma_j \in \{\pm 1\}$ and $a^{(+1)}(f) = a^*(f)$, $a^{(-1)}(f) = a(f)$. Let $\xi(N)$ be a function of N . Since $Na^*(f) = a^*(f)(N+1)$ we have $\xi(N)a^*(f) = a^*(f)\xi(N+1)$ and similarly $\xi(N)a(f) = a(f)\xi(N-1)$, so in short, $\xi(N)a^{(\sigma)}(f) = a^{(\sigma)}(f)\xi(N+\sigma)$. Taking $\xi(N) = (N+\ell)^{1/2}$,

$$\begin{aligned} K &= a^{(\sigma_1)}(f_1)(N+\ell)^{-1/2} \cdot (N+\ell)^{1/2} a^{(\sigma_2)}(f_2) \cdots a^{(\sigma_\ell)}(f_\ell) \\ &= a^{(\sigma_1)}(f_1)(N+\ell)^{-1/2} \cdot a^{(\sigma_2)}(f_2) \cdots a^{(\sigma_\ell)}(f_\ell) (N+\ell + \sum_{j=2}^{\ell} \sigma_j)^{1/2}. \end{aligned} \quad (3.66)$$

Using $(N+\ell)^{-1/2}(N+\ell)^{1/2} = \mathbb{1}$ next to every $a^{(\sigma_j)}(f_j)$ and pulling $(N+\ell)^{1/2}$ to the right as in (3.66) gives

$$K = a^{(\sigma_1)}(f_1)(N+\ell)^{-1/2} \cdots a^{(\sigma_\ell)}(f_\ell)(N+\ell)^{-1/2} \cdot B, \quad (3.67)$$

where

$$\begin{aligned} B &= (N+\ell)^{1/2}(N+\ell+\sigma_{\ell-1})^{1/2}(N+\ell+\sigma_{\ell-1}+\sigma_{\ell-2})^{1/2} \cdots (N+\ell+\sum_{j=2}^{\ell} \sigma_j)^{1/2} \\ &\leq (N+2\ell)^{\ell/2}. \end{aligned} \quad (3.68)$$

We know that $\|a^{(\sigma)}(f)(N+1)^{-1/2}\| \leq \|f\|_{L^2}$, see *e.g.* [6, 32]. It follows from (3.67) and (3.68),

$$\|Ke^{-\epsilon N}\| \leq \|f_1\|_{L^2} \cdots \|f_\ell\|_{L^2} \sup_{n \in \mathbb{N}} (n+2\ell)^{\ell/2} e^{-\epsilon n}. \quad (3.69)$$

Now for $0 < \epsilon < 1/4$ (which we can take without loss of generality), we have

$$\sup_{n \in \mathbb{N}} (n + 2\ell)^{\ell/2} e^{-\epsilon n} \leq \left(\frac{\ell}{2\epsilon}\right)^{\ell/2} \quad (3.70)$$

and so it follows from (3.69) and (3.70) that the statement of Lemma 3.2 holds for K a product of creation and annihilation operators and hence for all $K \in \mathcal{P}$. Next let

$$K = e^{i \sum_{r=1}^R B_r \otimes a^\sharp(f_r)} \in \mathcal{X}. \quad (3.71)$$

We expand the exponential,

$$K e^{-\epsilon N} = \sum_{\ell=0}^{\infty} \frac{i^\ell}{\ell!} \left[\sum_{r=1}^R B_r \otimes a^\sharp(f_r) \right]^\ell e^{-\epsilon N}. \quad (3.72)$$

We then multiply out the product $[\sum_{r=1}^R B_r \otimes a^\sharp(f_r)]^\ell$ into a sum of R^ℓ terms, each term being an element of the form $H \otimes Q \in \mathcal{P}$, where $H \in \mathcal{B}(\mathbb{C}^N)$ and Q is a product of ℓ creation and annihilation operators. By (3.69), (3.70), $\|Q e^{-\epsilon N}\| \leq C^\ell (\ell/(2\epsilon))^{\ell/2}$ for some constant C . The norm of the general term in the series (3.72) is bounded above by

$$\left\| \frac{i^\ell}{\ell!} \left[\sum_{r=1}^R B_r \otimes a^\sharp(f_r) \right]^\ell e^{-\epsilon N} \right\| \leq C^\ell \frac{1}{\ell!} \left(\frac{\ell}{2\epsilon}\right)^{\ell/2} \quad (3.73)$$

for another constant C (depending on R) and the series converges for any $\epsilon > 0$ (and any R), as is easily established using *e.g.* the ratio test. This shows that (3.72) is a bounded operator. This concludes the proof of Lemma 3.2. \square

The domain of definition of the operator $e^{\epsilon N}$, denoted $\text{Dom}(e^{\epsilon N})$, is a dense set in \mathcal{F} .

Lemma 3.3 *Given any $\epsilon > 0$, all operators in \mathfrak{C} are well defined on $\text{Dom}(e^{\epsilon N})$.*

Proof of Lemma 3.3. To control products of operators, we note that $\forall s \in \mathbb{R}$,

$$e^{sN} a^\sharp(f) e^{-sN} = e^{\pm s} a^\sharp(f) \quad (3.74)$$

$$e^{sN} e^{i \sum_{r=1}^R B_r \otimes a^\sharp(f_r)} e^{-sN} = e^{i \sum_{r=1}^R e^{\pm s} B_r \otimes a^\sharp(f_r)}, \quad (3.75)$$

where the $+s$ exponent is present for $a^\sharp = a^*$ and the $-s$ exponent for $a^\sharp = a$. Equations (3.74), (3.75) show that

$$e^{sN} \mathfrak{C} e^{-sN} = \mathfrak{C}, \quad \forall s \in \mathbb{R}. \quad (3.76)$$

Let now $K_\alpha \in \mathcal{X} \cup \mathcal{P}$, $\alpha = 1, \dots, \nu$. Then $\forall \epsilon > 0$,

$$\begin{aligned} & K_1 \cdots K_\nu \\ &= K_1 e^{-\epsilon N} (e^{\epsilon N} K_2 e^{-2\epsilon N}) (e^{2\epsilon N} K_3 e^{-3\epsilon N}) \cdots (e^{(\nu-1)\epsilon N} K_\nu e^{-\nu\epsilon N}) e^{\nu\epsilon N}. \end{aligned} \quad (3.77)$$

For $\ell \geq 1$ integer, $e^{(\ell-1)\epsilon N} K_\ell e^{-\ell\epsilon N} = e^{(\ell-1)\epsilon N} K_\ell e^{-(\ell-1)\epsilon N} e^{-\epsilon N} \equiv K_\ell(\epsilon) e^{-\epsilon N}$, where $K(\epsilon) \in \mathcal{X} \cup \mathcal{P}$ is the K with all single-particle functions f, g replaced by $e^{(\ell-1)\epsilon} f$ and $e^{-(\ell-1)\epsilon} g$ for creation and annihilation operators, respectively, according to (3.74), (3.75). As shown in Lemma 3.2, we have $\|K_\ell(\epsilon) e^{-\epsilon N}\| < \infty$ for any $\epsilon > 0$. It follows that

$$K_1 \cdots K_\nu = K_1 e^{-\epsilon N} K_2(\epsilon) e^{-\epsilon N} K_3(\epsilon) e^{-\epsilon N} \cdots K_\nu(\epsilon) e^{-\epsilon N} e^{\nu\epsilon N} \quad (3.78)$$

is a well defined operator on $\text{Dom}(e^{\nu\epsilon N})$, for any $\epsilon > 0$. This completes the proof of Lemma 3.3. \square

Proof of Proposition 2.1. To prove Proposition 2.1, we consider

$$\rho_{\mathbb{S},\beta} \otimes \omega_{\mathbb{R},\beta}(K^* e^{itH_\lambda} O e^{-itH_\lambda} K) = \langle \Omega_{\text{SR},\beta,0}, \pi(K^*) e^{itL_\lambda} \pi(O) e^{-itL_\lambda} \pi(K) \Omega_{\text{SR},\beta,0} \rangle \quad (3.79)$$

for some $K \in \mathfrak{C}$ and $O \in \mathcal{O}$. We only need to show the following result.

Lemma 3.4 *We have $\|\pi(K) \Omega_{\text{SR},\beta,0}\| < \infty$ for any $K \in \mathfrak{C}$.*

Proof of Lemma 3.4. According to (3.12) the operator $\pi(a^*(f))$ is the sum of a creation plus an annihilation operator on the Fock space $\mathcal{H}_{\mathbb{R}}$, (3.3), and so we have $\|\pi_\beta(a^*(f))(\mathcal{N}+1)^{-1/2}\| < \infty$. Here, \mathcal{N} is the number operator on the Fock space $\mathcal{H}_{\mathbb{R}}$, (3.3),

$$\mathcal{N} = d\Gamma(\mathbb{1}_{\mathcal{H}_{\mathbb{R}}}). \quad (3.80)$$

We can then proceed entirely analogously to the proof of Lemma 3.2 to show that for all $K \in \mathcal{P}$, we have $\|\pi(K) e^{-\epsilon \mathcal{N}}\| < \infty$, for any $\epsilon > 0$. Next, let K be given by (3.71). From (3.5), (3.8), (3.12) we get

$$\pi(B_r \otimes a^\sharp(f_r)) = B_r \otimes \mathbb{1}_{\mathbb{S}} \otimes (a_\beta^*(f_{r,+}) + a_\beta(f_{r,-})), \quad (3.81)$$

for functions $f_{r,+}, f_{r,-} \in L^2(\mathbb{R} \times S^2)$. It follows that

$$\pi(e^{i\sum_{r=1}^R B_r \otimes a^\sharp(f_r)}) = e^{i\sum_{r=1}^R B_r \otimes \mathbb{1}_{\mathbb{S}} \otimes [a_\beta^*(f_{r,+}) + a_\beta(f_{r,-})]}. \quad (3.82)$$

Expanding the exponential as in (3.72) and proceeding exactly as in the proof of Lemma 3.2 we see that $\|\pi(e^{i\sum_{r=1}^R B_r \otimes a^\sharp(f_r)}) e^{-\epsilon \mathcal{N}}\| < \infty$ for all $\epsilon > 0$.

So far in this proof, we have shown that

$$\|\pi(K) e^{-\epsilon \mathcal{N}}\| < \infty, \quad \forall \epsilon > 0, \quad \forall K \in \mathcal{X} \cup \mathcal{P}. \quad (3.83)$$

To see that $\|\pi(K_1 \cdots K_\nu) \Omega_{\text{SR},\beta,0}\| < \infty$ we proceed as in (3.77), inserting factors $\mathbb{1} = e^{-\ell\epsilon \mathcal{N}} e^{\ell\epsilon \mathcal{N}}$,

$$\pi(K_1 \cdots K_\nu) = \pi(K_1) e^{-\epsilon \mathcal{N}} (e^{\epsilon \mathcal{N}} \pi(K_2) e^{-2\epsilon \mathcal{N}}) \cdots (e^{(\nu-1)\epsilon \mathcal{N}} \pi(K_\nu) e^{-\nu\epsilon \mathcal{N}}) e^{\nu\epsilon \mathcal{N}}. \quad (3.84)$$

All that is left to do is showing that for any $\ell \geq 1$ integer,

$$\|e^{(\ell-1)\epsilon \mathcal{N}} \pi(K) e^{-\ell\epsilon \mathcal{N}}\| < \infty, \quad \forall \epsilon > 0, \quad \forall K \in \mathcal{X} \cup \mathcal{P}. \quad (3.85)$$

We do this as above in Lemma 3.3. Indeed, we have for all $s \in \mathbb{R}$,

$$\begin{aligned} e^{s\mathcal{N}} a_\beta^\sharp(v) e^{-s\mathcal{N}} &= e^{\pm s} a_\beta(v), \quad v \in L^2(\mathbb{R} \times S^2) \\ e^{s\mathcal{N}} \pi(e^{i\sum_{r=1}^R B_r \otimes a^\sharp(f_r)}) e^{-s\mathcal{N}} &= e^{i\sum_{r=1}^R B_r \otimes \mathbb{1}_S \otimes [e^s a_\beta^*(f_{r,+}) + e^{-s} a_\beta(f_{r,-})]}, \end{aligned} \quad (3.86)$$

where again, $+s$ and $-s$ are for the creation and the annihilation operator, respectively, as in (3.74), (3.75). The bound (3.85) now follows from (3.83) just as in the proof of Lemma 3.3. This shows that

$$\|\pi(K) e^{-\epsilon\mathcal{N}}\| < \infty, \quad \|e^{(\ell-1)\epsilon\mathcal{N}} \pi(K) e^{-\ell\epsilon\mathcal{N}}\| < \infty, \quad \forall \ell \in \mathbb{N}, \epsilon > 0, K \in \mathfrak{C}. \quad (3.87)$$

This concludes the proof of Lemma 3.4 and hence the proof of Proposition (2.1) is complete. \square

3.5 Set of regular vectors \mathcal{D} and proof of (3.34)

As in [31] we define the norms $\|\cdot\|_j$, for $j = 0, 1, 2, \dots$, on \mathcal{H}_{GNS} (3.2):

$$\|\phi\|_j = \|(1 + \bar{A}^2)^{j/2} \phi\|, \quad A = d\Gamma(i\partial_u), \quad \bar{A} = P_{\mathbb{R}}^\perp A P_{\mathbb{R}}^\perp |_{\text{Ran} P_{\mathbb{R}}^\perp}. \quad (3.88)$$

We have $\|\phi\|_k \leq \|\phi\|_\ell$ for $0 \leq k \leq \ell$. The dense set $\mathcal{D} \subset \mathcal{H}_{\text{GNS}}$ is given by

$$\mathcal{D} = \{\phi \in \mathcal{H}_{\text{GNS}} : \|\phi\|_3 < \infty\}. \quad (3.89)$$

We now verify that (3.34) holds, where the two vectors ϕ, ψ are given by

$$\begin{aligned} \phi &= \pi(K) \pi'(e^{\beta H_0/2} K e^{-\beta H_0/2}) \Omega_{\text{SR},\beta,0}, \\ \psi &= \pi(O) \Omega_{\text{SR},\beta,0}. \end{aligned} \quad (3.90)$$

We first show that $\|\phi\|_3 < \infty$. We have

$$e^{\beta H_0/2} (B \otimes a^\sharp(f)) e^{-\beta H_0/2} = e^{\beta H_S/2} B e^{-\beta H_S/2} \otimes a^\sharp(e^{\pm\beta|k|/2} f) \quad (3.91)$$

$$e^{\beta H_0/2} e^{i\sum_{r=1}^R B_r \otimes a^\sharp(f_r)} e^{-\beta H_0/2} = e^{i\sum_{r=1}^R e^{\beta H_S/2} B_r e^{-\beta H_S/2} \otimes a^\sharp(e^{\pm\beta|k|/2} f_r)} \quad (3.92)$$

where plus sign in the exponentials in (3.91), (3.92) is present if $a^\sharp = a^*$ and the minus sign if $a^\sharp = a$. Note that $e^{\pm\beta H_S/2}$ is bounded and $e^{\pm\beta|k|/2} f_r \in L^2$, so that the operators (3.91) and (3.92) have the same structure as the operators in \mathfrak{C} (except that here, the single-particle functions f appear with the weights $e^{\pm\beta|k|/2}$). It follows that analyzing ϕ in (3.90) reduces to analyzing vectors of the form $\phi' = \pi(K) \pi'(K') \Omega_{\text{SR},\beta,0}$, where $K, K' \in \mathfrak{C}_0$, and where \mathfrak{C}_0 is the algebra defined by (c.f. (2.22))

$$\mathfrak{C}_0 = \text{LinSpan}\{K_1 \cdots K_n : K_j \in \mathcal{X}_0 \cup \mathcal{P}_0 : n \in \mathbb{N}\}, \quad (3.93)$$

where \mathcal{X}_0 and \mathcal{P}_0 are as \mathcal{X} and \mathcal{P} given in (2.21) and (2.20), but with L_{cor}^2 replaced by L_{obs}^2 (we do not assume $e^{\beta|k|}f \in L^2(\mathbb{R}^3, d^3k)$). Using that $J\mathcal{N} = \mathcal{N}J$ and $\mathcal{N}\Omega_{\text{SR},\beta,0} = 0$, we get

$$\begin{aligned}\pi(K)\pi'(K')\Omega_{\text{SR},\beta,0} &= \pi(K)J\pi(K')J\Omega_{\text{SR},\beta,0} \\ &= \pi(K)e^{-\epsilon\mathcal{N}}Je^{\epsilon\mathcal{N}}\pi(K')e^{-2\epsilon\mathcal{N}}J\Omega_{\text{SR},\beta,0}.\end{aligned}\quad (3.94)$$

The relation (3.94) together with (3.87) (which holds for $K \in \mathfrak{C}_0$) then shows immediately that $\|\pi(K)\pi'(K')\Omega_{\text{SR},\beta,0}\| < \infty$, for all $K, K' \in \mathfrak{C}_0$. In other words, $\|\phi\|_0 < \infty$, where this is the norm (3.88) with $j = 0$ of the vector ϕ , (3.90). We now show that $\|\phi\|_3 < \infty$. Writing simply A for \bar{A} (see (3.88)) in the following argument, we have

$$\|\phi\|_j^2 = \langle \phi, (1 + A^2)^j \phi \rangle \leq C \langle \phi, (1 + A^{2j}) \phi \rangle = C(\|\phi\|^2 + \|A^j \phi\|^2), \quad (3.95)$$

for a constant C independent of ϕ . It follows that $\|\phi\|_j \leq C(\|\phi\| + \|A^j \phi\|)$. We thus only need to show that $\|A^3 \phi\| < \infty$, that is, we need to show that

$$\|A^3 \pi(K)\pi'(K')\Omega_{\text{SR},\beta,0}\| < \infty, \quad \text{for all } K, K' \in \mathfrak{C}_0. \quad (3.96)$$

We have for all $\alpha \in \mathbb{R}$ (see also (3.82)),

$$e^{i\alpha A} \pi(e^{i\sum_{r=1}^R B_r \otimes a^\sharp(f_r)}) e^{-i\alpha A} = e^{i\sum_{r=1}^R B_r \otimes \mathbb{1}_S \otimes [a_\beta^*(e^{-\alpha\partial_u} f_{r,+}) + a_\beta(e^{-\alpha\partial_u} f_{r,-})]}. \quad (3.97)$$

Applying the operation $-i\partial_\alpha|_{\alpha=0}$ to the left side of (3.97) gives the commutator of A with $\pi(e^{i\sum_{r=1}^R B_r \otimes a^\sharp(f_r)})$. To calculate the corresponding right hand side, we recall that well-known formula for an operator family $Y(\alpha)$ depending on $\alpha \in \mathbb{R}$,

$$\partial_\alpha e^{Y(\alpha)} = \int_0^1 e^{sY(\alpha)} (\partial_\alpha Y(\alpha)) e^{(1-s)Y(\alpha)} ds. \quad (3.98)$$

Thus $-i\partial_\alpha|_{\alpha=0}$ applied to both sides of (3.97) results in the expression

$$A\pi(e^{i\sum_{r=1}^R B_r \otimes a^\sharp(f_r)}) - \pi(e^{i\sum_{r=1}^R B_r \otimes a^\sharp(f_r)})A = \mathcal{C}, \quad (3.99)$$

where the commutator is

$$\begin{aligned}\mathcal{C} &= - \int_0^1 \pi(e^{is\sum_{r=1}^R B_r \otimes a^\sharp(f_r)}) \\ &\quad \times \left(\sum_{r=1}^R B_r \otimes \mathbb{1}_S \otimes [a_\beta^*(\partial_u f_{r,+}) + a_\beta(\partial_u f_{r,-})] \right) \pi(e^{i(1-s)\sum_{r=1}^R B_r \otimes a^\sharp(f_r)}) ds.\end{aligned}\quad (3.100)$$

Of course, \mathcal{C} is not a bounded operator, as usual, but by (3.87), we have

$$\|\mathcal{C}e^{-\epsilon\mathcal{N}}\| < \infty, \quad \|e^{\epsilon\mathcal{N}}\mathcal{C}e^{-2\epsilon\mathcal{N}}\| < \infty, \quad \forall \epsilon > 0. \quad (3.101)$$

Next, using that $Aa_\beta^*(v) - a_\beta^*(v)A = a_\beta^*(i\partial_u v)$ for any $v \in L^2(\mathbb{R} \times S^2)$, we see that for any polynomial $P \in \mathcal{P}_0$, we have $A\pi(P) - \pi(P)A = \mathcal{C}$ for an operator \mathcal{C} satisfying again (3.101). Let now L_1, \dots, L_n each be an operator belonging to $\mathcal{X}_0 \cup \mathcal{P}_0$. Then $A\pi(L_1 \cdots L_n) = \pi(L_1)A\pi(L_2 \cdots L_n) + \mathcal{C}_1\pi(L_2 \cdots L_n)$, and keeping up commuting A to the right through the operators L gives

$$A\pi(L_1 \cdots L_n) = \pi(L_1 \cdots L_n)A + \mathcal{C}, \quad (3.102)$$

where \mathcal{C} satisfies (3.101). Now since $\pi'(\cdot) = J\pi(\cdot)J$ and $JA = AJ$, we get with the same argument that

$$A\pi^\sharp(L_1) \cdots \pi^\sharp(L_n) = \pi^\sharp(L_1) \cdots \pi^\sharp(L_n)A + \mathcal{C}, \quad (3.103)$$

with \mathcal{C} satisfying (3.101). Here, each π^\sharp individually is either π or π' . Then by linearity, the formula (3.103) is also correct if each $L_j \in \mathfrak{C}_0$ (as opposed to being just an element of $\mathcal{X}_0 \cup \mathcal{P}_0$).

We now combine (3.103) with the fact that $A\Omega_{\text{SR},\beta,0} = 0$ to conclude that (3.96) holds true for A^3 replaced by A . In other words, we have $\|\phi\|_1 < \infty$. But applying A to both sides of (3.103) gives

$$\begin{aligned} A^2\pi^\sharp(L_1) \cdots \pi^\sharp(L_n) &= A\pi^\sharp(L_1) \cdots \pi^\sharp(L_n)A + A\mathcal{C}_1 \\ &= \pi^\sharp(L_1) \cdots \pi^\sharp(L_n)A^2 + \mathcal{C}_2A + A\mathcal{C}_1. \end{aligned} \quad (3.104)$$

We can commute A through \mathcal{C}_1 , $A\mathcal{C}_1 = \mathcal{C}_1A + \mathcal{C}'$. The operator \mathcal{C}' once again will satisfy $\|\mathcal{C}'e^{-\epsilon\mathcal{N}}\| < \infty$, any $\epsilon > 0$. This is easily seen since \mathcal{C}_1 is a sum of products of elements in \mathcal{P}_0 and operators of the form (3.100). One may then proceed as above to show the bound $\|\mathcal{C}'e^{-\epsilon\mathcal{N}}\| < \infty$, any $\epsilon > 0$. This shows that $\|\phi\|_2 < \infty$. We repeat the procedure and apply A to (3.104) to conclude that $\|\phi\|_3 < \infty$. The only limitation on the number of times we can repeat the procedure is that successive derivatives ∂_u of all functions $f_{r,+}$, $f_{r,-}$ involved should stay in $L^2(\mathbb{R} \times S^2)$. Each additional application of A requires one more such derivative to be L^2 . For $\|\phi\|_j < \infty$ we need the derivatives up to and including order j to be square integrable. This condition for $j = 0, \dots, 3$ is guaranteed by taking functions $f(k)$ from the set L_{cor}^2 , see after (2.18).

This shows that $\|\phi\|_3 < \infty$. Next we need to show that $\|\bar{L}_\lambda\phi\|_3 < \infty$ (see (3.34)). We have

$$A^3L_\lambda = L_0A^3 + 3i\mathcal{N}A^2 + \lambda(IA^3 + 3I_1A^2 + 3I_2A + I_3), \quad (3.105)$$

where I_k is the k fold commutator of I with A . We have $\|I(\mathcal{N} + 1)^{-1/2}\| < \infty$ and $\|I_k(\mathcal{N} + 1)^{-1/2}\| < \infty$. It follows that $\|\bar{L}_\lambda\phi\|_3 < \infty$ provided that

$$\|\mathcal{N}A^j\phi\| < \infty, \quad j = 0, \dots, 3 \quad \text{and} \quad \|L_R A^3\phi\| < \infty. \quad (3.106)$$

By the above arguments, we know that $\|e^{\epsilon\mathcal{N}}\phi\| < \infty$ and $\|e^{\epsilon\mathcal{N}}A^3\phi\| < \infty$ for all $\epsilon > 0$, so the bounds involving \mathcal{N} in (3.106) hold. To show that $A^3\phi \in \text{Dom}(L_R)$ we repeat the argument after (3.99) above. Instead of commuting A through elements of \mathfrak{C}_0 , now we have commute L_R through them. We have $L_R a_\beta^\sharp(v) - a_\beta^\sharp(v)L_R = \pm a_\beta^\sharp(uv)$, where the

plus sign is for $a_\beta^\sharp = a_\beta^*$ and uv is the function $u \cdot v(u, \Sigma)$. The multiplication by u of the functions $v(u, \Sigma)$ preserves the square integrability as guaranteed by the the definition of $L_{\text{obs}}^2, L_{\text{cor}}^2$ (2.18). The same argument as above then shows that $\|L_{\text{R}}A^3\phi\| < \infty$.

We have shown so far that $\phi, \bar{L}_\lambda\phi \in \mathcal{D}$. To finish the proof of (3.34) we also need to show that $\psi, \bar{L}_\lambda\psi \in \mathcal{D}$, where $\psi = \pi(O)\Omega_{\text{SR},\beta,0}$, see (3.32). According to (3.9) we have

$$\pi_\beta(W(f)) = e^{i\varphi_\beta(\tau_\beta f)} = e^{i[a_\beta^*(\tau_\beta f) + a_\beta(\tau_\beta f)]/\sqrt{2}} \in \mathfrak{C}_0. \quad (3.107)$$

It follows that $\mathcal{O} \subset \mathfrak{C}_0$ and hence showing $\psi, \bar{L}_\lambda\psi \in \mathcal{D}$ is a special case of the proof that $\phi, \bar{L}_\lambda\phi \in \mathcal{D}$. This completes the proof of (3.34). \square

3.6 Level shift operators

The level shift operators Λ_e are defined in (3.38). As I contains two terms, see (3.21), Λ_e is the sum of four terms,

$$\begin{aligned} \Lambda_e = & \quad (3.108) \\ & -P_e\{G \otimes \mathbb{1}_S \otimes \varphi_\beta(\tau_\beta g)\}(L_0 - e + i0_+)^{-1}\{G \otimes \mathbb{1}_S \otimes \varphi_\beta(\tau_\beta g)\}P_e \\ & +P_e\{G \otimes \mathbb{1}_S \otimes \varphi_\beta(\tau_\beta g)\}(L_0 - e + i0_+)^{-1}\{\mathbb{1}_S \otimes \mathcal{C}GC \otimes \varphi_\beta(e^{-\beta u/2}\tau_\beta g)\}P_e \\ & +P_e\{\mathbb{1}_S \otimes \mathcal{C}GC \otimes \varphi_\beta(e^{-\beta u/2}\tau_\beta g)\}(L_0 - e + i0_+)^{-1}\{G \otimes \mathbb{1}_S \otimes \varphi_\beta(\tau_\beta g)\}P_e \\ & -P_e\{\mathbb{1}_S \otimes \mathcal{C}GC \otimes \varphi_\beta(e^{-\beta u/2}\tau_\beta g)\}(L_0 - e + i0_+)^{-1}\{\mathbb{1}_S \otimes \mathcal{C}GC \otimes \varphi_\beta(e^{-\beta u/2}\tau_\beta g)\}P_e. \end{aligned}$$

The partial trace over the reservoir part is calculated using the formula

$$\begin{aligned} P_{\text{R}}\varphi_\beta(F)(L_0 - e + i0_+)^{-1}\varphi_\beta(G)P_{\text{R}} &= \frac{1}{2}P_{\text{R}}a_\beta(F)(L_0 - e + i0_+)^{-1}a_\beta^*(G)P_{\text{R}} \\ &= \frac{1}{2}P_{\text{R}} \int_{\mathbb{R} \times S^2} \bar{F}(u, \Sigma)G(u, \Sigma)(L_S - e + u + i0_+)^{-1}dud\Sigma, \quad (3.109) \end{aligned}$$

valid for any two functions $F, G \in L^2(\mathbb{R} \times S^2)$. One obtains from (3.108)

$$\begin{aligned} \Lambda_e = & \quad (3.110) \\ & -\frac{1}{2}P_{\text{S},e}(G \otimes \mathbb{1}_S) \int_{\mathbb{R} \times S^2} \frac{|g(|u|, \Sigma)|^2}{|1 - e^{-\beta u}|} (L_S - e + u + i0_+)^{-1}u^2dud\Sigma (G \otimes \mathbb{1}_S)P_{\text{S},e} \\ & +\frac{1}{2}P_{\text{S},e}(G \otimes \mathbb{1}_S) \int_{\mathbb{R} \times S^2} \frac{e^{-\beta u/2}|g(|u|, \Sigma)|^2}{|1 - e^{-\beta u}|} (L_S - e + u + i0_+)^{-1}u^2dud\Sigma (\mathbb{1}_S \otimes \mathcal{C}GC)P_{\text{S},e} \\ & +\frac{1}{2}P_{\text{S},e}(\mathbb{1}_S \otimes \mathcal{C}GC) \int_{\mathbb{R} \times S^2} \frac{e^{-\beta u/2}|g(|u|, \Sigma)|^2}{|1 - e^{-\beta u}|} (L_S - e + u + i0_+)^{-1}u^2dud\Sigma (G \otimes \mathbb{1}_S)P_{\text{S},e} \\ & -\frac{1}{2}P_{\text{S},e}(\mathbb{1}_S \otimes \mathcal{C}GC) \int_{\mathbb{R} \times S^2} \frac{|g(|u|, \Sigma)|^2}{|e^{\beta u} - 1|} (L_S - e + u + i0_+)^{-1}u^2dud\Sigma (\mathbb{1}_S \otimes \mathcal{C}GC)P_{\text{S},e}. \end{aligned}$$

The condition that Λ_e should have simple spectrum can then be verified for concrete cases, where g, G are given explicitly. Note that if e is a simple eigenvalue of L_S , then $P_{\text{S},e}$ has

rank one and so Λ_e has automatically simple spectrum. Note also that $e = 0$ is always a degenerate eigenvalue of L_S . The explicit form of the level shift operators for several models can be found in [26, 31]. Additional information on their structure is provided in [28].
