A Note on the Integrated Density of States of the 1D Anderson-Bernoulli Model at Rational Energies

Daniel Sánchez-Mendoza

August 16, 2021

Abstract

We give a closed form expression for the integrated density of states of the 1D discrete Anderson-Bernoulli model evaluated at a dense set of energies, provided the disorder parameter is large enough.

1 Introduction and Results

In the previous article [SM21] we showed that there are two sequences of energies, one increasing and one decreasing, at which the integrated density of states (IDS) of the 1D Anderson-Bernoulli model can be given explicitly whenever the disorder is strong enough. For having this property we called such energies special. In this article we prove that they are not special at all. In fact, we show there is a dense set of energies with the same property. Such dense set is the image of $(0, 1) \cap \mathbb{Q}$ under a continuous function, which is why we call its elements rational energies.

For $p \in (0, 1)$ and $\zeta > 0$ the Anderson-Bernoulli model is given by the random operator

$$H_{p,\zeta} := -\Delta + \zeta V_p : \ell^2(\mathbb{N}) \rightarrow \ell^2(\mathbb{N})$$

$$\phi \mapsto (H_{p,\zeta}\phi)(j) := [2\phi(j) - \phi(j+1) - \phi(j-1)] + \zeta V_p(j)\phi(j),$$

where the Laplacian has the Dirichlet boundary condition $\phi(0) = 0$ and the potential $\{V_p(j)\}_{j \in \mathbb{N}}$ is an independent and identically distributed (i.i.d.) sequence of random variables defined over a probability space $(\Omega, \mathcal{F}, \mathbb{P})$ following a Bernoulli($p$) distribution, i.e. $\mathbb{P}[V_p(j) = 1] = p = 1 - \mathbb{P}[V_p(j) = 0]$.

We will always assume $\zeta > 4$, hence the almost sure spectrum of $H_{p,\zeta}$ consists of two spectral bands

$$\sigma(H_{p,\zeta}) = [0, 4] \cup [\zeta, \zeta + 4].$$

For the IDS of $H_{p,\zeta}$, denoted $I_{p,\zeta}$, we use the eigenvalue counting definition

$$I_{p,\zeta}(x) := \lim_{L \to \infty} \frac{1}{L} \#\{\lambda \in \sigma(H_{p,\zeta}|_{\ell^2(\{1,\ldots,L\})}) \mid \lambda \leq x\}, \quad x \in \mathbb{R},$$

and recall that $I_{p,\zeta}$ is a deterministic function.

Before stating our main result we give some definitions. For $x \in (0, 4)$ we set

$$\beta(x) := \frac{\pi}{2 \arcsin(\sqrt{x}/2)}, \quad I_{p}^{\leq}(x) := p^2 \sum_{y=1}^{\infty} (1-p)^y \left\lfloor \frac{y+1}{\beta(x)} \right\rfloor,$$

where $\lfloor \cdot \rfloor$ is the integer part function. These two functions first appeared in [SM21], where $I_{p}^{\leq}$ had a different series representation; we will see later that they coincide.
Theorem 1. Let \( a, b \in \mathbb{N} \) with \( a < b \). If \( \zeta > 4 \max \left\{ 2, \frac{b}{\pi} + 1 \right\} \) then

\[
I_{p, \zeta}(\beta^{-1}(b/a)) = I_{p}^{\leq}(\beta^{-1}(b/a)) = \frac{p^2}{1 - (1-p)^b} \left( \frac{a(1-p)^b}{p} + \sum_{r=0}^{b-1} (1-p)^r \left\lfloor \frac{a(r+1)}{b} \right\rfloor \right).
\]

Moreover \( \lim_{\zeta \to \infty} I_{p, \zeta}(x) = I_{p}^{\leq}(x) \) for all \( x \in (0, 4) \).

Remarks.

1. The unitary map \((U\phi)(j) = (-1)^j \phi(j)\) transforms \( H_{p, \zeta} \) as \( UH_{p, \zeta}U^* = 4 + \zeta - (\Delta + \zeta[1 - V_p]) \).
   Since \( \{1 - V_p(j)\}_{j \in \mathbb{N}} \) is an i.i.d. Bernoulli \((1-p)\) potential, we have
   \[ I_{p, \zeta}(x) = 1 - I_{1-p, \zeta}(4 + \zeta - x). \]
   This equality allows us to derive a similar statement for energies in the second band of \( \sigma(H_{p, \zeta}) \).

2. The limit \( \lim_{\zeta \to \infty} I_{p, \zeta} = I_{p}^{\leq} \) is only point-wise since \( I_{p, \zeta} \) is continuous (see [DS84]) for every \( \zeta > 0 \) while \( I_{p}^{\leq} \) is not.

3. The condition \( \zeta > 4 \max \left\{ 2, \frac{b}{\pi} + 1 \right\} \) is not optimal. From [SM21, Corollary 2] we have
   \[ I_{p, \zeta}(\beta^{-1}(b/1)) = I_{p}^{\leq}(\beta^{-1}(b/1)) \quad \text{and} \quad I_{p, \zeta}(\beta^{-1}(b/b - 1)) = I_{p}^{\leq}(\beta^{-1}(b/b - 1)) \]
   as soon as \( \zeta \geq 4 \).

The proof of Theorem 1 consists of bounding \( I_{p, \zeta} \), from above and below, by the IDS of a direct sum of i.i.d. random operators whose spectra we know or can approximate very well. Most of the work is done as in [SM21]. Here we present it in a more compact form and use a different (neither weaker nor stronger) estimate over the spectra of the operators relevant to the upper bound.

2 Proof of Theorem 1

We define two sequences of random variables

\[
L_1 := \min\{j > 0 \mid V_p(j) = 1\}, \quad Y_1 := L_1 - 1, \\
L_{n+1} := \min\{j > L_n \mid V_p(j) = 1\}, \quad Y_{n+1} := L_{n+1} - L_n - 1,
\]

which give respectively, the position of the 1’s of \( V_p \) and the number of 0’s between them, as show in Figure 1. The \( Y_i \) are i.i.d. following a geometric distribution \( P[Y_i = k] = (1-p)^k p \) for \( k \in \mathbb{N} \cup \{0\} \). By definition \( L_n = n + \sum_{i=1}^{n} Y_i \), so by the Law of Large Numbers we have \( \lim_{n \to \infty} \frac{L_n}{n} = 1 + E[Y_1] = \frac{1}{p} \).

![Diagram](Figure 1: A possible realization of \( H_{p, \zeta} \). The Laplacian is given by the graph structure and the potential by the color of the vertices. White (resp. black) vertices represent points where \( V_p(j) = 0 \) (resp. \( V_p(j) = 1 \).)
We order the eigenvalues of any self-adjoint $n$-dimensional operator $O$ increasingly allowing for multiplicities

$$\lambda_1(O) \leq \lambda_2(O) \leq \cdots \leq \lambda_n(O),$$

and introduce the $n \times n$ matrices $A_n(i,j) := \delta_{i,j}\delta_{1,j} + \delta_{n,i}\delta_{n,j}$ and

$$-\Delta_n := \begin{pmatrix} 2 & -1 \\ -1 & \ddots & \ddots \\ \vdots & \ddots & \ddots & -1 \\ -1 & \cdots & \cdots & 2 \end{pmatrix}, \quad \sigma(-\Delta_n) = \left\{ \lambda_k(-\Delta_n) = 4\sin^2\left(\frac{\pi k}{2(n+1)}\right) \middle| k = 1, \ldots, n \right\}.$$

The lower bound of $I_{p,\zeta}$ just requires an application of the Cauchy Eigenvalue Interlacing Theorem to $H_{p,\zeta}|\ell^2_{\{1, \ldots, L_n\}} = -\Delta_{L_n} + \zeta V_p$. Indeed, if we delete $-\Delta_{L_n} + \zeta V_p$ the $j$-th row and $j$-th column for all $j \in \{1, \ldots, L_n\}$ such that $V_p(j) = 1$, the resulting sub-matrix is $\bigoplus_{i=1}^n -\Delta_{Y_i}$ and therefore

$$\lambda_k(-\Delta_{L_n} + \zeta V_p) \leq \lambda_k \left( \bigoplus_{i=1}^n -\Delta_{Y_i} \right), \quad k = 1, \ldots, \sum_{i=1}^n Y_i.$$

This comparison of eigenvalues gives the lower bound

$$\lim_{n \to \infty} \frac{1}{L_n} \# \left\{ \lambda \in \sigma \left( \bigoplus_{i=1}^n -\Delta_{Y_i} \right) \middle| \lambda \leq x \right\} \leq I_{p,\zeta}(x), \quad x \in \mathbb{R}, \quad \zeta > 0. \quad (1)$$

The limit on the left-hand side of (1) is the definition given to $I_p^\zeta$ in [SM21]. We can easily check that they coincide for $x \in (0,4)$ by applying the Law of Large Numbers:

$$\lim_{n \to \infty} \frac{1}{L_n} \# \left\{ \lambda \in \sigma \left( \bigoplus_{i=1}^n -\Delta_{Y_i} \right) \middle| \lambda \leq x \right\} = \lim_{n \to \infty} \frac{1}{L_n} \sum_{i=1}^n \# \{ \lambda \in \sigma(-\Delta_{Y_i}) \middle| \lambda \leq x \}
= p \mathbb{E} [\# \{ \lambda \in \sigma(-\Delta_{Y_1}) \middle| \lambda \leq x \}]
= p \sum_{y=0}^\infty \mathbb{P}[Y_1 = y] \# \{ \lambda \in \sigma(-\Delta_y) \middle| \lambda \leq x \}
= p^2 \sum_{y=1}^\infty (1-p)^y \max\{k \in \mathbb{N} \middle| k \leq y, \lambda_k(-\Delta_y) \leq x \}
= p^2 \sum_{y=1}^\infty (1-p)^y \left\lfloor \frac{y+1}{\beta(x)} \right\rfloor.$$

Hence we have shown

$$I_p^\zeta(x) \leq I_{p,\zeta}(x), \quad x \in (0,4), \quad \zeta > 0. \quad (2)$$

The upper bound is a bit more involved. From $-\Delta_{L_n} + \zeta V_p$ we define a new (dimensionally larger) operator $-\Delta_{L_n+n} + \zeta V'$ where $V'$ is constructed by doubling each point at which $V_p(j) = 1$ while maintaining the $Y_i$'s, as shown in Figure 2. To be precise, $V'(j) := \sum_{k=1}^\infty (\delta_{L_k+k-1,j} + \delta_{L_k+k,j})$ whereas $V_p(j) = \sum_{k=1}^\infty \delta_{L_k,j}$. In order to compare these two operators we define the linear map $T : \ell^2(\{1, \ldots, L_n\}) \to \ell^2(\{1, \ldots, L_n+n\})$,

$$(T\phi)(j) := \begin{cases} \phi(j-k), & \text{if } L_k+k+1 \leq j \leq L_{k+1}+(k+1)-1, \\ \phi(L_k), & \text{if } j = L_k+k, \end{cases}$$

$$\sum_{v \in \mathbb{Z}} \| \phi_v \|^2 \leq C \sum_{v \in \mathbb{Z}} \| (T\phi)_v \|^2 \quad \leq \sum_{v \in \mathbb{Z}} \| \phi_v \|^2,$$

for some constants $C$. We obtain the upper bound

$$\sum_{v \in \mathbb{Z}} \| \phi_v \|^2 \leq C \sum_{v \in \mathbb{Z}} \| (T\phi)_v \|^2 \quad \leq \sum_{v \in \mathbb{Z}} \| \phi_v \|^2,$$

for some constants $C$. We obtain the upper bound

$$\sum_{v \in \mathbb{Z}} \| \phi_v \|^2 \leq C \sum_{v \in \mathbb{Z}} \| (T\phi)_v \|^2 \quad \leq \sum_{v \in \mathbb{Z}} \| \phi_v \|^2,$$
with the convention \( L_0 = 0 \), which assigns to \( T\phi \) the same values of \( \phi \) according to Figure 2. The map \( T \) is injective and satisfies
\[
\langle \psi, (-\Delta L_n + \zeta V_p)\phi \rangle = \left\langle T\psi, \left(-\Delta L_{n+n} + \frac{\zeta}{2} V' + \zeta V_p\right) T\phi \right\rangle, \quad \psi, \phi \in \ell^2 (\{1, \ldots, L_n\}) .
\]
Let \( \phi_i \) be the normalized eigenvector associated to \( \lambda_i ( - \Delta L_n + \zeta V_p ) \). Define the subspace \( S := \text{Vect} \{ e_{L+k} \mid k = 1, \ldots, n \} \subseteq \ell^2 \left( \{1, \ldots, L_n + n\} \right) \) (where the \( e_i \) stand for the canonical basis) and denote its orthogonal projector \( P_S \). Then, since \( T \) is injective and \( (\text{Id} - P_S)T \) is an isometry, the Min-Max Principle gives for \( k \leq L_n \)
\[
\lambda_k \left( -\Delta L_{n+n} + \frac{\zeta}{2} V' \right) \leq \sup_{(x_1, \ldots, x_k) \in \mathbb{C}^k \setminus \{0\}} \frac{\left\langle \sum_{i=1}^k x_i T\phi_i, (-\Delta L_{n+n} + \frac{\zeta}{2} V') \sum_{i=1}^k x_i T\phi_i \right\rangle}{\left\| \sum_{i=1}^k x_i T\phi_i \right\|^2} \leq \sup_{(x_1, \ldots, x_k) \in \mathbb{C}^k \setminus \{0\}} \frac{\sum_{i=1}^k |x_i|^2 \lambda_i (-\Delta L_n + \zeta V_p)}{(\text{Id} - P_S) \left\| \sum_{i=1}^k x_i T\phi_i \right\|^2} = \sup_{(x_1, \ldots, x_k) \in \mathbb{C}^k \setminus \{0\}} \frac{\sum_{i=1}^k |x_i|^2 \lambda_i (-\Delta L_n + \zeta V_p)}{\sum_{i=1}^k |x_i|^2} = \lambda_k (-\Delta L_n + \zeta V_p)
\]

Figure 2: The first two rows show the of construction of \( V' \) and the action of \( T \). From the second to the third row we have deleted some edges, which lowers the operator and decomposes it into a direct sum.

We can construct form \(-\Delta L_{n+n} + \frac{\zeta}{2} V' \) an operator with further lower eigenvalues by disconnecting each \( Y_i \) together with its two adjacent points at the cost of having Neumann boundary conditions on the Laplacians (see Figure 2). This, together with the previous lower bound on \( \lambda_k (-\Delta L_n + \zeta V_p) \) and the fact that we can write the Neumann Laplacian as \(-\Delta N = -\Delta_n - A_n \) gives,
\[
\lambda_k \left( \text{Boundary term} \oplus \bigoplus_{i=2}^n -\Delta Y_{i+2} + \left( \frac{\zeta}{2} - 1 \right) A_{Y_{i+2}} \right) \leq \lambda_k (-\Delta L_n + \zeta V_p), \quad k = 1, \ldots, L_n.
\]
The Boundary term has $Y_1 + 2$ eigenvalues, so in the limit it disappears and we obtain

$$I_{p, \zeta}(x) \leq \lim_{n \to \infty} \frac{1}{L_n} \left\{ \lambda \in \sigma \left( \bigoplus_{i=1}^{n} -\Delta_{Y_1+2} + \left( \frac{\zeta}{2} - 1 \right) A_{Y_1+2} \right) \left| \lambda \leq x \right\}, \quad x \in \mathbb{R}, \ \zeta > 0. \quad (3)$$

To further bound (3) we need to estimate the eigenvalues of the operators that appear on it, which is the purpose of the next proposition. Before going into it, we remark that such eigenvalues are always simple since their eigenvectors satisfy a second order difference equation with two boundary conditions.

**Proposition 2.** Let $n \in \mathbb{N} \cup \{0\}$ and define $\mu_{k,n+2}(z) := \lambda_k(-\Delta_{n+2} +-zA_{n+2})$. If $z > 3$ then:

i) $0 < \lambda_k(-\Delta_{n+2}) \leq \mu_{k,n+2}(z) \leq \lambda_k(-\Delta_n)$ for $1 \leq k \leq n$.

ii) $4 < \mu_{n+1,n+2}(z) < \mu_{n+2,n+2}(z)$.

iii) $\mu_{k,n+2}(z) \geq 4 \sin^2 \left( \frac{\pi}{2(n+1)} \left[ k - \frac{2}{\pi(z-1)} \right] \right)$ for $1 \leq k \leq n$.

**Proof.**

i) The lower bound follows from $zA_{n+2} \geq 0$ while the upper bound follows from the Cauchy Eigenvalue Interlacing Theorem by deleting the rows (and columns) where $z$ appears.

ii) For $n = 0$ we compute directly

$$\sigma(-\Delta_2 + zA_2) = \sigma \begin{pmatrix} 2 + z & -1 \\ -1 & 2 + z \end{pmatrix} = \{1 + z, 3 + z\}.$$

For $n \geq 1$ we apply the Min-Max Principle (Max-Min in this case):

$$\mu_{n+1,n+2}(z) \geq \min_{\phi \in \text{Vect}(e_1,e_{n+2})} \langle \phi, (-\Delta_{n+2} +-zA_{n+2})\phi \rangle \left\| \phi \right\|_2^2 = 2 + z > 4.$$

iii) We recall that the characteristic polynomial of $-\Delta_n$ can be written as

$$\det(-\Delta_n - x) = (-1)^n U_n \left( \frac{x - 2}{2} \right),$$

where $U_n$ is the $n$-th Chebyshev polynomial of the second kind. For completeness we list here the properties of $U_n$ (see [MH03, Section 1.2.2]) that we will need:

- Recurrent definition:
  $$U_0(x) := 1, \quad U_1(x) := 2x, \quad U_{n+1}(x) := 2xU_n(x) - U_{n-1}(x).$$

- Parity:
  $$U_n(-x) = (-1)^n U_n(x).$$

- Image of $(-1, 1)$:
  $$U_n(\cos \theta) = \frac{\sin((n+1)\theta)}{\sin \theta}.$$
Now we start with the proof. A straightforward computation shows that we can expand the characteristic polynomial of \(-\Delta_{n+2} + zA_{n+2}\) as

\[
\det(-\Delta_{n+2} + zA_{n+2} - x) = (2 + z - x)^2 \det(-\Delta_n - x) - 2(2 + z - x) \det(-\Delta_{n-1} - x) + \det(-\Delta_{n-2} - x)
\]

\[
= (-1)^n \left[ (2 + z - x)^2 U_n \left( \frac{x - 2}{2} \right) + 2(2 + z - x) U_{n-1} \left( \frac{x - 2}{2} \right) + U_{n-2} \left( \frac{x - 2}{2} \right) \right].
\]

By introducing the change of variable \(x' := \frac{x - 2}{2}\) and using twice the recurrent definition of \(U_n\), the previous expression can be reduced to

\[
\det(-\Delta_{n+2} + zA_{n+2} - x) = (-1)^n \left[ (z^2 - 1) U_n(x') - 2(z - x') U_{n+1}(x') \right].
\]

By i) and ii), \(-\Delta_{n+2} + zA_{n+2}\) has exactly \(n\) simple eigenvalues in \((0,4)\). With this in mind, we introduce a parameter \(\theta \in (0,\pi)\) and notice, by evaluating the characteristic polynomial at \(x' = -\cos(\theta)\), that

\[
(z^2 - 1) \sin((n + 1)\theta) = -2(z + \cos \theta) \sin((n + 2)\theta).
\]  

(4)

The condition \(z > 3\) and the trigonometric identity

\[
\sin((n + 2)\theta) = \sin((n + 1)\theta) \cos \theta + \cos((n + 1)\theta) \sin \theta
\]

guarantee that there is no solution to (4) in the set \(\frac{\pi}{n+1} \mathbb{Z}\), hence we can rewrite the equation as

\[
\frac{\sin((n + 2)\theta)}{\sin((n + 1)\theta)} = -\frac{z^2 - 1}{2(z + \cos \theta)},
\]

\[
\cos \theta + \cot((n + 1)\theta) \sin \theta = -\frac{z^2 - 1}{2(z + \cos \theta)},
\]

\[
\tan((n + 1)\theta) = -\frac{2(z + \cos \theta) \sin \theta}{z^2 + 2z \cos \theta + \cos(2\theta)}.
\]  

(5)

To abbreviate we define

\[
f_z(\theta) := \frac{2(z + \cos \theta) \sin \theta}{z^2 + 2z \cos \theta + \cos(2\theta)}, \quad \theta \in (0,\pi),
\]

and remark that \(z > 3\) implies \(f_z(\theta) > 0\).

Applying arc-tangent to (5) and considering that i) actually constrains \(\theta\) to be in \(\left(0, \frac{\pi}{n+1}\right]\), we conclude for \(k = 1, \ldots, n\) that

\[
\mu_{k,n+2}(z) = 4 \sin^2(\theta_k/2) \quad \text{where} \quad \theta_k \text{ is defined by} \quad \theta_k = \frac{\pi k - \arctan f_z(\theta_k)}{n+1}.
\]

The existence of \(\theta_k\) is a consequence of tangent going from \(-\infty\) to \(+\infty\) over a period. Uniqueness comes from \(|\theta_{k+1} - \theta_k| \geq \frac{\pi}{2(n+1)}\) and the fact that \(-\Delta_{n+2} + zA_{n+2}\) has exactly \(n\) eigenvalues in \((0,4)\).
After bounding uniformly $f_z(\theta)$

\[
\sup_{\theta \in (0, \pi)} f_z(\theta) = \sup_{\theta \in (0, \pi)} \frac{2(z + \cos \theta) \sin \theta}{z^2 + 2z \cos \theta + \cos(2\theta)} \\
\leq 2 \sup_{\theta \in (0, \pi)} \frac{z + \cos \theta}{z^2 + 2z \cos \theta + \cos(2\theta)} \\
= 2 \frac{z + \cos \theta}{z^2 + 2z \cos \theta + \cos(2\theta)} \bigg|_{\theta = \pi} = \frac{2}{z - 1},
\]

and using the inequality $\arctan(x) \leq x$ for $x \geq 0$ we obtain

\[
\mu_{k,n+2}(z) \geq 4 \sin^2 \left( \frac{\pi}{2(n+1)} \left[ k - \frac{2}{\pi(z - 1)} \right] \right), \quad k = 1, \ldots, n.
\]

Define $z = z(\zeta) := \frac{\zeta}{\pi} - 1$. Then by (3), the Law of Large Numbers and ii) and iii) of Proposition 2 we have for $\zeta > 8$ (equivalently $z > 3$) and $x \in (0, 4)$:

\[
I_{p,\zeta}(x) \leq p \mathbb{E} \left[ \# \{ \lambda \in \sigma (-\Delta Y_{1+2} + zA_{1+2}) \mid \lambda \leq x \} \right] \\
= p^2 \sum_{y=0}^{\infty} (1 - p)^y \max \{ k \in \mathbb{N} \mid k \leq y + 2, \mu_{k,y+2}(z) \leq x \} \\
= p^2 \sum_{y=1}^{\infty} (1 - p)^y \max \{ k \in \mathbb{N} \mid k \leq y, \mu_{k,y+2}(z) \leq x \} \\
\leq p^2 \sum_{y=1}^{\infty} (1 - p)^y \max \{ k \in \mathbb{N} \mid k \leq y, 4 \sin^2 \left( \frac{\pi}{2(n+1)} \left[ k - \frac{2}{\pi(z - 1)} \right] \right) \leq x \} \\
= p^2 \sum_{y=1}^{\infty} (1 - p)^y \left[ \frac{y + 1}{\beta(x)} + \frac{2}{\pi(z - 1)} \right],
\]

(6)

From (2), (6) and the right continuity of $\lfloor \cdot \rfloor$ we can conclude

\[
\lim_{\zeta \to \infty} I_{p,\zeta}(x) = I_p^\zeta(x), \quad x \in (0, 4).
\]

Now let $a, b \in \mathbb{N}$, $a < b$ and further assume $\zeta > \frac{4b}{\pi} + 4$ (equivalently $z > \frac{2b}{\pi} + 1$). This implies $\frac{b-1}{b} + \frac{2}{\pi(z - 1)} < 1$ and therefore

\[
\left[ \frac{a(y + 1)}{b} + \frac{2}{\pi(z - 1)} \right] = \left[ \frac{a(y + 1)}{b} \right] + \left[ \frac{2}{\pi(z - 1)} \right] \\
\leq \left[ \frac{a(y + 1)}{b} \right] + \frac{b - 1}{b} + \frac{2}{\pi(z - 1)} \left[ \frac{a(y + 1)}{b} \right], \quad y \in \mathbb{N},
\]

where we have used the fractional part $\{x\} = x - \lfloor x \rfloor$. With this we have shown

\[
I_{p,\zeta}(\beta^{-1}(b/a)) = I_p^\zeta(\beta^{-1}(b/a)) = p^2 \sum_{y=1}^{\infty} (1 - p)^y \left[ \frac{a(y + 1)}{b} \right].
\]
It only remains to prove that we can replace the infinite series by a finite sum. This is simply done by using the euclidean division $y = bn + r$ and splitting the series over all possible reminders:

\[
I_p^\leq (\beta^{-1}(b/a)) = p^2 \sum_{y=1}^{\infty} (1 - p)^y \left\lfloor \frac{a(y + 1)}{b} \right\rfloor
\]

\[
= p^2 \sum_{r=0}^{b-1} (1 - p)^r \sum_{n=0}^{\infty} (1 - p)^{bn} \left( an + \left\lfloor \frac{a(r + 1)}{b} \right\rfloor \right)
\]

\[
= p^2 \sum_{r=0}^{b-1} (1 - p)^r \left( \frac{a(1 - p)^b}{1 - (1 - p)^b} + \left\lfloor \frac{a(r + 1)}{b} \right\rfloor \frac{1}{1 - (1 - p)^r} \right)
\]

\[
= \frac{p^2}{1 - (1 - p)^b} \left( \frac{a(1 - p)^b}{p} + \sum_{r=0}^{b-1} (1 - p)^r \left[ \frac{a(r + 1)}{b} \right] \right).
\]
