Global behavior of positive solutions
of a third order difference equations system

Abstract

In this paper, we consider the following system of difference equations
\[ x_{n+1} = \alpha + \frac{y_n^p}{y_{n-2}^p}, \quad y_{n+1} = \alpha + \frac{x_n^q}{x_{n-2}^q}, \quad n = 0, 1, 2, \ldots \]
where parameters \( \alpha, p, q \in (0, \infty) \) and the initial values \( x_{-i}, y_{-i} \) are arbitrary positive numbers for \( i = -2, -1, 0 \). Our main aim is to investigate semi-cycle analysis of solutions of above system. Also, we study the boundedness of the positive solutions and the global asymptotic stability of the equilibrium point in case \( \alpha > 1, 0 < p, q \leq 1 \). Moreover, the rate of convergence of the solutions is established. Finally, some numerical examples are given to illustrate our theoretical results.

Mathematics Subject Classification: 39A10.
Keywords: Semi-cycle, equilibrium, boundedness, global asymptotic stability, rate of convergence.

1 Introduction and preliminaries

Recently, nonlinear difference equations and systems are of wide interest due to their applications in real life. Such equations appear naturally as the mathematical models which describe biological, physical and economical phenomena. Although difference equations have very simple forms, however, it is extremely
difficult to understand completely the global behavior of their solutions.

In [1], Camouzis and Papaschinopoulos studied the boundedness, persistence and the global behavior of the positive solutions of the following system

\[
x_{n+1} = 1 + \frac{x_n}{y_{n-m}}, \quad y_{n+1} = 1 + \frac{y_n}{x_{n-m}}, \quad n = 0, 1, \ldots
\]

where \(x_i, y_i\) are positive numbers for \(i = -m, -m + 1, \ldots, 0\) and \(m\) is a positive integer.

In [16], Zhang et al. investigated the boundedness, persistence and global asymptotic stability of positive solutions of the system of two nonlinear difference equations

\[
x_{n+1} = A + \frac{x_{n-m}}{y_n}, \quad y_{n+1} = B + \frac{y_{n-m}}{x_n}, \quad n = 0, 1, \ldots
\]

where \(A, B, x_i, y_i \in (0, \infty)\) for \(i = -m, -m + 1, \ldots, 0\) and \(m \in \mathbb{Z}^+\).

In [6], Gümüş examined the global asymptotic stability of the unique positive equilibrium point and the rate of convergence of positive solutions of the system of two recursive sequences

\[
x_{n+1} = A + \frac{y_{n-m}}{y_n}, \quad y_{n+1} = A + \frac{x_{n-m}}{x_n}, \quad n = 0, 1, \ldots
\]

where \(A \in (0, \infty), x_i, y_i\) are arbitrary positive numbers for \(i = -m, -m + 1, \ldots, 0\) and \(m \in \mathbb{Z}^+\).

In [13], Taşdemir studied the global asymptotic stability of following system of difference equations with quadratic terms

\[
x_{n+1} = A + B \frac{y_n}{y_{n-1}^2}, \quad y_{n+1} = A + B \frac{x_n}{x_{n-1}^2}, \quad n = 0, 1, \ldots
\]

where \(A\) and \(B\) are positive numbers and the initial values \(x_i, y_i\), are positive numbers for \(i = -1, 0\).

In this paper, motivated by all above mentioned systems we consider the following system of difference equations

\[
x_{n+1} = \alpha + \frac{y_n^p}{y_{n-2}}, \quad y_{n+1} = \alpha + \frac{x_n^q}{x_{n-2}^q}, \quad n = 0, 1, 2, \ldots \tag{1.1}
\]

where \(\alpha, p, q \in (0, \infty)\) and the initial values \(x_{-i}, y_{-i} \in (0, \infty), i = -2, -1, 0\). More precisely, we investigate semi-cycle analysis of solutions of (1.1). In addition, we study the boundedness of the positive solutions and the global
asymptotic stability of the unique equilibrium point in case $\alpha > 1$, $0 < p$, $q \leq 1$. Furthermore, we examine the rate of convergence of the solutions of (1.1). Finally, some numerical examples are given to verify our theoretical results.

We now present some definitions and known theorems which will be used in this paper.

Let $I$ be some interval of real numbers and let

$$ f, g : I \times I \rightarrow I \tag{1.2} $$

be continuously differentiable functions. Then, the system of difference equations

$$ x_{n+1} = f(y_n, y_{n-2}), \quad y_{n+1} = g(x_n, x_{n-2}), \quad n = 0, 1, 2, \ldots, \tag{1.3} $$

has a unique solution $\{(x_n, y_n)\}_{n=1}^{\infty}$ corresponds to initial values $(x_k, y_k) \in I \times I$ for $k = -2, -1, 0$.

**Definition 1.1.** (see, [14]) A point $(\bar{x}, \bar{y})$ is called an equilibrium point of the system (1.3) if

$$ \bar{x} = f(\bar{y}, \bar{y}), \quad \bar{y} = g(\bar{x}, \bar{x}). \tag{1.4} $$

It is easy to see that the system (1.1) has an unique positive equilibrium point $(\bar{x}, \bar{y}) = (\alpha + 1, \alpha + 1)$.

**Definition 1.2.** (see, [17]) Let $(\bar{x}, \bar{y})$ be a positive equilibrium point of the system (1.3).

A "string" of consecutive terms $\{x_s, \ldots, x_m\}$ (resp., $\{y_s, \ldots, y_m\}$), $s \geq -2$, $m \leq \infty$ is said to be a positive semi-cycle if $x_i \geq \bar{x}$ (resp., $y_i \geq \bar{y}$), $i \in \{s, \ldots, m\}$, $x_{s-1} < \bar{x}$ (resp., $y_{s-1} < \bar{y}$), and $x_{m+1} < \bar{x}$ (resp., $y_{m+1} < \bar{y}$).

A "string" of consecutive terms $\{x_s, \ldots, x_m\}$ (resp., $\{y_s, \ldots, y_m\}$), $s \geq -2$, $m \leq \infty$ is said to be a negative semi-cycle if $x_i < \bar{x}$ (resp., $y_i < \bar{y}$), $i \in \{s, \ldots, m\}$, $x_{s-1} \geq \bar{x}$ (resp., $y_{s-1} \geq \bar{y}$), and $x_{m+1} \geq \bar{x}$ (resp., $y_{m+1} \geq \bar{y}$).

A "string" of consecutive terms $\{(x_s, y_s), \ldots, (x_m, y_m)\}$ is said to be a positive semi-cycle (resp., negative semi-cycle) if both $\{x_s, \ldots, x_m\}$ and $\{y_s, \ldots, y_m\}$ are positive semi-cycles (resp., negative semi-cycles).

**Definition 1.3.** (see, [17]) Let $(\bar{x}, \bar{y})$ be a positive equilibrium point of the system (1.3).
A sequence \( x_n \) (resp., \( y_n \)) is said to oscillate about \( \bar{x} \) (resp., \( \bar{y} \)) if for every \( n_0 \in \mathbb{N} \) there exist \( l, m \in \mathbb{N}, l \geq n_0, m \geq n_0 \) such that
\[
(x_l - \bar{x})(x_m - \bar{x}) \leq 0 \quad \text{(resp.,} \quad (y_l - \bar{y})(y_m - \bar{y}) \leq 0).
\]
We say that a solution \( \{(x_n, y_n)\} \) of system (1.3) oscillates about \( (\bar{x}, \bar{y}) \) if \( x_n \) oscillates about \( \bar{x} \) or \( y_n \) oscillates about \( \bar{y} \).

**Definition 1.4.** (see, [7]) Let \( (\bar{x}, \bar{y}) \) be an equilibrium point of a map \( F = (f, g) \), where \( f \) and \( g \) are continuously differentiable functions at \( (\bar{x}, \bar{y}) \). The linearized system of (1.1) about the equilibrium point \( (\bar{x}, \bar{y}) \) is
\[
X_{n+1} = F(X_n) = AX_n,
\]
where \( X_n = (x_n, x_{n-1}, x_{n-2}, y_n, y_{n-1}, y_{n-2})^T \) and \( A \) is a Jacobian matrix of the system (1.1) about the equilibrium point \( (\bar{x}, \bar{y}) \).

**Theorem 1.1.** (see, [7]) For the system \( X_{n+1} = F(X_n), \ n = 0, 1, \ldots, \) of difference equations such that \( \bar{X} \) is a fixed point of \( F \). If all the eigenvalues of the Jacobian matrix \( A \) about \( \bar{X} \) lie inside the open unit disk \( |\lambda| < 1 \), then \( \bar{X} \) is locally asymptotically stable. If one of them has a modulus greater than one, then \( \bar{X} \) is unstable.

Some related systems of difference equations can be found in [15]-[12]. More results concerning difference equations and their systems are included in [7, 4, 5].

## 2 Semi-cycle analysis of (1.1)

In this section, we study the behavior of positive solutions of system (1.1) by using semi-cycle analysis. It is clearly that system (1.1) has a unique positive equilibrium point \( (\bar{x}, \bar{y}) = (\alpha + 1, \alpha + 1) \).

**Lemma 2.1.** Assume that \( \{(x_n, y_n)\}_{n=-2}^\infty \) is a solution of the system (1.1). Then, either \( \{(x_n, y_n)\}_{n=-2}^\infty \) is non-oscillatory or it oscillates about the equilibrium \( (\bar{x}, \bar{y}) = (\alpha + 1, \alpha + 1) \) with semi-cycles that if there exists a semi-cycle with at least two terms, then every consecutive semi-cycle has at least three terms.
Proof. Suppose that \(\{(x_n, y_n)\}_{n=-2}^{\infty}\) is a solution of the system (1.1), and there exists \(n_0 \geq 0\) such that \((x_{n_0}, y_{n_0})\) is the final term of a semi-cycle that has at least two terms. Then, the following two cases can be occurred.

**Case 1:** \(\ldots, x_{n_0-1}, x_{n_0} < \alpha + 1 \leq x_{n_0+1}\) and \(\ldots, y_{n_0-1}, y_{n_0} < \alpha + 1 \leq y_{n_0+1}\).

**Case 2:** \(\ldots, x_{n_0-1}, x_{n_0} \geq \alpha + 1 > x_{n_0+1}\) and \(\ldots, y_{n_0-1}, y_{n_0} \geq \alpha + 1 > y_{n_0+1}\).

We now examine the first case, the second case is similar and will be neglected.

Assume that \(\ldots, x_{n_0-1}, x_{n_0} < \alpha + 1 \leq x_{n_0+1}\) and \(\ldots, y_{n_0-1}, y_{n_0} < \alpha + 1 \leq y_{n_0+1}\).

Then, from (1.1) we obtain
\[
x_{n_0+2} = \alpha + \frac{y_{n_0+1}^p}{y_{n_0-1}^p} > \alpha + 1, \quad y_{n_0+2} = \alpha + \frac{x_{n_0+1}^q}{x_{n_0-1}^q} > \alpha + 1.
\] (2.1)

Similarly to (2.1), we have \(x_{n_0+3} > \alpha + 1\) and \(y_{n_0+3} > \alpha + 1\). Hence, the semi-cycle beginning with \((x_{n_0+1}, y_{n_0+1})\) has at least three terms. Suppose that the semi-cycle which starts with \((x_{n_0+1}, y_{n_0+1})\) has length three, then the next semi-cycle will begin with \((x_{n_0+4}, y_{n_0+4})\) such that \(x_{n_0+1}, x_{n_0+2}, x_{n_0+3} \geq \alpha + 1 > x_{n_0+4}\) and \(y_{n_0+1}, y_{n_0+2}, y_{n_0+3} \geq \alpha + 1 > y_{n_0+4}\), then
\[
x_{n_0+5} = \alpha + \frac{y_{n_0+4}^p}{y_{n_0+2}^p} < \alpha + 1, \quad y_{n_0+2} = \alpha + \frac{x_{n_0+4}^q}{x_{n_0+2}^q} < \alpha + 1.
\] (2.2)

By arguing similar to (2.2), we have \(x_{n_0+6} < \alpha + 1\) and \(y_{n_0+6} < \alpha + 1\). From above arguments, we can conclude that the semi-cycle containing \((x_{n_0+1}, y_{n_0+1})\) and every semi-cycle after that has at least three terms. The proof is completed.

Lemma 2.2. System (1.1) has no nontrivial two periodic solutions.

**Proof.** Suppose that system (1.1) has a two periodic solution. Then \((x_{n-2}, y_{n-2}) = (x_n, y_n)\), for all \(n \geq 0\). Therefore,
\[
x_{n+1} = \alpha + \frac{y_n^p}{y_{n-2}^p} = \alpha + 1, \quad y_{n+1} = \alpha + \frac{x_n^q}{x_{n-2}^q} = \alpha + 1, \text{ for all } n \geq 0.
\]

Hence, the solution \((x_n, y_n) = (\alpha + 1, \alpha + 1)\) is the equilibrium solution of system (1.1).

Lemma 2.3. If the system (1.1) has an increasing solution then it is non-oscillatory positive solution.
Proof. Assume that \( \{(x_n, y_n)\}_{n=-2}^{\infty} \) is an increasing solution of the system (1.1). Then, either \( \alpha + 1 \leq x_1 \) and \( \alpha + 1 \leq y_1 \) or \( x_1 < \alpha + 1 \) and \( y_1 < \alpha + 1 \). The first case is trivial so it will be omitted. We now consider the second case. If \( x_1 < \alpha + 1 \) and \( y_1 < \alpha + 1 \), then we can assert that the semi-cycle containing \((x_1, y_1)\) has at most three terms. Assume by contradiction that the negative semi-cycle beginning with \((x_1, y_1)\) involves \((x_4, y_4)\). Then from

\[
x_4 = \alpha + \frac{y_3^p}{y_1^p} \alpha + 1 \quad \text{and} \quad y_4 = \alpha + \frac{x_3^q}{x_1^q} \alpha + 1
\]

imply that \( y_3 < y_1 \) and \( x_3 < x_1 \) which contradicts the fact that the solution is increasing, so any increasing solution of system (1.1) is non-oscillatory positive solution.

Lemma 2.4. System (1.1) has no non-oscillatory negative solutions (has no infinite negative semi-cycle).

Proof. Assume by contradiction that system (1.1) has a non-oscillatory solution \( \{(x_n, y_n)\}_{n=-2}^{\infty} \) which has an infinite negative semi-cycle, and assume this semi-cycle begins with \((x_N, y_N)\), where \( N \geq -2 \). Then for all \( n \geq N \), \((x_n, y_n) < (\alpha + 1, \alpha + 1)\). From,

\[
x_{n+1} = \alpha + \frac{y_n^p}{y_{n-2}^p} < \alpha + 1, \quad y_{n+1} = \alpha + \frac{x_n^q}{x_{n-2}^q} < \alpha + 1, \quad \text{for all } n \geq N + 2,
\]

we imply \( y_n < y_{n-2} \) and \( x_n < x_{n-2} \). So, we have \( \alpha < x_{n+2} < x_n < x_{n-2} < \alpha + 1 \) and \( \alpha < y_{n+2} < y_n < y_{n-2} < \alpha + 1 \) for all \( n \geq N + 2 \), which means that \( \{x_n\}, \{y_n\} \) have two subsequences \( \{x_{2n}\}, \{x_{2n+1}\} \) and \( \{y_{2n}\}, \{y_{2n+1}\} \) that are decreasing and bounded from below. Hence, there exist \( a_1, a_2, b_1, b_2 \) such that

\[
\lim_{n \to \infty} x_{2n} = a_1, \quad \lim_{n \to \infty} x_{2n+1} = a_2,
\]

\[
\lim_{n \to \infty} y_{2n} = b_1, \quad \lim_{n \to \infty} y_{2n+1} = b_2.
\]

Thus, \((a_1, b_1), (a_2, b_2)\) is a periodic solution of period two of system (1.1), which contradicts Lemma 2.2 unless the solution is the trivial solution. Hence, the solution converges to the equilibrium, which is a contradiction, because the solution is diverging from the equilibrium. This proves that system (1.1) has no non-oscillatory negative solutions. \( \square \)
Lemma 2.5. System \((1.1)\) has no decreasing non-oscillatory solutions.

Proof. Assume that system \((1.1)\) has a decreasing non-oscillatory solutions. Then we have one of two following cases will be occurred.

Case 1: \(\ldots \leq x_3 \leq x_2 \leq x_1 \leq \alpha + 1\) and \(\ldots \leq y_3 \leq y_2 \leq y_1 \leq \alpha + 1\).

Case 2: There exists a positive integer \(n_0 \geq 3\), such that \(\ldots \leq x_{n_0+2} \leq x_{n_0+1} \leq \alpha + 1 \leq x_{n_0} \leq x_{n_0-1} \leq \ldots \) and \(\ldots \leq y_{n_0+2} \leq y_{n_0+1} \leq \alpha + 1 \leq y_{n_0} \leq y_{n_0-1} \leq \ldots \).

In both cases, the solution has an infinite negative semi-cycle which contradicts Lemma 2.4. Therefore, system \((1.1)\) has no decreasing non-oscillatory solutions.

3 Boundedness and persistence of system \((1.1)\)

In this section, we will examine the boundedness and persistence of system \((1.1)\) in case \(\alpha > 1\) and \(0 < p, q \leq 1\).

Theorem 3.1. Assume that \(\alpha > 1\) and \(0 < p, q \leq 1\). Then every positive solution of system \((1.1)\) is bounded and persists. In detail, we have

\[
\alpha < x_{2n+2} \leq x_2 a^n + \frac{b}{1-a}(1-a^n)
\]

and

\[
\alpha < x_{2n+3} \leq x_3 a^n + \frac{b}{1-a}(1-a^n),
\]

similarly,

\[
\alpha < y_{2n+2} \leq y_2 a^n + \frac{c}{1-a}(1-a^n)
\]

and

\[
\alpha < y_{2n+3} \leq y_3 a^n + \frac{c}{1-a}(1-a^n),
\]

for all \(n \geq 0\), where \(a = \frac{1}{\alpha^{p+q}},\ b = \alpha^{1-p} + \alpha\) and \(c = \alpha^{1-q} + \alpha\).

Proof. Assume that \(\alpha > 1\) and \(\{(x_n,y_n)\}_{n=-2}^{\infty}\) is a positive solution of the system \((1.1)\). Obviously, from \((1.1)\) we imply

\[
x_n, y_n > \alpha \text{ for all } n \geq 1. \quad (3.1)
\]
By combining (1.1) and (3.1), we obtain
\[\begin{align*}
    x_n &= \alpha + \frac{y_{n-1}^p}{y_{n-3}} < \alpha + \frac{1}{\alpha^p} y_{n-1}^p < \alpha + \frac{1}{\alpha^p} y_{n-1}, \\
y_n &= \alpha + \frac{x_{n-1}^q}{x_{n-3}^q} < \alpha + \frac{1}{\alpha^q} x_{n-1}^q < \alpha + \frac{1}{\alpha^q} x_{n-1},
\end{align*}\] (3.2)
for all \(n \geq 4\).

Assume that \(\{s_n, t_n\}\) is a solution of the following system
\[\begin{align*}
s_n &= \alpha + \frac{1}{\alpha^p} t_{n-1}, \
t_n &= \alpha + \frac{1}{\alpha^q} s_{n-1}, \text{ for all } n \geq 4,
\end{align*}\] (3.3)
such that
\[s_i = x_i, \quad t_i = y_i, \quad i = 1, 2, 3.\] (3.4)

Now, we use induction to prove that
\[x_n < s_n, \quad y_n < t_n, \text{ for all } n \geq 4.\] (3.5)
Clearly, (3.5) is true for \(n = 4\), suppose that it is true for \(n = k > 4\). Then, from (3.2), we get
\[\begin{align*}
x_{k+1} &= \alpha + \frac{1}{\alpha^p} y_k < \alpha + \frac{1}{\alpha^p} t_k = s_{k+1}, \\
y_{k+1} &= \alpha + \frac{1}{\alpha^q} x_k < \alpha + \frac{1}{\alpha^q} s_k = t_{k+1}.
\end{align*}\] (3.6)
Hence, (3.5) is proven.

From (3.3) and (3.4), we get
\[s_{n+2} = \frac{1}{\alpha^{p+q}} s_n + \alpha^{1-p} + \alpha, \quad t_{n+2} = \frac{1}{\alpha^{p+q}} t_n + \alpha^{1-q} + \alpha, \quad n \geq 2,\] (3.7)
for simplicity, let \(a = \frac{1}{\alpha^{p+q}}, \quad b = \alpha^{1-p} + \alpha\) and \(c = \alpha^{1-q} + \alpha\). Then (3.7) turns into
\[s_{n+2} = as_n + b, \quad t_{n+2} = at_n + c, \quad n \geq 2,\] (3.8)
Solve (3.8), we obtain
\[s_{2n+2} = x_2a^n + \frac{b}{1-a}(1-a^n), \quad s_{2n+3} = x_3a^n + \frac{b}{1-a}(1-a^n), \text{ for all } n \geq 0,\] (3.9)
and
\[t_{2n+2} = y_2a^n + \frac{c}{1-a}(1-a^n), \quad t_{2n+3} = y_3a^n + \frac{c}{1-a}(1-a^n), \text{ for all } n \geq 0.\] (3.10)
Then, from (3.1), (3.5), (3.9) and (3.10), it follows that for all \( n \geq 0 \), we have

\[
\alpha < x_{2n+2} \leq x_2 a^n + \frac{b}{1-a} (1-a^n), \\
\alpha < x_{2n+3} \leq x_3 a^n + \frac{b}{1-a} (1-a^n),
\]

and

\[
\alpha < y_{2n+2} \leq y_2 a^n + \frac{c}{1-a} (1-a^n), \\
\alpha < y_{2n+3} \leq y_3 a^n + \frac{c}{1-a} (1-a^n).
\]

The proof is complete.

4 Global behavior of system (1.1)

In the next theorem, we will show that the unique positive equilibrium is global attractor.

**Theorem 4.1.** Suppose that \( \alpha > 1, 0 < p, q \leq 1 \). Then every positive solution of system (1.1) converges to the equilibrium point \((\bar{x}, \bar{y}) = (\alpha + 1, \alpha + 1)\) as \( n \to \infty \).

**Proof.** Let

\[
l_1 = \liminf_{n \to \infty} x_n, \quad l_2 = \liminf_{n \to \infty} y_n, \\
L_1 = \limsup_{n \to \infty} x_n, \quad L_2 = \limsup_{n \to \infty} y_n.
\]

Obviously, \( 1 < l_1 \leq L_1 \) and \( 1 < l_2 \leq L_2 \). From system (1.1) we indicate that

\[
l_1 \geq \alpha + \frac{p}{L_2} \geq \alpha + \frac{l_2}{L_2}, \quad l_2 \geq \alpha + \frac{l_1}{L_1}, \quad L_1 \leq \alpha + \frac{L_2}{l_2}, \quad L_2 \leq \alpha + \frac{L_1}{l_1}.
\]

From (4.1), we get

\[
l_1 L_2 \geq \alpha L_2 + l_2, \quad l_2 L_1 \geq \alpha L_1 + l_1, \\
l_2 L_1 \leq \alpha l_2 + L_2, \quad l_1 L_2 \leq \alpha l_1 + L_1.
\]
From (4.2) and (4.5) imply that
\[ \alpha L_2 + l_2 \leq \alpha l_1 + L_1. \]  
(4.6)

From (4.3) and (4.4) indicate that
\[ \alpha L_1 + l_1 \leq \alpha l_2 + L_2. \]  
(4.7)

From (4.6) and (4.7), we obtain
\[ \alpha L_2 + l_2 - \alpha l_2 - L_2 \leq \alpha l_1 + L_1 - \alpha L_1 - l_1, \]  
(4.8)

which is equivalent to
\[ (\alpha - 1)(L_2 - l_2 + L_1 - l_1) \leq 0. \]  
(4.9)

Since \( \alpha - 1 > 0 \), so we can infer from (4.9) that \( (L_2 - l_2 + L_1 - l_1) \leq 0 \). But \( L_2 - l_2 \geq 0 \) and \( L_1 - l_1 \geq 0 \), so \( (L_2 - l_2 + L_1 - l_1) \geq 0 \). Hence, \( L_2 - l_2 = 0 \) and \( L_1 - l_1 = 0 \), so \( L_2 = l_2 \) and \( L_1 = l_1 \). Back to (4.2) and (4.4), we get \( l_1 \geq \alpha + 1 \) and \( L_1 \leq \alpha + 1 \), so \( \lim_{n \to \infty} x_n = L_1 = l_1 = \alpha + 1 \). Similarly, we imply \( \lim_{n \to \infty} x_n = L_2 = l_2 = \alpha + 1 \). We complete the proof of the theorem.

**Theorem 4.2.** Assume that \( \alpha > 1 \) and \( 0 < p, q \leq 1 \), then the unique positive equilibrium \((\bar{x}, \bar{y}) = (\alpha + 1, \alpha + 1)\) of system (1.1) is locally asymptotically stable.

**Proof.** Set
\[ u_n^{(1)} = x_n, u_n^{(2)} = x_{n-1}, u_n^{(3)} = x_{n-2}, u_n^{(4)} = y_n, u_n^{(5)} = y_{n-1}, u_n^{(6)} = y_{n-2}, \]
\[ U_n = \left( u_n^{(1)}, u_n^{(2)}, u_n^{(3)}, u_n^{(4)}, u_n^{(5)}, u_n^{(6)} \right)^T. \]

Then the linearized equation of system (1.1) about the equilibrium point \((\bar{x}, \bar{y}) = (\alpha + 1, \alpha + 1)\) is
\[ U_{n+1} = AU_n, \]
where
\[ U_{n+1} = \left( u_{n+1}^{(1)}, u_{n+1}^{(2)}, u_{n+1}^{(3)}, u_{n+1}^{(4)}, u_{n+1}^{(5)}, u_{n+1}^{(6)} \right)^T \]
\[ = \left( \alpha + \frac{(u_n^{(4)})^p}{(u_n^{(6)})^p}, u_n^{(1)}, u_n^{(2)}, \alpha + \frac{(u_n^{(1)})^q}{(u_n^{(3)})^q}, u_n^{(4)}, u_n^{(5)} \right)^T, \]
and $A$ is the Jacobian matrix, which is determined by

$$
A = \begin{pmatrix}
0 & 0 & 0 & \frac{p}{\alpha + 1} & 0 & -\frac{p}{\alpha + 1} \\
1 & 0 & 0 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 & 0 \\
\frac{q}{\alpha + 1} & 0 & -\frac{q}{\alpha + 1} & 0 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 0 & 1 & 0
\end{pmatrix}.
$$

Let $\lambda_1, \lambda_2, \ldots, \lambda_6$ denote the eigenvalues of matrix $A$ and let

$$
D = \text{diag}(d_1, d_2, \ldots, d_6)
$$

be a diagonal matrix in which

$$
d_1 = d_4 = 1, d_2 = d_5 = 1 - 2\epsilon, d_3 = d_6 = 1 - 3\epsilon,
$$

(4.10)

with $0 < \epsilon < \frac{1}{3}$, so $\det D = (1 - 2\epsilon)(1 - 3\epsilon) > 0$. Therefore, $D$ is an invertible matrix. Computing matrix $DAD^{-1}$, we have

$$
DAD^{-1} = \begin{pmatrix}
0 & 0 & 0 & \frac{d_1}{d_4} \frac{p}{\alpha + 1} & 0 & -\frac{d_1}{d_6} \frac{p}{\alpha + 1} \\
\frac{d_2}{d_1} & 0 & 0 & 0 & 0 & 0 \\
0 & \frac{d_3}{d_2} & 0 & 0 & 0 & 0 \\
\frac{d_4}{d_1} \frac{q}{\alpha + 1} & 0 & -\frac{d_4}{d_5} \frac{q}{\alpha + 1} & 0 & 0 & 0 \\
0 & 0 & 0 & \frac{d_5}{d_4} & 0 & 0 \\
0 & 0 & 0 & 0 & \frac{d_6}{d_5} & 0
\end{pmatrix}.
$$

It is well known that $A$ has the same eigenvalues as $DAD^{-1}$, we have that

$$
\max |\lambda_i| \leq \|DAD^{-1}\|_{\infty}
$$

$$
= \max \left\{ \frac{d_2}{d_1}, \frac{d_3}{d_2}, \frac{d_5}{d_4}, \frac{d_6}{d_4} \frac{p}{\alpha + 1} + \frac{d_1}{d_6} \frac{p}{\alpha + 1}, \frac{d_4}{d_1} \frac{q}{\alpha + 1} + \frac{d_4}{d_3} \frac{q}{\alpha + 1} \right\}.
$$

From (4.10), we imply that

$$
\frac{d_2}{d_1} < 1, \frac{d_3}{d_2} < 1, \frac{d_5}{d_4} < 1, \frac{d_6}{d_5} < 1.
$$

(4.11)
Now, we consider
\[
\frac{d_1}{d_4} \frac{p}{\alpha + 1} + \frac{d_1}{d_6} \frac{p}{\alpha + 1} = \frac{p}{\alpha + 1} + \frac{1}{(1 - 3\epsilon)(\alpha + 1)} \frac{p}{2(1 - 3\epsilon)} < \frac{2p}{\alpha + 1(1 - 3\epsilon)} < 1. \tag{4.12}
\]
Solve (4.12), we obtain
\[
\epsilon < \frac{\alpha + 1 - 2p}{3(\alpha + 1)} \tag{4.13}
\]
Similarly, if \(\epsilon\) satisfies
\[
\epsilon < \frac{\alpha + 1 - 2q}{3(\alpha + 1)} \tag{4.14}
\]
then
\[
\frac{d_4}{d_1} \frac{q}{\alpha + 1} + \frac{d_4}{d_3} \frac{q}{\alpha + 1} < 1. \tag{4.15}
\]
From (4.11), (4.12), (4.13), (4.14) and (4.15), we can choose \(\epsilon\) such that
\[
0 < \epsilon < \min \left\{ \frac{\alpha + 1 - 2p}{3(\alpha + 1)}, \frac{\alpha + 1 - 2q}{3(\alpha + 1)} \right\}, \tag{4.16}
\]
then
\[
\max |\lambda_i| \leq \|DAD^{-1}\|_\infty < 1.
\]
It means that all eigenvalues of \(A\) lie inside the unit disk. This implies that the unique positive equilibrium \((\bar{x}, \bar{y}) = (\alpha + 1, \alpha + 1)\) of system (1.1) is locally asymptotically stable. Thus, the proof is completed.

Combining Theorem 4.1 and Theorem 4.2, we get the next theorem.

**Theorem 4.3.** If \(\alpha > 1\) and \(0 < p, q \leq 1\), then the unique positive equilibrium point \((\bar{x}, \bar{y}) = (\alpha + 1, \alpha + 1)\) of system (1.1) is globally asymptotically stable.

## 5 Rate of convergence

In this section we give the rate of convergence of a solution that converges to the equilibrium point \((\bar{x}, \bar{y}) = (\alpha + 1, \alpha + 1)\) of the systems (1.1) for \(\alpha > 1\) and \(0 < p, q \leq 1\). More results on the rate of convergence of solutions for some two-dimensional difference equations systems have been obtained in [8] and [9].
The following results give the rate of convergence of solutions of a system of difference equations

\[ V_{n+1} = [A + B(n)]V_n \]  

(5.1)

where \( V_n \) is a \( k \)-dimensional vector, \( A \in \mathbb{C}^{k \times k} \) is a constant matrix, and \( B : \mathbb{Z}^+ \to \mathbb{C}^{k \times k} \) is a matrix function satisfying

\[ \|B(n)\| \to 0 \text{ when } n \to \infty, \]  

(5.2)

where \( \| \cdot \| \) denotes any matrix norm which is associated with the vector norm; \( \| \cdot \| \) also denotes the Euclidean norm in \( \mathbb{R}^2 \) given by

\[ \|(x, y)\| = \sqrt{x^2 + y^2}. \]  

(5.3)

**Theorem 5.1.** (Perron’s Theorem, \([10]\)) Assume that condition (5.2) holds. If \( V_n \) is a solution of system (5.1), then either \( V_n = 0 \) for all large \( n \), or

\[ \rho = \lim_{n \to \infty} \sqrt{\|V_n\|} \]

or

\[ \rho = \lim_{n \to \infty} \frac{\|V_{n+1}\|}{\|V_n\|} \]

exists and \( \rho \) is equal to the modulus of one of the eigenvalues of matrix \( A \).

**Theorem 5.2.** Assume that \( \{(x_n, y_n)\} \) is a solution of the system (1.1) such that \( \lim_{n \to \infty} x_n = \bar{x}, \lim_{n \to \infty} y_n = \bar{y} \). Then the error vector

\[ e_n = \begin{pmatrix} e_{1n}^1 \\ e_{2n}^1 \\ e_{1n}^2 \\ e_{2n}^2 \\ e_{1n}^3 \\ e_{2n}^3 \end{pmatrix} = \begin{pmatrix} x_n - \bar{x} \\ x_{n-1} - \bar{x} \\ x_{n-2} - \bar{x} \\ y_n - \bar{y} \\ y_{n-1} - \bar{y} \\ y_{n-2} - \bar{y} \end{pmatrix} \]

of every solution of (1.1) satisfies both of the following asymptotic relations:

\[ \lim_{n \to \infty} \sqrt{\|e_n\|} = |\lambda_i J_F(\bar{x}, \bar{y})| \]  

for some \( i \in \{1, 2, \ldots, 6\} \)

and

\[ \lim_{n \to \infty} \frac{\|e_{n+1}\|}{\|e_n\|} = |\lambda_i J_F(\bar{x}, \bar{y})| \]  

for some \( i \in \{1, 2, \ldots, 6\} \)

where \( |\lambda_i J_F(\bar{x}, \bar{y})| \) is equal to the modulus of one the eigenvalues of the Jacobian matrix evaluated at the equilibrium \((\bar{x}, \bar{y})\).
Proof. We will find a system satisfied by the error terms, which are given as

\[ x_{n+1} - \bar{x} = \sum_{i=0}^{2} a_i (x_{n-i} - \bar{x}) + \sum_{i=0}^{2} b_i (y_{n-i} - \bar{x}) \]

\[ y_{n+1} - \bar{y} = \sum_{i=0}^{2} c_i (x_{n-i} - \bar{x}) + \sum_{i=0}^{2} d_i (y_{n-i} - \bar{x}) \]  

(5.4)

Let \( e_1^n = x_n - \bar{x} \) and \( e_2^n = y_n - \bar{y} \), then system (5.4) can be written as following form

\[ e_{n+1}^1 = \sum_{i=0}^{2} a_i e_{n-i}^1 + \sum_{i=0}^{2} b_i e_{n-i}^2, \]

\[ e_{n+1}^2 = \sum_{i=0}^{2} c_i e_{n-i}^1 + \sum_{i=0}^{2} d_i e_{n-i}^2, \]

where

\[ a_0 = a_1 = a_2 = 0, \]

\[ b_0 = \frac{py^{p-1}_{n-2}}{y^{p}_{n-2}}, b_1 = 0, b_2 = -\frac{py^{p}_{n+1}}{y^{p+1}_{n-2}}, \]

\[ c_0 = \frac{qx^{q-1}_{n-2}}{x^{q}_{n-2}}, c_1 = 0, c_2 = -\frac{qx^{q}_{n+1}}{x^{q+1}_{n-2}}, \]

\[ d_0 = d_1 = d_2 = 0. \]

Taking the limmits of \( a_i, b_i, c_i \) and \( d_i \) as \( n \to \infty \) for \( i = 0, 1, 2 \), we obtain

\[ \lim_{n \to \infty} a_i = 0, \text{ for } i = 0, 1, 2, \]

\[ \lim_{n \to \infty} b_0 = \frac{p}{y}, \lim_{n \to \infty} b_1 = 0, \lim_{n \to \infty} b_2 = -\frac{p}{y}, \]

\[ \lim_{n \to \infty} c_0 = \frac{q}{x}, \lim_{n \to \infty} c_1 = 0, \lim_{n \to \infty} c_2 = -\frac{q}{x}, \]

\[ \lim_{n \to \infty} d_i = 0, \text{ for } i = 0, 1, 2. \]

That is

\[ b_0 = \frac{p}{y} + \beta_n, \quad b_2 = -\frac{p}{y} + \gamma_n, \]

\[ c_0 = \frac{q}{x} + \delta_n, \quad c_2 = -\frac{q}{x} + \eta_n, \]

where \( \beta_n \to 0, \quad \gamma_n \to 0, \quad \delta_n \to 0 \) and \( \eta_n \to 0 \) as \( n \to \infty \).

Now, we have the following system of the form (5.1):

\[ e_{n+1} = [A + B(n)]e_n, \]
where \( e_n = (e_{1n}, e_{1n-1}, e_{1n-2}, e_{2n}, e_{2n-1}, e_{2n-2})^T \) and

\[
A = J_F(\bar{x}, \bar{y}) = \begin{pmatrix}
0 & 0 & 0 & \frac{p}{\alpha + 1} & 0 & -\frac{p}{\alpha + 1} \\
1 & 0 & 0 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 & 0 \\
q & 0 & -q & \frac{1}{\alpha + 1} & 0 & 0 \\
0 & 0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 0 & 1 & 0
\end{pmatrix},
\]

\[
B(n) = \begin{pmatrix}
0 & 0 & 0 & \beta_n & 0 & \gamma_n \\
0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 \\
\delta_n & 0 & \eta_n & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0
\end{pmatrix},
\]

and

\[\|B(n)\| \to 0 \text{ as } n \to \infty.\]

Thus, the limiting system of error terms can be written as:

\[
\begin{pmatrix}
e_{1n+1} \\
e_1 \\
e_{1n-1} \\
e_{2n+1} \\
e_2 \\
e_{2n-1}
\end{pmatrix} = \begin{pmatrix}
0 & 0 & 0 & \frac{p}{\alpha + 1} & 0 & -\frac{p}{\alpha + 1} \\
1 & 0 & 0 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 & 0 \\
q & 0 & -q & \frac{1}{\alpha + 1} & 0 & 0 \\
\frac{\alpha + 1}{\alpha + 1} & 0 & \frac{1}{\alpha + 1} & 0 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 & 0
\end{pmatrix} \begin{pmatrix}
e_1 \\
e_{1n-1} \\
e_{2n} \\
e_{2n-1}
\end{pmatrix}.
\]

The system is exactly linearized system of (1.1) evaluated at the equilibrium \((\bar{x}, \bar{y}) = (\alpha + 1, \alpha + 1)\). From Theorem 5.1 we imply the result.

6 Examples

In order to verify our theoretical results and to support our theoretical discussion, we consider several interesting numerical examples. These examples represent different types of qualitative behavior of solutions of the systems (1.1). All plots in this section are drawn with Matlab.
Example 6.1. Let $\alpha = 2, p = 0.6, q = 0.9$. The system (1.1) can be written as

\[ x_{n+1} = 2 + \frac{y_n^{0.6}}{y_{n-2}^{0.6}}, \quad y_{n+1} = 2 + \frac{x_n^{0.9}}{x_{n-2}^{0.9}}. \tag{6.1} \]

Consider (6.1) with initial conditions $x_{-2} = 2.5, x_{-1} = 6, x_0 = 2, y_{-2} = 4, y_{-1} = 2$ and $y_0 = 5$.

![Figure 1: Plots for the system (6.1)]

In this case, $\alpha > 1$ and $0 < p, q < 1$, so the unique positive equilibrium point $(\bar{x}, \bar{y}) = (3, 3)$ of the system (1.1) is globally asymptotically stable (see Theorem 4.3). In Figure 1, the plot of $x_n$ is shown in Figure 1 (a), the plot of $y_n$ is shown in Figure 1 (b), and an attractor of the system (6.1) is shown in Figure 1 (c).

Example 6.2. Let $\alpha = 1.3, p = 0.9, q = 0.8$. The system (1.1) can be written
Consider \( (6.2) \) with initial conditions \( x_{-2} = 2.6, \ x_{-1} = 1.8, \ x_0 = 3, \ y_{-2} = 3, \ y_{-1} = 5 \) and \( y_0 = 1 \).

\[
x_{n+1} = 1.3 + \frac{y_n^{0.9}}{y_{n-2}^{0.9}}, \quad y_{n+1} = 1.3 + \frac{x_n^{0.8}}{x_{n-2}^{0.8}}. \tag{6.2}
\]

Example 6.3. Let \( \alpha = 0.6, p = 0.8, q = 1.9 \). The system \( (1.1) \) can be written as

\[
x_{n+1} = 0.6 + \frac{y_n^{0.8}}{y_{n-2}^{0.8}}, \quad y_{n+1} = 0.6 + \frac{x_n^{1.9}}{x_{n-2}^{1.9}}. \tag{6.3}
\]
Examine system (6.3) with initial conditions $x_{-2} = 1.6$, $x_{-1} = 2.8$, $x_0 = 4$, $y_{-2} = 4$, $y_{-1} = 1.5$ and $y_0 = 6$.

![Plot of $x_n$ for the system (6.3)](image)

![Plot of $y_n$ for the system (6.3)](image)

![Phase portrait of the system (6.3)](image)

Figure 3: Plots for the system (6.3)

In this situation, since $\alpha < 1$ and $q > 1$, so they are not satisfied conditions of Theorem 4.3. Therefore, the unique positive equilibrium point $(\bar{x}, \bar{y}) = (1.6, 1.6)$ of the system (1.1) is not globally asymptotically stable. In Figure 3, the plot of $x_n$ is shown in Figure 3 (a), the plot of $y_n$ is shown in Figure 3 (b), and a phase portrait of the system (6.3) is shown in Figure 3 (c).

**Example 6.4.** Let $\alpha = 0.3$, $p = 1.2$, $q = 1.5$. The system (1.1) can be written as

$$
x_{n+1} = 0.3 + \frac{y_{n-2}^{1.2}}{y_{n-2}^{1.2}}, \quad y_{n+1} = 0.3 + \frac{x_{n-2}^{1.5}}{x_{n-2}^{1.5}}.
$$

(6.4)

Study system (6.4) with initial conditions $x_{-2} = 6$, $x_{-1} = 8$, $x_0 = 3$, $y_{-2} = 3$, $y_{-1} = 5$ and $y_0 = 1$. 

18
In this case, because $\alpha < 1$, $p, q > 1$, so they are not satisfied conditions of Theorem 4.3, thus the unique positive equilibrium point $(\bar{x}, \bar{y}) = (1.3, 1.3)$ of the system (1.1) is not globally asymptotically stable. In Figure 4, the plot of $x_n$ is shown in Figure 4 (a), the plot of $y_n$ is shown in Figure 4 (b), and a phase portrait of the system (6.4) is shown in Figure 4 (c).
