Abstract

In a graph $G$, a vertex dominates itself and its neighbors. A subset $S \subseteq V(G)$ is said to be a double dominating set of $G$ if $S$ dominates every vertex of $G$ at least twice. The double domination number $\gamma_{x2}(G)$ is the minimum cardinality of a double dominating set of $G$. We show that if $G$ is a maximal outerplanar graph on $n \geq 3$ vertices, then $\gamma_{x2}(G) \leq \lfloor \frac{2n}{3} \rfloor$. Further, if $n \geq 4$, then $\gamma_{x2}(G) \leq \min\{\lfloor \frac{n+2}{2} \rfloor, n-t\}$, where $t$ is the number of vertices of degree 2 in $G$. These bounds are shown to be tight. In addition, we also study the case that $G$ is a striped maximal outerplanar graph.

Keywords Maximal outerplanar graph, striped maximal outerplanar graph, double domination

1 Introduction

For a simple graph $G = (V, E)$, $V$ and $E$ are the sets of vertices and edges of $G$, respectively. We denote by $|V(G)|$ the order of a graph $G$. If the graph $G$ is clear from the context, we simply write $|G|$ or $n$ rather than $|V(G)|$. For a vertex $v \in V(G)$, let $N_G(v)$ and $N_G[v]$ denote the open neighborhood and the closed neighborhood of $v$, respectively; thus $N_G(v) = \{u \mid uv \in E(G)\}$ and $N_G[v] = \{v\} \cup N_G(v)$. A graph $G$ is outerplanar if it has embedding in the plane such that all vertices belong to the boundary of its outer face. An outerplanar graph $G$ is maximal if $G + uv$ is not outerplanar for any two nonadjacent vertices $u$ and $v$.

A dominating set of a graph $G$ is a set $S \subseteq V(G)$ such that every vertex in $G$ is either in $S$ or is adjacent to a vertex in $S$. A set $D \subseteq V(G)$ is a double dominating set of $G$ if every vertex in $V(G) - D$ has at least two neighbors in $D$ and every vertex of $D$ has

a neighbor in $D$. The domination number (double domination number, respectively) of $G$, denoted by $\gamma(G)$ ($\gamma_{\times 2}(G)$, respectively), is the minimum cardinality of a dominating set (double dominating set, respectively). A double dominating set of $G$ of cardinality $\gamma_{\times 2}(G)$ is called a $\gamma_{\times 2}(G)$-set. If the graph $G$ is clear from the context, we simply write $\gamma_{\times 2}$-set rather than $\gamma_{\times 2}(G)$-set. We say a vertex $v$ in $G$ is double dominated, by a set $S$, if $|NG[v] \cap S| \geq 2$.

The concept of double domination was introduced by Harary and Haynes [11] and further studied in, for example, [2, 5, 6, 9, 10, 13, 16].

In 1996, Matheson and Tarjan [17] proved that any triangulated disc $G$ with $n$ vertices satisfies $\gamma(G) \leq \left\lfloor \frac{n}{3} \right\rfloor$, and conjectured that $\gamma(G) \leq \left\lfloor \frac{n}{4} \right\rfloor$ for every $n$-vertex triangulation $G$ with sufficiently large $n$. In 2013, Campos and Wakabayashi investigated this problem for maximal outerplanar graphs and showed in [4] that if $G$ is a maximal outerplanar graph of order $n$, then $\gamma(G) \leq \frac{n + k}{4}$ where $k$ is the number of vertices of degree 2 in $G$. Tokunaga proved the same result independently in [18]. Li et al. [15] improved the result by showing that $\gamma(G) \leq \frac{n + t}{4}$, where $t$ is the number of pairs of consecutive 2-degree vertices with distance at least 3 on the outer cycle. For results on other types of domination in maximal outerplanar graphs, we refer the reader to [1, 3, 7, 8, 12, 14, 19, 20].

In this paper, we apply the idea of coloring to investigated the same question for double domination. We show that if $G$ is a maximal outerplanar graph on $n \geq 3$ vertices, then $\gamma_{\times 2}(G) \leq \left\lfloor \frac{2n}{3} \right\rfloor$. Further, if $n \geq 4$, then $\gamma_{\times 2}(G) \leq \min\{\left\lfloor \frac{n + t}{2} \right\rfloor, n - t\}$, where $t$ is the number of vertices of degree 2 in $G$. These bounds are shown to be tight. In addition, we also study the case that $G$ is a striped maximal outerplanar graph.

## 2 Preliminaries

A maximal outerplanar graph $G$ can be embedded in the plane such that the boundary of the outer face is a Hamiltonian cycle and each inner face is a triangle. A maximal outerplanar graph embedded in the plane is called a maximal outerplane graph. For such an embedding of $G$, we denote by $H_G$ the Hamiltonian cycle which is boundary of the outer face. An inner face of a maximal outerplane graph $G$ is an internal triangle if it is not adjacent to outer face. A maximal outerplane graph without internal triangles is called stripped. The following results are useful for our study.

**Proposition 2.1** [4] Let $G$ be a maximal outerplanar graph of order $n \geq 4$. If $G$ has $k$ internal triangles, then $G$ has $k + 2$ vertices of degree 2.

**Proposition 2.2** [7] If $G$ is a maximal outerplanar graph of order $n \geq 4$, then the set of vertices of $G$ of degree 2 is an independent set of $G$ of size at most $\frac{n}{2}$.

**Proposition 2.3** [11] Let $C$ be a cycle of order $n \geq 3$, then $\gamma_{\times 2}(C) = \left\lfloor \frac{2n}{3} \right\rfloor$. 

2
3 Main result

Let $G$ be any maximal outerplanar graph. We know that there exists a Hamiltonian cycle in $G$, say $H_G$. It is easy to see that a $\gamma_{x2}$-set of $H_G$ is a double dominating set of $G$. Hence, the following result is immediate from Proposition 2.3.

**Observation 3.1** Let $G$ be a maximal outerplanar graph of order $n \geq 3$, then $\gamma_{x2}(G) \leq \lceil \frac{2n}{3} \rceil$.

This conclusion is obvious, so we are ready to improve it. Next, we will give some definitions which are helpful for our investigations.

A *minor* of a graph $G$ is a graph which can be obtained from $G$ by deleting vertices and deleting or contracting edges. Given a graph $H$, a graph $G$ is *$H$-minor free* if no minor of $G$ is isomorphic to $H$. A $K_4$-minor free graph $G$ is *maximal* if $G + uv$ is not a $K_4$-minor free graph for any two non-adjacent vertices $u$ and $v$ of $G$. A 2-tree is defined recursively as follows. A single edge is a 2-tree. Any graph obtained from a 2-tree by adding a new vertex and making it adjacent to the end vertices of an existing edge is also a 2-tree. It is well known that the maximal $K_4$-minor free graphs are exactly the 2-trees.

We know that a maximal outerplanar graph must be a maximal $K_4$-minor free graph. Hence, before giving the upper bound for the double domination number of a maximal outerplanar graph, we intend to prove the stronger result as follows.

**Theorem 3.2** Let $G$ be a maximal $K_4$-minor free graph of order $n \geq 3$, then $\gamma_{x2}(G) \leq \lfloor \frac{2n}{3} \rfloor$.

**Proof.** Let $G_i = G_{i-1} - v_i$ for $i = 1, 2, \cdots, n - 3$, where $v_i$ is a vertex of degree 2 in $G_{i-1}$, $G_0 = G$. Since a maximal $K_4$-minor free graph is exactly a 2-tree and according to the definition of 2-tree, we have that $G_{n-3}$ is a $K_3$. We can give a proper 3-coloring to $G_0$ by assigning color 1, 2 and 3 to the three vertices of $G_{n-3}$ respectively and color $v_i$ with the remaining color which does not appear in $N_{G_{i-1}}(v_i)$ at each stage. Let $V_i$ be the set of vertices assigned color $t$, where $t = 1, 2, 3$. Choosing two suitable color classes, say $V_1$ and $V_2$, such that $|V_1| + |V_2| \leq \lfloor \frac{2}{3}|G_0| \rfloor$. Let $S = V_1 \cup V_2$. Next, we will show that $S$ is a double dominating set of $G$.

Clearly, each of the three vertices is double dominated by $S \cap V(G_{n-3})$ in $G_{n-3}$. And in $V(G_{i-1})$ ($i = n-3, n-4, \cdots, 2, 1$), $|N_{G_{i-1}}[v_i] \cap (S \cap V(G_{i-1}))| = 2$. It means that each vertex of $G$ is double dominated by $S$. \hfill $\square$

Based on the above theorem, we have that the following conclusion.

**Corollary 3.3** Let $G$ be a maximal outerplanar graph of order $n \geq 3$, then $\gamma_{x2}(G) \leq \lceil \frac{2n}{3} \rceil$. 

3
In order to show that this bound is tight. We are ready to construct an infinite family of graphs as follows. Let $H$ be any maximal outerplanar graph, and $C = a_1a_2 \cdots a_{2k-1}a_{2k}a_1$ is the unique Hamiltonian cycle of $H$. We note that $C$ is the boundary of the outer face of $H$. Let $G_H$ be the graph obtained from $H$ by adding $k$ new vertices $u_1, u_2, \cdots, u_k$ and $2k$ new edges $u_1a_1, u_1a_2, u_2a_3, u_2a_4, \cdots, u_k a_{2k-1}, u_k a_{2k}$ (see Fig.1, the non-triangular face can be triangulated in any way so as to obtain a maximal outerplanar graph). Let $\mathcal{H}$ be a family consisting of all such graphs $G_H$. Take a $\gamma_{\times 2}$-set of $G_H$, say $S$. Let $v$ be a vertex of degree two in $G_H$, it is easy to see that $|N_{G_H}[v] \cap S| \geq 2$. It means that $|S| \geq 2k = \frac{2|G_H|}{3}$. On the other hand, it follows from Corollary 3.3 that $|S| \leq \frac{2|G_H|}{3}$. Hence, $\gamma_{\times 2}(G_H) = \frac{2|G_H|}{3}$.

![Fig.1](image)

But the result of Corollary 3.3 is still not good enough, it only slightly improves Observation 3.1, so we hope to further improve the result of Corollary 3.3. Next, we will give two upper bounds in terms of the order and the number of 2-degree vertices, and the first one is inspired by [18].

**Lemma 3.4 ([18])** A maximal outerplanar graph $G$ can be 4-colored such that every cycle of length 4 in $G$ has all four colors.

**Theorem 3.5** Let $G$ be a maximal outerplanar graph of order $n \geq 3$. If $t$ is the number of vertices of degree 2 in $G$, then $\gamma_{\times 2}(G) \leq \left\lfloor \frac{n+1}{2} \right\rfloor$.

**Proof.** Let $R = \{a_1, a_2, \cdots, a_t\}$ be the set of vertices of $G$ having degree 2. For each $a_i$, let $b_i$ be one of its neighbors. We construct a graph $G'$ from $G$ by adding $t$ new vertices $u_1, u_2, \cdots, u_t$, and $2t$ new edges $a_1u_1, b_1u_1, a_2u_2, b_2u_2, \cdots, a_tu_t, b_tu_t$. Note that $G'$ is also a maximal outerplanar graph. By Lemma 3.4, $G'$ can be 4-colored such that every cycle of length 4 in $G'$ has all four colors. Let $V_p$ be the set of vertices assigned color $p$, where $p = 1, 2, 3, 4$. Choosing two suitable color classes, say $V_1$ and $V_2$, such that $|V_1| + |V_2| \leq \left\lfloor \frac{n+1}{2} \right\rfloor$. Let $D = V_1 \cup V_2$.

Let $D \cap \{u_1, u_2, \cdots, u_t\} = \{u'_1, u'_2, \cdots, u'_k\}$, where $k \leq t$. For any $u'_i$, at least one of its neighbors, say $v_i$, does not belong to $D$. We construct a new set $D' = (D \setminus \{u'_1, u'_2, \cdots, u'_k\}) \cup \{v_1, v_2, \cdots, v_k\}$.
Now, for any vertex $x$ of $G'$ of degree at least 3. Let $x_1, x_2$ and $x_3$ be consecutive vertices of $N_{G'}(x)$ in this order. Clearly, $x_1x_2x_3$ forms a cycle of length 4, and two of $\{x, x_1, x_2, x_3\}$ belong to $D$. Since there is at most one vertex of degree two in $\{x, x_1, x_2, x_3\}$, at least two of those vertices of degree at least three belong to $D'$. It means that $x$ is double dominated by $D'$. And then, $D'$ is a double dominating set of $G$. □

On the other hand, for a maximal outerplanar graph $G$ of order at least four, it is easy to see that all vertices of $G$ of degree at least three form a double dominating set of $G$. Hence we have the following conclusion.

**Observation 3.6** Let $G$ be a maximal outerplanar graph of order $n \geq 4$. If $t$ is the number of vertices of degree 2 in $G$, then $\gamma_{x^2}(G) \leq n - t$.

Clearly, each graph of $\mathcal{Y}$ achieves equalities in Theorem 3.5 and Observation 3.6. That is, the bounds of Theorem 3.5 and Observation 3.6 are also tight. The following conclusion is immediate from Theorem 3.5 and Observation 3.6.

**Corollary 3.7** Let $G$ be a maximal outerplanar graph of order $n \geq 4$. If $t$ is the number of vertices of degree 2 in $G$, then

$$\gamma_{x^2}(G) \leq \begin{cases} \left\lfloor \frac{n+t}{2} \right\rfloor, & \text{if } t < \frac{n}{3}; \\ n-t, & \text{otherwise} \end{cases}$$

Next, we compare the bound in Corollary 3.3 with that in Corollary 3.7. From Proposition 2.2, we know that there are at most $\frac{n}{2}$ vertices of degree 2 in a maximal outerplanar graph. It is easy to see that $\left\lfloor \frac{n+t}{2} \right\rfloor < \left\lfloor \frac{n}{3} \right\rfloor$ when $t < \frac{n}{3}$, and $n - t < \left\lfloor \frac{n}{3} \right\rfloor$ when $\frac{n}{3} < t \leq \frac{n}{2}$. Thus, the bound in Corollary 3.7 is better than that in Corollary 3.3.

Based on the above analysis, it is natural to consider the following question: can the upper bound for Corollary 3.7 be improved for the striped maximal outerplanar graph? From the above result, we know that $\left\lfloor \frac{n+t}{2} \right\rfloor < n - t$ when $t$ is far less than $n$. Then combining Proposition 2.1, we have the following.

**Corollary 3.8** Let $G$ be a striped maximal outerplanar graph with $n \geq 3$ vertices. Then, $\gamma_{x^2}(G) \leq \left\lceil \frac{n}{2} \right\rceil + 1$.

Next, we construct a striped maximal outerplanar graph $G$ of order $n \geq 6$. Let $C = a_1a_2\cdots a_{q-1}a_qb_qb_{q-1}\cdots b_2b_1a_1$ is the unique Hamiltonian cycle of $G$, where $q \equiv 1 (\mod 4)$ or $q \equiv 3 (\mod 4)$. We know that $C$ is the boundary of the outer face of $G$. Let $E_1 = \{a_2b_2, a_3b_3, \cdots, a_{q-1}b_{q-1}\}$, $E(G) = E(C) \cup E_1 \cup \{a_1b_2, a_2b_3, a_4b_3, a_5b_4, a_6b_6, a_8b_7, a_9b_8, \cdots, a_{q-4}b_{q-4}, a_{q-3}b_{q-3}, a_{q-1}b_{q-2}, a_qb_{q-1}\}$ when $q \equiv 1 (\mod 4)$; and $E(G) = E(C) \cup E_1 \cup \{a_1b_2, a_2b_3, a_4b_3, a_5b_6, a_6b_7, a_8b_8, \cdots, a_{q-4}b_{q-4}, a_{q-3}b_{q-3}, a_{q-2}b_{q-2}, a_qb_{q-1}, a_{q-1}b_q\}$ when $q \equiv 3 (\mod 4)$ (see Fig.2). Note that $|G| \equiv 2 (\mod 4)$. Let $\mathcal{A}$ be a family consisting of all such graph $G$. We will show that each graph of $\mathcal{A}$ attains the bound of Corollary 3.8.
Theorem 3.9 If a striped maximal outerplanar graph $G$ belongs to $\mathcal{A}$, then $\gamma_{\times 2}(G) = \frac{|G|}{2} + 1$.

Proof. If $n = 6$, the result holds. This establishes the base cases. So we let $n \geq 10$ (Note that $n \equiv 2(mod 4)$). Assume that $G$ is a striped maximal outerplanar graph of $\mathcal{A}$ with minimum order, such that $\gamma_{\times 2}(G) < \frac{|G|}{2} + 1$. 
Let $C = a_1 a_2 \cdots a_{q-1} a_q b_q b_{q-1} \cdots b_2 b_1 a_1$ be the unique Hamiltonian cycle of $G$, and $S$ be a $\gamma_{x2}$-set of $G$. We know that $G$ has exactly two vertices of degree two, without loss of generality, suppose that $a_q$ is one of them. Clearly, $|N[a_q] \cap S| \geq 2$, and $S_1 = (S \setminus N[a_q]) \cup \{a_{q-1}, b_q\}$ is still a $\gamma_{x2}$-set of $G$. Moreover, $|N[b_{q-2}] \cap S_1| \geq 2$, and $S_2 = (S_1 \setminus N[b_{q-2}]) \cup \{a_{q-2}, b_{q-3}\}$ is also a $\gamma_{x2}$-set of $G$.

Let $G' = G - \{a_{q-1}, b_{q-1}, a_q, b_q\}$ (see Fig.3). Note that $G'$ is also a striped maximal outerplanar graph which belongs to $\mathcal{A}$, and $S_2 \setminus \{a_{q-1}, b_q\}$ is a double dominating set of $G'$. Thus, $\gamma_{x2}(G') \leq \gamma_{x2}(G) - 2 < \frac{|G|}{2} - 1 = \frac{|G'|+4}{2} - 1 = \frac{|G'|}{2} + 1$. It contradicts the assumption that $\gamma_{x2}(G') = \frac{|G'|}{2} + 1$. \hfill $\square$

From the above result, we know that Corollary 3.8 is tight for striped maximal outerplanar graphs.
