

USUBA'S PRINCIPLE UB_λ CAN FAIL AT SINGULAR CARDINALS

MOHAMMAD GOLSHANI AND SAHARON SHELAH

ABSTRACT. We answer a question of Usuba by showing that the combinatorial principle UB_λ can fail at a singular cardinal. Furthermore, λ can be taken to be \aleph_ω .

§ 1. INTRODUCTION

In [4], Usuba introduced a new combinatorial principle, denoted UB_λ .¹ He showed that UB_λ holds for all regular uncountable cardinals and that for singular cardinals, some very weak assumptions like weak square or even ADS_λ imply it. It is known that ADS_λ can fail for singular cardinals, for example if κ is supercompact and $\lambda > \kappa$ is such that $cf(\lambda) < \kappa$. Motivated by this results, Usuba asked the following question:

Question 1.1. ([4, Question 2.11]) Is it consistent that UB_λ fails for some singular cardinal λ ?

In this paper we give a positive answer to the above question by showing that Chang's transfer principle $(\aleph_{\omega+1}, \aleph_\omega) \rightarrow (\aleph_1, \aleph_0)$ implies the failure of UB_{\aleph_ω} , see Theorem 3.1, where a stronger result is proved.

The paper is organized as follows. In Section 2, we present some preliminaries and results and then in Section 3, we prove our main result.

2020 *Mathematics Subject Classification.* Primary:03E05, 03E55 .

Key words and phrases. Usuba's question, singular cardinals, Chang's conjecture.

¹See Section 2 for the statement of the principle.

§ 2. SOME PRELIMINARIES

In this section we proved some definitions and results that are needed for later section of this paper. Let us start by giving a definition of Usuba's principle.

Definition 2.1. Let λ be an uncountable cardinal. The principle UB_λ is the statement: there exists a function $f : [\lambda^+]^{<\omega} \rightarrow \lambda^+$ such that if $x, y \subseteq \lambda^+$ are closed under f , $x \cap \lambda = y \cap \lambda$ and $\sup(x \cap \lambda) = \lambda$, then $x \subseteq y$ or $y \subseteq x$.

It turned out this principle has many equivalent formulations. To state a few of it, let $S = \{x \subseteq \lambda : \sup(x) = \lambda\}$, $\theta > \lambda$ be large enough regular and let \triangleleft be a well-ordering of $H(\theta)$. Then the following are equivalent (see [4]):

- (1) UB_λ ,
- (2) If $M, N \prec (H(\theta), \in, \triangleleft, \lambda, S, \dots)$ are such that $M \cap \lambda = N \cap \lambda \in S$, then either $M \cap \lambda^+ \subseteq N \cap \lambda^+$ or $N \cap \lambda^+ \subseteq M \cap \lambda^+$,
- (3) If $M, N \prec (H(\theta), \in, \triangleleft, \lambda, S, \dots)$ are such that $M \cap \lambda = N \cap \lambda \in S$, and $\sup(M \cap \lambda^+) \leq \sup(N \cap \lambda^+)$, then $M \cap \lambda^+$ is an initial segment of $N \cap \lambda^+$.

The principle UB_λ has many nice implications. Here we only consider its relation with Chang transfer principles which is also related to our work.

Definition 2.2. Suppose $\lambda > \mu$ are infinite cardinal. The Chang's transfer principle $(\lambda^+, \lambda) \rightarrow (\mu^+, \mu)$ is the statement: if \mathcal{L} is a countable first order language which contains a unary predicate U , then for any \mathcal{L} -structure $\mathcal{M} = (M, U^{\mathcal{M}}, \dots)$ with $|M| = \lambda^+$ and $|U^{\mathcal{M}}| = \lambda$, there exists an elementary submodel $\mathcal{N} = (N, U^{\mathcal{N}}, \dots)$ of \mathcal{M} with $|N| = \mu^+$ and $|U^{\mathcal{N}}| = \mu$.

The next lemma shows the relation between UB_{\aleph_ω} and Chang's transfer principles.

Lemma 2.3. ([4, Corollary 4.2]) *Suppose UB_{\aleph_ω} holds. Then the Chang transfer principles $(\aleph_{\omega+1}, \aleph_\omega) \rightarrow (\aleph_{n+1}, \aleph_n)$ fail for all $1 \leq n < \omega$.*

Since the consistency of the transfer principle $(\aleph_{\omega+1}, \aleph_\omega) \rightarrow (\aleph_{n+1}, \aleph_n)$ is open for $n \geq 1$, one can not use the above result to get the consistent failure of UB_{\aleph_ω} .

In the next section we show that UB_{\aleph_ω} implies the failure of $(\aleph_{\omega+1}, \aleph_\omega) \rightarrow (\aleph_1, \aleph_0)$ as well, and hence by the results of [3] (see also [1] and [2], where the consistency of $(\aleph_{\omega+1}, \aleph_\omega) \rightarrow (\aleph_1, \aleph_0)$ is proved using weaker large cardinal assumptions) UB_{\aleph_ω} can fail. We also need the following notion.

Definition 2.4. An uncountable cardinal κ is said to be Jonsson, if for every function $f : [\kappa]^{<\omega} \rightarrow \kappa$ there exists a set $H \subseteq \kappa$ of order type κ such that for each n , $f''[H]^n \neq \kappa$.

§ 3. UB_λ CAN FAIL AT SINGULAR CARDINALS

In this section we prove the following theorem which answers Usuba's question 1.1.

Theorem 3.1. UB_λ fails if at least one of the following hold:

- (a) $\lambda = \aleph_\omega$ and the Chang's transfer principle $(\lambda^+, \lambda) \rightarrow (\aleph_1, \aleph_0)$ holds,
- (b) $\lambda > \mu \geq \text{cf}(\mu)$ are such that $(\lambda^+, \lambda) \rightarrow (\mu^+, \mu)$ holds,
- (c) $\lambda > \mu \geq \text{cf}(\lambda)$ and for every model M with universe λ^+ and vocabulary of cardinality $\text{cf}(\lambda)$, we can find a sequence $\vec{\alpha} = \langle \alpha_i : i < \mu^+ \rangle$ of ordinals less than λ such that

$$S_{\vec{\alpha}}^M = \{i < \mu^+ : \text{cl}(\{\alpha_i\}, M) \cap \lambda \subseteq \text{cl}(\{\alpha_j : j < i\}, M)\}$$

is stationary in μ^+

- (d) there exists χ with $\lambda > \chi = \text{cf}(\chi) > \text{cf}(\lambda)$ such that for every model M with universe λ^+ and vocabulary of cardinality $\text{cf}(\lambda)$, we can find a sequence $\vec{\alpha} = \langle \alpha_i : i < \chi \rangle$ of ordinals less than λ such that

$$S_{\vec{\alpha}}^M = \{i < \chi : \text{cl}(\{\alpha_i\}, M) \cap \lambda \subseteq \text{cl}(\{\alpha_j : j < i\}, M)\}$$

is stationary in χ

- (e) there is no sequence $\vec{X} = \langle U_i : i < \lambda^+ \rangle$ of cofinal subsets $U_i \subseteq [\lambda]^{\text{cf}(\lambda)}$ such that for every $i < \lambda^+$ there is a sequence $\vec{X}_i = \langle (\alpha_{i,j}, \beta_{i,j}) : j < i \rangle$ such that:

- \vec{X}_i has no repetition,

- $\alpha_{i,j} \in U_i$,
- $\beta_{i,j} \in U_j$,

Furthermore, the statement (e) is equivalent to $\neg\text{UB}_\lambda$, provided that $\text{cf}(\lambda)$ is not a Jonsson cardinal.

Remark 3.2. Given a model M as in (c) and a subset A of M , by $\text{cl}(A, M)$ we mean the least substructure of M which includes A as a subset.

Proof. We prove the theorem is a sequence of claims. First note that (a) is a special case of (b) and that (c) implies (d).

Claim 3.3. (b) implies (c)

Proof. Let M be a model with universe λ^+ and vocabulary of cardinality at most $\text{cf}(\lambda)$. By (b), there exists an elementary submodel $N \prec M$ such that $\|N\| = \mu^+$ and $|N \cap \lambda| = \mu$. Let $\vec{\alpha} = \langle \alpha_i : i < \mu^+ \rangle$ list in increasing order the first μ^+ elements of N . So for $i < \mu^+$ we have

$$\text{cl}(\{\alpha_i\}, M) \cap \lambda \subseteq N \cap \lambda,$$

and since $N \cap \lambda$ has size μ , we can find some $i(*) < \mu^+$ such that

$$\forall i < \mu^+, \text{cl}(\{\alpha_i\}, M) \cap \lambda \subseteq \bigcup_{j < i(*)} \text{cl}(\{\alpha_i\}, N).$$

Hence the set $S_{\vec{\alpha}}^M$ includes $[i(*), \mu^+)$ and so is stationary in μ^+ , as requested. \square

Claim 3.4. (d) implies (e).

Proof. Suppose towards a contradiction that (d) holds but (e) fails. As (e) fails, we can find sequences $\vec{X} = \langle U_i : i < \lambda^+ \rangle$ and $\vec{X}_i = \langle (\alpha_{i,j}, \beta_{i,j}) : j < i \rangle$ as in clause (e). Let M be a model in a vocabulary \mathcal{L} such that:

- (1) $|\mathcal{L}| = \text{cf}(\lambda)$,
- (2) M has universe λ^+ ,
- (3) $M = (\lambda^+, \langle \tau_i^M : i < \text{cf}(\lambda) \rangle, F^M, G^M, H^M)$, where
 - (a) $\tau_i^M = i$,

- (b) F^M is a unary function which maps $\text{cf}(\lambda)$ to an unbounded subset of λ ,
- (c) G^M is a 3-place function such that for all $j < i$, $G^M(i, \alpha_{j,i}, \beta_{j,i}) = j$,
- (d) H^M is a 2-place function such that for all i , $U_i = \langle H^M(i, \alpha) : \alpha < \text{cf}(\lambda) \rangle$.

Now by (d) applied to the model M , we can find a sequence $\vec{\zeta} = \langle \zeta_i : i < \chi \rangle$ of ordinals less than λ such that the set $S_{\vec{\zeta}}^M$ is stationary in χ . Let $\zeta = \sup_{i < \chi} \zeta_i$.

Consider the sequence $\vec{X}_\zeta = \langle \langle \alpha_{\zeta, \xi}, \beta_{\zeta, \xi} \rangle : \xi < \zeta \rangle$.

As $\chi = \text{cf}(\chi) > \text{cf}(\lambda) \geq |\text{cl}(\{\zeta\}, M)|$, for some β_* and some stationary set $U \subseteq S_{\vec{\zeta}}^M$,

$$i \in U \implies \beta_{\zeta_i, \zeta} = \beta_*.$$

For $i < \chi$ let

$$W_i = \{\lambda \cap \text{cl}(\{\zeta_j\}, M) : j < i\}.$$

So $\langle W_i : i < \chi \rangle$ is a \subseteq -increasing and continuous sequence of sets each of cardinality $< \chi$. We get some $i_i < i_2$ in U such that $\alpha_{\zeta_{i_1}, \zeta} = \alpha_{\zeta_{i_2}, \zeta}$, and we get a contradiction to the choice of \vec{X}_ζ . \square

Claim 3.5. (e) implies $\neg UB_\lambda$.

Proof. Suppose not. Thus we can assume that both (e) and UB_λ hold. Let $f : [\lambda^+]^{<\omega} \rightarrow \lambda^+$ witness UB_λ . Choose a vocabulary \mathcal{L} of size $\text{cf}(\lambda)$ and an \mathcal{L} -model M such that:

- (1) M has universe λ^+ ,
- (2) $M = (\lambda^+, \langle \tau_i^M : i < \text{cf}(\lambda) \rangle, F^M, \langle F_n^M : n < \omega \rangle, p^M)$
 - (a) $\tau_i^M = i$,
 - (b) F^M is a unary function which maps $\text{cf}(\lambda)$ to an unbounded subset of λ ,
 - (c) F_n^M is an n -ary function such that

$$F_n^M(\alpha_0, \dots, \alpha_{n-1}) = f(\{\alpha_0, \dots, \alpha_{n-1}\}),$$

- (d) p^M is a pairing function on λ^+ ,

For $\alpha < \lambda$, set $N_\alpha = cl(\{\alpha\}, M)$.

(*)₁ N_α belongs to $[\lambda^+]^{cf(\lambda)}$ and it contains an unbounded subset of λ .

Proof. As \mathcal{L} has size $cf(\lambda)$, so $|N_\alpha| \leq cf(\lambda)$. On the other hand by clause (2)(a), $cf(\lambda) \subseteq N_\alpha$ and hence N_α belongs to $[\lambda^+]^{cf(\lambda)}$. As $N_\alpha \supseteq cf(\lambda)$, $range(F^M) \subseteq N_\alpha$, and thus by clause (2)(b), N_α contains an unbounded subset of λ . \square

Let

$$E = \{\delta \in (\lambda, \lambda^+) : \delta = cl(\delta, M)\}.$$

E is clearly a club of λ^+ and $E \cap \lambda = \emptyset$.

(*)₂ Suppose $\xi < \zeta$ are in E . Then

$$\xi \in cl(\{\xi\} \cup (N_\xi \cap \lambda) \cup (N_\zeta \cap \lambda), M).$$

Proof. Let $V = (N_\xi \cap \lambda) \cup (N_\zeta \cap \lambda)$, $X = cl(\{\xi\} \cup V, M)$ and $Y = cl(\{\zeta\} \cup V, M)$. Thus X and Y are f -closed subsets of λ^+ , $\xi \in X$ and $\zeta \in Y$. Furthermore, by the choice of $\zeta \in E$, we have $\zeta \notin X$. By UB_λ it follows that $X \subseteq Y$, and hence $\xi \in Y$, which gives the result. \square

Let $\langle \sigma_i(x_0, \dots, x_{n(i)-1}) : i < cf(\lambda) \rangle$ list all terms of \mathcal{L} . By (*)₂, for each $\xi < \zeta$ from E , we can choose some $i(\xi, \zeta) < cf(\lambda)$ together with sequences $\vec{a}_{\xi, \zeta} \in (N_\xi \cap \lambda)^{<\omega}$ and $\vec{b}_{\xi, \zeta} \in (N_\zeta \cap \lambda)^{<\omega}$ such that

$$\xi = \sigma_{i(\xi, \zeta)}(\xi, \vec{a}_{\xi, \zeta}, \vec{b}_{\xi, \zeta}).$$

For $\xi \in E$ set $u_\xi = N_\xi \cap \min(E)$. It follows that $u_\xi = cl(u_\xi, M)$. For $\xi < \zeta$ use the pairing function p^M to find $\alpha_{\xi, \zeta}$ and $\beta_{\xi, \zeta}$ such that $\alpha_{\xi, \zeta}$ codes $\langle i(\xi, \zeta) \rangle \frown \vec{a}_{\xi, \zeta}$ and $\beta_{\xi, \zeta}$ codes $\langle i(\xi, \zeta) \rangle \frown \vec{b}_{\xi, \zeta}$.

Now the sequences $\vec{X} = \langle U_x i : \xi \in E \rangle$ and $\langle \langle (\alpha_{\xi, \zeta}, \beta_{\xi, \zeta}) : \xi \in \zeta \cap E \rangle : \zeta \in E$ witness the failure of (e). We get a contradiction and the claim follows. \square

Thus so far we have shown that

$$(a) \implies (b) \implies (c) \implies (d) \implies (e) \implies \neg UB_\lambda.$$

Now suppose that in (e), $cf(\lambda)$ is not a Jonsson cardinal and we show that $\neg UB_\lambda$ also implies (e). Thus suppose towards a contradiction that (e) fails and let \vec{X}

and $\langle \vec{X}_i : i < \lambda^+ \rangle$ as in clause (e) witness this failure. Let $\langle \lambda_i : i < \text{cf}(\lambda) \rangle$ be an increasing sequence cofinal in λ and define the function $c : \lambda \rightarrow \text{cf}(\lambda)$ as

$$c(\alpha) = \min\{i < \text{cf}(\lambda) : \alpha < \kappa_i\}.$$

For $\xi < \lambda^+$ let $\langle \gamma_{\xi,i} : i < \text{cf}(\lambda) \rangle$ enumerate U_ξ . Let $f : [\lambda^+]^{<\omega} \rightarrow \lambda^+$ be such that:

- (1) if $\xi < \zeta < \lambda^+$, then

$$f(\alpha_{\xi,\zeta}, \beta_{\xi,\zeta}, \xi) = \xi,$$

- (2) if $\zeta < \lambda^+$ and $\xi < \text{cf}(\lambda)$, then for arbitrary large $j < \text{cf}(\lambda)$, we have

$$\sup_{i < j} \lambda_i < \alpha \implies f(\alpha, \zeta) = \gamma_{\zeta,j}.$$

- (3) if $A \in [\text{cf}(\lambda)]^{\text{cf}(\lambda)}$, $c(\alpha_i) = i$ for $i \in A$ and $j < \text{cf}(\lambda)$, then for some n and some sequence $\vec{\xi} = \langle \xi_0, \dots, \xi_{n-1} \rangle \in A^n$, we have

$$j = c(f(\alpha_{\xi_0}, \dots, \alpha_{\xi_{n-1}})).$$

Since $\text{cf}(\lambda)$ is not a Jonsson cardinal, we can define such a function f^2 . Then f witnesses that UB_λ holds, which contradicts our assumption. This completes the proof of the theorem. \square

Remark 3.6. The above proof shows that the following are equivalent:

- (1) clause (e) of Theorem 3.1,
- (2) for each model M with universe λ^+ and vocabulary of cardinality $\text{cf}(\lambda)$, there are substructures N_0, N_1 of M such that $N_0 \cap \lambda = N_1 \cap \lambda$, $N_0 \not\subseteq N_1$ and $N_1 \not\subseteq N_0$.

As we noticed earlier, it is consistent relative to the existence of large cardinals that Chang's transfer principle $(\aleph_{\omega+1}, \aleph_\omega) \rightarrow (\aleph_1, \aleph_0)$ holds. Hence by our main theorem, we have the following corollary.

Corollary 3.7. *It is consistent, relative to the existence of large cardinals, that UB_{\aleph_ω} fails.*

²this assumption is used to guarantee clause (3) in definition of f holds.
