DIRECTIONAL MEAN DIMENSION AND CONTINUUM-WISE EXPANSIVE $\mathbb{Z}^k$-ACTIONS

SEBASTIÁN DONOSO, LEI JIN, ALEJANDRO MAASS, AND YIXIAO QIAO

Abstract. We study directional mean dimension of $\mathbb{Z}^k$-actions (where $k$ is a positive integer). On the one hand, we show that there is a $\mathbb{Z}^2$-action whose directional mean dimension (considered as a $[0, +\infty]$-valued function on the torus) is not continuous. On the other hand, we prove that if a $\mathbb{Z}^k$-action is continuum-wise expansive, then the values of its $(k-1)$-dimensional directional mean dimension are bounded. This is a generalization (with a view towards Meyerovitch and Tsukamoto’s theorem on mean dimension and expansive multiparameter actions) of a classical result due to Mañé: Any compact metrizable space admitting an expansive homeomorphism (with respect to a compatible metric) is finite-dimensional.

1. Introduction

The notion of expansiveness (or unstable homeomorphisms), introduced in 1950 by Utz [Utz50], is a dynamical property shared by a class of systems exhibiting chaotic behaviors. Let $(X,d)$ be a compact metric space. A homeomorphism $T: X \to X$ is said to be expansive if there is a constant $c > 0$ satisfying that for any distinct points $x, x' \in X$ there exists $n \in \mathbb{Z}$ such that $d(T^n x, T^n x') > c$. In 1979, Mañé [Man79] established a fairly surprising result which states that any compact metrizable space admitting an expansive homeomorphism (with respect to a compatible metric) is finite dimensional. In contrast to $\mathbb{Z}$-actions, there do exist expansive $\mathbb{Z}^2$-actions on infinite dimensional compact metric spaces [MT19, SZ05]. Such examples seem to indicate that Mañé’s theorem cannot be extended to $\mathbb{Z}^k$-actions, for $k \geq 2$ or to more general group actions. However, Meyerovitch and Tsukamoto [MT19] succeeded in finding a reasonable framework to study extension of Mañé’s results, with a view towards mean dimension.

Mean dimension was introduced by Gromov [Gro99] in 1999. It is a topological invariant of dynamical systems, whose advantage has been shown excellently in the study of infinite dimensional and infinite topological entropy systems. We will review its definition in Subsection 2.4. It is worth mentioning that mean dimension has deep and significant applications to dynamical systems. In particular, it is intimately connected with the embedding problem. For related results we refer to [GLT16, GQT19, GT20, Lin99, LT18, LT19, LW00].

Meyerovitch and Tsukamoto [MT19] provided a striking generalization of Mañé’s theorem to $\mathbb{Z}^k$-actions. They showed that if $(X,\mathbb{Z}^k, T)$ is an expansive $\mathbb{Z}^k$-action (where $k$ is a positive integer) and if a $\mathbb{Z}^{k-1}$-action $(X,\mathbb{Z}^{k-1}, R)$ satisfies that $R: \mathbb{Z}^{k-1} \times X \to X$ commutes with $T: \mathbb{Z}^k \times X \to X$, then $(X,\mathbb{Z}^k, T)$ has finite mean dimension. Note that this statement reduces to Mañé’s result when $k = 1$, since a trivial action has finite mean dimension if and only if the space is finite dimensional. Moreover, they introduced the notion of directional mean dimension [MT19], which was initially suggested by Lind, mimicking the definition of directional entropy in [BL97]. Directional mean dimension is able to measure the “averaged dimension” of a dynamical system along a given subspace or direction. We state its precise definition (for $\mathbb{Z}^k$-actions) in Section 3. This is the starting point of what we plan to investigate in the present paper. Our motivation lies mainly in two aspects, which we explain shortly as follows.

For a $\mathbb{Z}^2$-action, let us consider its directional mean dimension as a $[0, +\infty]$-valued function on the torus. An immediate and natural problem is if such a function is continuous. We remark that if this is true, then Meyerovitch and Tsukamoto’s theorem will imply that if a $\mathbb{Z}^2$-action is expansive then its directional mean dimension along any direction is finite (because a continuous $[0, +\infty]$-valued function on a compact metric space is bounded by a finite real number provided it is finite at some point). However, it turns out that we cannot expect directional mean dimension functions to have such a strong property. We will construct a $\mathbb{Z}^2$-action whose directional mean dimension function fails to be continuous on the torus.

Let $S = \{\vec{v} = (v_1, v_2) \in \mathbb{R}^2 : v_1^2 + v_2^2 = 1\}$. For a $\mathbb{Z}^2$-action $(X,\mathbb{Z}^2, T)$ we denote by $\text{mdim}(X, T; (\vec{v})^\perp)$ the directional mean dimension of $(X,\mathbb{Z}^2, T)$ with respect to the 1-dimensional subspace of $\mathbb{R}^2$ orthogonal to a direction $\vec{v} \in S$.

**Theorem 1.1.** For any $0 \leq r \leq +\infty$ there is a $\mathbb{Z}^2$-action $(X,\mathbb{Z}^2, T)$ such that

- if $\vec{v} \in \{(-1,0), (1,0)\}$ then $\text{mdim}(X, T; (\vec{v})^\perp) = r$;
- if $\vec{v} \in S \setminus \{(-1,0), (1,0)\}$ then $\text{mdim}(X, T; (\vec{v})^\perp) = 0$.

Theorem 1.1 shows in particular that directional mean dimension need not depend continuously on directions, but still leaves open if expansive $\mathbb{Z}^2$-actions have finite directional mean dimension for all directions. We shall address this question in a wider context. Indeed, different versions of expansiveness were well explored previously. For instance, there are entropy-expansiveness [Bow72], continuum-wise expansiveness [Kat93], pointwise expansiveness [Red70] and positive expansiveness [Sch52]. Among all the variants, *continuum-wise expansiveness* attracts a lot of attention. We will recall its definition formally in Subsection 2.2. It is worth mentioning that the class of continuum-wise expansive homeomorphisms contains, in addition to expansive homeomorphisms, many important homeomorphisms which are not expansive; for example, the shift maps of Knaster’s indecomposa-bly chainable continua [Kat93]; meanwhile, in contrast to expansive homeomorphisms, there exist continuum-wise expansive homeomorphisms on the pseudo-arc. Kato [Kat93] extended Mañé’s result to the setting of continuum-wise expansive homeomorphisms. A purpose of this paper is to prove that all continuum-wise expansive $\mathbb{Z}^k$-actions (in particular, all expansive $\mathbb{Z}^k$-actions) must have finite directional mean dimension.

**Theorem 1.2.** Let $k$ be a positive integer. If a $\mathbb{Z}^k$-action $(X,\mathbb{Z}^k, T)$ is continuum-wise expansive, then the $(k-1)$-dimensional directional mean dimension of $(X,\mathbb{Z}^k, T)$

---

1We shall use the word “direction” even if the subspace is not one dimensional
with respect to any direction is finite. More precisely, they are uniformly bounded by a finite number which depends only on \((X, \mathbb{Z}^k, T)\).

We remark that the finiteness in the statement of Theorem 1.2 cannot be improved to zero. In fact, it is possible to construct an expansive \(\mathbb{Z}^2\)-action (even minimal) of positive directional mean dimension (for details see [MT19]). When \(k = 1\), Theorem 1.2 coincides with Mañé's and Kato's results.

This paper is organized as follows: In Section 2, we collect basic notions, terminologies, and some known propositions in mean dimension and continuum theory. In Section 3, we study directional mean dimension of \(\mathbb{Z}^k\)-actions, where we shall present its fundamental properties and where we shall provide a constructive proof of Theorem 1.1. In Section 4, we will prove Theorem 1.2.

2. Preliminaries

2.1. Continua. By a continuum we understand a connected compact metric space. We refer to [Nad78, Nad92] for a systematic study of continuum theory. Let \((X, d)\) be a compact metric space. By the hyperspace of \(X\), denoted by \(2^X\), we mean the space of all nonempty closed subsets of \(X\), equipped with the Hausdorff metric \(d_H(A, B) = \inf\{\epsilon > 0 : B \subset U_\epsilon(A), A \subset U_\epsilon(B)\}\), where \(U_\epsilon(A)\) denotes the \(\epsilon\)-neighbourhood (with respect to the metric \(d\) on \(X\)) of \(A\) in \(X\). We denote by \(C(X)\) the space of all nonempty connected closed subsets of \(X\), endowed with the Hausdorff metric \(d_H\). It is well known [Nad92, Theorems 4.13, 4.17] that if \(X\) is a compact metric space, then both \(2^X\) and \(C(X)\) are compact. For a topological space \(X\) the connected component of a point \(x \in X\) is the union of all the connected subsets of \(X\) containing \(x\). Every connected component is connected and closed in \(X\). The connected components of the points of \(X\) form a partition of \(X\). When concerning a space the term nondegenerate will always mean that the space consists of at least two points.

2.2. Continuum-wise expansive \(\mathbb{Z}^k\)-actions. Let \(k\) be a positive integer. We say that a triple \((X, \mathbb{Z}^k, T)\) is a \(\mathbb{Z}^k\)-action if \(X\) is a compact metric space and \(T: \mathbb{Z}^k \times X \to X\), \((n, x) \mapsto T^n x\) is a continuous mapping satisfying \(T^0 x = x\) and \(T^{m+n}(x) = T^m(T^n(x))\) for all \(m, n \in \mathbb{Z}^k\) and all \(x \in X\). A \(\mathbb{Z}^k\)-action \((X, \mathbb{Z}^k, T)\) is said to be continuum-wise expansive if there is a constant \(c > 0\) satisfying that for every nondegenerate \(A \in C(X)\) there exists \(n \in \mathbb{Z}^k\) such that \(\text{diam } T^n(A) > c\). Such a constant \(c > 0\) is called an expansivity constant for \((X, \mathbb{Z}^k, T)\). Note that expansive \(\mathbb{Z}^k\)-actions are obviously continuum-wise expansive.

2.3. Topological dimension. Let \(X\) be a compact metric space. The join of open covers \(\mathcal{U}\) and \(\mathcal{V}\) of \(X\) is the open cover \(\mathcal{U} \vee \mathcal{V} := \{U \cap V : U \in \mathcal{U}, V \in \mathcal{V}\}\). For a cover \(\mathcal{U}\) of \(X\) we set \(\text{mesh}(\mathcal{U}, d) = \sup_{U \in \mathcal{U}} \text{diam}(U)\). A cover \(\mathcal{V}\) refines \(\mathcal{U}\) if for every \(V \in \mathcal{V}\) there exists \(U \in \mathcal{U}\) with \(V \subset U\). Let \(\mathcal{U} = \{U_i\}_{i=1}^n\) be a finite cover of \(X\). We define the order of \(\mathcal{U}\) by \(\text{ord}(\mathcal{U}) = \max_{x \in X} \sum_{i=1}^n 1_{U_i}(x) - 1\) and the degree of \(\mathcal{U}\) by \(\mathcal{D}(\mathcal{U}) = \min_{\mathcal{V}} \text{ord}(\mathcal{V})\), where \(\mathcal{V}\) runs over all finite open covers of \(X\) refining \(\mathcal{U}\). The topological dimension of \(X\) is defined by \(\text{dim}(X) = \sup\{\mathcal{D}(\mathcal{U}) : \mathcal{U}\) runs over all finite open covers of \(X\). As follows we list some elementary propositions about \(\mathcal{D}\), which will be used in this paper.

**Lemma 2.1** ([Coo15, Propositions 1.6.5, 4.4.5]). Let \(X\) be a compact metric space and \(\alpha\) a finite open cover of \(X\). Then the following statements hold:
where $\mathcal{U}$ and define the

\[ \dim(Z, T) = \lim_{N \to +\infty} \frac{\mathcal{D}(V_{n \in [-N,N]^k} T^n U)}{(2N + 1)^k} \]

and define the mean dimension of $(X, \mathbb{Z}^k, T)$ by

\[ \text{mdim}(X, \mathbb{Z}^k, T) = \sup_{\mathcal{U}} \text{mdim}(X, T; \mathcal{U}), \]

where $\mathcal{U}$ ranges over all finite open covers of $X$. The limit in (2.1) always exists due to Lemma 2.2. Clearly, $\text{mdim}(X, \mathbb{Z}^k, T) \in [0, +\infty]$. An easy observation is that if $\dim(X) < +\infty$ then $\text{mdim}(X, \mathbb{Z}^k, T) = 0$. Moreover, it was shown [LW00, Theorem 4.2] that if $(X, \mathbb{Z}^k, T)$ has finite topological entropy, then $\text{mdim}(X, \mathbb{Z}^k, T) = 0$. Typical examples of dynamical systems having positive mean dimension are full shifts (over a positive dimension alphabet). Let $D$ be a positive integer. The full shift on $([0,1]^D)\mathbb{Z}^k$ is defined by $\sigma: \mathbb{Z}^k \times ([0,1]^D)\mathbb{Z}^k \to ([0,1]^D)\mathbb{Z}^k$, $(n, (x_m)_{m \in \mathbb{Z}^k}) \mapsto (x_{m+n})_{m \in \mathbb{Z}^k}$. It was proved in [LW00] that $\text{mdim}(([0,1]^D)\mathbb{Z}^k, \sigma) = D$. Let $d$ be a compatible metric on $X$. For any finite subset $\Omega$ of $\mathbb{Z}^k$ we define $d_T^\Omega$ by

\[ d_T^\Omega(x, x') = \max_{n \in \Omega} d(T^n x, T^n x'), \quad \text{for } x, x' \in X. \]

It is clear that $d_T^\Omega$ is also a compatible metric on $X$. Furthermore, we can verify that

\[ \text{mdim}(X, \mathbb{Z}^k, T) = \lim_{\epsilon \to 0} \left( \lim_{N \to +\infty} \frac{\text{Widim}_r(X, d_T^\Omega [-N,N]^k)}{(2N + 1)^k} \right). \]
3. Directional mean dimension

Let $k \in \mathbb{N}$ and fix a real number $r > \sqrt{k}/2$. Let $V \subset \mathbb{R}^k$ be $h$-dimensional subspace of $\mathbb{R}^k$. Define $B_r(V) := \{ u \in \mathbb{Z}^k : |u - w| < r \text{ for some } w \in V \}$. For a $\mathbb{Z}^k$-action $(X, \mathbb{Z}^k, T)$, with a compatible metric $d$ on $X$, we define the $h$-dimensional directional mean dimension of $(X, \mathbb{Z}^k, T)$ with respect to $V$ by

$$mdim(X, T, V) = \lim_{\epsilon \to 0} \left( \lim_{N \to +\infty} \frac{\text{Widim}_\epsilon(X, d^{T^{(\epsilon)}}_{B_r(V) \cap [-N,N]^k})}{\text{vol}(B_r(V) \cap [-N,N]^k)} \right),$$

where $\text{vol}(B_r(V) \cap [-N,N]^k)$ denotes the volume (in the $k$-dimensional Euclidean space) of the intersection of $B_r(V)$ and the cube $[-N,N]^k$.

We note that we shall write $|A|$ for the cardinality of a set $A$ in the sequel.

The constant $r > \sqrt{k}/2$ is to guarantee that for every point $u \in V$ there is $v \in \mathbb{Z}^k$ with $|u - v| < r$, and hence $B_r(V)$ is always an infinite set. We do not include $r$ in the notation $mdim(X, T, V)$ because the definition of directional mean dimension is independent of the choices of $r > \sqrt{k}/2$ and the compatible metrics $d$ on $X$ (see Proposition 3.1).

For each $1 \leq i \leq k$ we let $Z^i$ be the subgroup of $\mathbb{Z}^k$ consisting of all the elements having zero on the $i$-th coordinate. For a $\mathbb{Z}^k$-action $(X, \mathbb{Z}^k, T)$ and every $1 \leq i \leq k$ we let $(X, \mathbb{Z}^{k-1}, T|_{Z^i})$ (which is a $\mathbb{Z}^{k-1}$-action) be the restriction of $T$ to the subgroup $Z^i$.

**Proposition 3.1.** The following statements are true for all $\mathbb{Z}^k$-actions $(X, \mathbb{Z}^k, T)$:

1. For any $1 \leq h \leq k$ and any $h$-dimensional subspace $V \subseteq \mathbb{R}^k$, the value $mdim(X, T, V)$ is independent of $r > \sqrt{k}/2$.
2. Directional mean dimension does not depend on a choice of a compatible metric on $X$; more precisely, for any $h$-dimensional subspace $V \subseteq \mathbb{R}^k$ and $r > \sqrt{k}/2$

$$mdim(X, T, V) = \sup_U \left( \lim_{N \to +\infty} \frac{D(V_n \cap [-N,N]^k)}{\text{vol}(B_r(V) \cap [-N,N]^k)} \right),$$

where $U$ ranges over all finite open covers of $X$.
3. For any $1 \leq i \leq k$ we have $mdim(X, T, (e_i^\perp)) = mdim(X, \mathbb{Z}^{k-1}, T|_{Z^i})$.

**Proof.** (1) Take $\sqrt{k}/2 < r_1 < r_2$. We remind the reader that in the first part of the proof we shall use the notation $mdim(X, T, V; r_i)$ (or $mdim(X, T, V; r_2)$), instead of $mdim(X, T, V)$, since our current goal is to show $mdim(X, T, V; r_1) = mdim(X, T, V; r_2)$. On the one hand, since

$$d^{T^{(\epsilon)}}_{B_{r_1}(V) \cap [-N,N]^k}(x, y) \leq d^{T^{(\epsilon)}}_{B_{r_2}(V) \cap [-N,N]^k}(x, y)$$

for all $x, y \in X$ and $N \in \mathbb{N}$, we have

$$\text{Widim}_\epsilon(X, d^{T^{(\epsilon)}}_{B_{r_1}(V) \cap [-N,N]^k}) \leq \text{Widim}_\epsilon(X, d^{T^{(\epsilon)}}_{B_{r_2}(V) \cap [-N,N]^k})$$

for all $N \in \mathbb{N}$ and $\epsilon > 0$. Thus $mdim(X, T, \bar{v}; r_1) \leq mdim(X, T, \bar{v}; r_2)$. On the other hand, there exists a finite subset $F$ of $\mathbb{Z}^k$ such that for any $N \in \mathbb{N}$ the set $B_{r_2}(V) \cap [-N,N]^k$ is contained in $\bigcup_{m \in F} (B_{r_1}(V) \cap [-N,N]^k + m)$. For a given

---

2It is possible to give a much more general definition, following the notions of directional entropy in [BL97], but for the sake of simplicity of the paper, we do not do so here.
To show
\[
\sup_{\mathcal{U}} \left( \liminf_{N \to +\infty} \frac{D(\bigvee_{n \in B_{r}(V) \cap [-N,N]^{k}} T^{n}\mathcal{U})}{\text{vol}(B_{r}(V) \cap [-N,N]^{k})} \right) \leq \text{mdim}(X,T,\vec{v}),
\]
we take a finite open cover $\mathcal{U}$ of $X$ and let $\lambda > 0$ be a Lebesgue number of $\mathcal{U}$ with respect to a compatible metric $d$ on $X$. It suffices to prove for every $N \in \mathbb{N}$ that
\[
D(\bigvee_{n \in B_{r}(V) \cap [-N,N]^{k}} T^{n}\mathcal{U}) \leq \text{Widim}(X,d_{B_{r}(V) \cap [-N,N]^{k}},\lambda).
\]
In fact, we take a compact metric space $P$ with $\text{dim}(P) = \text{Widim}(X,d_{B_{r}(V) \cap [-N,N]^{k}},\lambda)$ and a $\lambda$-embedding $f: X \to P$ with respect to $d_{B_{r}(V) \cap [-N,N]^{k}}$. Then it follows that $\text{dim}(T^{n}(f^{-1}(p)) < \lambda$ and hence $T^{n}(f^{-1}(p))$ is contained in some element in $\mathcal{U}$ for every $n \in B_{r}(V) \cap [-N,N]^{k}$ and every $p \in P$. Thus, $f^{-1}(p)$ is contained in some element in $\bigvee_{n \in B_{r}(V) \cap [-N,N]^{k}} T^{n}\mathcal{U}$ for every $p \in P$. For every $U \in \bigvee_{n \in B_{r}(V) \cap [-N,N]^{k}} T^{n}\mathcal{U}$ we set $\hat{U} = \{p \in P : f^{-1}(p) \subseteq U\}.\] Clearly, $f^{-1}(\hat{U}) \subseteq U$, the sets $U$’s cover, and each $\hat{U}$ is open in $Y$. So $f$ is $\bigvee_{n \in B_{r}(V) \cap [-N,N]^{k}} T^{n}\mathcal{U}$-compatible, and therefore by Lemma 2.1 we see that $D(\bigvee_{n \in B_{r}(V) \cap [-N,N]^{k}} T^{n}\mathcal{U}) \leq \text{dim}(P)$. To show
\[
\text{mdim}(X,T,\vec{v}) \leq \sup_{\mathcal{U}} \left( \liminf_{N \to +\infty} \frac{D(\bigvee_{n \in B_{r}(V) \cap [-N,N]^{k}} T^{n}\mathcal{U})}{\text{vol}(B_{r}(V) \cap [-N,N]^{k})} \right),
\]
we let $\epsilon > 0$, $N \in \mathbb{N}$, and take a finite open cover $\mathcal{U}$ of $X$ with $\text{mesh}(\mathcal{U},d) < \epsilon$. By Lemma 2.1, we can find a compact metric space $P$ with
\[
\text{dim}(P) = D(\bigvee_{n \in B_{r}(V) \cap [-N,N]^{k}} T^{n}\mathcal{U})
\]
and a continuous $f: X \to P$ which is $\bigvee_{n \in B_{r}(V) \cap [-N,N]^{k}} T^{n}\mathcal{U}$-compatible. So we have $\text{Widim}(X,d_{B_{r}(V) \cap [-N,N]^{k}},\lambda) \leq \text{dim}(P)$, as required.

Statement (3) follows directly from definition. \hfill \square

In what follows we are mainly interested in $(k-1)$-dimensional subspaces of $\mathbb{Z}^{k}$. Note that via the orthogonal complement, these subspaces can be parametrized with a single vector of $\mathbb{R}^{k}$. The next result shows that $\mathbb{Z}^{k}$-actions of positive mean dimension must have infinite directional mean dimension with respect to each $\langle \vec{e}_{i} \rangle^{\perp}$ $(1 \leq i \leq k)$.

**Proposition 3.2.** If a $\mathbb{Z}^{k}$-action $(X,\mathbb{Z}^{k},T)$ satisfies $\min_{1 \leq i \leq k} \text{mdim}(X,T,\langle \vec{e}_{i} \rangle^{\perp}) < +\infty$ then $\text{mdim}(X,\mathbb{Z}^{k},T) = 0$.

**Proof.** Without loss of generality we assume $\text{mdim}(X,T,\langle \vec{e}_{k} \rangle^{\perp}) < +\infty$. For any positive integers $N$ and $j$ we put $F(N,M;j) = [-jN,jN]^{k-1} \times [-jM,jM]$. We set $\mathcal{F} = \{F(N,M;j) : N,M \geq 1\}$. Clearly, $\{F(N,M;j)\}^{\infty}_{j=1}$ is a Følner sequence of $\mathbb{Z}^{k}$, for any positive integers $N$ and $M$; and $\mathcal{F} = \bigcup_{N,M \geq 1} \{F(N,M;j)\}^{\infty}_{j=1}$. We rewrite the definition of $\text{mdim}(X,T;\mathcal{U})$ using $\{F(N,M;j)\}^{\infty}_{j=1}$ in (2.1). By subadditivity of $D$ we have for any finite open cover $\mathcal{U}$ of $X$ and any $N,M \geq 1$
\[
\text{mdim}(X,T;\mathcal{U}) = \lim_{j \to +\infty} \frac{D(\bigvee_{n \in F(N,M;j)} T^{n}\mathcal{U})}{|F(N,M;j)|} = \inf_{j \geq 1} \frac{D(\bigvee_{n \in F(N,M;j)} T^{n}\mathcal{U})}{|F(N,M;j)|}.
\]
Thus,

\[
\text{mdim}(X, T; U) = \inf_{N, M, j \geq 1} \frac{D(\nabla_{n \in F(N, M; j)} T^n U)}{|F(N, M; j)|} = \inf_{F \in \mathcal{F}} \frac{D(\nabla_{n \in F} T^n U)}{|F|}
\]

\[
= \inf_{N, M \geq 1} \frac{1}{2M + 1} \cdot \frac{D(\nabla_{n \in [-N, N]^{k-1}} (T|_{\mathbb{Z}^k}) (\nabla_{m \in [-M, M]} T|_{\mathbb{Z}^k})))}{(2N + 1)^{k-1}}
\]

\[
= \inf_{M \geq 1} \frac{1}{M + 1} \cdot \inf_{N \geq 1} \frac{D(\nabla_{n \in [-N, N]^{k-1}} (T|_{\mathbb{Z}^k}) (\nabla_{m \in [-M, M]} T|_{\mathbb{Z}^k})))}{(2M + 1)^{k-1}}.
\]

Since \(\nabla_{m \in [-M, M]} T|_{\mathbb{Z}^k} \) is independent of \(N\), we have

\[
\text{mdim}(X, T; U) \leq \inf_{M \geq 1} \frac{\text{mdim}(X, \mathbb{Z}^{k-1}, T|_{\mathbb{Z}^k})}{2M + 1} = \inf_{M \geq 1} \frac{\text{mdim}(X, T, (\mathcal{E}_k)^+)_{m \mathbb{Z}^k}}{2M + 1}.
\]

Since \(\text{mdim}(X, T, (\mathcal{E}_k)^+)_{m \mathbb{Z}^k}\) is finite and since \(U\) is an arbitrary finite open cover of \(X\), we conclude that \(\text{mdim}(X, \mathbb{Z}^k, T) = 0\).

We note that for a \(\mathbb{Z}^k\)-action it is possible for us to consider its \((k-1)\)-dimensional directional mean dimension as the \([0, +\infty]\)-valued function on the \((k-1)\)-sphere \(S^{k-1} = \{\vec{v} : ||\vec{v}|| = 1\}\) by associating to \(\vec{v} \in S^{k-1}\) the value of \(\text{mdim}(X, T, (\vec{v})^+)\). The next theorem reveals this function is not necessarily continuous on \(S^{k-1}\) even for \(k = 2\).

**Theorem 3.3** (=-Theorem 1.1). For any \(r \in [0, +\infty]\) there is a \(\mathbb{Z}^2\)-action \((X, \mathbb{Z}^2, T)\) such that if \(\vec{v} \in \{(-1, 0), (1, 0)\}\) then \(\text{mdim}(X, T, (\vec{v})^+) = r\); if \(\vec{v} \in \mathbb{S}\) \(\setminus \{(-1, 0), (1, 0)\}\) then \(\text{mdim}(X, T, (\vec{v})^+) = 0\). In particular, if \(r > 0\), the \((k-1)\)-dimensional directional mean dimension of \((X, \mathbb{Z}^2, T)\) is not continuous on \(\mathbb{S}\).

**Proof.** We provide a constructive proof, following the idea of Example 6.6 in [BL97]. The case \(r = 0\) is trivial. We can suppose \(r = 1\). Indeed, we may replace (in the following argument) \([0, 1]^{2}\) by \([0, 1]^{2}\) if \(r = +\infty\); or by a subshift (even minimal [LW00]) of some \([0, 1]^{2}\) (where \(d > r\)), whose mean dimension is equal to \(r\), if \(0 < r < +\infty\). So we assume \(r = 1\) for simplicity.

We let \(\sigma\) be the full shift on \([0, 1]^{2}\), \(\sigma : \mathbb{Z} \times [0, 1]^{2} \to [0, 1]^{2}\), \((n, (x_m)_{m \in \mathbb{Z}}) \mapsto (x_{m+n})_{m \in \mathbb{Z}}\). We set \(Y = [0, 1]^{2} \times \mathbb{Z}\). We consider an action on \(Y\) as follows:

\[
(3.2) \quad \mathbb{Z}^2 \times Y \to Y, \quad (m, n)(x, i) = (\sigma^m x, n + i), \quad \forall m, n, i \in \mathbb{Z}, \forall x \in [0, 1]^{2}.
\]

Let \(X = Y \cup \{\infty\}\) be the one-point compactification of \(Y\). By defining \((m, n)\infty = \infty\) for all \((m, n) \in \mathbb{Z}^2\) (i.e. \(\infty\) is a fixed point) we may extend the action (3.2) of \(\mathbb{Z}^2\) on \(Y\) continuously to a \(\mathbb{Z}^2\)-action \(T\) on \(X\).

In the remaining part of the proof we shall compute the directional mean dimension of \((X, \mathbb{Z}^2, T)\). We fix an arbitrary \(\vec{v} = (v_1, v_2) \in S\).

**Case 1.** Suppose \(v_2 \neq 0\). We are going to prove \(\text{mdim}(X, T, (\vec{v})^+) = 0\).

In fact, for any finite open cover \(U\) of \(X\) there exist \(M \in \mathbb{N}\) sufficiently large and a finite open cover \(\alpha\) of \([0, 1]^{2}\) such that \(V\) refines \(U\), where \(V\) is a finite open cover of \(X\) consisting of the following members:

- \(A \times \{i\} \subset X, \forall A \in \alpha, \forall i \in [-M, M]\),
- \([0, 1]^{2} \times (\mathbb{Z} \setminus [-M, M]) \cup \{\infty\} \subset X\).
Hence $T^{(m,n)}\mathcal{V}$ ($(m, n) \in \mathbb{Z}^2$) consists of the following members:

- $\sigma^m(A) \times \{i + n\}$, $\forall A \in \alpha$, $\forall i \in [-M, M]$,
- $[0, 1]^2 \times (\mathbb{Z} \setminus [n - M, n + M]) \cup \{\infty\}$.

We thus observe for any $(m, n) \in \mathbb{Z}^2$ with $n \geq 2M + 1$ that $\mathcal{V} \lor T^{(m,n)}\mathcal{V}$ consists of the following members:

- $[0, 1]^2 \times (\mathbb{Z} \setminus [n - M, n + M]) \cup \{\infty\}$,
- $A \times \{i\}$, $\forall A \in \alpha$, $\forall i \in [-M, M]$,
- $\sigma^m(A) \times \{i + n\}$, $\forall A \in \alpha$, $\forall i \in [-M, M]$.

We note that any two elements coming from distinct lines (in the above three) are disjoint. So we have $\mathcal{D}(\mathcal{V}) \leq \mathcal{D}(\mathcal{V} \lor T^{(m,n)}\mathcal{V}) \leq \max\{\mathcal{D}(\mathcal{V}), \mathcal{D}(T^{(m,n)}\mathcal{V})\} = \mathcal{D}(\mathcal{V})$. Similarly, for any $(m, n) \in \mathbb{Z}^2$ with $n \leq -2M - 1$ we also have $\mathcal{D}(\mathcal{V} \lor T^{(m,n)}\mathcal{V}) = \mathcal{D}(\mathcal{V})$. Therefore, by induction we deduce that if a finite subset $F$ of $\mathbb{Z}^2$ satisfies that $|q_1 - q_2| \geq 2M + 1$ whenever $(p_1, q_1) \neq (p_2, q_2) \in F$, then $\mathcal{D}(\bigvee_{(p,q) \in F} T^{(p,q)\mathcal{V}}) = \mathcal{D}(\mathcal{V})$. Thus for any $N \in \mathbb{N}$ we have

$$
\mathcal{D}(\bigvee_{(m,n) \in B_1((\vec{v})^\perp) \cap [-N,N]^2} T^{(m,n)}\mathcal{V}) \leq |B_1((\vec{v})^\perp) \cap [-M - 1, M + 1]^2| : \mathcal{D}(\mathcal{V})
$$

It follows that

$$
\text{mdim}(X, T, (\vec{v})^\perp) = \sup_{\mathcal{U}} \liminf_{N \to +\infty} \frac{\mathcal{D}(\bigvee_{(m,n) \in B_1((\vec{v})^\perp) \cap [-N,N]^2} T^{(m,n)}\mathcal{U})}{\text{vol}(B_1((\vec{v})^\perp) \cap [-N,N]^2)}
\leq \sup_{\mathcal{U}} \liminf_{N \to +\infty} \frac{\mathcal{D}(\bigvee_{(m,n) \in B_1((\vec{v})^\perp) \cap [-N,N]^2} T^{(m,n)})}{\text{vol}(B_1((\vec{v})^\perp) \cap [-N,N]^2)}
\leq \sup_{\mathcal{U}} \liminf_{N \to +\infty} \frac{|B_1((\vec{v})^\perp) \cap [-M - 1, M + 1]^2| : \mathcal{D}(\mathcal{V})}{\text{vol}(B_1((\vec{v})^\perp) \cap [-N,N]^2)}
= 0.
$$

**Case 2.** Suppose $v_2 = 0$. We are going to show $\text{mdim}(X, T, (\vec{v})^\perp) = 1$. In fact, we have

$$
\text{mdim}(X, T, (\vec{v})^\perp) = \sup_{\alpha, M} \liminf_{N \to +\infty} \frac{\mathcal{D}(\bigvee_{n \in [-N,N]} T^{(n,0)}\mathcal{U}_{\alpha,M})}{2N + 1},
$$

where $\mathcal{U}_{\alpha,M}$ is the finite open cover of $X$ consisting of the following members:

- $A \times \{i\}$, $\forall A \in \alpha$, $\forall i \in [-M, M]$,
- $[0, 1]^2 \times (\mathbb{Z} \setminus [-M, M]) \cup \{\infty\},$

and where $\alpha$ ranges over finite open covers of $[0, 1]^2$ and $M$ runs over $\mathbb{N}$. Meanwhile, it is clear that $\mathcal{D}(\bigvee_{n \in [-N,N]} T^{(n,0)}\mathcal{U}_{\alpha,M}) = \mathcal{D}(\bigvee_{n \in [-N,N]} \sigma^n\alpha)$. Thus we deduce

$$
\text{mdim}(X, T, (\vec{v})^\perp) = \sup_{\alpha} \liminf_{N \to +\infty} \frac{\mathcal{D}(\bigvee_{n \in [-N,N]} \sigma^n\alpha)}{2N + 1} = \text{mdim}([0, 1]^2, \sigma) = 1.
$$

$\square$
4. Proof of Theorem 1.2

**Lemma 4.1** ([Nad78, Theorems 1.25, 1.26]). For any compact metric space $X$, $A \in \mathcal{C}(X)$ and $a \in A$ there is a continuous mapping $\kappa : [0, 1] \to \mathcal{C}(X)$ such that $\kappa(0) = \{a\}$, $\kappa(1) = A$, and $\kappa(x) \subset \kappa(y)$ for all $0 \leq x \leq y \leq 1$.

**Lemma 4.2.** Let $X$ be a compact metric space and $C$ a connected component of $X$. Then there exists an open sequence $\{F_n\}_{n=1}^{\infty}$ of clopen subsets of $X$ satisfying $F_1 \supset F_2 \supset \cdots \supset F_n \supset F_{n+1} \supset \cdots \supset \bigcap_{n=1}^{\infty} F_n = C$.

**Proof.** Without loss of generality we assume $C \neq X$. Fix $x \in C$. We denote by $Q_x$ the set of all clopen neighborhoods of $x$ in $X$. Put $Q = \bigcap_{V \in Q_x} V$.

We must claim $C = Q$. To see $C \subseteq Q$, we take $V \in Q_x$ arbitrarily. Since $C \subseteq V$ is a nonempty clopen subset of the connected space $C$, we have $C \cap V = C$ and hence $C \subseteq Q$. To show $Q \subseteq C$, it suffices to prove that $C$ is connected (which, together with the fact that $x \in Q \cap C$ and that $C$ is a connected component of $X$, implies $Q \subset C$). Let $A_1$ and $A_2$ be two disjoint closed subsets of $Q$ such that $A_1 \cup A_2 = Q$. Without loss of generality we may assume $x \in A_1$. Since $A_1$ and $A_2$ are closed in $X$ as well, there exist open subsets $U_1$ and $U_2$ of $X$ such that $A_1 \subset U_1$, $A_2 \subset U_2$, $U_1 \cap U_2 = \emptyset$. It follows that $Q \subset U_1 \cup U_2$ and thus $\{X \setminus V : V \in Q_x\}$ covers $X \setminus (U_1 \cup U_2)$. As the space $X \setminus (U_1 \cup U_2)$ is compact, there exist $V_1, \ldots, V_n \in Q_x$ such that $X \setminus (U_1 \cup U_2) \subset \bigcup_{k=1}^{n} V_k$. This implies $\bigcap_{k=1}^{n} V_k \subset U_1 \cup U_2$. Set $\Omega = \bigcap_{k=1}^{n} V_k$. Clearly, the set $\Omega \cap U_1 = \Omega \cap U_2$ is a clopen neighborhood of $x$ in $X$. Therefore $Q \subset \Omega \cap U_1 \subset \Omega \setminus A_2$. So we have $Q = A_1$. Thus, $Q$ is connected. This proves the claim.

The above claim indicates that $C$ is the intersection of all clopen neighborhoods of $C$ in $X$. Thus for every $a \in X \setminus C$ there must be a clopen subset $C_a$ of $X$ such that $C \subset C_a$ and $a \notin C_a$. This implies that there is an open neighborhood $U_a$ of $a$ in $X$ with $U_a \subset X \setminus C_a \subset X \setminus C$. We notice that $X \setminus C$ is a Lindel"of space and that $\{U_a : a \in X \setminus C\}$ is an open cover of $X \setminus C$. So we can find $\{a_i\}_{i=1}^{\infty} \subset X \setminus C$ such that $X \setminus C = \bigcup_{i=1}^{\infty} U_{a_i}$. Let $F = \bigcap_{i=1}^{\infty} C_{a_i}$. Since for every $c \in X \setminus C$ there is some $i \in \mathbb{N}$ with $c \in U_{a_i} \subset X \setminus C_{a_i} \subset X \setminus F$, we see $F \subset C$. Thus, $F = C$. For each $n \in \mathbb{N}$ we set $F_n = \bigcap_{i=1}^{n} C_{a_i}$. It is simple to check that $\{F_n\}_{n=1}^{\infty}$ is as required. $\square$

Let $(X, \mathbb{Z}^k, T)$ be a continuum-wise expansive $\mathbb{Z}^k$-action with an expansivity constant $2c > 0$.

**Lemma 4.3.** (1) There is $\delta > 0$ such that if $A \subset \mathcal{C}(X)$ and $N \geq 1$ satisfy the condition $c \leq \max\{\text{diam } T^n(A) : n \in [-N, N]^k\} \leq 2c \max\{\text{diam } T^n(A) : n \in \partial[-N, N]^k\} > \delta$.

(2) For any $c > 0$ there is $m = m(c) > 0$ such that if $A \subset \mathcal{C}(X)$ satisfies the condition $\max\{\text{diam } T^n(A) : n \in [-m, m]^k\} \leq 2c \text{ diam } A < \delta$.

**Proof.** (1) Suppose that the statement is false. There exist $\{A_i\}_{i \in \mathbb{N}} \subset \mathcal{C}(X)$ and $\{N_i\}_{i \in \mathbb{N}} \subset \mathbb{N}$ satisfying that

$$c \leq \max\{\text{diam } T^n(A_i) : n \in [-N_i, N_i]^k\} \leq 2c, \quad \forall i \in \mathbb{N};$$

$$\max\{\text{diam } T^n(A_i) : n \in \partial[-N_i, N_i]^k\} \leq 1/i, \quad \forall i \in \mathbb{N}. $$

Suppose that the sequence $\{N_i\}_{i \in \mathbb{N}} \subset \mathbb{N}$ is bounded by some $0 < M < +\infty$. We may assume (by the compactness of $\mathcal{C}(X)$) that $\{A_i\}_{i \in \mathbb{N}}$ converges to some $A \in \mathcal{C}(X)$. Hence (4.1) and (4.2) lead to a contradiction for $\text{diam } T^n(A)$ for some
$n \in [-M, M]^k$. So we assume without loss of generality (by taking a subsequence) that $N_i \to +\infty$ as $i \to \infty$.

We take a sequence \( \{n_i\}_{i \in \mathbb{N}} \subset [-N_i, N_i]^k \) with \( \operatorname{diam} T^{n_i}(A_i) = \max \{\operatorname{diam} T^n(A_i) : n \in [-N_i, N_i]^k\} \) for all $i \in \mathbb{N}$. We claim that the distance between $n_i$ and \( \partial [-N_i, N_i]^k \) goes to $+\infty$ as $i \to \infty$. In fact, if this assertion is not true, then there exists $l \in \mathbb{N}$ such that \( n_i \notin [-N_i + l, N_i - l]^k \) for infinitely many $i \in \mathbb{N}$. For all these $i \in \mathbb{N}$ we write $n_i = p_i + q_i$ with $p_i \in [-l, l]^k$ and $q_i \in \partial [-N_i, N_i]^k$. We take $\epsilon > 0$ sufficiently small such that \( \operatorname{diam} T^n(A) < c/2 \) for all $n \in [-l, l]^k$ whenever \( \operatorname{diam} A < \epsilon \). It follows from (4.2) that \( \operatorname{diam} T^{n_i}(A_i) = \operatorname{diam} T^{n_i}([T^n(A_i)] < c/2 \) for all sufficiently large $i$ (with $1/i < \epsilon$), which contradicts (4.1), and thus proves the claim.

We assume (by choosing a subsequence) that \( T^{n_i}(A_i) \) tends to $B \in C(X)$ as $i \to \infty$. For any given $m \in \mathbb{Z}^k$ there is some $i_0 \in \mathbb{N}$ such that $m + n_i \in [-N_i, N_i]^k$, for all $i \geq i_0$, which, together with (4.1), implies \( \operatorname{diam} T^{m + n_i}(A_i) \leq \max \{\operatorname{diam} T^n(A_i) : n \in [-N_i, N_i]^k\} \leq 2c$. Letting $i \to \infty$ in the above inequality we obtain \( \operatorname{diam} T^m(B) \leq 2c $. Since $B$ is nondegenerate, this is a contradiction.

(2) Suppose that the statement is false. There exist $\epsilon_0 > 0$ and a sequence \( \{A_i\}_{i \in \mathbb{N}} \subset C(X) \) such that \( \max \{\operatorname{diam} T^n(A_i) : n \in [-i, i]^k\} \leq 2c \) and \( \operatorname{diam} A_i \geq \epsilon_0 \) for all $i \in \mathbb{N}$. Choose a subsequence of \( \{A_i\}_{i \in \mathbb{N}} \) tending to some $A \in C(X)$. Clearly, \( \operatorname{diam} T^n(A) \leq 2c \) for all $n \in \mathbb{Z}^k$, and \( \operatorname{diam} A \geq \epsilon_0 \). This is a contradiction. \( \square \)

**Lemma 4.4.** There is a constant $K > 0$ and a sequence \( \{W_N\}_{N \geq 1} \) of finite closed covers of $X$ satisfying that \( \operatorname{mesh}(W_N, d^T_{[-N, N]^k}) < 2c \) and \( \operatorname{ord}(W_N) \leq K N^{k-1} \), for all $N \geq 1$.

**Proof.** Let $\delta > 0$ be a constant introduced in Lemma 4.3 (1). Choose a finite open cover $U = \{U_1, \ldots, U_L\}$ of $X$ with $\operatorname{mesh}(U, d) < \delta/2$. For each $N \geq 1$ we let $U_N$ be an open cover of $X$ defined by $U_N = \bigvee_{\nu \in \partial [-N, N]^k} T^{-\nu}U$. By Lemma 2.2

\begin{equation}
\mathcal{D}(U_N) \leq |\partial [-N, N]^k| : \mathcal{D}(U) \leq 2^k (2N + 1)^{k-1} L, \quad \forall N \geq 1.
\end{equation}

By Lemma 2.1, for each $N \geq 1$ there is a finite closed cover $\mathcal{V}_N$ of $X$, which refines $U_N$ and which satisfies $\operatorname{ord}(\mathcal{V}_N) = \mathcal{D}(U_N)$. For every $V \in \mathcal{V}_N$ we denote by $C_V$ the set of all connected components of $V$. We set $\mathcal{C}_N = \{C \subset V : V \in \mathcal{V}_N, C \in C_V\}$. Note that the sets in $\mathcal{C}_V$ are pairwise disjoint, which implies that the order of $\mathcal{C}_N$ does not increase. So $\mathcal{C}_N$ is obviously a closed (not necessarily finite) cover of $X$, which refines $\mathcal{V}_N$ and which satisfies $\operatorname{ord}(\mathcal{C}_N) = \operatorname{ord}(\mathcal{V}_N)$.

**Claim 1.** For every $N \geq 1$ we have \( \operatorname{mesh}(\mathcal{C}_N, d^T_{[-N, N]^k}) < 2c \).

**Proof of Claim 1.** If $\operatorname{mesh}(\mathcal{C}_N, d^T_{[-N, N]^k}) \geq 2c$ for some $N \geq 1$, then there exists $C \in \mathcal{C}_N$ such that $\max \{\operatorname{diam} T^n(C) : n \in [-N, N]^k\} \geq 2c$ which implies that $d^T_{[-N, N]^k}(x, y) \geq 2c$ for some $x, y \in C$. We assume $C \in \mathcal{C}_V$ for some $V \in \mathcal{V}_N$. By Lemma 4.1, there is a continuous mapping $\kappa : [0, 1] \to C(V)$ satisfying $\kappa(0) = \{x\}$, $\kappa(1) = C$, and $\kappa(s) \subset \kappa(t)$ whenever $0 \leq s \leq t \leq 1$. We define a continuous mapping $F : [0, 1] \to [0, +\infty)$ by sending $t \to \max \{\operatorname{diam} T^n(\kappa(t)) : n \in [-N, N]^k\}$. Clearly, $F(0) = 0$ and $F(1) \geq 2c$. So there is some $0 < t_0 < 1$ with $F(t_0) = 3c/2$. By Lemma 4.3 (1) we get $\max \{\operatorname{diam} T^n(\kappa(t_0)) : n \in \partial [-N, N]^k\} > \delta$ and hence $\max \{\operatorname{diam} T^n(C) : n \in \partial [-N, N]^k\} > \delta$. However, since $\mathcal{C}_N$ refines $U_N$ and since $\operatorname{mesh}(\mathcal{U}, d^T_{[-N, N]^k}) < \delta/2$, we have $\max \{\operatorname{diam} T^n(C) : n \in \partial [-N, N]^k\} < \delta/2$, a contradiction. This shows Claim 1.

**Claim 2.** For every $N \geq 1$ there exists a finite closed cover $\mathcal{W}_N$ of $X$ satisfying that
Proof of Claim 2. We fix \( N \geq 1 \). We take an arbitrary \( V \in \mathcal{V}_N \) for the moment. By Claim 1, \( \text{mesh}(\mathcal{C}_V, d^T_{[-N,N]^k}) < 2c \). Applying Lemma 4.2 to each connected component \( C \) of \( V \) we find a clopen subset \( F_C \supset C \) of \( V \), whose diameter is strictly smaller than \( 2c \) with respect to \( d^T_{[-N,N]^k} \). So we obtain a clopen cover \( \{F_C : C \in \mathcal{C}_V\} \) of \( V \). Since \( V \) is compact, there is a finite subcover \( \{F_{C_1}, F_{C_2}, \ldots, F_{C_{i(V)}}\} \) of \( \{F_C : C \in \mathcal{C}_V\} \). We set \( W^V_1 = F_{C_1}, W^V_2 = F_{C_2} \setminus F_{C_1}, \ldots, W^V_{i(V)} = F_{C_{i(V)}} \setminus \bigcup_{j=1}^{i(V)-1} F_{C_j} \). It follows that \( \{W^V_1, W^V_2, \ldots, W^V_{i(V)}\} \) is a finite closed cover of \( V \) satisfying that \( W^V_s \cap W^V_t = \emptyset \) for all \( 1 \leq s < t \leq i(V) \). Thus, we know that \( W^V_1 = \{W^V_j : 1 \leq j \leq i(V), V \in \mathcal{V}_N\} \) is a finite closed cover of \( V \). This shows Claim 2.

Now by (4.3) and noting that \( \text{ord}(\mathcal{W}_N) \leq \mathcal{D}(\mathcal{U}_N) \) we finish the proof of the lemma.

\[ \square \]

Proof of Theorem 1.2. We fix a nonzero vector \( \vec{v} \in \mathbb{R}^k \). We take \( \epsilon' > 0 \) arbitrarily. We choose a finite open cover \( \alpha \) of \( X \), which consists of open balls of diameter smaller than \( \epsilon' \) and which has a Lebesgue number \( \epsilon > 0 \), with respect to the distance \( d \) on \( X \). Note that we ensure \( \epsilon < \epsilon' \). Applying Lemma 4.3 (2) to \( \epsilon > 0 \), there exists \( m = m(\epsilon) > 0 \) such that for \( A \in \mathcal{C}(X) \), if \( \max(\text{diam } T^{u+u'}(A) : u \in B_1((\vec{v})^+) \cap [-N, N]^k, u' \in [-m, m]^k) \leq 2c \) then \( \max(\text{diam } T^u(A) : u \in B_1((\vec{v})^+) \cap [-N, N]^k) < \epsilon \). By Lemma 4.4, there is some constant \( K > 0 \) such that for every \( N \in \mathbb{N} \) we can find a finite closed cover \( \mathcal{W}_{N+m} = \{W_i\}_{i \in I_N} \) of \( X \) satisfying \( \text{mesh}(\mathcal{W}_{N+m}, d^T_{[-N-m,N+m]^k}) < 2c \) and \( \text{ord}(\mathcal{W}_{N+m}) < K \cdot (N + m)^{k-1} \). For each \( i \in I_N \) we denote by \( P_i \) the set of all connected components of \( W_i \). We put \( C_N = \bigcup_{i \in I_N} P_i \). We notice that connected subsets in \( W_i \) (\( i \in I_N \)) are also connected in \( X \). It follows that \( \text{ord}(C_N) = \text{ord}(\mathcal{W}_{N+m}) \) and \( \text{mesh}(C_N, d^T_{B_1((\vec{v})^+)\cap[-N,N]^k}) < \epsilon \). By a similar argument as in Claim 2 (in Lemma 4.4 above) we can find a finite closed cover \( C'_N \) of \( X \) satisfying that \( \text{ord}(C'_N) = \text{ord}(C_N) \) and \( \text{mesh}(C'_N, d^T_{B_1((\vec{v})^+)\cap[-N,N]^k}) < \epsilon \). Clearly, \( C'_N \) refines \( \bigvee_{n \in B_1((\vec{v})^+)\cap[-N,N]^k} T^n \alpha \). It follows from Lemma 2.1 that \( \mathcal{D}(\bigvee_{n \in B_1((\vec{v})^+)\cap[-N,N]^k} T^n \alpha) \leq \text{ord}(C'_N) < K \cdot (N + m)^{k-1} \) and thus

\[ \text{Widim}_e(X, d^T_{B_1((\vec{v})^+)\cap[-N,N]^k}) \leq \text{ord}(C'_N) < K \cdot (N + m)^{k-1}. \]

We remark that the constant \( K \) depends only on \( (X, \mathbb{Z}^k, T) \). Since \( m \) is independent of \( N \) and since \( \epsilon' > 0 \) is arbitrary, the definition (3.1) allows us to conclude.

\[ \square \]

To end this paper we remark that we also have the following result which unifies Meyerovitch and Tsukamoto’s theorem and Kato’s theorem and which does not include Theorem 1.2. We omit its proof because it is highly similar to Theorem 1.2 and the previously-known results.

- Let \( k \) be a positive integer. If \((X, \mathbb{Z}^k, T)\) is a continuum-wise expansive \( \mathbb{Z}^k \)-action and if a \( \mathbb{Z}^{k-1} \)-action \((X, \mathbb{Z}^{k-1}, R)\) satisfies that \( R : \mathbb{Z}^{k-1} \times X \to X \) commutes with \( T : \mathbb{Z}^k \times X \to X \) (namely \( T^m \circ R^n(x) = R^n \circ T^m(x) \) for all \( m \in \mathbb{Z}^k, n \in \mathbb{Z}^{k-1} \) and \( x \in X \)), then \((X, \mathbb{Z}^{k-1}, R)\) has finite mean dimension.
