A hypergeometric proof that $\text{Iso}$ is bijective

Alin Bostan* and Sergey Yurkevich†

August 17, 2021

Abstract

We provide a short and elementary proof of the main technical result of the recent article “On the uniqueness of Clifford torus with prescribed isoperimetric ratio” [4] by Thomas Yu and Jingmin Chen. The key of the new proof is an explicit expression of the central function ($\text{Iso}$, to be proved bijective) as a quotient of Gaussian hypergeometric functions.

In their recent paper [4], Thomas Yu and Jingmin Chen needed to prove, as a crucial intermediate result, that a certain real-valued function $\text{Iso}$ (related to isoperimetric ratios of Clifford tori) is monotonic increasing. They reduced the proof of this fact to the positivity of a sequence of rational numbers $(d_n)_{n \geq 0}$, defined explicitly in terms of nested binomial sums. This positivity was subsequently proved by Stephen Melczer and Marc Mezzarobba [3], who used a computer-assisted approach relying on analytic combinatorics and rigorous numerics, combined with the fact (proved in [4]) that the sequence $(d_n)_{n \geq 0}$ satisfies an explicit linear recurrence of order seven with polynomial coefficients in $n$.

In this note, we provide a shorter and more conceptual proof of the monotonicity of the function $\text{Iso}$. Our approach is different in spirit from the ones in [4] and [3]. Our main result (Theorem 2 below) is that the function $\text{Iso}(z)$ can be expressed in terms of Gaussian hypergeometric functions $\mathbb{2}_F_1$ defined by

$$
\mathbb{2}_F_1 \left[ \begin{array}{c} a & b \\ c & \end{array} ; z \right] = \sum_{n=0}^{\infty} \frac{(a)_n (b)_n}{(c)_n n!} z^n,
$$

where $(a)_n$ denotes the rising factorial $(a)_n = a(a+1) \cdots (a+n-1)$ for $n \in \mathbb{N}$.

In the notation of Yu and Chen, the function

$$
\text{Iso} : [0, \sqrt{2} - 1) \to \left[ \frac{3}{2} \cdot \left(2\pi^2\right)^{-1/4}, 1 \right)
$$

is given as

$$
\text{Iso}(z) = 6\sqrt{\pi} \cdot \frac{V(z)}{A^{3/2}(z)},
$$

*Inria, Univ. Paris-Saclay, France, alin.bostan@inria.fr.
†U. Wien, Austria and Inria, Univ. Paris-Saclay, France, sergey.yurkevich@univie.ac.at.
where $A(z) = \sum_{n \geq 0} \alpha_n z^{2n}$ and $V(z) = \sum_{n \geq 0} \nu_n z^{2n}$ are complex holomorphic functions in the disk $\{ z : |z| < \sqrt{2} - 1 \}$, given by the power series expansions

$$A(z) = \sqrt{2\pi} \cdot \left( 4 + 52z^2 + 477z^4 + 3808z^6 + \frac{451625}{16} z^8 + \ldots \right),$$

$$V(z) = \sqrt{2\pi^2} \cdot \left( 2 + 48z^2 + \frac{1269}{2} z^4 + 6600z^6 + \frac{1928025}{32} z^8 + \ldots \right).$$

The precise definitions of $A$ and $V$ are given in Section 4.3 of [4], notably in equations (4.2)–(4.3). Since the sequences $(\alpha_n)_{n \geq 0}$ and $(\nu_n)_{n \geq 0}$ are expressed in terms of nested binomial sums, $A(z)$ and $V(z)$ satisfy linear differential equations with polynomial coefficients in $z$, that can be found and proved automatically using creative telescoping [2]. Yu and Chen, resp. Melczer and Mezzarobba, use this methodology to find a linear recurrence satisfied by the coefficients $(d_n)_{n \geq 0}$ of

$$F(z) := \frac{1}{4\pi^4} \left( 2V'(\sqrt{z}) A(\sqrt{z}) - 3V(\sqrt{z}) A'(\sqrt{z}) \right) = 72 + 1932z + 31248z^3 + \ldots,$$

respectively a linear differential equation satisfied by the function $F(z)$. Similarly, one can compute linear differential equations satisfied individually by

$$\bar{A}(z) := \frac{1}{\sqrt{2\pi^2}} \cdot A(\sqrt{z}) = 4 + 52z + 477z^2 + 3809z^3 + \frac{451625}{16} z^4 + \ldots$$

and by

$$\bar{V}(z) := \frac{1}{\sqrt{2\pi^2}} \cdot V(\sqrt{z}) = 2 + 48z + \frac{1269}{2} z^2 + 6600z^3 + \frac{1928025}{32} z^4 + \ldots.$$ 

Concretely, $\bar{A}(z)$ and $\bar{V}(z)$ satisfy second-order linear differential equations:

$$z(z-1)(z^2-6z+1)(z+1)^2 \bar{A}''(z)+(z+1)(5z^4-8z^3-32z^2+28z-1)\bar{A}'(z) + (4z^4+11z^3-z^2-43z+13)\bar{A}(z) = 0$$

and respectively

$$z(z-1)(z+1)(z^2-6z+1)^2 \bar{V}''(z) + (z^2-6z+1)(7z^4-22z^3-18z^2+26z-1)\bar{V}'(z) + 3(3z^5-24z^4-2z^3+56z^2-25z+8)\bar{V}(z) = 0.$$ 

From these equations, we deduce the following closed-form expressions:

**Theorem 1.** The following equalities hold for all $z \in \mathbb{R}$ with $0 \leq z \leq \sqrt{2} - 1$:

$$A(z) = \frac{4(1-z^2)}{(z^2-6z+1)^2} \cdot _2F_1 \left[ \begin{array}{c} -\frac{1}{3} \quad -\frac{1}{3} \\ 1 \quad \frac{4z}{(1-z)^2} \end{array} ; \frac{4z}{(1-z)^2} \right]$$

and

$$\bar{V}(z) = \frac{2(1-z)^3}{(z^2-6z+1)^3} \cdot _2F_1 \left[ \begin{array}{c} -\frac{1}{3} \quad -\frac{1}{3} \\ 1 \quad \frac{4z}{(1-z)^2} \end{array} ; \frac{4z}{(1-z)^2} \right] .$$

2
Proof. It is enough to check that the right-hand side expressions satisfy the same linear differential equations as $A$ and $\tilde{V}$, with the same initial conditions. □

As a direct consequence of Theorem 1 and of definition (2) we get:

**Theorem 2.** The function $\text{Iso}$ admits the following closed-form expression:

\[
\text{Iso}^2(z) = \frac{9\sqrt{2}}{8\pi} \cdot \frac{2F1\left[\frac{-3}{4}, -1; \frac{1}{1-2z}; \frac{4z^2}{(1-2z)^2}\right]^2}{2F1\left[\frac{-\frac{1}{4}}{2}, -\frac{1}{4}; \frac{1}{1-2z}; \frac{4z^2}{(1-2z)^2}\right]^3} \cdot \left(\frac{1-z^2}{1+z^2}\right)^3.
\]

Using the expression in Theorem 2, we can now prove the main result of [4].

**Theorem 3.** $\text{Iso}$ is a monotonic increasing function and $\lim_{z \to \sqrt{2} - 1} \text{Iso}(z) = 1$. In particular, $\text{Iso}$ is a bijection.

**Proof.** The value of $\text{Iso}^2(z)$ at $z = \sqrt{2} - 1$ is equal to

\[
\text{Iso}^2(\sqrt{2} - 1) = \frac{9\sqrt{2}}{8\pi} \cdot \frac{2F1\left[\frac{-3}{4}, -1; \frac{1}{1-2z}; \frac{4z^2}{(1-2z)^2}\right]^2}{2F1\left[\frac{-\frac{1}{4}}{2}, -\frac{1}{4}; \frac{1}{1-2z}; \frac{4z^2}{(1-2z)^2}\right]^3} \cdot \frac{\sqrt{2}}{4}.
\]

From Gauss’s summation theorem [1, Th. 2.2.2] it follows that $2F1\left[\frac{-3}{4}, -1; \frac{1}{1-2z}; \frac{4z^2}{(1-2z)^2}\right] = 32/(3\pi)$ and $2F1\left[\frac{-\frac{1}{4}}{2}, -\frac{1}{4}; \frac{1}{1-2z}; \frac{4z^2}{(1-2z)^2}\right] = 4/\pi$; therefore,

\[
\text{Iso}^2(\sqrt{2} - 1) = \frac{9\sqrt{2}}{8\pi} \cdot \frac{(32/(3\pi))^2}{(4/\pi)^3} \cdot \frac{\sqrt{2}}{4} = 1.
\]

It remains to prove that $\text{Iso}$ is monotonic increasing. It is enough to show that

\[
z \mapsto \frac{2F1\left[\frac{-\frac{1}{4}}{2}, \frac{1}{2}; \frac{1}{1-z}; \frac{4z}{(1-z)^2}\right]^2}{2F1\left[\frac{-\frac{1}{4}}{2}, -\frac{1}{4}; \frac{1}{1-z}; \frac{4z}{(1-z)^2}\right]^3} \cdot \left(\frac{1-z}{1+z}\right)^3
\]

is increasing on $[0, 3-2\sqrt{2})$. Equivalently, via the change of variables $x = \frac{4z}{(1-z)^2}$, it is enough to prove that the function

\[
x \mapsto \frac{2F1\left[\frac{-\frac{1}{4}}{2}, -\frac{1}{4}; x, \frac{1}{x+1}\right]^2}{2F1\left[\frac{-\frac{1}{4}}{2}, -\frac{1}{4}; x, \frac{1}{x+1}\right]^3} \cdot (x+1)^{-\frac{3}{2}}
\]

is increasing on $[0, 1)$. Clearly, $h$ can be written as $h = f^3 \cdot g^2$, where

\[
f(x) = \frac{\sqrt{x+1}}{2F1\left[\frac{-\frac{1}{4}}{2}, -\frac{1}{4}; \frac{1}{x+1}\right]} \quad \text{and} \quad g(x) = \frac{2F1\left[\frac{-\frac{1}{4}}{2}, -\frac{1}{4}; x\right]}{(x+1)^{\frac{3}{2}}}.
\]
Hence, it is enough to prove that both \( f \) and \( g \) are increasing on \([0, 1]\). We will actually prove a more general fact in Proposition 1, which may be of independent interest. Using that \( w_{1/2} = 1/f \) and \( w_{3/2} = g \), we deduce from Proposition 1 that both \( f \) and \( g \) are increasing. This concludes the proof of Theorem 3. □

**Proposition 1.** Let \( a \geq 0 \) and let \( w_a : [0, 1] \to \mathbb{R} \) be defined by

\[
w_a(x) = \frac{2F_1[\frac{-a}{1} - a; x]}{(x + 1)^a}.
\]

Then \( w_a \) is: decreasing if \( 0 < a < 1 \); increasing if \( a > 1 \); constant if \( a \in \{0, 1\} \).

**Proof.** Clearly, if \( a \in \{0, 1\} \), then \( w_a(x) \) is constant, equal to 1 on \([0, 1] \).

Consider now the case \( a > 0 \) with \( a \neq 1 \). The derivative of \( w_a(x) \) satisfies the hypergeometric identity

\[
\frac{w'_a(x) \cdot (x + 1)^{a+1}}{a \cdot (a-1) \cdot (1-x)^{2a}} = 2F_1\left[\frac{a+1}{2}; x\right],
\]

which is a direct consequence of Euler’s transformation formula [1, Eq. (2.2.7), p. 68] and of Lemma 1 with \( a \) substituted by \(-a\).

Since \( a > 0 \), the right-hand side of (3) has only positive Taylor coefficients, therefore it is positive on \([0, 1]\). It follows that \( w'_a(x) \geq 0 \) on \([0, 1]\) if \( a - 1 > 0 \), and \( w'_a(x) \leq 0 \) on \([0, 1]\) if \( a - 1 < 0 \). Equivalently, \( w_a \) is increasing on \([0, 1]\) if \( a > 1 \), and decreasing on \([0, 1]\) if \( a < 1 \).

**Lemma 1.** The following identity holds:

\[
(a+1)(1-x) \cdot 2F_1\left[\frac{a+1}{2}; x\right] = a(x+1) \cdot 2F_1\left[\frac{a+1}{2}; x\right] + 2F_1\left[\frac{a}{1}; x\right].
\]

**Proof.** We will use two of the classical Gauss’ contiguous relations [1, §2.5]:

\[
2F_1\left[\frac{a+1}{c+1}; x\right] = \frac{c}{b} \cdot \left(2F_1\left[\frac{a+1}{c}; x\right] - 2F_1\left[\frac{a}{c}; x\right]\right)
\]

and

\[
a \cdot \left(2F_1\left[\frac{a+1}{c}; x\right] - 2F_1\left[\frac{a}{c}; x\right]\right) = \frac{(c-b) \cdot 2F_1\left[\frac{a+1}{c}; x\right] + (b-c+ax) \cdot 2F_1\left[\frac{a}{c}; x\right]}{1-x}.
\]

Applying (4) twice, once with \((b, c) = (a, 1)\) and once with \((b, c) = (a+1, 1)\), the proof of the lemma is reduced to that of the identity

\[
(x-1) \cdot 2F_1\left[\frac{a+1}{1}; x\right] + 2 \cdot 2F_1\left[\frac{a+1}{1}; x\right] = 2F_1\left[\frac{a}{1}; x\right],
\]

which follows from (5) with \((b, c) = (a+1, 1)\).
