Abstract

Erdős and Turán proved a classical inequality on the distribution of roots for a complex polynomial in 1950, depicting the fundamental interplay between the size of the coefficients of a polynomial and the distribution of its roots on the complex plane. Various results have been dedicated to improving the constant in this inequality, while the optimal constant remains open. In this paper, we give the optimal constant, i.e., prove the sharp Erdős-Turán inequality. To achieve this goal, we reformulate the inequality into an optimization problem, whose equilibriums coincide with a class of energy minimizers with the logarithmic interaction and external potentials. This allows us to study their properties by taking advantage of the recent development of energy minimization and potential theory, and to give explicit constructions via complex analysis. Finally the sharp Erdős-Turán inequality is obtained based on a thorough understanding of these equilibrium distributions.

1. Introduction

1.1. Main Results and Consequences. Erdős and Turán prove a beautiful result on the distribution of roots for polynomials $f(z) \in \mathbb{C}[z]$ in their 1950 work [ET50], that is, if $|f(z)|$ attains small value on the unit circle $|z| = 1$, then firstly the magnitudes of roots of $f(z)$ are close to 1, secondly the angular distribution of the roots is close to equidistribution on $\mathbb{T}$. See [Sou19 Figure 1] for a pictorial illustration. The statement on the magnitude of roots is a consequence of Jensen’s formula in complex analysis, see e.g. [Sou19 Theorem 1] for a compact treatment. The statement on the angular distribution requires much more work.

The main goal of this paper is to give a sharp inequality characterizing this phenomenon of equidistribution in angles. Let $f(z) = \sum_{k=0}^{n} a_k z^k$ be a degree $n$ polynomial with complex coefficients and $a_0 \neq 0$. We denote its roots by $r_j e^{2\pi i \theta_j}$ for $1 \leq j \leq n$ with $\theta_j \in \mathbb{T} = \mathbb{R}/\mathbb{Z}$. For $\alpha \leq \beta < \alpha + 1$, we write $N_f(\alpha, \beta)$ to be the number of roots with $\theta_j \in [\alpha, \beta]$ when considered as a subset in $\mathbb{T}$. The theorem relates two quantities of $f(z)$. We first define the discrepancy of a polynomial $f$ to be

$$D[f] := \max_{\alpha \leq \beta < \alpha + 1} \frac{N_f(\alpha, \beta)}{n} - (\beta - \alpha),$$

measuring the deviation of the angle distribution of roots away from the uniform distribution on the unit circle, then we define the height of a polynomial by

$$H[f] := \frac{1}{n} \log \max_{|z|=1} |f(z)|,$$

measuring how large $f$ is on the unit circle. Our main theorem is the following.

**Theorem 1.1** (Sharp Erdős-Turán Inequality). For any polynomial $f(z) \in \mathbb{C}[z]$ with $f(0) \neq 0$, we have

$$D[f] \leq \sqrt{2} \cdot \sqrt{H[f]},$$

Moreover, this inequality is sharp.

Theorem 1.1 gives a sharp improvement upon the original inequality of Erdős and Turán, where the constant $\sqrt{2}$ is replaced with 16.

Historically, one of the motivations for Erdős and Turán to study this type of inequality is from number theory. The question of bounding the number of real solutions of a polynomial is of great interest. One perspective for the Erdős-Turán inequality is to give an error term for the angular distribution when the uniform distribution is considered as the main term in $n$

$$N_f(\alpha, \beta) = (\beta - \alpha) \cdot n + O_f(\sqrt{n}).$$

The dependence of $f$ in the error term can be bounded by $\|f\|_{L^\infty(|z|=1)}/\sqrt{|a_0 a_n|}$ by Theorem 1.1. Bloch and Pólya [BP32] first investigated how to bound the number of real zeros of a polynomial $f(z)$ using the size of its coefficients. Schmidt [Sch32] and Schur [Sch33] refined the result by giving a bound in terms of certain height just involving the degree $n$ and sum of coefficients. By applying the inequality to small intervals near the axis, Erdős and Turán recover the result of Schmidt and Schur as an immediate consequence. Moreover due to a different choice of height function, the upper bound of Erdős and Turán gives a slight improvement up to the constant. We denote $N_+(f)$ (respectively $N_-(f)$) to be the number of roots with angle $\theta$ (respectively positive and negative) of $f(z) \in \mathbb{C}[z]$. As a by-product of Theorem 1.1, we also obtain sharp estimates for the number of real roots with a given sign in terms of $H[f]$.

**Theorem 1.2** (Sharp Estimates for Signed Real Roots). For any polynomial $f(z) \in \mathbb{C}[z]$ with $f(0) \neq 0$ and any $\theta \in \mathbb{T}$, we have the sharp inequality

$$N_\theta(f) \leq \sqrt{2} \cdot \sqrt{H[f]} \cdot n.$$
In particular, we have the sharp estimate
\[
N_+(f) \leq \sqrt{2} \cdot \sqrt{\mathcal{H}[f]} \cdot n, \quad N_-(f) \leq \sqrt{2} \cdot \sqrt{\mathcal{H}[f]} \cdot n,
\]
for the number of positive real roots of \( f(z) \) and the number of negative real roots of \( f(z) \).

Although the sharp estimate for the total number of real roots does not follow directly from Theorem 1.1, we will prove in a separate forthcoming note the sharp estimate for the number of real roots in terms of \( \mathcal{H}[f] \) from a similar approach we prove Theorem 1.1.

This inequality also has close connections to the theory of complex analysis and harmonic functions. In [Gan54], Ganelius first made the connection of this inequality to harmonic functions. Let \( u \) and \( v \) be a pair of conjugate harmonic functions inside the unit circle. Ganelius proved a theorem bounding the difference of \( v \) by the maximal value of \( u \) and \( \partial v / \partial \theta \) in the unit disk. He then applies it to deduce the inequality of Erdős and Turán with a better constant. Mignotte [Mig92] slightly refined the result by replacing the upper bound of \( u \) with the integral of \( u_+ \) (the positive part of \( u \)) on the unit circle. We manage to show that Ganelius’ conjugate function problem turns out to be equivalent to the Erdős and Turán inequality, thus Theorem 1.1, in turn, implies a sharp estimate on harmonic functions. To our knowledge, such an equivalence has been neither noticed nor utilized before.

**Theorem 1.3 (Sharp Estimates for Harmonic Functions).** Let \( f(z) = u(z) + iv(z) \) be an analytic function in \( |z| < 1 \) with \( f(0) = 0 \). Suppose \( u \leq H \) and \( \partial v / \partial \theta \leq K \) in \( |z| < 1 \), where \( H, K > 0 \), we prove the following sharp estimate
\[
|v(z_1) - v(z_2)| \leq \sqrt{2\pi} \cdot \sqrt{HK}, \quad \text{for } |z_1|, |z_2| < 1.
\]

1.2. **Questions and History.** The original work of Erdős and Turán [ET50] is partly motivated by number theoretic questions like bounding real roots for a polynomial. Indeed another earlier work of Erdős and Turán [ET40] in particular studies the distribution \( \{a_n\} \subseteq [-1, 1] \) depending on the value of \( f(z) = \prod_j (z - a_j) \) on \([-1, 1]\). The height function \( \mathcal{H}[f] \) is reasonably defined for a polynomial \( f(z) \) with the normalizing factor \( \sqrt{|a_0 a_n|} \), since the reflection of \( f \) with respect to the unit circle preserves the angular distribution up to a rotation. Therefore it is natural to imagine that the interesting case to study is actually when all the roots of \( f \) lie on \( |z| = 1 \). This in fact has been observed and justified by [Sch33]. Therefore the question at the core is fundamentally the following: given \( f(z) = \prod_j (z - z_j) \) with \( z_j = e^{2\pi i \theta_j} \), what is the minimal value of \( \max_{|z| = 1} |f(z)| \)?

With such a simple and clean form of this question, the inequality of Erdős and Turán inevitably has connections to many questions in different areas. In [ET50] the inequality is also applied to recover the result of Jentzsch [Jen10] and Szegő [Sze31] in complex analysis that every point of the circle of convergence for a power series is a limit point of zeros of its partial sums. It is also noted by [ET40] that such an equidistribution theorem has a potential theoretic characterization that dates back to Hilbert in 1897. We can imagine that the roots of a polynomial are negatively charged particles and they repel each other with a force, and equidistribution corresponds to a state where the energy is minimized. Indeed, one of our main tools in this paper will be to apply recent development in modern potential theory and energy minimization to review this old question. Potential theoretic approach has also appeared in studies of closely related questions, for example in Bilu’s result on equidistribution of roots for \( f(z) \in \mathbb{Z}[x] \) [Bil97], see [Grad07] for a nice exposition. This result also has applications towards small points on abelian varieties [Zha93, Zha98]. In [CGPS00], this inequality is applied to study distribution of roots of Fekete polynomials, which has applications on the distribution of \( L \)-function values.

After the fundamental works of Erdős and Turán [ET40, Erd32, ET50] in the 1940s, questions on equidistribution and discrepancy have been generalized in various directions. We refer
interested audiences to [AB02] for a collection of results on generalizations. We give some examples, far from being exhaustive, in the following. Instead of using this notion of height \( \mathcal{H}(f) \), one can bound the discrepancy \( D(f) \) using other quantities. Mignotte in [Mig92] gives a bound of \( D(f) \) in terms of \( h[f] := \int_{\mathbb{T}} (\log |f(e^{i\theta})|)_{+} d\theta \leq \mathcal{H}(f) \), which is equivalent to take \( L^1(\mathbb{T}) \) norm of \( \log |f(z)| / \sqrt{|a_0a_n|} \) whereas \( \mathcal{H}(f) \) is close to a \( L^\infty \) norm of \( \log |f(z)| / \sqrt{|a_0a_n|} \). See also [Sou19, CDF+21] for inequalities involving \( h[f] \). In [Bil97], Bilu uses the Mahler measure for an integral polynomial \( M[f] = \exp(\int_{\mathbb{T}} \log |f(z)| d\theta) \) to bound the discrepancy. This is also generalized to higher dimensions. Hiëussing [Hue01] has used energy to bound discrepancy for signed measures. Instead of working over \( \mathbb{R} \), Soundararajan uses \( \mu \) on a general quasiconformal curve and bound the discrepancy in terms of the value \( \log(\mathcal{H}(f)) \) on the curve. On the segment \([-1,1] \), [Bla92, Tot93] studies the equidistribution distribution of simple roots of a polynomial. Results in higher dimensions are also studied in [Ste21]. More recently, in [Sjö72, G00], Steinerberger studies the bound for Wasserstein distance from the uniform distribution, which generalizes the notion of discrepancy on \( \mathbb{T} \). We also mention works on roots distribution of polynomials related to Erdős-Turán inequality. For more refined discussion on the modulus of roots for polynomials, see [Erd08]. Erdős-Turán inequality is also applied to study roots of polynomials with small coefficients [OP93], Fekete polynomials [CGPS00], and random polynomials [HN08, PS14].

Despite the huge amount of generalization, the original form of Erdős and Turán inequality hasn’t been improved much ever since the early 1950s. As commented in [AB02], the constant remains the only factor that is not sharp in this inequality. Early work of Ganelius [Gan54] improved this constant to \( \sqrt{2\pi/k} \approx 2.5619 \) where \( k \) is the Catalan constant. In a very recent work [Son19], Soundararajan uses \( h[f] \) to bound \( D(f) \) by an elegant Fourier argument. As a consequence it sharpens the constant to \( 8/\pi \approx 2.5464 \). In the AIM workshop in 2021, a group involving the second author sharpens the tools of Soundararajan. In [CDF+21], the group improves the constant to \( 4/\sqrt{\pi} \approx 2.2567 \) by giving a complete solution of a Fourier optimization problem. This seems to be the best one can extract from this Fourier argument. We remark that optimizing the inequality with respect to \( h[f] \) will be a different problem, as the optimal polynomial will probably be different. It is observed by Mignotte [Mig92], an unpublished note of Soundararajan and the recent AIM work [CDF+21], that the optimal constant for bounding \( D(f) \) by \( h[f] \) is at least about 1.7593, which is achieved when \( f(z) = (z - 1)^n \). We mention that Mignotte and Amoroso [AM96] constructed a sequence of polynomials with \( \mathcal{H}(f)/D(f)^2 \) approaching to 1/2, indicating that the optimal constant in the Erdős-Turán inequality cannot be smaller than \( \sqrt{2} \), which is exactly the constant we prove in Theorem 1.1.

1.3. Methods.

1.3.1. Schur’s Observation. A crucial simplification for Theorem 1.1 is due to Schur. In [Sch33] Schur showed that to state Theorem 1.1 for all polynomials, it suffices to prove it for \( f(z) \) where all roots are unimodular. Indeed, given \( f(z) = a_n \prod_j (z - r_j e^{i\theta_j}) \) and \( \bar{f}(z) = \prod_j (z - e^{-i\theta_j}) \), one can observe that

\[
\frac{|f(z)|}{\sqrt{|a_0a_n|}} \leq |\bar{f}(z)|, \text{ for } |z| = 1,
\]

whereas the discrepancy remains the same, see for example [Son19, Section 3]. Therefore to study the optimal constant, it suffices to focus on \( f \) with all roots on the unit circle \( \mathbb{T} \). After normalization to monic polynomials, we can assume \( |a_n| = a_n = 1 \), so \( \mathcal{H}(f) \) is simply the maximal value of \( \log(|f(z)|^{1/n}) \) on unit circle \( \mathbb{T} \).

To demonstrate the phenomenon quantified by this inequality, we look at two contrasting polynomials \( (z - 1)^n \) and \( z^n - 1 \) with all roots on the unit circle. The polynomial \( f(z) = (z - 1)^n \)
is the most discrepant polynomial with degree \( n \) since \( z = 1 \) is a root of multiplicity \( n \) and the angular distribution is supported on a single point \( \theta = 0 \), which is far away from being equidistributed. Meanwhile \( |f(z)| \) attains the maximal value \( 2^n \) at \( z = -1 \), which is exponentially large in the degree, and \( \mathcal{D}[f] \) is achieved at \( \alpha = \beta = 0 \) with the value \( \mathcal{D}[f] = 1 \). Theorem 1.1 predicts \( 1 \leq \sqrt{2 \cdot \log 2} \approx 1.18 \). The other polynomial \( f(z) = z^n - 1 \) has all roots that are \( n \)-th roots of unity, and is the most evenly distributed polynomial with degree \( n \). The discrepancy is \( \mathcal{D}[f] = 1/n \) and \( \max_{|z|=1} |f(z)| \) is as small as 2. In this case Theorem 1.1 says \( 1/n \leq \sqrt{2 \log 2/n} \).

This also implies that \( \mathcal{H}/\mathcal{D}^2 \) cannot be bounded from above.

### 1.3.2. From Discrete to Continuous

Although this question is originally stated as one about roots distribution of polynomials, it can be considered as a question just about distributions of \( n \) points on the unit circle, thanks to Schur’s observation and the convenient translation between polynomials and their roots. Since the degree of \( f \) can be arbitrarily large, the extreme case will clearly take place when \( n \) is large enough. This leads to one of the main ideas in proving Theorem 1.1 that is, to solve the discrete problem using continuous methods. Instead of considering discrete measures supported on \( n \) points, we will enlarge the class of distributions of consideration to all probability measures \( \mathcal{M} \) on \( \mathbb{T} \).

Under the language of probability measures, we can describe the root distribution of \( f(z) \) by an empirical measure of \( n \) points

\[
\rho_f = \frac{1}{n} \sum_j \delta_{\theta_j},
\]

where \( \delta_{\theta_j} \) is the Dirac function at \( \theta_j \). The concepts of discrepancy \( \mathcal{D}[f] \) and height \( \mathcal{H}[f] \) of a polynomial can now be naturally extended to an arbitrary probability measure \( \rho \) by defining

\[
\mathcal{D}[\rho] := \sup_I \int_I (\rho - 1) \, d\theta, \quad \mathcal{H}[\rho] := -\text{ess inf}_{T} \mathcal{H}(W \ast \rho),
\]

where \( I \subset \mathbb{T} \) is any closed interval on the unit circle and \( W(x) = -\log |1 - e^{2\pi i x}| = -\log |2 \sin(\pi x)| \).

We then extend the question to an optimization problem of \( \mathcal{H}[\rho]/\mathcal{D}[\rho]^2 \) for general \( \rho \in \mathcal{M} \). Notice that we can also conveniently approximate a probability distribution by empirical measures with large \( n \), see Section 7 for the details. Therefore it suffices for us to prove the following.

**Theorem 1.4.** For all probability measure \( \rho \in \mathcal{M} \) on \( \mathbb{T} \), we have the sharp inequality

\[
\mathcal{D}[\rho] \leq \sqrt{2} \cdot \sqrt{\mathcal{H}[\rho]}.
\]

1.3.3. **Potential Theory.** As an optimization problem, we see that the optimizer is not among the trivially extremal ones, in view of the two previous examples. So one of the main challenges is to construct distributions with the optimal value. The main tool for us to characterize the shape of the optimal distribution is potential theory and energy minimization.

We start by giving a potential theoretic description of Theorem 1.4. The reader can also find basic potential theoretic facts in [ST13]. As we noted before \( \mathcal{H}[\rho] = -\text{ess inf}(W \ast \rho) \), where \( W(x) = -\log |2 \sin(\pi x)| \). We can view \( W \) as a pairwise interaction potential among particles. Its negative sign stands for the repulsion when two particles are close. For a probability distribution \( \rho \in \mathcal{M} \), we denote \( V[\rho] := W \ast \rho \) to be the potential field generated by \( \rho \) with the logarithmic potential \( W \), then the total potential energy of \( \rho \) is

\[
\mathcal{E}[\rho] := \frac{1}{2} \int_{\mathbb{T}} (W \ast \rho) \cdot \rho \, d\theta.
\]

Since \( W(x) \) is mean zero over \( \mathbb{T} \), we see \( V[1_{\mathbb{T}}] = W \ast 1_{\mathbb{T}} \equiv 0 \) and it is easy to show that \( 1_{\mathbb{T}} \) is the unique probability measure with \( \mathcal{E}[1_{\mathbb{T}}] \leq 0 \). Such a probability measure \( \rho \) that minimizes the total energy is called the energy minimizer or equilibrium. On the other hand, it was shown in
that \( D[\rho] := 2 \cdot d_\infty(\rho, 1_T) \), which is the Wasserstein-infinity distance between \( \rho \) and the uniform distribution \( 1_T \). We mention that Wasserstein distances are the most natural distance in studies like optimal transport.

Then \((1.10)\) as
\[
d_\infty(1_T, \rho) \leq \frac{1}{\sqrt{2}} \cdot \|(V[1_T] - V[\rho])_+\|_\infty^{1/2} = \frac{1}{\sqrt{2}} \cdot \sqrt{\text{ess inf} V[\rho]}.
\] (1.12)

Now we can interpret Theorem \((1.4)\) as saying if the potential generated by \( \rho \) is close to the equilibrium, then \( \rho \) is close to the equilibrium under the \( d_\infty \) metric. In a forthcoming work, the authors will exactly use this formulation and give an application of Erdős-Turán type inequality towards stability of energy minimizers.

### 1.3.4. Energy Minimization

In this part, we characterize the property for the optimal distributions. We first restrict this optimization problem of \( \mathcal{H}/\mathcal{D}^2 \) from \( \rho \in \mathcal{M} \) to \( \rho \in \mathcal{M}_{D \geq d} \), where \( D[\rho] \geq d \). Then the optimal value for \( \mathcal{H}/\mathcal{D}^2 \) can be approximated as \( d \) approaches 0,
\[
\inf_{\rho \in \mathcal{M}} \mathcal{H}[\rho]/D[\rho]^2 = \lim_{d \to 0^+} \inf_{\rho \in \mathcal{M}_{D \geq d}} \mathcal{H}[\rho]/D[\rho]^2.
\] (1.13)

Then in Section \([3]\) our main goal is to translate the problem of optimizing \( \mathcal{H}[\rho]/D[\rho]^2 \) with fixed \( d \) into an energy minimization problem with certain fixed external potentials \( U \). Given an external potential \( U \), we define
\[
V_U[\rho] := U + W \ast \rho, \quad \mathcal{E}_U[\rho] := \frac{1}{2} \int_T (W \ast \rho)(x) \cdot \rho(x) \, dx + \int_T U(x) \rho(x) \, dx,
\] (1.14)
for arbitrary \( \rho \in \mathcal{M}_m \), which is the set of measures over \( T \) with total mass \( m \). We study the properties of energy minimizers in Section \([3.3]\). The theory of energy minimization guarantees that for fixed \( m \) and \( U \), if \( W \) and \( U \) are both nice, then there exists a unique \( \rho \in \mathcal{M} \) with minimal \( \mathcal{E}_U \). Moreover, such an energy minimizer \( \rho \) always satisfies the condition
\[
V_U[\rho](x) \leq \text{ess inf}(V_U[\rho]), \quad \forall x \in \text{supp } \rho.
\] (1.15)

We say that a measure \( \rho \) satisfying \((1.15)\) is sediment with respect to \( U \). Intuitively this condition is saying that all of the mass of \( \rho \) is resting at the bottom of the total potential \( V_U[\rho] \) generated by \( \rho \) and \( U \). It is shown that such a sediment distribution \( \rho \) is unique. Moreover among all \( \rho \in \mathcal{M}_m \), the unique sediment \( \rho \) sees the highest bottom, i.e. has the largest ess inf \( V_U[\rho] \). See Proposition \([3.5]\) for detailed treatment.

On the other hand, we develop a transport plan called microscopic diffusion in Section \([3.2]\) to study the minimizer of \( \mathcal{H}/\mathcal{D}^2 \) in \( \mathcal{M}_{D \geq d} \). It shows that if a certain \( \rho \in \mathcal{M}_{D \geq d} \) has \((W \ast \rho)(x_0) > \text{ess inf}(W \ast \rho)\) for some \( x_0 \in \text{supp } \rho \), then we can always construct a local diffusion such that \( W \ast \rho \) increases for \( x \) away from \( x_0 \). Therefore as long as the local operation stays away from the endpoints of \( I \) witnessing \( D \), we will be able to decrease \( \mathcal{H}/\mathcal{D}^2 \). The key of this argument lies in the convexity of our potential function \( W(x) = -\log(2 \sin(\pi x)) \). What it implies is an ultimate surprise and stunning connection, the minimizer of \( \mathcal{H}/\mathcal{D}^2 \) in \( \mathcal{M}_{D \geq d} \) is the unique sediment distribution with respect to the external potential \( U \) generated by Dirac mass(es) at endpoints of \( I \). This leads to the characterization of minimizer(s) for \( \mathcal{H}/\mathcal{D}^2 \) in Theorem \([3.1]\). For this part, our method will also work in general for \( \mathcal{H}/\mathcal{D}^\alpha \) for any \( \alpha \geq 0 \) and for a more general class of interaction potentials \( W \).

### 1.3.5. Construction of Minimizers

Next, our goal is to construct explicit distributions satisfying the characterization in Theorem \([3.1]\). For each Dirac mass(es) configuration \( \rho_d \) (position \( M \) and mass \( m \)), there exists a unique sediment distribution with respect to \( U = W \ast \rho_d \). Therefore it suffices to construct sediment distributions for each \( M \) and \( m \) in order to find a pool of candidates
for the minimizer. In Section 4 we start with constructing a larger family of distributions, called stationary distribution with respect to $U$, which satisfies

$$V_U[\rho](x) = 0, \quad x \in \text{supp } \rho.$$

Intuitively these are the distributions where all mass of $\rho$ are stationary and has total force 0. The construction heavily depends on the fact that the kernel of the Hilbert transform is derivative of logarithm. Due to this elegant connection between logarithmic potential and Hilbert transform, we are able to construct these distributions $\rho$ as the real part $\Re(g)$ of some nice analytic functions $g(z)$, while $\Im(g) = -\frac{1}{\pi} (W * \Re(g))'$ is the derivative of the generated potential. By constructing analytic functions $g(z)$ which are either totally real or totally imaginary, we thus obtain $\rho$ where $(W * \Re(g))' = V_U[\rho]'$ is 0 on supp $\rho$. In order to evaluate the minimal value of $\mathcal{H}/\mathcal{D}^2$ conveniently, we also give the analogous construction for a similar class of distributions over $\mathbb{R}$, using the Hilbert transform over $\mathbb{R}$.

From this construction, we obtain a family of distributions over $\mathbb{T}$ parametrized by $M$, $m$ and another parameter $m_1 = \int_{(M,-M)} \rho(x) dx$. By imposing the condition that $\rho$ is sediment with respect to its Dirac masses configuration, we then get rid of the parameter and obtain a family just parametrized by $M$ and $m$. We can discuss distributions over $\mathbb{R}$ similarly, and obtain a class of distributions called admissible distribution, also parametrized by two parameters.

We expect this construction to be useful for various types of optimization problems.

1.3.6. Estimation of Min Value. Now given this two-parameter family of energy minimizers $\rho_{M,m}$ where the external potentials $U = W * \rho_d$ with $\rho_d = m(\delta_M + \delta_{-M})$. Our goal is to show that $1/2$ is a lower bound for $\mathcal{H}[\rho]/\mathcal{D}[\rho]^2$ for every $\rho = \rho_{m,M}$.

In order to reduce the complexity of the problem over $\mathbb{T}$, we make a comparison between sediment distributions over $\mathbb{T}$ and admissible distributions over $\mathbb{R}$. A natural operation to get a distribution over $\mathbb{T}$ from a distribution $\mu$ over $\mathbb{R}$ is to take the periodization $\rho_\mu$, see (6.1),(6.2). Notice that both families are parametrized by their Dirac mass(es) configurations. Therefore we can associate each sediment distribution $\rho$ with a periodization $\rho_\mu$ of a unique admissible distribution $\mu$ over $\mathbb{R}$. Then in Section 6 we firstly relate two functionals $\tilde{\mathcal{H}}$ and $\tilde{\mathcal{D}}$ for distributions over $\mathbb{R}$ (see Section 4 for the definitions of $\tilde{\mathcal{H}}$ and $\tilde{\mathcal{D}}$ for distributions over $\mathbb{R}$) to $\mathcal{H}$ and $\mathcal{D}$ over $\mathbb{T}$, and prove the first comparison theorem

$$\frac{\tilde{\mathcal{H}}[\mu]}{\tilde{\mathcal{D}}[\mu]^2} \leq \frac{\mathcal{H}[\rho_\mu]}{\mathcal{D}[\rho_\mu]^2};$$

(1.17)

for periodizations in Section 6.1, see Proposition 6.2. This reduces the optimization problem over $\mathbb{T}$ to an optimization problem over $\mathbb{R}$, where a great benefit is that we can get rid of one more parameter due to scaling invariant, see Section 5.1. We solve this new optimization problem for admissible distributions over $\mathbb{R}$ in Section 5 and show that

$$\frac{1}{2} \leq \frac{\tilde{\mathcal{H}}[\mu]}{\tilde{\mathcal{D}}[\mu]^2};$$

(1.18)

for admissible $\mu$. Finally in Section 6 via a technical convexity argument, see Section 6.2, we prove the second comparison theorem

$$\frac{\mathcal{H}[\rho_\mu]}{\mathcal{D}[\rho_\mu]^2} \leq \frac{\mathcal{H}[\rho]}{\mathcal{D}[\rho]^2};$$

(1.19)

where $\rho_\mu$ and $\rho$ are both distributions over $\mathbb{T}$ and share the Dirac masses configuration, see Theorem 6.7. This concludes the chain of comparisons and proves the inequality in Theorem 1.3.
2. Notations and Preliminaries

We will denote the torus $\mathbb{T} = \mathbb{R}/\mathbb{Z}$, and use a real number $x$ to indicate a point in $\mathbb{T}$. Similarly, we will use an interval $[a, b] \subseteq \mathbb{R}$ with length less than 1 to indicate an interval $I$ in $\mathbb{T}$. For an interval $I$ in $\mathbb{T}$, we use $I^c$ to denote its complement.

By measures over $\mathbb{T}$, we always mean Borel measures on $\mathbb{T}$. We denote $\mathcal{M}_m$ to be the set of all measures $\rho$ with total mass $\int_{\mathbb{T}} \rho = m$, thus $\mathcal{M} = \mathcal{M}_1$ is the set of all probability measures on $\mathbb{T}$. For a point $x \in \mathbb{T}$, we will denote a Dirac function located at $x$ by $\delta_x$. A sequence $\{\rho_n\}$ of probability measures weakly converges to $\rho$ if for all $f \in C(\mathbb{T})$, we have $\lim_{n \to \infty} \int_{\mathbb{T}} f \, d\rho_n = \int_{\mathbb{T}} f \, d\rho$, we will write $\rho_n \rightharpoonup \rho$. Since $\mathbb{T}$ is compact, it is a well known fact that every sequence of probability measures has a weakly convergent subsequence.

We will always use $W$ to denote a potential function that describes the pairwise interaction between particles. In some occasions, there is also an external potential which we denote by $U$. For $\rho \in \mathcal{M}$, we denote $V_\rho := W \ast \rho$ to be the potential generated by $\rho$ and $V_{U,\rho} := W \ast \rho + U$ to be the total potential.

For $\rho \in \mathcal{M}$, for $W$ a potential function, several important functionals we use are

$$
\mathcal{D}[\rho] := \sup_{I} \int_{I} (\rho - 1) \, dx, \quad \mathcal{H}_W[\rho] := - \essinf_{\mathbb{T}} (W \ast \rho), \quad \mathcal{G}[\rho] := \frac{\mathcal{H}_W[\rho]}{\mathcal{D}[\rho]^2},
$$

where $\essinf(f) = \sup\{\alpha \in \mathbb{R} : \{x \in \mathbb{T} : f(x) < \alpha\} = \emptyset\}$ is the essential infimum of $f$. We will suppress the dependence of $W$ in $\mathcal{H}_W[\rho]$ when there is no confusion. We denote

$$
\mathcal{M}_{D \geq d} := \{\rho \in \mathcal{M} : \mathcal{D}[\rho] \geq d\},
$$

for some positive real number $0 < d \leq 1$.

For us, the Fourier transform (respectively Fourier coefficients) of $u$ is defined by

$$
\hat{u}(\xi) = \int_{\mathbb{R}} u(x) e^{-2\pi i x \xi} \, dx, \quad \xi \in \mathbb{R}, \quad \hat{u}(k) = \int_{\mathbb{T}} u(x) e^{-2\pi i x k} \, dx, \quad k \in \mathbb{Z}
$$

respectively when $u$ is a function over $\mathbb{R}$ and $\mathbb{T}$.

As an auxiliary mollifier, we define $\psi$ as

$$
\psi(x) = \max\{1 - |x|, 0\}, \quad \psi_a(x) = \frac{1}{a} \psi\left(\frac{x}{a}\right), \quad a > 0
$$

on $\mathbb{R}$. It is even and supported on $[-a, a]$. For $a \leq 1/2$, $\psi_a$ can be interpreted as a function on $\mathbb{T}$ via identifying $\mathbb{T}$ with $[-1/2, 1/2)$, and then $\psi_a(k) = \hat{\psi}(ak)$ for $k \in \mathbb{Z}$ where $\hat{\psi}$ is the Fourier transform of $\psi$ on $\mathbb{R}$.

3. Minimizer in $\mathcal{M}_{D \geq d}$

In this section, we will study minimizer(s) of $\mathcal{G}$ among probability measures over $\mathbb{T}$ with $\mathcal{D}[\rho] \geq d$. In particular, for fixed $0 < d < 1$, we are interested in what the value $\inf_{\mathcal{M}_{D \geq d}} \mathcal{G}$ is, and whether it can be achieved and whether it is unique, and if it can be achieved or approximated how the minimizer(s) look like.

We will focus on the last two questions above in this section, and save the discussion on the minimal value in Section 4 and Section 5. Instead of just working with the functional $\mathcal{G}[\rho] = \mathcal{H}[\rho]/\mathcal{D}[\rho]^2$ where $\mathcal{H}[\rho] = - \essinf_{\mathbb{T}} (W \ast \rho)$ with $W = - \log|2 \sin(\pi x)|$, in this section we will work in general with functional in the form

$$
\mathcal{G}_\alpha[\rho] := \mathcal{H}[\rho]/\mathcal{D}[\rho]^\alpha,
$$

where $\alpha \geq 0$ is an arbitrary real number and $W : \mathbb{T} \to (-\infty, \infty]$ is any potential function satisfying the following assumptions:

- (H1): $W \in L^1(\mathbb{T}) \cap C^2(\mathbb{T}\setminus\{0\})$ with $\int_{\mathbb{T}} W \, dx = 0$.
- (H2): $W$ is an even function: $W(x) = W(-x)$.
• (H3): \( \lim_{x \to 0} W(x) = W(0) = \infty. \)
• (H4): there exists a constant \( C_1 > 0 \) such that \( W''(x) \geq C_1 \) for \( x \in T \setminus \{0\} \).
• (H5): there exists a constant \( C_2 > 0 \) such that for all \( 0 < r < 1/2 \) and \( x \in T \),

\[
\frac{1}{2r} \int_{x-r}^{x+r} W(y) dy - 2 \inf W \leq C_1(W(x) - 2 \inf W). \tag{3.2}
\]

It is straightforward to verify that \( W(x) = -\log |2 \sin(\pi x)| \) satisfies (H1) - (H5). We compute that \( W'' = 2\pi/(1 - \cos(2\pi x)) = \pi/\sin^2 \pi x \geq \pi \). It follows from Jensen’s formula that \( W \) has mean value 0. For (H5), it suffices to notice that \(-c \log |x| \leq W(x) - 2 \inf W \leq -C \log |x| \) for some positive constants \( c \) and \( C \) for \( x \in [-1/2, 1/2] \) and \( \log |x| \) satisfies the condition via a computation.

Our main theorem for this section is the following:

**Theorem 3.1.** Assume \( W \) satisfies (H1)-(H4). Let \( \alpha \geq 0 \), \( 0 < d \leq 1 \). Then

(i) There exists a minimizer \( \rho \in M_{\mathcal{D}^{d}} \) for \( \mathcal{G}_\alpha \) that is even and \( D[\rho] = \int_I (\rho - 1) \) with \( I = [-M, M] \) for some \( 0 < M < 1/2 \).

(ii) Let \( \rho \) be a minimizer as in 1. Then \( \rho \) is in the form

\[
\rho = m(\delta_M + \delta_{-M}) + \rho_1 \tag{3.3}
\]

for some \( 0 < m \leq 1/2 \), and \( \rho_1 \in M_{1-2m} \) is supported on two (possibly empty) closed intervals \( J \subseteq I^c \) and \( K \subseteq I \).

(iii) Let \( \rho \) be a minimizer as in 1. Then \( \rho \) is a sediment distribution with respect to \( W \), i.e.,

\[
V[\rho](x) \leq \inf \{ V[\rho], x \in \text{supp } \rho \} \{ \pm M \}. \tag{3.4}
\]

(iv) Further assume that \( W \) satisfies (H5). Let \( \rho \) be a minimizer. Then \( \rho \) is the unique probability measure satisfying [3.4] in the class of probability measures with the same Dirac mass configuration.

Theorem 3.1 shows the existence of the minimizer(s) for \( \mathcal{G}_\alpha \) within \( M_{\mathcal{D}^{d}} \) and describes the shape of minimizer(s) to a great extent. Moreover, it shows that minimizer(s) have a characterizing property [3.4] and is the unique measure to satisfy this property with a fixed Dirac mass configuration. This translates the problem of constructing minimizers of \( \mathcal{G}_\alpha \) to a problem of constructing sediment distributions, which we will do in Section 4.

We organize this section as the following. We first prove Theorem 3.1(i) in Section 3.1, see Corollary 3.3. In Section 3.2, we prove (ii) and (iii) in Theorem 3.3. Finally, we prove (iv) in Section 3.3 in Corollary 3.5.

### 3.1. Properties of \( \mathcal{D} \) and \( \mathcal{H} \)

In this subsection, we will give some basic results about the functionals \( \mathcal{D} \) and \( \mathcal{H} \) in Lemma 3.2. Then we will show that it implies Theorem 3.1(i) as a corollary.

**Lemma 3.2.** Assume \( W \) satisfies (H1)-(H4) and \( \alpha > 0 \). Let \( \rho \in \mathcal{M} \).

(i) There exists a closed interval \( I \) such that \( \mathcal{D}[\rho] = \int_I (\rho - 1) dx \).

(ii) If \( \rho_n \rightharpoonup \rho \) in \( \mathcal{M} \), then \( \mathcal{D}[\rho] = \lim_{n \to \infty} \mathcal{D}[\rho_n] \).

(iii) If \( \rho_n \to \rho \) in \( \mathcal{M} \), then \( \mathcal{H}[\rho] = \lim_{n \to \infty} \mathcal{H}[\rho_n] \).

(iv) If \( \rho_n \rightharpoonup \rho \) in \( \mathcal{M} \), then \( \mathcal{G}_\alpha[\rho] = \lim_{n \to \infty} \mathcal{G}_\alpha[\rho_n] \).

Before we prove this lemma, we first apply it to show Theorem 3.1(i).

**Corollary 3.3.** Assume \( W \) satisfies (H1)-(H4), \( \alpha \geq 0 \) and \( 0 < d \leq 1 \). There exists a minimizer \( \rho \) for \( \mathcal{G}_\alpha \) in \( M_{\mathcal{D}^{d}} \) that is even and \( \mathcal{D}[\rho] = \int_I (\rho - 1) \) with \( I = [-M, M] \) for some \( 0 \leq M < 1/2 \).
Proof. Lemma 3.2(ii) shows that if \( \rho_n \to \rho \) and \( \rho_n \in \mathcal{M}_{D^2} \), then \( \rho \in \mathcal{M}_{D^2} \). If \( \{ \rho_n \} \) is a minimizing sequence of \( \mathcal{G} = \mathcal{H}_D^\phi \) in the class \( \mathcal{M}_{D^2} \), then we can take a weakly convergent subsequence, still denoted as \( \{ \rho_n \} \), and \( \rho_n \to \rho \in \mathcal{M}_{D^2} \). Combined with Lemma 3.2(iv), this shows the existence of a minimizer \( \rho \in \mathcal{M}_{D^2} \).

We further show that \( \rho \) can be made even. Without loss of generality, we assume that \( I = [-M,M] \) is an interval witnessing \( \mathcal{D}[\rho] \). We define \( \bar{\rho}(x) = (\rho(x) + \rho(-x))/2 \). Then \( \mathcal{D}[\bar{\rho}] \geq \mathcal{D}[\rho] \) since

\[
\int_I (\bar{\rho} - 1) \, dx = \int_I (\rho - 1) \, dx,
\]

and \( \mathcal{H}[\bar{\rho}] \leq \mathcal{H}[\rho] \) since

\[
\text{ess inf} W * \bar{\rho} \geq \frac{1}{2} \left( \text{ess inf} (W * \rho) + \text{ess inf} (W * \rho(-x)) \right) = \text{ess inf} (W * \rho).
\]

Therefore \( \mathcal{D}[\bar{\rho}] = \mathcal{D}[\rho] \) and \( \mathcal{H}[\bar{\rho}] = \mathcal{H}[\rho] \) and \( \bar{\rho} \) is the desired minimizer.

Now we focus on proving Lemma 3.2.

Proof of Lemma 3.2. Proof of (i):

If \( \mathcal{D}[\rho] = 0 \), then \( \rho = 1 \) which implies that \( \mathcal{D}[\rho] \) is achieved at any closed interval \( I \). So we assume \( \mathcal{D}[\rho] > 0 \). Let \( \{ I_n \} \) be a maximizing sequence of \( \mathcal{D}[\rho] \) where each \( I_n \) is a closed interval on \( T \). We may represent \( I_n \) by \([a_n, b_n]\) for some \( a_n \in [0,1), b_n \in [a_n, a_n+1) \). By compactness of \( T \), one can form a subsequence, still denoted as \( \{ I_n = [a_n, b_n] \} \), such that \( \lim_{n \to \infty} a_n = a \) and \( \lim_{n \to \infty} b_n = b \). By dominated convergence theorem

\[
\mathcal{D}[\rho] = \lim_{n \to \infty} \int_{I_n} (\rho - 1) \, dx \leq \lim_{n \to \infty} \int_{I_n \cup [a,b]} (\rho - 1) \, dx = \int_I (\rho - 1) \, dx,
\]

where \( I = [a, b] \) is a closed interval witnessing \( \mathcal{D}[\rho] \).

Proof of (ii):

Let \( I = [a, b] \) be a closed interval witnessing \( \mathcal{D}[\rho] \) and \( \rho_n \to \rho \) in \( \mathcal{M} \). We first prove \( \lim \inf_{n \to \infty} \mathcal{D}[\rho_n] \geq \mathcal{D}[\rho] \). For \( \epsilon > 0 \) with \( b - a < 1 - 2\epsilon \) we define the continuous function

\[
\phi_\epsilon(x) = \begin{cases} 
1, & a \leq x \leq b \\
1 - \frac{a - x}{\epsilon}, & a - \epsilon \leq x \leq a \\
1 - \frac{x - b}{\epsilon}, & b \leq x \leq b + \epsilon \\
0 & \text{otherwise}.
\end{cases}
\]

Then for any \( n \) and \( \epsilon > 0 \), by definition of \( \mathcal{D} \) and \( \phi_\epsilon \), we have

\[
\mathcal{D}[\rho_n] \geq \int_{[a-c,b+c]} (\rho_n - 1) \, dx \geq \int_T (\rho_n - 1) \phi_\epsilon \, dx - 2\epsilon.
\]

Therefore for any \( \epsilon > 0 \), by weak convergence of the sequence

\[
\lim \inf_n \mathcal{D}[\rho_n] \geq \int_T (\rho - 1) \phi_\epsilon \, dx - 2\epsilon,
\]

which implies \( \lim \inf_n \mathcal{D}[\rho_n] \geq \mathcal{D}[\rho] \) as \( \epsilon \to 0 \).

Next we prove \( \lim \sup_{n \to \infty} \mathcal{D}[\rho_n] \leq \mathcal{D}[\rho] \). Let \( I_n = [a_n, b_n] \) be the intervals witnessing \( \mathcal{D}[\rho_n] \). We may take a subsequence of \( \{ \rho_n \} \), still denoted as \( \{ \rho_n \} \), such that \( \lim_{n \to \infty} \mathcal{D}[\rho_n] = \lim \sup_{n \to \infty} \mathcal{D}[\rho_n] \), and \( \lim_{n \to \infty} a_n = a_0, \lim_{n \to \infty} b_n = b_0 \) exist. For any \( \epsilon > 0 \), let \( \phi_\epsilon(x) \) be given as in (3.8) with \( a, b \) replaced by \( a_0 - \epsilon, b_0 + \epsilon \) respectively, then for sufficiently large \( n \), we have

\[
|a_n - a_0| < \epsilon, \quad |b_n - b_0| < \epsilon, \quad \mathcal{D}[\rho_n] = \int_{[a_n, b_n]} (\rho_n - 1) \, dx > \lim_{n \to \infty} \mathcal{D}[\rho_n] - \epsilon.
\]
and
\[ \int_{\mathcal{T}} \hat{\phi}_\epsilon (\rho - 1) \, dx \geq \int_{\mathcal{T}} \hat{\phi}_\epsilon (\rho_n - 1) \, dx - \epsilon. \]  
(3.12)
since \( \rho_n \rightharpoonup \rho \). Therefore for any \( \epsilon > 0 \) and \( I_\epsilon = [a_0 - \epsilon, b_0 + \epsilon] \), we have
\[ \mathcal{D}[\rho] \geq \int_{I_\epsilon} (\rho - 1) \, dx \geq \int_{I_\epsilon} (\rho_n - 1) \, dx - 2\epsilon \geq \int_{I_\epsilon} \hat{\phi}_\epsilon (\rho_n - 1) \, dx - 3\epsilon \geq \int_{[a_n, b_n]} (\rho_n(x) - 1) \, dx - 7\epsilon \]  
(3.13)
when \( n \) is sufficiently large. Since \( \epsilon \) is arbitrary, we obtain \( \limsup_{n \to \infty} \mathcal{D}[\rho_n] \leq \mathcal{D}[\rho] \).

**Proof of (iii):**
Let \( \rho_n \rightharpoonup \rho \in \mathcal{M} \). It suffices to prove
\[ (W \ast \rho)(x) \geq \limsup_{n \to \infty} \left( \text{ess inf}(W \ast \rho_n) \right), \quad a.e. \, x \]  
(3.14)
Assume on the contrary that (3.14) is false. Since \( W \ast \rho \in L^1 \), almost every \( x \in \mathbb{T} \) is a Lebesgue point for \( W \ast \rho \). Without loss of generality, assume \( x = 0 \) is a Lebesgue point and there exists \( \epsilon > 0 \) and a subsequence \( \{\rho_{n_k}\} \) such that
\[ (W \ast \rho)(0) < \text{ess inf}(W \ast \rho_{n_k}) - \epsilon, \quad \forall k. \]  
(3.15)
By definition of Lebesgue points,
\[ (W \ast \rho)(0) = \lim_{a \to 0} \int (W \ast \rho)(x) \psi_a(x) \, dx, \]  
(3.16)
where \( \psi_a \) is as in (2.3). Therefore, one can choose \( a \) such that
\[ \int (W \ast \rho)(x) \psi_a(x) \, dx < \text{ess inf}(W \ast \rho_{n_k}) - \epsilon, \quad \forall k. \]  
(3.17)
Notice that
\[ \int (W \ast \rho)(x) \psi_a(x) \, dx = (W \ast \rho \ast \psi_a)(0) = \int (W \ast \psi_a)(x) \rho(x) \, dx \]  
(3.18)
and \( W \ast \psi_a \) is a continuous function. Therefore, by the weak convergence of \( \{\rho_{n_k}\} \), we have
\[ \int (W \ast \rho)(x) \psi_a(x) \, dx = \lim_{k \to \infty} \int (W \ast \rho_{n_k})(x) \psi_a(x) \, dx \]  
(3.19)
Notice that \( \int (W \ast \rho_{n_k})(x) \psi_a(x) \, dx \geq \text{ess inf}(W \ast \rho_{n_k}) \). Therefore we get a contradiction with (3.17).

Finally, (iv) on lower semi-continuity of \( \mathcal{G}_\alpha \) follows directly from (ii) and (iii).

3.2. Microscopic Diffusion. In this section, we prove Theorem 3.1(ii) and (iii) in Theorem 3.6 and Corollary 3.5. Let \( \rho \) be an even minimizer of \( \mathcal{G}_\alpha \) in \( \mathcal{M}_{D^2} \). The core tool is what we call microscopic diffusion. It is a local transport plan for probability measures that can decrease \( \mathcal{H} \) while maintaining or increasing \( \mathcal{D} \), thus decreasing \( \mathcal{G}_\alpha \) overall.

Recall the setup and notations \( U \), \( V[\rho] \) and \( V_U[\rho] \) in Section 2.

**Lemma 3.4** (Microscopic Diffusion). Assume \( W \) satisfies (H1)-(H4) and \( U \) is a function on \( \mathbb{T} \) bounded from below. Given \( \rho \in \mathcal{M} \). For a given \( x_0 \in \mathbb{T} \) and \( 0 < \epsilon < \frac{1}{2} \), if \( V_U[\rho](x) \) \( \geq \text{ess inf} V_U[\rho] + c \) (possibly \( \infty \)) for \( x \in [x_0 - \epsilon, x_0 + \epsilon] \) with some \( c > 0 \) and \( \sup \rho \cap [x_0 - \epsilon/2, x_0 + \epsilon/2] \neq \emptyset \), then we define
\[ \rho_\lambda(x) = \rho(x) + \lambda \left( m_1 \delta_{x_0 - \epsilon} + m_2 \delta_{x_0 + \epsilon} - \rho(x) \chi_{(x_0 - \epsilon, x_0 + \epsilon)} \right) \]  
(3.20)
where \( m_1, m_2 > 0 \) are determined by the moment conditions
\[ \int_{(x_0 - \epsilon, x_0 + \epsilon)} \left( m_1 \delta_{x_0 - \epsilon}(y) + m_2 \delta_{x_0 + \epsilon}(y) - \rho(y) \right) \cdot y^k \, dy = 0, \quad k = 0, 1. \]  
(3.21)
Then for \( \lambda > 0 \) sufficiently small, \( \rho_\lambda \) is a probability measure with
\[ - \text{ess inf} V_U[\rho_\lambda] < - \text{ess inf} V_U[\rho]. \]  
(3.22)
determined because the coefficient matrix in (3.21) is invertible. Now for any \( x \neq \rho \) which are both positive since \( \text{supp} u \), then the difference of potential from splitting the Dirac mass at \( x = \rho \) is strictly larger than \( \text{ess inf} (W \rho)\), which is increasing away from \( x_0 \) and decreasing near \( x_0 \).

![Figure 1](image-url)

**Figure 1.** Microscopic Diffusion: horizontal arrows indicate the diffusion of mass near \( x_0 \), vertical arrows indicate the change of the generated potential \( W \rho \), which is increasing away from \( x_0 \) and decreasing near \( x_0 \).

See Figure [1] for illustration.

**Proof.** We start by showing the sign of a finite difference using the convexity of \( W \). For any \( x \notin [-\epsilon, \epsilon] \) and \( u \in (-\epsilon, \epsilon) \), if \( a_1(u), a_2(u) \) are determined by the moment conditions

\[
\int_{(-\epsilon, \epsilon)} \left( (a_1 \delta_{-\epsilon} + a_2 \delta_{\epsilon}) - \delta_{\rho}(y) \right) \cdot y^k \, dy = 0, \quad k = 0, 1
\]

(3.23)

that is,

\[
a_1(u) = \frac{1}{2}(1 - \frac{u}{\epsilon}), \quad a_2(u) = \frac{1}{2}(1 + \frac{u}{\epsilon}),
\]

(3.24)

then the difference of potential from splitting the Dirac mass at \( u \) is

\[
(W \ast (a_1 \delta_{-\epsilon} + a_2 \delta_{\epsilon}))(x)
\]

\[
= a_1 W(x + \epsilon) + a_2 W(x - \epsilon) - W(x - u)
\]

\[
= a_1 \int_{x - u}^{x + \epsilon} W''(z) \, dz \, dy + a_2 \int_{x - u}^{x - \epsilon} W''(z) \, dz \, dy
\]

(3.25)

\[
\geq C_1 \left( a_1 \int_{x - u}^{x + \epsilon} dz \, dy + a_2 \int_{x - u}^{x - \epsilon} dz \, dy \right) > 0,
\]

where \( c(\epsilon, u) := a_1 \int_{x - u}^{x + \epsilon} dz \, dy + a_2 \int_{x - u}^{x - \epsilon} dz \, dy > 0 \) and \( C_1 > 0 \) is as given in (H4).

Integrating (3.25) in \( u \in (-\epsilon, \epsilon) \) with weight \( \rho(x_0 + u) \), we obtain (3.21) with

\[
m_1 = \int_{(-\epsilon, \epsilon)} \frac{1}{2} (1 - \frac{u}{\epsilon}) \rho(x_0 + u) \, du, \quad m_2 = \int_{(-\epsilon, \epsilon)} \frac{1}{2} (1 + \frac{u}{\epsilon}) \rho(x_0 + u) \, du,
\]

(3.26)

which are both positive since \( \text{supp} \rho \cap (x_0 - \epsilon/2, x_0 + \epsilon/2) \neq \emptyset \). Here \( m_1 \) and \( m_2 \) are uniquely determined because the coefficient matrix in (3.21) is invertible. Now for any \( x \notin [x_0 - \epsilon, x_0 + \epsilon] \)

\[
(W \ast (m_1 \delta_{x_0 - \epsilon} + m_2 \delta_{x_0 + \epsilon} - \rho(x) \chi_{\{x_0 - \epsilon, x_0 + \epsilon\}}))(x) \geq C_1 \int_{(-\epsilon, \epsilon)} c(\epsilon, u) \rho(x_0 + u) \, du > 0.
\]

(3.27)

For \( x \in [x_0 - \epsilon, x_0 + \epsilon] \), notice that \( \rho_\lambda = (1 - \lambda) \rho + \lambda \rho_1 \) we have

\[
V_U[\rho_\lambda](x) = (1 - \lambda) V_U[\rho](x) + \lambda V_U[\rho_1](x) \geq (1 - \lambda) (\text{ess inf} V_U[\rho] + c) + \lambda (\text{inf} W + \text{inf} U),
\]

(3.28)

which is strictly larger than \( \text{ess inf} V_U[\rho] \) by taking \( \lambda > 0 \) small enough. Therefore we obtain the conclusion. \( \square \)
Microscopic diffusion operation basically implies that if \( \rho \) is a minimizer of \( G_\alpha \) with \( I = [-M, M] \), then \( V[\rho](x) \leq \text{ess inf} V[\rho] \) as long as \( x \in \text{supp} \rho \setminus \{ \pm M \} \). Suppose not, by Proposition \[10.1\] we can always find a small neighborhood \((x_0 - \epsilon, x_0 + \epsilon)\) for some \( x_0 \in \text{supp} \rho \setminus \{ \pm M \} \) to apply microscopic diffusion and strictly decrease \( H \). Since the diffusion operation is local and away from \( \pm M \), it won’t decrease \( D \), we then get a contradiction with \( \rho \) being a minimizer. This proves Theorem \[3.1\](iii).

**Corollary 3.5.** Assume \( W \) satisfies (H1)-(H4). Let \( \alpha \geq 0, 0 < d \leq 1 \). Let \( \rho \) be an even minimizer of \( G_\alpha \) in \( \mathcal{M}_{\geq 0} \) with \( I = [-M, M] \) witnessing \( D[\rho] \). Then \( V[\rho](x) \leq \text{ess inf} V[\rho] \) for \( x \in \text{supp} \rho \setminus \{ \pm M \} \).

This in turn imposes a really strong restriction on the shape of \( \text{supp} \rho \) for a minimizer \( \rho \). Suppose \((x_1, x_2) \subset (\text{supp} \rho)^c \) and \( x_1, x_2 \in \text{supp} \rho \) and \( x_1 \) are not \( \pm M \). Then by Corollary \[3.5\] \( V[\rho](x_1) = V[\rho](x_2) \leq \text{ess inf} V[\rho] \). The generated potential \( V[\rho] \) is continuous and convex at \( x \notin \text{supp} \rho, V[\rho] \) is right continuous at \( x_1 \) and left continuous at \( x_2 \) by Proposition \[10.1\]. Therefore by convexity \( V[\rho](x) < \text{ess inf} V[\rho] \) for \( x \in (x_1, x_2) \), which is a contradiction. Therefore there exists no \((x_1, x_2) \subset (\text{supp} \rho)^c \) with \( x_1 \in \text{supp}(\rho) \setminus \{ \pm M \} \). This helps us to further characterize the shape of the minimizer in the following theorem.

**Theorem 3.6.** Assume \( W \) satisfies (H1)-(H4). Let \( \alpha \geq 0, 0 < d \leq 1 \). Let \( \rho \) be an even minimizer of \( G_\alpha \) in \( \mathcal{M}_{\geq 0} \) with \( I = [-M, M] \) witnessing \( D[\rho] \). Then
\[
\rho = m(\delta_M + \delta_{-M}) + \rho_1
\]
for some \( 0 < m \leq 1/2 \), and \( \rho_1 \in \mathcal{M}_{1-2m} \) is supported and non-zero on two (possibly empty) closed intervals \( J \subseteq I^c \) and \( K \subseteq I \).

Before we give the proof of Theorem \[3.6\] we first give a lemma on \( W \).

**Lemma 3.7.** Assume \( W \) satisfies (H1), (H2), (H4). Then \( \tilde{W}(k) > 0 \) for any \( k \in \mathbb{Z}, k \neq 0 \).

**Proof.** By (H2) \( W \) is even, therefore \( W'(x) \) is odd for \( x \neq 0 \) with \( W'(1/2) = W'(-1/2) = 0 \). By (H4) \( W''(x) > 0 \) for any \( x \neq 0 \), therefore \( W' \) is a strictly increasing function which maps \([-1/2, 0) \) onto \([0, A) \) with \( A = \lim_{x \to -\infty} W''(x) \in (0, \infty) \), and \( \inf_{T'} W = W(-1/2) \). Let \( u \) be the inverse function of \( W'|_{-1/2, 0} \), which is strictly increasing on \((0, A) \).

For \( x \in [-1/2, 0) \cup (0, 1/2] \), we have \( W(x) = W(-|x|) \) and
\[
W(x) - W(-1/2) = \int_{-1/2}^{-|x|} W'(y) dy = \int_0^A \max\{-|x| - u(h), 0\} dh.
\]
Therefore for \( k \neq 0 \)
\[
\tilde{W}(k) = \int_T (W(x) - W(-1/2))e^{-2\pi i k x} dx = \int_0^A dh \int_T \max\{-|x| - u(h), 0\} e^{-2\pi i k x} dx.
\]
For each fixed \( h \), we get \( \beta = -u(h) \in (0, 1/2) \). It suffices to notice that \( \max\{\beta - |x|, 0\} \) has positive Fourier coefficients at \( k \neq 0 \) for almost every \( \beta \).

Now we are ready to prove Theorem \[3.6\]

**Proof of Theorem 3.6.** Firstly, since \( I \) is maximizing \( \int_I (\rho - 1) \), its endpoints \( \pm M \in \text{supp} \rho \). By the reasoning above Theorem \[3.6\] there is no open interval \((x_1, x_2) \subset (\text{supp} \rho)^c \) with \( x_i \in \text{supp} \rho \in \{ \pm M \} \), there is at most one closed interval \( J \subset I^c \) (closure of the open set \( I^c \)) and at most one closed interval \( K \subset I \) (empty when \( M = 0 \), i.e., \( \text{supp} \rho = \{ \pm M \} \cup J \cup K \).

We will show that \( J \neq I^c \) and \( K \neq I \). If \( \{ \pm M \} \subset J \cup K \) then \( V[\rho](\pm M) = \text{ess inf} V[\rho] \), by 1 in Proposition \[10.1\] and by Corollary \[3.5\]. Moreover, combining 3 in Proposition \[10.1\] we see that \( V[\rho] \) is now continuous with \( V[\rho](x) \leq \text{ess inf} V[\rho] \) for \( x \in \text{supp} \rho = J \cup K \). Since \( T \setminus (J \cup K) \) is a disjoint union of two open intervals or a single open interval, by convexity of \( V[\rho] \) for all \( x \in T \)
we have $V[\rho](x) \leq \text{ess inf } V[\rho]$. This implies that $V[\rho] = W * \rho = 0$. Then $\hat{W} * \rho = \hat{W} \cdot \hat{\rho} = 0$, therefore $\hat{\rho}(k) = 0$ for every $k \neq 0$ by Lemma 3.7 and $\rho$ must be the uniform distribution. This contradicts with $d > 0$.

Finally, since $J \subseteq I^c$ and $K \subseteq I$ and $I$ witnesses $D[\rho]$, it follows that $\rho$ must have Dirac masses at $\pm M$.

3.3. Energy Minimization. Our main goal in this section is to prove the uniqueness in Theorem 3.1(iv). We will do so by using the idea of energy minimization in potential theory.

To set up the question, we will consider an external potential $U \in L^1(\mathbb{T})$ of the form

$$U = W * (\rho_+ - \rho_- + \rho_d)$$  \hspace{1cm} (3.32)

where $\rho_+$ and $\rho_-$ are nonnegative continuous functions, $\rho_d$ is the sum of finitely many positive Dirac masses and $W$ satisfies (H1)-(H4). As a consequence, $U$ is bounded from below and at every point $x \in \mathbb{T} \setminus \text{supp } \rho_d$ we have $U(x) < \infty$ and continuous. Define the total energy functional

$$E_U[\rho] = \frac{1}{2} \int (W * \rho)(x) \rho(x) \, dx + \int U(x) \rho(x) \, dx$$  \hspace{1cm} (3.33)

for $\rho \in \mathcal{M}_m$ with $m \geq 0$. The dependence of $E_U$ on $U$ will be omitted when it is clear from the context. Here the two terms in (3.33) physically represent the pairwise interaction energy and potential energy respectively. For any $\rho \in \mathcal{M}_m$, both terms in $E_U[\rho]$ take value in $(-\infty, \infty)$ since $U$ and $W$ (implied by (H1) and (H3)) are bounded from below, therefore finiteness of $E_U[\rho]$ implies finiteness of both terms.

**Proposition 3.8.** Assume $W$ satisfies (H1)-(H5), $U$ has the form (3.32) and $m \geq 0$. Then there exists a unique minimizer $\rho$ of $E$ in $\mathcal{M}_m$. It is the only element in $\mathcal{M}_m$ satisfying

$$V_U[\rho](x) \leq \text{ess inf } V_U[\rho], \ x \in \text{supp } \rho.$$  \hspace{1cm} (3.34)

Furthermore, $\rho$ is also the unique maximizer of $\text{ess inf } V_U[\rho]$ for $\rho \in \mathcal{M}_m$.

**Proof.** Existence of energy minimizer:

Let $\{\rho_n\}$ be a minimizing sequence of $E$, and take a weakly convergent subsequence, still denoted as $\{\rho_n\}$, which converges weakly to some $\rho_\infty \in \mathcal{M}_{m_0}$. Since both $W$ and $U$ are lower semicontinuous, we apply [vdVW96 Theorem 1.3.4 (i)(iv)] and get

$$\int\int_{\mathbb{T}^2} W(x-y)\rho_\infty(y)\rho_\infty(x) \, dx \, dy \leq \liminf_{n \to \infty} \int\int_{\mathbb{T}^2} W(x-y)\rho_n(y)\rho_n(x) \, dx \, dy,$$  \hspace{1cm} (3.35)

and

$$\int U(x)\rho_\infty(x) \, dx \leq \liminf_{n \to \infty} \int U(x)\rho_n(x) \, dx.$$  \hspace{1cm} (3.36)

Therefore

$$E[\rho_\infty] \leq \liminf_{n \to \infty} E[\rho_n] = \inf_{\rho \in \mathcal{M}_{m_0}} E[\rho].$$  \hspace{1cm} (3.37)

**Characterizing property:**

If $\rho_\infty$ does not satisfy (3.34), we will give a transport plan to construct $\rho$ with smaller $E$. Under this assumption, by lower continuity of $V_\infty := V_U[\rho_\infty]$ in Proposition 10.1 there exists $x_0 \in \text{supp } \rho$, $a > 0$ and $\epsilon > 0$ such that $V_\infty(x) \geq \text{ess inf } V_\infty + 2\epsilon$ for $x \in [x_0 - a, x_0 + a]$. Since $x_0 \in \text{supp } \rho_\infty$, we have $\int_{[x_0-a,x_0+a]} \rho_\infty \, dx > 0$. By the definition of $\text{ess inf } V_\infty$, there exists a set $S$ with positive measure such that $V_\infty(x) \leq \text{ess inf } V_\infty + \epsilon$ for $x \in S$. Now consider

$$\varphi_1 = \rho_\infty \cdot \chi_{[x_0-a,x_0+a]}, \quad \varphi_2 = \chi_S \cdot \frac{1}{|S|} \int_{\mathbb{T}} \varphi_1 \, dx, \quad \rho_\beta = \rho_\infty + \beta(-\varphi_1 + \varphi_2)$$  \hspace{1cm} (3.38)
for $0 < \beta < 1$. Notice that $\varphi_1, \varphi_2$ are nonnegative and $\gamma := \int_\mathbb{T} \varphi_1 \, dx = \int_\mathbb{T} \varphi_2 \, dx > 0$, and $\rho_\infty - \beta \varphi_1 \geq 0$ by the construction of $\varphi_1$. Therefore $\rho_\beta$ is in $\mathcal{M}_m$. Then

$$\mathcal{E}[\rho_\beta] = \mathcal{E}[\rho_\infty] + \beta \int V_\infty \cdot (-\varphi_1 + \varphi_2) \, dx + \frac{\beta^2}{2} \int (W \ast (-\varphi_1 + \varphi_2)) \cdot (-\varphi_1 + \varphi_2) \, dx$$

$$\leq \mathcal{E}[\rho_\infty] - \beta \cdot (\text{ess inf} \, V_\infty + 2\epsilon) \int \varphi_1 \, dx + \beta \cdot (\text{ess inf} \, V_\infty + \epsilon) \int \varphi_2 \, dx + C\beta^2$$

(3.39)

$$= \mathcal{E}[\rho_\infty] - \beta \epsilon \beta + C\beta^2$$

where $C = \int (W \ast (-\varphi_1 + \varphi_2)) \cdot (-\varphi_1 + \varphi_2) \, dx < \infty$ from the construction of $\varphi_1$ and (H1). Therefore we obtain a contradiction with the minimality of $\rho_\infty$ by taking $\beta$ small enough.

**Uniqueness of minimizer:**

Assume $\rho_0$ and $\rho_1$ are two distinct minimizers of $\mathcal{E}$ in $\mathcal{M}_m$. Define $\rho_t = (1-t)\rho_0 + t\rho_1 \in \mathcal{M}_m$ for $0 \leq t \leq 1$. Then

$$\mathcal{E}[\rho_t] = \frac{(1-t)^2}{2} \int (W \ast \rho_0) \cdot \rho_0 \, dx + \frac{t^2}{2} \int (W \ast \rho_1) \cdot \rho_1 \, dx$$

$$+ (1-t) \int U \cdot \rho_0 \, dx + t \int U \cdot \rho_1 \, dx,$$

(3.40)

is a quadratic function in $t$, with

$$\frac{d^2}{dt^2} \mathcal{E}[\rho_t] = \int (W \ast (\rho_1 - \rho_0))(x)(\rho_1 - \rho_0)(x) \, dx = \sum_{k \in \mathbb{Z}} \hat{W}(k)(\hat{\rho}_1(k) - \hat{\rho}_0(k))^2$$

(3.41)

by Proposition 11.1. Since $\rho_0 \neq \rho_1$ and $\hat{\rho}_0(0) = \hat{\rho}_1(0) = m$, there exists some $k \neq 0$ such that $\hat{\rho}_1(k) \neq \hat{\rho}_0(k)$. Notice $W(k) > 0$ for $k \neq 0$ by Lemma 3.7. Therefore $\frac{d^2}{dt^2} \mathcal{E}[\rho_t] > 0$ and $\mathcal{E}[\rho_{t/2}] < \mathcal{E}[\rho_0] = \mathcal{E}[\rho_1]$. Contradiction.

**Uniqueness of $\rho$ satisfying (3.34):**

Assume $\rho_1 \neq \rho_\infty$ satisfies (3.34) with $\rho_\infty$ being the unique minimizer. Let $a > 0$ be small, and $\rho_0 = \rho_\infty \ast \psi_a$, where $\psi_a$ is as defined in (2.3). Then we define $\rho_t = (1-t)\rho_0 + t\rho_1 \in \mathcal{M}_m$ for $0 \leq t \leq 1$, and $\mathcal{E}[\rho_t]$ is given by (3.40) and satisfies (3.41). We also have

$$\frac{d}{dt} \mathcal{E}[\rho_t] = - (1-t) \int (W \ast \rho_0) \cdot \rho_0 \, dx + t \int (W \ast \rho_1) \cdot \rho_1 \, dx + (1-2t) \int (W \ast \rho_1) \cdot \rho_0 \, dx$$

$$- \int U \cdot \rho_0 \, dx + \int U \cdot \rho_1 \, dx$$

(3.42)

Evaluating at $t = 1$, we obtain

$$\frac{d}{dt} \bigg|_{t=1} \mathcal{E}[\rho_t] = \int V_U[\rho_1] \cdot (\rho_1 - \rho_0) \, dx \leq \text{ess inf} \, V_U[\rho_1] m - \text{ess inf} \, V_U[\rho_1] m = 0,$$

(3.43)

using (3.34) for $\rho_1$ and the fact that $\rho_0$ is a continuous function.

Then we integrate the inequality $\frac{dt}{dt} \mathcal{E}[\rho_t] \geq 0$ from $t = 0$ to $1$ and get

$$\frac{d}{dt} \mathcal{E}[\rho_t] = \frac{d}{dt} \bigg|_{t=1} \mathcal{E}[\rho_1] - \int_0^1 \frac{d^2}{dt^2} \mathcal{E}[\rho_t] \, ds \leq 0, \quad \forall 0 \leq t \leq 1,$$

(3.44)

therefore $\mathcal{E}[\rho_0] \geq \mathcal{E}[\rho_1]$. Since $\mathcal{E}[\rho_\infty] - \mathcal{E}[\rho_1] < 0$, by Proposition 11.1 we can take $a > 0$ small enough such that $\mathcal{E}[\rho_0] < \mathcal{E}[\rho_1]$. Contradiction.

**Maximizers of $\text{ess inf} \, V_U[\rho]$ satisfying (3.34):**

We first note that the maximizer of $\text{ess inf} \, V_U[\rho]$ exists. If $U = 0$, the existence of maximizer of $\text{ess inf} \, V[\rho] = -\mathcal{H}[\rho]$ is equivalent to the existence of minimizer of $\mathcal{H}$, which follows from lower semi-continuous of $\mathcal{H}$ in Lemma 3.2 after scaling with $m$. For general $U$ in the form of (3.32), the same proof in Lemma 3.2 applies when $W \ast \rho$ is replaced with $W \ast (\rho + \rho_+ - \rho_- + \rho_d)$. 
Let \( \rho_\infty \) be a maximizer of \( \text{ess inf} \ V_U[\rho] \). Suppose the statement is not true, then by lower semicontinuity of \( V_U[\rho_\infty] \), there exists \( x_0 \in \text{supp} \rho_\infty \), \( a > 0 \) and \( \epsilon > 0 \) such that
\[
V_U[\rho_\infty](x) > \text{ess inf} \ V_U[\rho_\infty] + \epsilon, \quad x \in [x_0 - a, x_0 + a]
\] (3.45)
Then applying Lemma 3.4 to \( [x_0 - a, x_0 + a] \) with the external potential \( U \), we obtain \( \rho_\infty \) with \( \text{ess inf} \ V_U[\rho_\infty] > \text{ess inf} \ V_U[\rho_\infty] \). Contradiction. It follows that the unique minimizer of \( \mathcal{E}_U[\rho] \) is simultaneously the unique maximizer of \( \text{ess inf} \ V_U[\rho] \) and the unique element satisfying (3.34). \( \square \)

Now we are ready to prove Theorem 3.1(iv) following Proposition 3.8. Recall Theorem 3.6(ii) and Theorem 3.6, we can always write \( \rho = m(\delta_M + \delta_{-M}) + \rho_1 \). By letting \( U = W \star m(\delta_M + \delta_{-M}) \) and \( \rho_1 \) be the unique minimizer of \( \mathcal{E}_U \), we obtain that \( V_U[\rho_1] = V[\rho] \) satisfying the \( (1.15) \). Since \( \rho_1 \) is the energy minimizer of \( \mathcal{E}_U \), it is clear that \( \rho_1 \) does not contain any Dirac mass. Therefore the Dirac mass configuration of \( \rho \) is completely determined by \( m \) and \( M \) in \( U \).

Corollary 3.9. Assume \( W \) satisfies (H1)-(H5). Let \( \alpha \geq 0 \), \( 0 < d \leq 1 \). Following Theorem 3.6, let \( \rho = m(\delta_M + \delta_{-M}) + \rho_1 \) be an even minimizer of \( \mathcal{G}_\alpha \) in \( \mathcal{D}_{\geq d} \) with \( I = [-M, M] \) witnessing \( D[\rho] \). Then \( \rho_1 \) is the unique minimizer of \( \mathcal{E}_U \) in \( \mathcal{M}_{1-2m} \) where \( U = m(\delta_M + \delta_{-M}) \). Furthermore \( \rho \) is the unique probability measure satisfying (1.15) in the class of probability measures with the same Dirac mass configuration.

For the purpose of our discussion in Section 4, we also give a refined version of Proposition 3.8 in the case that \( U \) is the sum of two Dirac masses of the same size at \( -M \) and \( M \), where we restrict \( \rho \) to a smaller class of measures with the prescribed total mass on the two intervals \( (-M, M) \) and \( (M, 1 - M) \).

Corollary 3.10. Let \( 0 < m \leq 1/2 \), \( 0 < M < 1/2 \), \( \rho_d = m(\delta_M + \delta_{-M}) \) and \( U(x) = W \star \rho_d \) and \( m_1, m_2 \geq 0 \) with \( m_1 + m_2 = 1 - 2m \). Then there exists a unique minimizer \( \rho_\infty, m_1, m_2 \) of \( \mathcal{E}_U \) in \( \mathcal{M}_{m_1, m_2} \) if
\[
\mathcal{M}_{m_1, m_2} = \left\{ \rho \in \mathcal{M}_{1-2m} : \int_{(-M, M)} \rho \, dx = m_1, \int_{(M, 1-M)} \rho \, dx = m_2 \right\},
\] (3.46)
which is the unique \( \rho \) satisfying
\[
V_U[\rho](x) \leq \text{ess inf}_{y \in (-M, M)} V_U[\rho(y)], \quad x \in \text{supp} \rho \cap (-M, M)
\]
\[
V_U[\rho](x) \leq \text{ess inf}_{y \in (M, 1-M)} V_U[\rho(y)], \quad x \in \text{supp} \rho \cap (M, 1-M)
\] (3.47)
There exists a unique \( (m_1, m_2) \) with either of the following holds:
- \( m_1 = 0 \), \( \text{ess inf}_{y \in (-M, M)} V_U[\rho_{\infty, m_1, m_2}](y) \geq \text{ess inf}_{y \in (M, 1-M)} V_U[\rho_{\infty, m_1, m_2}](y) \).
- \( m_2 = 0 \), \( \text{ess inf}_{y \in (-M, M)} V_U[\rho_{\infty, m_1, m_2}](y) \leq \text{ess inf}_{y \in (M, 1-M)} V_U[\rho_{\infty, m_1, m_2}](y) \).
- \( m_1 > 0, m_2 > 0 \), \( \text{ess inf}_{y \in (-M, M)} V_U[\rho_{\infty, m_1, m_2}](y) = \text{ess inf}_{y \in (M, 1-M)} V_U[\rho_{\infty, m_1, m_2}](y) \).

and in this case \( \rho_{\infty, m_1, m_2} = \rho_\infty \) is the minimizer of \( \mathcal{E}_U \) in \( \mathcal{M}_{1-2m} \).

Since the proof is very similar to Proposition 3.8, we will only give a sketch of the proof.

Proof. Existence of energy minimizer: Let \( \rho_n \to \rho \in \mathcal{M}_{m_1, m_2} \) minimizing \( \mathcal{E}_U \). Then \( \rho \) is a minimizer of \( \mathcal{E} \) by lower semicontinuity of \( \mathcal{E} \) with respect to weak convergence.

Characterizing property: If \( \rho_{\infty, m_1, m_2} \) does not satisfy the first line in (3.47), a similar transport plan with (3.38) where \( S \) is now a subset of \( (-M, M) \) will construct \( \rho_{\beta} \) with smaller \( \mathcal{E}_U \). Similarly for the second line of (3.47).

Uniqueness of minimizer in \( \mathcal{M}_{m_1, m_2} \). One can prove by contradiction using a linear interpolation \( \rho_t = (1-t)\rho_0 + t\rho \in \mathcal{M}_{m_1, m_2} \) between two minimizers of \( \mathcal{E} \) in \( \mathcal{M}_{m_1, m_2} \).

Relation between \( \rho_{\infty, m_1, m_2} \) and \( \rho_\infty \): Let \( 1 - 2m \geq 0 \), and \( \rho_\infty \) be the minimizer of \( \mathcal{E} \) in \( \mathcal{M}_{1-2m} \), whose existence and uniqueness are guaranteed by Proposition 3.8 Since \( \mathcal{E}_U[\rho_\infty] < \infty \),
\( \rho_{\infty} \) does not contain Dirac masses, therefore the uniqueness and existence of the pair \((m_1, m_2)\) follows. The conditions on \( \rho_{\infty, m_1, m_2} \) follow from \([3.34]\) directly.

\[ \square \]

4. Construction of Distributions

Our main goal for this section is to construct a class of measures that are candidates for the unique minimizer of \( \mathcal{G} \). In Section 3, we prove that the unique minimizer of \( \mathcal{G}_\alpha \) in \( \mathcal{M}_{D \geq d} \) must be a certain Dirac mass configuration in the format \( \rho_d = m(\delta_M + \delta_{-M}) \) together with the unique sediment distribution with respect to \( U = W \ast \rho_d \) in \( \mathcal{M}_{1-2m} \) under the potential \( W \). In this section, we will first give the constructions of a class of (signed) measures which we loosely refer to as stationary distribution. These measures satisfy the condition that \( V_U[\rho]'(x) = 0 \) for \( x \in \text{supp} \rho \). It clearly forms a larger class of measures since a differentiable \( V_U[\rho] \) for a sediment distribution \( \rho \) satisfies \( V_U[\rho] = \text{ess inf} V_U[\rho] \) in \( \text{supp} \rho \), which is a constant.\(^1\) We demonstrate the inclusion of all mentioned classes as following:

\[
\{ \text{stationary measures w.r.t } U \} \supset \{ \text{sediment measures w.r.t } U \} = \{ \text{minimizers of } \mathcal{E}_U \} \supset \{ \text{minimizer of } \mathcal{G}_\alpha \text{ in } \mathcal{M}_{D \geq d} \text{ subtracts its Dirac masses } \}
\]

Although our final goal and the above inclusions are all about measures over \( \mathbb{T} \), we take a detour to discuss signed measures over \( \mathbb{R} \) where the minimal value of another functional \( \tilde{\mathcal{G}} \), defined in \([5.2]\) as an analogue of \( \mathcal{G} \), is relatively easier to determine. We will discuss the minimal value of \( \tilde{\mathcal{G}} \) in Section 6 and its analogue \( \tilde{\mathcal{G}} \) over \( \mathbb{R} \) in Section 5. For the current section, we will focus on the construction of interesting measures. From now on, we will take \( W(x) = -\log |2 \sin(\pi x)| \) for \( x \in \mathbb{T} \) and \( \tilde{W}(x) = -\log |x| \) for \( x \in \mathbb{R} \). The construction heavily deploys the facts that we are using logarithmic potential, which is closely related to the kernel of Hilbert transform, on both \( \mathbb{R} \) and \( \mathbb{T} \). We will first give the construction over \( \mathbb{R} \) since it is relatively cleaner, and save the construction over \( \mathbb{T} \) to after.

4.1. Stationary Distributions over \( \mathbb{R} \). In this section, we firstly construct a family of signed measures over \( \mathbb{R} \). To simplify the notation, given a sequence of real numbers

\[ L_1 < M_1 < R_1 \leq L_2 < M_2 < R_2 \leq \cdots \leq L_n < M_n < R_n, \]

we denote \( S \subset \mathbb{R} \) to be the union of intervals

\[ S := (-\infty, L_1] \cup \bigcup_{j=1}^{n-1} [R_j, L_{j+1}] \cup [R_n, \infty), \]

and denote the product

\[ T_L(x) := \prod_{j=1}^{n} |x - L_j|, \quad T_{L,k}(x) := \prod_{j \neq k} |x - L_j|. \]

Similarly for \( T_M \) and \( T_R \).

**Lemma 4.1.** Given a sequence of real numbers \( L_1 < M_1 < R_1 \leq \cdots \leq L_n < M_n < R_n \). We define \( \mu(x) = -1 + \mu_c(x) + \mu_d(x) \) where

\[ \mu_c(x) = \frac{\sqrt{T_L(x)T_R(x)}}{T_M(x)} \chi_S, \quad \mu_d(x) = \sum_{j=1}^{n} a_j \delta_{M_j}, \]

with

\[ a_k = \pi \prod_{j=1}^{n} \frac{\sqrt{T_L(M_k)T_R(M_k)}}{T_M(M_k)}, \quad a_k > 0. \]

\(^1\)This concept of the stationary distribution is closely related to the stationary state (or steady state) and local energy minimizer in potential theory, see e.g. \([CS21]\).
Then $\mu(x)$ satisfies
\[
\text{p.v.}(\tilde{W}'*\mu)(x) = \begin{cases} 
-\pi \cdot \text{sgn}(x-M_k) \frac{\sqrt{T_L(x)T_R(x)}}{T_M(x)}, & x \in [L_k, M_k) \cup (M_k, R_k] \\
0, & x \in S 
\end{cases}
\] (4.6)

If further more
\[
\sum_{j=1}^{n} (L_j + R_j - 2M_j) = 0,
\] (4.7)
then $|\mu(x)| \leq \frac{C}{R}$ as $|x| \to \infty$ and $\int_{\mathbb{R}} |\mu(x)| \, dx < \infty$ and $\int_{\mathbb{R}} \mu(x) \, dx = 0$.

**Proof.** We define a function $g(z) = -1 + g_c(z) + g_d(z)$ where
\[
g_c(z) = \prod_{j=1}^{n} \phi(z-L_j) \phi(z-R_j) \frac{\sqrt{T_L(x)T_R(x)}}{T_M(x)}, \quad g_d(z) = -\sum_{j=1}^{n} \frac{a_j}{\pi} \frac{i}{z-M_j}
\] (4.8)
where $a_k$ is given by (4.5) and $\phi(z) = \sqrt{z}$ is the analytic function on $\mathbb{C} \setminus i\mathbb{R}_{\leq 0}$. It is clear that $g(z)$ is holomorphic on the upper half plane $\mathbb{C}_{y>0}$. Moreover, $g(z)$ is continuous in $\mathbb{C}_{y \geq 0}$ since the pole of $g_c(z)$ at $M_k$ is exactly cancelled by that of $g_d(z)$ due to the value of $a_k$.

Now we analyze $g$ on the real line. If $x \in S$ then $g_c(x) = \mu_c(x)$ is real and positive. If $x \in [L_k, M_k) \cup (M_k, R_k]$, then
\[
g_c(x) = i \cdot \text{sgn}(x-M_k) \frac{\prod_{j=1}^{n} \phi(z-L_j) \phi(z-R_j)}{\prod_{j=1}^{n} |x-M_j|} = i \cdot \text{sgn}(x-M_k) \frac{\sqrt{T_L(x)T_R(x)}}{T_M(x)}
\] (4.9)
is purely imaginary. Therefore for $x \in \mathbb{R} \setminus \{M_k \mid 1 \leq k \leq n\}$ we have
\[
\Re(g)(x) = -1 + \mu_c(x),
\]
\[
\Im(g)(x) = \sum_{k=1}^{n} \chi_{[L_k, R_k]}(x) \text{sgn}(x-M_k) \frac{\sqrt{T_L(x)T_R(x)}}{T_M(x)} - \sum_{j=1}^{n} \frac{a_j}{\pi} \frac{1}{x-M_j}.
\] (4.10)
The function $\Im(g)(x)$ can be extended to $\mathbb{R}$ continuously since $g$ is continuous on $\mathbb{C}_{y \geq 0}$. The function $\Re(g)(x)$ is continuous at any $x \in \mathbb{R}$ and $\Re(g) \in L^2(\mathbb{R})$, since as $|x| \to \infty$
\[
|
\Re(g)(x)| = \left| -1 + \frac{1}{1 - \sum_{j=1}^{n} M_j |x|^{-2} + O(1/|x|^2)} \right| \leq C/|x|.
\] (4.11)
Therefore Hilbert transform $H[\Re(g)]$ exists and it is a standard property that
\[
H[\Re(g)] = \text{p.v.} \frac{1}{\pi y} * (-1 + \mu_c(y)) = \text{p.v.} \frac{\tilde{W}'}{\pi} * (-1 + \mu_c(y)) = \Im(g),
\] (4.12)
where the second equality follows since $\tilde{W}'(x) = -\frac{1}{x}$. We finished proving (4.6) by adding the term $-\tilde{W}'/\pi * \mu_d$ to both sides of (4.12).

Using the assumption (4.7), we can refine (4.11) to $|\Re(g)(x)| \leq C/|x|^2$, and therefore $\mu = \Re(g) + \mu_d$ satisfies $\int_{\mathbb{R}} |\mu(x)| \, dx < \infty$.

Finally, we prove $\int_{\mathbb{R}} \mu \, dx = 0$. We take a contour integral of $g$ along
\[
\gamma_{r,\epsilon} := \{re^{i\theta} : 0 \leq \theta \leq \pi\} \cup \left( \cup_{P \in (L_j, R_j)} \{e^{i\theta} + P : 0 \leq \theta \leq \pi\} \right)
\cup \left( [-r, r] \setminus \cup_{P \in (L_j, R_j)} \{P - \epsilon, P + \epsilon\} \right)
\] (4.13)
for a large $r$ and small $\epsilon$, with counterclockwise direction. Since $g$ is analytic in a neighborhood of the domain enclosed by $\gamma = \gamma_{r,\epsilon}$, we have $\int_{\gamma} g(z) \, dz = 0$. Therefore its real part is
\[
\int_{r=r} (-1 + \mu_c(x)) \, dx + \Re \left( \int_{|e^{i\theta}| \leq \pi} g(z) \, dz \right) - \sum_{P \in (L_j, R_j)} \Re \left( \int_{|e^{i\theta} + P| \leq \pi} g(z) \, dz \right) = 0.
\] (4.14)
Finally, by taking $V_T$ represent points in the unit disc to the upper half plane. Notice that $\omega$ next for $R > 0$ since $g(z)$ is continuous in a neighborhood of $L_k$ and $R_k$. Therefore by letting $r \to \infty$ and $\epsilon \to 0$, we obtain $\int_{\partial} \mu(x) dx = 0$.

**Remark 4.2.** If (4.7) holds then $|\mu(x)| \leq \frac{C}{r^2}$ for large $|x|$, thus $\tilde{W} * \mu$ is well-defined on $\mathbb{R}$ except at $M_k$. We can imagine that $\mu_d$ generates an external potential $U = \tilde{W} * \mu_d$ and $\mu_e - 1$ is a signed measure on $\mathbb{R}$. Since $(\tilde{W} * \mu)' = \text{p.v.} \tilde{W}' * \mu = 0$ in $S = \text{supp} \mu_e$, the total potential $V_U[\mu_e - 1] = \tilde{W} * \mu$ is a constant on each connected component of $\text{supp} \mu_e$. This is the reason why we consider $\mu$ as stationarity distributions.

Then we apply the above lemma to obtain the following type I, II, III measures on $\mathbb{R}$, denoted as $\mu_1, \mu_{II}, \mu_{III}$, which are stationary in the sense of Remark 4.2. Firstly by taking the sequence $-1/\pi < 0 < 1/\pi$, we obtain

**Type I:** $\mu_1(x) = -1 + \frac{\sqrt{x^2 - \pi^2}}{|x|} x |\chi|_{x \leq \pi^{-1}} + \delta(x), \quad (\tilde{W} * \mu_1)'(x) = -\frac{\pi \sqrt{(x^2 - \pi^2)}}{x} |\chi|_{x \leq \pi^{-1}}.$

Next for $R > 1$, by taking $-R < -1 < 0 < 1 < R$ we obtain

**Type II:** $\mu_{II}(x) = -1 + \frac{\sqrt{(x^2 - R^2)x^2}}{|x^2 - 1|} |\chi|_{x \geq R} + m(\delta_1 + \delta_{-1}), \quad (\tilde{W} * \mu_{II})'(x) = -\frac{\pi x \sqrt{(x^2 - R^2)}}{x^2 - 1} |\chi|_{x \leq R}.$

Finally, by taking $-R < -1 < -L < 0 < L < 1 < R$ we obtain

**Type III:** $\mu_{III}(x) = -1 + \frac{\sqrt{(x^2 - R^2)(x^2 - L^2)}}{|x^2 - 1|} |\chi|_{x \in [0, L] \cup [R, \infty)} + m(\delta_1 + \delta_{-1}), \quad (\tilde{W} * \mu_{III})'(x) = -\frac{\pi \text{sgn}(x) \sqrt{(x^2 - R^2)(x^2 - L^2)}}{x^2 - 1} |\chi|_{L \leq |x| \leq R}.$

See Figure 3 for examples of constructions above.

4.2. Stationary Distributions over $\mathbb{T}$. We now construct a family of stationary measures over $\mathbb{T}$. It will contain the unique minimizer of $\mathcal{E}_U$ with $U$ being generated by the Dirac mass configuration $\mu_d = m(\delta_M + \delta_{-M})$ in Proposition 3.8 for all $m$ and $M$, therefore includes the unique minimizer of $G_0$ in Theorem 3.3 (after subtracting $\mu_d$).

The construction is similar to that of Lemma 4.1. For this construction, we will always represent points in $\mathbb{T}$ as $[-1/2, 1/2)$. We will use the conformal mapping $\omega(z) = i\frac{1-z}{1+z}$ that maps the unit disc to the upper half plane. Notice that $\omega(e^{2\pi i x}) = \tan \pi x$ for any $-1/2 < x < 1/2$. We also similarly simplify the notation before the construction. Given a sequence of real numbers $\frac{-1}{2} < t_1 < m_1 < t_1 + l_1 < \cdots < t_n < m_n < t_n < \frac{1}{2}$, we denote $S := [-1/2, t_1] \cup \bigcup_{j=1}^{n-1} [t_j, t_{j+1}] \cup [t_n, 1/2)$

and $T_i(x) := \prod_{j=1}^{i} |\tan \pi x - \tan \pi t_j|, \quad T_{i,k}(x) := \prod_{j \neq k} |\tan \pi x - \tan \pi t_j|$. (4.22)
Similarly for $T_m(x)$ and $T_r(x)$.

**Lemma 4.3.** Given a sequence of points on $\mathbb{T}$ denoted by
\[-\frac{1}{2} < \ell_1 < m_1 < \tau_1 < \ell_2 < m_2 < \tau_2 < \cdots < \ell_n < m_n < \tau_n < \frac{1}{2},\]
(4.23)

We define $\rho = \rho_c + \rho_d$ on $\mathbb{T}$ be given by
\[
\rho_c(x) = \frac{\sqrt{T_l(x)T_r(x)}}{T_m(x)} \chi_S, \quad \rho_d(x) = \sum_{j=1}^{n} a_j \delta(x - m_j),
\]
(4.24)
with
\[
a_k = \frac{\sqrt{T_l(m_k)T_r(m_k)}}{T_{m,k}(m_k)} \cdot \cos^2 \pi m_k > 0.
\]
(4.25)

Then there exists a constant $C_1$ such that
\[
(W * \rho')(x) - \pi C_1 = \begin{cases} -\pi \text{sgn}(x - m_k) \frac{\sqrt{T_l(x)T_r(x)}}{T_m(x)}, & x \in [\ell_k, m_k) \cup (m_k, r_k] \\ 0, & x \in S \end{cases}
\]
(4.26)

**Proof.** Let $L_j = w(e^{2\pi i \ell_j}) = \tan \pi \ell_j, M_j = \tan \pi m_j, R_j = \tan \pi r_j$. Then similar to the function $g$ in (4.8), we define $g = g_c + g_d - C_0$ for $|z| \leq 1$ with
\[
g_c(z) = \prod_{j=1}^{n} \frac{\phi(\omega(z) - L_j)\phi(\omega(z) - R_j)}{\phi(\omega(z) - M_j)}, \quad g_d(z) = - \sum_{j=1}^{n} a_j \frac{i}{\omega(-e^{2\pi i m_j})},
\]
(4.27)

where $\phi$ is as appeared in (4.8), $a_j$ is given in (4.25), and $C_0 = C_0 + iC_1$ is a complex constant such that $g(0) = 0$. Similarly with Lemma 4.1 here $g$ is analytic in the unit disc and continuous on $|z| = 1$. At $z = -1$ we have $\lim_{z \to -1, |z| < 1} g(z) = 1 - \sum_{j=1}^{n} a_j \frac{i}{\omega(-e^{2\pi i m_j})}$.

Then, similar to the proof of Lemma 4.1 we have
\[
\Re(g(e^{2\pi i x})) = \rho_c(x) - C_0, \quad (4.28)
\]
\[
\Im(g(e^{2\pi i x})) = \sum_{k=1}^{n} \chi_{[\ell_k, \tau_k]} \text{sgn}(x - m_k) \frac{\sqrt{T_l(x)T_r(x)}}{T_m(x)} - \sum_{j=1}^{n} a_j \cot \pi(x - m_j) - C_1 \quad (4.29)
\]
which are functions in $L^2(\mathbb{T})$. The kernel for the Hilbert transform on $\mathbb{T}$ is exactly
\[
\cot \pi x = -\frac{1}{\pi} W'(x).
\]
(4.30)

By construction $g(0) = 0$, we get
\[
\left(\text{p.v. cot} \pi y * (\rho_c - C_0)\right)(x) = \Im(g), \quad (4.31)
\]
therefore
\[
(W * \rho)' = -\pi \left(\text{p.v. cot} \pi y * \rho\right)(x) = -\pi \left(\sum_{k=1}^{n} \chi_{[\ell_k, \tau_k]} \text{sgn}(x - m_k) \frac{\sqrt{T_l(x)T_r(x)}}{T_m(x)} - C_1\right).
\]
(4.32)

\[
\square
\]

The above lemma is useful for our application to the energy minimizers only when $C_1 = 0$. Using $\omega(0) = i$ and $g_d(0) = -\sum_i a_i$, this condition is
\[
\Im\left(\prod_{j=1}^{n} \frac{\phi(i - L_j)\phi(i - R_j)}{\phi(i - M_j)}\right) = 0 \quad (4.33)
\]
Then we may apply the mean value principle to the analytic function $g$ to get
\[
\int_{\mathbb{T}} \rho_c \, dx = C_0 = \Re\left(\prod_{j=1}^{n} \frac{\phi(i - L_j)\phi(i - R_j)}{\phi(i - M_j)}\right) - \sum_i a_i, \quad (4.34)
\]
where
\[
\int_T \rho \, dx = \Re \left( \prod_{j=1}^n \phi(i - L_j) \phi(i - R_j) / \prod_{j=1}^n (i - M_j) \right). \tag{4.35}
\]

Then we will construct some energy minimizers. Using the sequence \(-\frac{1}{\pi} \sin^{-1} 2m < 0 < \frac{1}{\pi} \sin^{-1} 2m\) with \(n = 1\) in Lemma 4.3, we obtain the following:

**Proposition 4.4.** For \(0 < m \leq 1/2\), we have the probability measures \(\rho_{1,m}(x) = \rho_{1,c} + \rho_{1,d}\) on \(T\) where
\[
\rho_{1,c}(x) = \sqrt{1 - \frac{4m^2}{\sin^2 \pi x}} \chi_{|x| \geq \frac{1}{\pi} \sin^{-1} 2m}; \quad \rho_{1,d}(x) = 2m \delta(x). \tag{4.36}
\]
The measure \(\rho_{1,c}\) is the unique minimizer of \(\mathcal{E}_U\) in \(\mathcal{M}_{1-2m}\) for \(U = W \ast \rho_{1,d}\).

**Proof.** We verify (4.33) and invoke (4.35) by computing
\[
\frac{\phi(i - L_1) \phi(i - R_1)}{i - M_1} = \frac{\phi(i + \tan(\sin^{-1} 2m)) \phi(i - \tan(\sin^{-1} 2m))}{i} = \frac{1}{\sqrt{1 - 4m^2}} = \int_T \rho \, dx,
\]
where the corresponding measure \(\rho\) in Lemma 4.3 is
\[
\rho(x) = \frac{\sqrt{(|\tan \pi x - \tan(\sin^{-1} 2m)| (\tan \pi x + \tan(\sin^{-1} 2m))|)}}{|\tan \pi x|} + \frac{2m}{\sqrt{1 - 4m^2}} \delta(x). \tag{4.38}
\]
In order to construct a probability measure, we divide \(\rho\) by its total mass and obtain \(\rho_1\), which is the sum of \(\rho_{1,c}\) and \(\rho_{1,d}\) given in (4.36).

By Lemma 4.3, we obtain the formula for \((W \ast \rho_1)'\). It is positive in \([-\frac{1}{\pi} \sin^{-1} 2m, 0]\) and negative in \((0, \frac{1}{\pi} \sin^{-1} 2m]\) and zero otherwise, indicating that \(W \ast \rho_1\) is smallest in \(\text{supp} \rho_{1,c}\). Therefore \(\rho_{1,c} \in \mathcal{M}_{1-2m}\) satisfies the characterizing condition (3.34) for \(U = \rho_{1,d} \ast W\) with \(M = 0\), and by Proposition 3.8, it is also the unique minimizer of \(\mathcal{E}_U\) and maximizer of \(\text{ess inf} V_U\) in \(\mathcal{M}_{1-2m}\).

Similarly we can obtain the unique minimizer when \(M \neq 0\) by applying Lemma 4.3 using the sequence \(-R < -M < -L \leq L < M < R\) with \(n = 2\), we obtain the following:

**Proposition 4.5.** For \(0 \leq L < M < R < 1/2\), we have probability measures \(\rho_{11,M,R,L} = \rho_{11,c} + \rho_{11,d}\) on \(T\) where
\[
\rho_{11,c}(x) = \frac{\sin \pi(x - R) \sin \pi(x + R) \sin \pi(x - L) \sin \pi(x + L)}{\sin \pi(x - M) \sin \pi(x + M)} \chi_{|x| \in [0,L]\cup[R,1/2]} \tag{4.39}
\]
and
\[
\rho_{11,d}(x) = m(\delta(x + M) + \delta(x - M))
\]
where
\[
m = \frac{\sin 2\pi M}{\sin \pi(M - R) \sin \pi(M + R) \sin \pi(M - L) \sin \pi(M + L)}. \tag{4.40}
\]
The measure \(\rho_{11,c}\) is the unique minimizer of \(\mathcal{E}_U\) where \(U = W \ast \rho_{11,d}\) in \(\mathcal{M}_{m_1,m_2}\) with
\[
m_1 = \int_{(-M,M)} \rho_{11,M,R,L} \, dx, \quad m_2 = 1 - 2m - m_1. \tag{4.41}
\]

See Figure 2 (b), (c) and (d) for examples of this construction.

**Proof.** Similarly with Proposition 4.5, we verify (4.33) and invoke (4.35) by computing
\[
\frac{\prod_{j=1}^n \phi(i - L_j) \phi(i - R_j)}{\prod_{j=1}^n (i - M_j)} = \frac{\cos \pi x}{\cos \pi x} \frac{\cos \pi x}{\cos \pi x} = \frac{\cos^2 \pi M}{\cos \pi R \cos \pi L} = \int_T \rho \, dx, \tag{4.42}
\]
where the corresponding $\rho = \rho_e + \rho_d$ in Lemma 4.3 is

$$\rho_e(x) = \sqrt{\left(\tan^2 \pi x - \tan^2 \pi R\right) \left(\tan^2 \pi x - \tan^2 \pi M\right)} \chi_{|x|\in[0,L]|R,1/2]}$$

$$\rho_d(x) = a(\delta(x + M) + \delta(x - M)),$$

with

$$a = \sqrt{\left[\left(\tan^2 \pi M - \tan^2 \pi R\right)\left(\tan^2 \pi M - \tan^2 \pi L\right)\right]/\left(2 \tan \pi M\right)}. \quad (4.44)$$

We divide $\rho$ by its total mass to obtain $\rho_{1M,R,L}(x)$, and still denote the corresponding terms by $\rho_{1L,c}$ and $\rho_{1L,d}$.

By Lemma 4.3 for $\rho_{11} = \rho_{11M,R,L}$, we obtain the formula for $(W * \rho_{11}(x))'$. It indicates that $W * \rho_{11}$ is a constant in both connected components $[-L, L]$ and $T\setminus[-M, M]$ of $\text{supp} \rho_{1L,c}$.

Therefore the measure $\rho_{1L,c} \in \mathcal{M}_{1-2m}$ satisfies the characterizing condition in (4.47) for $m_1$ and $m_2$ given in (4.41) and $U = W * \rho_{1L,d}$, and by Corollary 3.10 it is also the unique minimizer of $\mathcal{E}_U$ in $\mathcal{M}_{m_1, m_2}$.

Combining Corollary 3.10 and Proposition 4.4 and 4.5, given $U = W * m(\delta_M + \delta_{-M})$ and $m_1 \leq 1 - 2m$, the unique minimizer of $\mathcal{E}_U$ in $\mathcal{M}_{m_1,1-2m-m_1}$ must be in the form of either $\rho_{1L,c}(x)$ (when $M = 0$) as in (4.39) or $\rho_{1L,d}(x)$ (when $M \neq 0$) as in (4.39). Let’s denote this unique minimizer in $\mathcal{M}_{m_1,1-2m-m_1}$ to be $\rho_{M,m_1}$. We thus obtain a three-parameter family of probability measures over $T$,

$$\eta_{M,m_1} := \rho_{M,m_1} + m(\delta_M + \delta_{-M}), \quad (4.45)$$

which includes the minimizer of $\mathcal{G}_\alpha$ in $\mathcal{M}_{D_{2d}}$ by Theorem 3.1.

4.3. Sediment Distributions over $T$. In Section 4.2 we have constructed a three-parameter family $\eta_{M,m_1} \in \mathcal{M}$ in (4.45) that serves as candidates for the minimizer of $\mathcal{G}_\alpha$ in $\mathcal{M}_{D_{2d}}$. These measures are all composed of Dirac masses in the form of $m(\delta_M + \delta_{-M})$ together with a stationary measure in $\mathcal{M}_{1-2m}$ with respect to $U = W * m(\delta_M + \delta_{-M})$.

We are going to show in this section that we can further narrow down candidates from stationary distributions to sediment distributions. While doing so, we will eliminate the parameter $m_1$ and reduce the number of parameters from three to two.

Proposition 4.6. Fix $0 < M < 1/2$ and $0 < m \leq 1/2$. There exists a unique $m_1$ such that $\rho_{M,m_1}$ is a sediment distribution with respect to $U = W * m(\delta_M + \delta_{-M})$. Moreover, for fixed $M$ and $m$, $(W * \rho_{M,m_1})(0) - (W * \rho_{M,m_1})(1/2)$ is an increasing function of $m_1$.

See Figure 2(c) and (d) for a comparison between non-sediment distributions and sediment distributions. Before we prove Proposition 4.6, we first give a lemma which is a comparison principle for moments against the decreasing function $W$.

Lemma 4.7. Let $U$ be a $C^1$ function on $(0, X)$ with $X \in (0, \infty]$ and $U' < 0$, and $\mu_1, \mu_2$ be signed measures on $(0, X)$ with $\int_{(0,X)} \mu_1 \, dx = \int_{(0,X)} \mu_2 \, dx$. If

$$\int_{(0,x)} \mu_1(y) \, dy \leq \int_{(0,x)} \mu_2(y) \, dy, \quad \forall x \in (0, X), \quad (4.46)$$

and

$$\int_{(0,X)} (|\mu_1| + |\mu_2|) U \, dx < \infty, \quad (4.47)$$

$$\lim_{x \to 0^+} U(x) \int_{(0,x)} (\mu_1(y) - \mu_2(y)) \, dy = \lim_{x \to X^-} U(x) \int_{(0,x)} (\mu_1(y) - \mu_2(y)) \, dy = 0, \quad (4.48)$$
then
\[ \int_{(0,X)} \mu_1 U \, dx \leq \int_{(0,X)} \mu_2 U \, dx. \] (4.49)

And strict inequality holds as long as \( \mu_1 \neq \mu_2 \).

Proof. Denote \( m_i(x) = \int_{(0,x)} \mu_i(y) \, dy \). Then integration by parts gives
\[ \int_{(\epsilon,R)} \mu_i U \, dx = U(R) \cdot m_i(R) - U(\epsilon) \cdot m_i(\epsilon) - \int_{(\epsilon,R)} m_i U' \, dx, \] (4.50)
for \( 0 < \epsilon < R < X \). Then
\[ \int_{(\epsilon,R)} \mu_2 U \, dx - \int_{(\epsilon,R)} \mu_1 U \, dx \]
\[ = U(R) \cdot (m_2(R) - m_1(R)) - U(\epsilon) \cdot (m_2(\epsilon) - m_1(\epsilon)) - \int_{(\epsilon,R)} (m_2 - m_1) U' \, dx. \] (4.51)

Taking \( \epsilon \to 0^+ \) and \( R \to X^- \), using the assumption \( \text{4.47} \) and \( U'(x) < 0 \) and \( m_1(x) < m_2(x) \)
for \( x \in (0,X) \), we get
\[ \int_{(0,X)} \mu_2 U \, dx - \int_{(0,X)} \mu_1 U \, dx = - \int_{(0,X)} (m_2 - m_1) U' \, dx \geq 0, \] (4.52)
where the last inequality is strict if \( \mu_1 \neq \mu_2 \). \( \square \)

Proof of Proposition 4.6. The uniqueness of \( m_1 \) follows directly from the uniqueness of minimizer of \( \mathcal{E}_U \) in \( \mathcal{M}_{1-2m} \) in Corollary 3.10.
To show the monotonicity of \((W * \rho_{M,m,m_1})(0) - (W * \rho_{M,m,m_1})(1/2)\), we first show the monotonicity of \(L\) and \(R\) as a function of \(m_1\) when \(M\) and \(m\) is fixed. The measure \(\rho_{M,m,m_1}\) has the form of \(\rho_{1,c}(x)\) as given in (4.39) where \(R\) and \(L\) are implicitly determined by (4.40) and (4.41). For \(i = 1, 2\), let’s say \(R_i\) and \(L_i\) are determined by taking \(m_1 = m_{1,i}\), and \(\rho_i = \rho_{M,m,m_1}\), is the corresponding \(\rho_{1,c}\) in (4.39). Using \(\sin \pi (M - R) \sin \pi (M + R) = (\cos 2\pi R - \cos 2\pi M) / 2\), we can see from (4.40) that either \(L_1 < L_2 < M < R_1 < R_2\) or \(L_2 < L_1 < M < R_2 < R_1\). Now using (4.39) and (4.41), we see that if \(m_{1,1} < m_{1,2}\) then \(L_1 < L_2 < M < R_1 < R_2\).

This implies that if \(m_{1,1} < m_{1,2}\), then \(\rho_1(x) \leq \rho_2(x)\) for \(0 < x < M\) and \(\rho_1(x) \geq \rho_2(x)\) for \(M < x < 1/2\). Therefore

\[
\int_{|x| < X} \rho_1(x) \, dx \leq \int_{|x| < X} \rho_2(x) \, dx
\]

for any \(0 \leq X \leq 1/2\). Then, since \(\rho_1, \rho_2, W\) are even and \(W(x)\) is decreasing on \((0, 1/2)\), we have

\[
(W * \rho_1)(0) = \int_T W(x) \rho_1(x) \, dx \leq \int_T W(x) \rho_2(x) \, dx = (W * \rho_2)(0),
\]

by Lemma 4.7 (with \(X = 1/2\)). Similarly we have \((W * \rho_1)(1/2) \geq (W * \rho_2)(1/2)\) by applying Lemma 4.7 to \(\rho_1(1/2 - x)\). Then the conclusion follows.

\[
\square
\]

4.4. Admissible Distributions over \(\mathbb{R}\). In this section, we will give a statement for distributions over \(\mathbb{R}\) that serves as the analogue of Proposition 4.6 in Section 4.3. We will not only prove similar qualitative results like existence and uniqueness in Proposition 4.6, but also provide quantitative analysis for this family of distributions over \(\mathbb{R}\).

Recall the three types of distributions defined in (4.16), (4.17) and (4.19). The distributions \(\mu_{II}\) and \(\mu_{III}\) form a family parametrized by two parameters \(R\) and \(L\) where \(\mu_{II}\) corresponds to cases where \(L = 0\). We will first make the observation in Proposition 4.8 that \((\tilde{W} * \mu)(x) = 0\) for all three types of \(\mu\). Then by imposing the condition

\[
(\tilde{W} * \mu)(x) = \text{ess inf}(\tilde{W} * \mu), \quad \text{for } x \in \text{supp } \mu_c,
\]

we further cut down by one parameter and obtain a family of stationary measures \(\mu\) over \(\mathbb{R}\) just parametrized by \(R\) in Proposition 4.11. We call this family of signed measures over \(\mathbb{R}\) together with \(\mu_I\) the admissible distributions. Figure 2 (c) and (d) illustrate the difference between admissible distributions and non-admissible distributions. Although technically speaking they are not measures and do not satisfy the sediment condition, they serve a similar role on \(\mathbb{R}\) with that of sediment measures (together with the Dirac masses) over \(\mathbb{T}\). Such connection will be made clearer in Section 3.

**Proposition 4.8.** For \(\mu\) be given in (4.16), (4.17) or (4.19), we have

\[
\lim_{x \to \infty} (\tilde{W} * \mu)(x) = 0.
\]

**Proof.** Let \(\mu\) be given by (4.16), (4.17) or (4.19). We know from Lemma 4.1 that \(\int_{\mathbb{R}} \mu(x) \, dx = 0\) and \(|\mu(x)| \leq \frac{1}{|x|^2}\). To see (4.56), we use the mean-zero property of \(\mu\) and write

\[
\int_{\mathbb{R}} \tilde{W}(x - y) \mu(y) \, dy = \int_{\mathbb{R}} (\tilde{W}(x - y) - \tilde{W}(x)) \mu(y) \, dy = \int_{\mathbb{R}} -\ln |1 - \frac{y}{x}| \cdot \mu(y) \, dy
\]

for large \(|x|\). We can assume \(x > 0\) since \(\tilde{W} * \mu\) is even.

For \(|y| \leq \sqrt{x}/2\), we have \(|\ln |1 - \frac{y}{x}|| \leq \frac{1}{\sqrt{x}}\), thus

\[
\left| \int_{|y| \leq \sqrt{x}/2} -\ln |1 - \frac{y}{x}| \cdot \mu(y) \, dy \right| \leq \frac{1}{\sqrt{x}} \int_{\mathbb{R}} |\mu(y)| \, dy.
\]
Figure 3. Stationary Distribution over $\mathbb{R}$: (a) Top left: Type I over $\mathbb{R}$; (b) Top right: Type II over $\mathbb{R}$ ($L = 0, R = 2.1$); (c) Bottom left: non-admissible Type III over $\mathbb{R}$ ($L = 0.7, R = 1.4$); (d) Bottom right: admissible Type III over $\mathbb{R}$ ($L \approx 0.60, R = 1.4$).

Next for $\sqrt{3}/2 < |y| \leq x/2$, similarly we have $|\ln|1 - \frac{y}{x}|| \lesssim \frac{|y|}{x}$ and $|\mu(y)| \lesssim 1/y^2$, thus

$$\left| \int_{\sqrt{3}/2 < |y| \leq x/2} - \ln|1 - \frac{y}{x}| \cdot \mu(y) \, dy \right| \lesssim \frac{1}{x} \int_{\sqrt{3}/2 < |y| \leq x/2} \frac{1}{|y|} \, dy \lesssim \frac{\ln x}{x}. \quad (4.59)$$

Finally for $|y| > x/2$ using a change of variable $y = xy_1$ we get

$$\left| \int_{|y| > x/2} - \ln|1 - \frac{y}{x}| \cdot \mu(y) \, dy \right| \lesssim \int_{|y| > x/2} \left| \ln|1 - \frac{y}{x}| \right| \frac{1}{y^2} \, dy \lesssim \frac{1}{x} \int_{|y_1| > 1/2} \left| \ln|1 - y_1| \right| \frac{1}{y_1^2} \, dy_1 \lesssim \frac{1}{x}. \quad (4.60)$$

Therefore (4.56) is proved. \hfill \Box

Remark 4.9. It follows from Proposition 4.8 and the stationary property of $\mu$ (in (4.6)) that $(\hat{W} * \mu)(x) = 0$ when $|x| \geq 1/\pi$ for Type I and $(\hat{W} * \mu)(x) = 0$ when $|x| \geq R$ for Type II and III.

In the following proposition, by imposing (4.55), we will further get rid of the parameter $L$ and obtain a one-parameter family of distributions parametrized by $R$. We first explain how the condition (4.55) is equivalent to a condition on $(\hat{W} * \mu)(0)$. For Type II, we recall in Lemma 4.1 that $\text{supp} \mu_c = (-\infty, -R] \cup [R, \infty)$ and $(\hat{W} * \mu') = \text{p.v.} \hat{W}' * \mu$ is positive in $[0, 1)$ and negative in $(1, R]$ and $\hat{W} * \mu$ approaches to $\infty$ as $x \to 1$. Therefore (4.55) is equivalent to $(\hat{W} * \mu)(0) \geq 0$ since $(\hat{W} * \mu)(\infty) = 0$ by Proposition 4.8. For Type III, we recall that $\text{supp} \mu_c = (-\infty, -R] \cup [-L, L] \cup [R, \infty)$ and $(\hat{W} * \mu')$ is positive in $[L, 1)$ and negative in $(1, R]$, therefore (4.55) is equivalent to $(\hat{W} * \mu)(0) = 0$. 

25
We now give the formula for \((\hat{W} \ast \mu)(0)\) for \(\mu\) constructed in \((4.17)\) and \((4.19)\) by integrating against \((\hat{W} \ast \mu)'\). Although \(\hat{W} \ast \mu\) is not continuous at \(x = 1\), we still have

\[
p.v. \int_L^R (\hat{W} \ast \mu)'(x) \, dx = \lim_{\epsilon \to 0^+} \left( (\hat{W} \ast \mu)(1 - \epsilon) - (\hat{W} \ast \mu)(L) + (\hat{W} \ast \mu)(R) - (\hat{W} \ast \mu)(1 + \epsilon) \right) = (\hat{W} \ast \mu)(R) - (\hat{W} \ast \mu)(L) = -(\hat{W} \ast \mu)(L),
\]

where we plug in \(\mu = (-1 + \mu_c) + \mu_d\) by Lemma 4.1 for the second equality. The third equality follows from Remark 4.9. Then by the explicit expression of \((\hat{W} \ast \mu)'\) in \((4.18)\) and \((4.20)\) we obtain

\[
(\hat{W} \ast \mu)(0) = -p.v. \int_L^R (\hat{W} \ast \mu)'(x) \, dx = p.v. \int_L^R \frac{\pi \sqrt{-(x^2 - R^2)(x^2 - L^2)}}{x^2 - 1} \, dx := \Phi(L, R).
\]

We denote the last integral by \(\Phi(L, R)\).

In order to study \((\hat{W} \ast \mu)(0)\) for Type II and III distributions over \(\mathbb{R}\), we first prove some useful properties of this function \(\Phi(L, R)\).

**Lemma 4.10.** For \(0 \leq L < R\), let \(\Phi(L, R)\) be given in \((4.62)\).

(i) The function \(\Phi(L, R)\) is strictly increasing in both \(L\) and \(R\).

(ii) There exists a unique real number \(R = R_c \approx 1.8102\) such that \(\Phi(0, R) = 0\).

(iii) If \(\Phi(L, R) = 0\), then \(L + R < 2\) and \(L^2 + R^2 > 2\).

See Figure 3 (a) for a graph of \(\Phi(L, R) = 0\).

**Proof.** **Proof of (i):** We denote \(\mu_{L,R}\) for \(\mu\) of Type II (where \(L = 0\)) and Type III. Recall the expression of \(\mu_{L,R}\) and \(m(L, R)\) in \((4.20)\). If \(R_2 > R_1\), then \(m(L, R_2) > m(L, R_1)\), and

\[
\mu_{L,R_2}(x) \leq \mu_{L,R_1}(x) \text{ for } |x| > 1, \quad \mu_{L,R_1}(x) \geq \mu_{L,R_1}(x) \text{ for } |x| \leq 1.
\]

This verifies the condition \((4.46)\) with \(\mu_i = \mu_{L,R_1}\) using the mean zero property of \(\mu_{\text{III}}(x)\). One can also check the condition \((4.47)\) with \(U = \hat{W}\) since \(\mu_i\) are \(L^\infty\) functions near 0, have the mean-zero property, and decay at least as \(1/|x|^2\) at infinity. Therefore, noticing that \(\mu_i\) are even, we can apply Lemma 4.7 (with \(X = \infty\)) to get \(\Phi(L, R_2) > \Phi(L, R_1)\) by the decreasing property of \(\hat{W}(x)\) in \(|x|\). Similarly one can prove the monotonicity in \(L\).

**Proof of (ii):** Since \(\Phi(0, R)\) is strictly increasing in \(R\), it suffices to show that

\[
\lim_{R \to 1^+} \Phi(0, R) < 0, \quad \lim_{R \to \infty} \Phi(0, R) > 0.
\]

Notice that \(\Phi(0, R)\) can be explicitly evaluated as

\[
p.v. \int_0^R \frac{x \sqrt{-(x^2 - R^2)}}{x^2 - 1} \, dx = \sqrt{R^2 - 1} \ln(R + \sqrt{R^2 - 1}) - R, \quad \text{for } R > 1,
\]

which indicates the sign of limit as \(R \to 1^+\) and \(R \to \infty\). We denote the unique root in \((1, \infty)\) of \(\sqrt{R^2 - 1} \ln(R + \sqrt{R^2 - 1}) - R = 0\) by \(R_c\). It is approximately 1.8102.

**Proof of (iii):** Note that it follows \(\Phi(0, R_c) = 0\) and the monotonicity of \(\Phi\) that if \(\Phi(L, R) = 0\) for some \(L \geq 0\), then \(R \leq R_c\). Now since \(\Phi(L, R)\) is increasing in both \(L\) and \(R\), it suffices to show for any \(R_c \geq R > 1\) that

\[
\Phi(2 - R, R) > 0, \quad \Phi(\sqrt{2 - R^2}, R) < 0.
\]
To see \( \Phi(\sqrt{2-R^2}, R) < 0 \), we use a change of variable \( u = x^2 \) and then write \( \frac{1}{2} \Phi(\sqrt{2-R^2}, R) \) as

\[
p.v. \int_{2-R^2}^{R^2} \sqrt{(R^2-u)(u-(2-R^2))} \frac{du}{(u-1)\sqrt{u}} = \lim_{\epsilon \to 0^+} \int_{2-R^2}^{1+\epsilon} \sqrt{(R^2-u)(u-(2-R^2))} \frac{du}{(u-1)\sqrt{u}} + \int_{1+\epsilon}^{R^2} \sqrt{(R^2-u)(u-(2-R^2))} \frac{du}{(u-1)\sqrt{u}} \tag{4.67}
\]

\[
= \lim_{\epsilon \to 0^+} \int_{1+\epsilon}^{R} \sqrt{(R^2-u)(u-(2-R^2))} \frac{1}{\sqrt{u}} \left( \frac{1}{\sqrt{2-u}} - \frac{1}{\sqrt{2-u}} \right) du < 0.
\]

Similarly to see \( \Phi(2-R, R) > 0 \), we write \( \frac{1}{2} \Phi(2-R, R) \) as

\[
p.v. \int_{2-R}^{R} \sqrt{(R^2-x^2)(x^2-(2-R^2))} \frac{dx}{x^2-1} = \lim_{\epsilon \to 0^+} \int_{2-R}^{1+\epsilon} \sqrt{(R^2-x^2)(x^2-(2-R^2))} \frac{dx}{x^2-1} + \int_{1+\epsilon}^{R} \sqrt{(R^2-x^2)(x^2-(2-R^2))} \frac{dx}{x^2-1} \tag{4.68}
\]

The last integrand is clearly positive since

\[
-(R^2 - (2-x)^2)((2-x)^2-(2-R^2))(x^2-1)^2 + (R^2-x^2)(x^2-(2-R^2))(1-(2-x)^2)^2 \\
= -8(R-1)^2(x-1)^3(R(2-R)-x(2-x)) > 0.
\]

Now we are ready to state the following.

**Proposition 4.11.** Let \( \mu \) be given in (4.17) or (4.19).

(i) For Type II, \( (\tilde{W} \ast \mu_1)(0) \geq 0 \) if and only if \( R \geq R_c \), where \( R_c \approx 1.8102 \) is the unique number in \((1, \infty)\) satisfying

\[
\sqrt{R^2 - 1} \ln \left( R + \sqrt{R^2 - 1} \right) - R = 0. \tag{4.70}
\]

In this case \( \mu_1(x) < 0 \) for \( |x| \neq 1 \).

(ii) For Type III, \( (\tilde{W} \ast \mu_1)(0) = 0 \) if and only if \( 1 < R < R_c \) and \( L = L(R) \), where \( L(R) \in (0, 1) \) is the unique number satisfying

\[
\Phi(L, R) := p.v. \int_{L}^{R} \pi \sqrt{-\frac{(x^2-R^2)(x^2-L^2)}{x^2-1}} \, dx = 0. \tag{4.71}
\]

In this case \( \mu_1(x) < 0 \) for \( |x| \neq 1 \). This function \( L(R) \) is decreasing in \( R \).

**Proof of Proposition 4.11.**

Proof of (i): Lemma 4.10(i) and (ii) implies that \( \Phi(0, R) = (\tilde{W} \ast \mu_1)(0) \geq 0 \) if and only if \( R \geq R_c \). To see that \( \mu_1(x) < 0 \) for \( |x| \neq 1 \), we notice that for \( x \geq R_c \),

\[
\mu_1(x) = -1 + \sqrt{\frac{1-\frac{R^2}{x^2}}{1-\frac{x^2}{R^2}}} < -1 + \sqrt{\frac{1-\frac{R^2}{1}}{1-\frac{1}{R^2}} < 0, \text{ for } R \geq R_c. \tag{4.72}
\]
Proof of (ii): By Lemma 4.10, the function $\Phi(L, R)$ is increasing in both $L$ and $R$. Therefore for each $1 < R < R_c$ we have $\Phi(0, R) < \Phi(0, R_c) = 0$. On the other hand, by (4.62),
\[
\lim_{L \to 1-} \Phi(L, R) = \pi \int_1^R \sqrt{\frac{R^2 - x^2}{x^2 - 1}} \, dx > 0.
\]
Therefore, there exists a unique $L = L(R)$ such that $\Phi(L, R) = 0$. The decreasing property of $L(R)$ then follows from the monotonicity of $\Phi(L, R)$ in $R$ and $L$.

To see $\mu^{\text{III}}(x) < 0$ for $|x| \neq 1$ when $1 < R < R_c$ and $L = L(R)$, it suffices to note
\[
(x^2 - R^2)(x^2 - L^2) = x^4 - (R^2 + L^2)x^2 + R^2L^2 = x^4 - (R^2 + L^2)x^2 + \frac{1}{4}((R + L)^2 - (R^2 + L^2))^2 < x^4 - 2x^2 + \frac{1}{4}(4 - 2)^2 = (x^2 - 1)^2.
\]
The last inequality follows from Lemma 4.10(iii). □

5. An Optimization Problem over $\mathbb{R}$

In this section, our goal is to determine the minimal value of an analogous goal functional $\tilde{G}$ for admissible distributions over $\mathbb{R}$. Recall that we have constructed and defined admissible distributions in Section 4.4 and Definition 4.12. Now we define for admissible $\mu$ that
\[
\tilde{H}[\mu] = \int_{\mathbb{R}} \tilde{W} * \mu \, dx, \quad \tilde{D}[\mu_1(\cdot \lambda)] = \lambda, \quad \tilde{D}[\mu_{\text{II or III}}(\cdot \lambda)] = \int_{[-\lambda, \lambda]} \mu_{\text{II or III}}(\cdot \lambda) \, dx,
\]
and
\[
\tilde{G}[\mu] = \frac{\tilde{H}[\mu]}{\tilde{D}^2[\mu]}.
\]
The relation between $\tilde{H}$, $\tilde{D}$ and the functionals $H$, $D$ on $\mathbb{T}$ will be revealed in Section 6 by Proposition 6.2 and Theorem 6.7. Then we state the main result of this chapter as an optimization problem.

Theorem 5.1. For admissible $\mu$, we have $\tilde{G}[\mu] \geq \frac{1}{2}$. The equality holds if and only if $\mu$ is of Type I.

See Figure 4(b) for a graph of $\tilde{G}[\mu]$ for $\mu$ of Type II and III indexed by $R$. 28
5.1. **Dimension Reduction.** Recall that admissible distribution is either of Type I, parametrized by \( \lambda > 0 \), or of Type II and III, parametrized by two parameters \( \lambda > 0 \) and \( R > 1 \). In this section, we will show that the goal functional \( \tilde{G} \) remains invariant under scaling, i.e., \( \tilde{G}(\mu) \) does not depend on the \( \lambda \) parameter in all cases.

**Lemma 5.2.** If \( \mu \) is admissible, then \( \tilde{G}[\mu] = \tilde{G}[\mu(\frac{x}{\lambda})] \) for any \( \lambda > 0 \).

**Proof.** By change of variables,

\[
\tilde{H}[\mu(\frac{x}{\lambda})] = \int_{R} (\tilde{W} * \mu(\frac{x}{\lambda}))(x) \, dx = -\int_{R} \int_{R} \ln |y| \mu(\frac{x-y}{\lambda}) \, dy \, dx \\
= -\lambda^2 \int_{R} \int_{R} \ln |y| \mu(x-y) \, dy \, dx = -\lambda^2 \int_{R} \int_{R} \ln |y| \mu(x-y) \, dy \, dx = \lambda^2 \tilde{H}[\mu] \tag{5.3}
\]

where we use the mean-zero property of \( \mu \), shown in Lemma 4.1, in the fourth inequality.

Then we discuss \( \tilde{D} \). Firstly \( \tilde{D}[\mu(\frac{x}{\lambda})] = \lambda = \lambda \tilde{D}[\mu] \) by definition. If \( \mu = \mu_{II,R} \) or \( \mu_{III,L(R),R} \), then

\[
\tilde{D}[\mu(\frac{x}{\lambda})] = \int_{[-\lambda,\lambda]} \mu(\frac{x}{\lambda}) \, dx = \lambda \int_{[-1,1]} \mu(x) \, dx = \lambda \tilde{D}[\mu]. \tag{5.4}
\]

Therefore \( \tilde{G}[\mu(\frac{x}{\lambda})] = \lambda^2 \tilde{H}[\mu]/(\lambda \tilde{D}[\mu])^2 = \tilde{G}[\mu] \).

It follows from Lemma 5.2 that it suffices to consider \( \mu_1 \), \( \mu_{II} \) and \( \mu_{III} \) to determine minimal value of \( \tilde{G} \). We first compute this value for \( \mu_1 \) directly.

**Proposition 5.3.** For admissible \( \mu \) of Type I, we have \( \tilde{G}[\mu] = \frac{1}{2} \).

**Proof.** It suffices to consider \( \mu = \mu_1 \) by Lemma 5.2. Clearly \( \tilde{D}[\mu] = 1 \). By Remark 4.9 and (4.16),

\[
\tilde{H}[\mu] = 2 \int_{0}^{\frac{1}{2}} (\tilde{W} * \mu)(x) \, dx = -2 \int_{0}^{\frac{1}{2}} \int_{x}^{\frac{1}{2}} (\tilde{W} * \mu)'(y) \, dy \, dx \\
= -2 \int_{0}^{\frac{1}{2}} y(\tilde{W} * \mu)'(y) \, dy = 2\pi \int_{0}^{\frac{1}{2}} \sqrt{-(y^2 - \pi^2)} \, dy = \frac{1}{2}. \tag{5.5}
\]

**5.2. Large \( R \).** In this section, we consider the value \( \tilde{G}[\mu] \) for \( \mu = \mu_{II,R} \) with \( R \geq R_c \) and \( \mu_{III,L(R),R} \) with \( R \) away from 1. We first compute explicitly \( \tilde{G}[\mu_{II,R}] \) in Proposition 5.4. Then we estimate \( \tilde{G}[\mu_{III,L(R),R}] \) when \( R \) is away from 1 ( \( R_c = R > 1.1 \) ) using the monotonicity of \( \tilde{H} \) and \( \tilde{D} \) proved in Lemma 5.5.

**Proposition 5.4.** For admissible \( \mu \) of Type II, we have \( \tilde{G}[\mu] > \frac{1}{2} \).
Proof. Let $\mu = \mu_{II,R}$ for $R \geq R_c$. We have $D[\mu] = \int_{[-1,1]} \mu \, dx = 2m - 2 = \pi \sqrt{R^2 - 1} - 2$ where

$m = m(R)$ is given in (4.18).

Similar with (5.5), we compute

$$\tilde{H}[\mu] = -2 \text{p.v.} \int_0^R y(\tilde{W} * \mu)'(y) \, dy = 2 \text{p.v.} \int_0^R y^2 \sqrt{R^2 - y^2} \, dy. \quad (5.6)$$

This integral can be calculated explicitly by reducing to rational integrals. We get

$$\tilde{H}[\mu] = \frac{\pi^2}{2} (R^2 - 2), \quad \tilde{G}[\mu] = \frac{\tilde{H}[\mu]}{\tilde{D}[\mu]^2} = \frac{\pi^2 (R^2 - 2)}{(\pi \sqrt{R^2 - 1} - 2)^2}. \quad (5.7)$$

Then $\tilde{G}[\mu] > \frac{1}{2}$ is equivalent to $R > \sqrt{(\frac{1}{4} + \frac{\varepsilon^2}{4})^2 + 1} \approx 1.49$, which holds since $R \geq R_c$. \hfill $\square$

Before we study $\tilde{G}[\mu_{III}]$, we first give a lemma on the monotonicity of $\tilde{H}$ and $\tilde{D}$.

**Lemma 5.5.** For $1 < R < R_c$, both functions $\tilde{H}[\mu_{III,L(R),R}]$ and $\tilde{D}[\mu_{III,L(R),R}]$ are strictly increasing in $R$.

**Proof.** Let $\mu = \mu_{III,L(R),R}$. We first consider $\tilde{H}$. Similar with (5.5), we compute

$$\tilde{H}[\mu] = 2 \int_L^R (\tilde{W} * \mu)(y) \, dy = 2 \text{p.v.} \int_L^R (R - x)(\tilde{W} * \mu)'(x) \, dx$$

$$= 2 \text{p.v.} \int_L^R (x - R) \frac{\pi \sqrt{(x^2 - R^2)(x^2 - L^2)}}{x^2 - 1} \, dx \quad (5.8)$$

$$= 2 \text{p.v.} \int_L^R (x - 1) \frac{\pi \sqrt{(x^2 - R^2)(x^2 - L^2)}}{x^2 - 1} \, dx = 2 \pi \int_L^R \frac{\sqrt{(R^2 - x^2)(x^2 - L^2)}}{x + 1} \, dx$$

where the third equality uses (4.18), and the second last equality follows from (4.71) for $L = L(R)$. Then $\tilde{H}[\mu_{III,L(R),R}]$ is strictly increasing in $R$ since $L(R)$ is strictly decreasing in $R$.

By definition of $\tilde{D}$ and the mean-zero property of $\mu$, $\tilde{D}$ being increasing in $R$ is equivalent to $\int_{(1,\infty)} \mu_{III,L(R),R} \, dx$ being decreasing in $R$. For $i = 1, 2$ and $1 < R_i < R_c$, we denote $L_i := L(R_i)$ and $\mu_i := \mu_{III,L_i,R_i}$. Suppose the contrary, then there exists $1 < R_1 < R_2 < R_c$ such that

$$\int_{(1,\infty)} \mu_1(x) \, dx \leq \int_{(1,\infty)} \mu_2(x) \, dx. \quad (5.9)$$

We now compare the numerator of $\mu_i$ in (4.19), which is

$$(x^2 - R_1^2)(x^2 - L_1^2) = (x^2 - R_2^2)(x^2 - L_2^2) = (R_2^2 + L_2^2 - R_1^2 - L_1^2)x^2 + (R_1^2 L_1^2 - R_2^2 L_2^2). \quad (5.10)$$

By the assumption (5.9) and the fact that $\mu_1(R_2) > \mu_2(R_2) = 0$, we see that $\mu_1 - \mu_2$ must be decreasing in $x$ and negative when $x$ is large enough. Therefore there exists some $x_0 \in (R_2, \infty)$ such that

$$\mu_1(x) \geq \mu_2(x) \text{ for } 0 \leq x < 1 \text{ and } 1 < x \leq x_0, \quad \mu_1(x) \leq \mu_2(x) \text{ for } x > x_0. \quad (5.11)$$

We claim that

$$\int_{(0,\infty)} \mu_1(x) \, dx > \int_{(0,\infty)} \mu_2(x) \, dx, \quad \forall X > 0. \quad (5.12)$$

In fact, this can be seen by separating into the following cases. If $0 < X \leq 1$, we use the first inequality in (5.11); if $1 < X \leq x_0$, we firstly notice that (5.9) implies that $\int_{(0,1)} \mu_1(x) \, dx > \int_{(0,1)} \mu_2(x) \, dx$ by the mean-zero property of $\mu$, then we use the first inequality in (5.11) for $(1, X)$; if $X > x_0$, then the second inequality in (5.11) implies that $\int_{(X,\infty)} \mu_1(x) \, dx < \int_{(X,\infty)} \mu_2(x) \, dx$, then we apply the mean-zero property of $\mu$.

Now we apply Lemma 4.7 with $X = \infty$ and get

$$(\tilde{W} * \mu_1)(0) = \int_{\mathbb{R}} \tilde{W}(x) \mu_1(x) \, dx > \int_{\mathbb{R}} \tilde{W}(x) \mu_2(x) \, dx = (\tilde{W} * \mu_2)(0), \quad (5.13)$$

where $\mu_1(x)$ and $\mu_2(x)$ are defined in (5.11).
which contradicts the property $(\tilde{W} * \mu)(0) = 0$ for $\mu$ of Type III, proved in Proposition 4.11. □

Now we consider $\mu_{III, L(R), R}$ with $R_c \geq R \geq 1.1$. We take a discretization $R_0 < R_1 < \cdots < R_n = R_c$ of $R$ with $n = 19$ and denote $\mu_i := \mu_{III, L(R_i), R_i}$ and $\tilde{\mathcal{H}} := \tilde{\mathcal{H}}[\mu_i]$ and $\tilde{\mathcal{D}} := \tilde{\mathcal{D}}[\mu_i]$. We then numerically verify in Table 5.2 that

$$\frac{\tilde{\mathcal{H}}_k}{\tilde{\mathcal{D}}_{k+1}^2} > \frac{1}{2},$$

(5.14)

for $0 \leq k \leq n - 1$. \footnote{Approximation of integrals are computed in Matlab with error no more than $10^{-4}$. As a result, the error of $\frac{\tilde{H}_k}{\tilde{D}_{k+1}^2}$ is no more than $10^{-3}$ for any $k$.}

<table>

</table>

Table 1. Numerical verification of $\frac{\tilde{H}_k}{\tilde{D}_{k+1}^2}$.

It then follows from Lemma 5.5 that for any $R \in (R_k, R_{k+1}]$ and $\mu = \mu_{III, L(R), R}$

$$\frac{\tilde{\mathcal{H}}[\mu]}{\tilde{\mathcal{D}}[\mu]^2} \geq \frac{\tilde{\mathcal{H}}_k}{\tilde{\mathcal{D}}_{k+1}^2} > \frac{1}{2},$$

(5.15)

We thus prove the following.

**Proposition 5.6.** For $1.1 \leq R \leq R_c$ and $\mu = \mu_{III, L(R), R}$, we have $\tilde{\mathcal{G}}[\mu] > 1/2$.

5.3. Small $R$. In this section, we give an estimate of $\tilde{\mathcal{G}}[\mu]$ for $\mu = \mu_{III, L(R), R}$ when $R$ is close to 1. In Section 5.2 we have shown Theorem 5.1 for $R \geq 1.1$, therefore we focus on $1 < R \leq 1.1$. We start with giving a lower bound for $\tilde{\mathcal{H}}$ and an upper bound for $\tilde{\mathcal{D}}$ in terms of $R$ and $L = L(R)$. They serve as good approximations of $\tilde{\mathcal{H}}$ and $\tilde{\mathcal{D}}$ when $R$ is close to 1.

**Lemma 5.7.** For any $1 < R < R_c$ and $\mu = \mu_{III, L(R), R}$, we have

$$\tilde{\mathcal{H}}[\mu] \geq \frac{\pi^2}{2(R+1)R} \cdot \frac{(R^2 - L^2)}{2}^2, \quad \tilde{\mathcal{D}}[\mu] \leq \pi(1 - L) \left(1 + \frac{2}{\pi(1 - L)}\right).$$

(5.16)

**Proof.** The lower bound for $\tilde{\mathcal{H}}$ follows from estimating the integral in (5.8). By a change of variable $x = \sqrt{y}$, we have

$$\tilde{\mathcal{H}}[\mu] = \pi \int_{L^2}^{R^2} \sqrt{(R^2 - y)(y - L^2)} \, dy \geq \pi \int_{L^2}^{R^2} \sqrt{(R^2 - y)(y - L^2)} \, dy \geq \frac{\pi^2}{2(R+1)R} \cdot \frac{(R^2 - L^2)}{2}^2.$$  

(5.17)
For the upper bound of \( \tilde{D} \), we estimate

\[
\tilde{D}[\mu] = \int_{[-1,1]} \mu(x) \, dx = 2m - 2 + 2 \int_0^L \frac{\sqrt{(R^2 - x^2)(L^2 - x^2)}}{1 - x^2} \, dx, \tag{5.18}
\]

where \( m = n(L, R) = \pi \sqrt{(R^2 - 1)(1 - L^2)/2} \) in \( \square \). Noticing that

\[
\left( \frac{\sqrt{(R^2 - x^2)(L^2 - x^2)}}{1 - x^2} \right)^2 = \frac{(R + x)(L + x)}{(1 + x)^2} \cdot \frac{R - x}{2 - L - x} < 1, \tag{5.19}
\]

since \( L + R < 2 \) and \( LR < 1 \) by Lemma 4.10, we get

\[
\tilde{D}[\mu] < 2m - 2 + 2 \int_0^L \frac{\sqrt{(L - x)(2 - L - x)}}{1 - x} \, dx. \tag{5.20}
\]

The last integral in \( \square \) can be related to the total mass of Type I. In fact, by a change of variable \( y = \frac{1-x}{\pi(1-L)} \),

\[
\int_0^L \frac{\sqrt{(L - x)(2 - L - x)}}{1 - x} \, dx = \pi(1 - L) \int_{1/\pi}^{1/(\pi(1-L))} \sqrt{y^2 - \pi^{-2}} \, dy \tag{5.21}
\]

By the even and mean-zero property of \( \mu_1 \), we have

\[
\int_{1/\pi}^{\infty} \left( \sqrt{y^2 - \pi^{-2}} - 1 \right) \, dy = -\frac{1}{2} + \frac{1}{\pi}. \tag{5.22}
\]

Therefore the integral in \( \square \) equals

\[
\pi(1 - L) \left( \frac{1}{\pi(1-L)} - \frac{1}{\pi} \cdot \frac{1}{2} + \frac{1}{\pi} - \int_{1/(\pi(1-L))}^{\infty} \left( \sqrt{y^2 - \pi^{-2}} - 1 \right) \, dy \right) = 1 - \frac{\pi(1 - L)}{2} + \frac{1}{\pi} \left( -\frac{1}{2} + \frac{1}{\pi} \right) \left( 1 - L \right) \int_{1/(\pi(1-L))}^{\infty} \frac{1}{y^2} \, dy < 1 - \frac{\pi(1 - L)}{2} + (1 - L)^2. \tag{5.23}
\]

Combining \( \square \) and \( \square \), we get

\[
\tilde{D}[\mu] < 2m - 2 + 2(1 - \frac{\pi(1 - L)}{2} + (1 - L)^2)
\]

\[
= \pi(1 - L) \left( 1 - \frac{\pi(1 - L)}{2} + (1 - L)^2 \right)
\]

\[
< (1 - L) \left( \frac{(R + 1)(R - 1)(1 + L)}{1 - L} - 1 + \frac{2}{\pi} (1 - L) \right) \tag{5.24}
\]

where the last inequality holds since \( R - 1 < 1 - L \) and thus \((R+1)(1+L) < (R+1)(3-R) < 4 \). \( \square \)

**Proposition 5.8.** For \( 1 < R \leq 1.1 \) and \( \mu = \mu_{11, L(R), R} \), we have \( \tilde{G}[\mu] > 1/2 \).

**Proof.** Using Lemma 5.7 and \( R^2 + L^2 > 2 \) and \( R + L < 2 \) from Lemma 4.10, we obtain that

\[
\frac{\tilde{H}[\mu]}{\tilde{D}[\mu]^2} \geq \frac{1}{2(R + 1)R} \cdot \frac{(1 + \frac{2}{\pi} (1 - L))}{(1 + \frac{2}{\pi}(1 - L)^2)} \geq \frac{1}{2(R + 1)R} \cdot \frac{(1 + \frac{2}{\pi} (1 - L))}{(1 + \frac{2}{\pi}(1 - L)^2)} \tag{5.25}
\]

We notice that the last expression is equal to 1 when \( L = 1 \), therefore it is larger than 1/2 when \( L \) is close to 1, equivalently when \( R \) is close to 1. In fact, this can be quantified by observing that the last expression is increasing in \( L \). When \( L = 0.85 \), it is approximately 0.58, therefore it
must be greater than 1/2 for any 0.85 ≤ L < 1. Since \( R \geq \sqrt{2-L^2} \), we have verified \( \tilde{G}[\mu] > 1/2 \) for any \( 1 < R \leq \sqrt{2-0.85^2} \), and in particular, it is true for \( 1 < R \leq 1.1 \).

\[ \square \]

\section{6. From \( \mathbb{R} \) to \( \mathbb{T} \)}

In this section, we will compare the values of \( \tilde{G}[\mu] \) with \( G[\rho] \), where \( \mu \) is admissible over \( \mathbb{R} \) and \( \rho \) (without its Dirac masses) is sediment over \( \mathbb{T} \). We have constructed these two family of distributions in Section 4.4 and 4.3 respectively. In Section 5 we have determined \( \tilde{G}[\mu] \geq 1/2 \) for all admissible \( \mu \). In order to establish a comparison, we first introduce a way to associate a signed measure \( \rho_\circ \in \mathcal{M} \) with each admissible distribution \( \mu \) over \( \mathbb{R} \), via periodization, in Section 6.1. We then relate the quantities \( \tilde{\mu} \) distributions in Section 4.4 and 4.3 respectively. In Section 5, we have determined \( \tilde{\mu} \) for any \( 1 \leq \lambda \leq \frac{1}{2} \) for \( \mu \) of type II or III. Finally, we prove a comparison principle using the convexity of logarithmic potential, showing that for each minimizer \( \rho \in \mathcal{M} \) of \( G \) in \( \mathcal{M}_{\mathbb{T} \geq d} \) there exists a unique admissible \( \mu \) such that \( \tilde{G}[\mu] \geq G[\rho] \).

\subsection{6.1. Periodization}

In this section, we will relate the admissible distributions over \( \mathbb{R} \) to distributions over \( \mathbb{T} \) via a periodization. For each signed measure \( \mu \) with \( \int_{\mathbb{R}} |\mu(x)| \, dx < \infty \) over \( \mathbb{R} \), we define its \textit{periodization}

\[ \mu_\tau(x) := \sum_{j \in \mathbb{Z}} \mu(x-j), \quad x \in \mathbb{T}. \]  

(6.1)

This definition does not depend on the choice of representatives for \( x \in \mathbb{T} \). Now for each admissible \( \mu \), we associate a signed measure over \( \mathbb{T} \)

\[ \rho_\circ[\mu](x) := 1 + \mu_\tau(x), \quad x \in \mathbb{T}. \]  

(6.2)

If \( \mu \) is in (4.16), (4.17) and (4.19) up to a scaling factor \( \lambda \), then \( \mu = -1 + \mu_c + \mu_d \) using the notation in Lemma 4.1, we can break down \( \rho_\circ[\mu] = \rho_\circ_c[\mu] + \rho_\circ_d[\mu] \) where

\[ \rho_\circ_c[\mu](x) := 1 + (-1 + \mu_c) \tau(x), \quad \rho_\circ_d[\mu](x) := (\mu_d) \tau(x). \]  

(6.3)

For simplicity, we will drop the associated \( \mu \) in these notations when there is no confusion.

We now characterize properties of \( \rho_\circ_c \) and \( \rho_\circ_d \) for \( \mu \).

\textbf{Proposition 6.1.} Given \( \mu \) an admissible distribution over \( \mathbb{R} \) and \( \rho_\circ = \rho_\circ[\mu] \). Let \( m = m(\mathbb{R}, \mathcal{L}(\mathbb{R})) \) be given by (4.20) for \( \mu \) of Type II and III and \( \lambda \) the scaling factor of \( \mu \). Assume \( \lambda \leq 1 \) for \( \mu \) of type I and \( \lambda \leq \frac{1}{2} \), \( \lambda m < \frac{1}{2} \) for \( \mu \) of type II or III. Then \( \rho_\circ \) is even with \( \int_\mathbb{T} \rho_\circ \, dx = 1 \), and

(i) \( \rho_\circ_d \) is \( \lambda \delta \) for \( \mu \) of Type I and is \( \lambda m(\delta_\lambda + \delta_{-\lambda}) \) for \( \mu \) of Type II or III.

(ii) \( \rho_\circ_c \) is Hölder continuous with Hölder exponent \( 1/2 \).

(iii) \( \rho_\circ_c \) is \( C^2 \) and \( \rho_\circ_c'' < 0 \) on \( \mathbb{T} \backslash B \), where \( B = \{ \lambda \pi^{-1} \} \) for \( \mu \) of Type I and \( B = \{ \pm \lambda L, \pm \lambda R \} \) for \( \mu \) of Type II and III.

If \( \mu \) is of Type II or III then

(iv) \( \{ x \in (-\lambda, \lambda) : \rho_\circ(x) \geq 0 \} \) is either \( \emptyset \) or \( [-L_0, L_0] \) for some \( L_0 \in [0, \lambda L] \).

(v) \( \{ x \in (\lambda, 1-\lambda) : \rho_\circ(x) \geq 0 \} \) is either \( \emptyset \), or \( [R_0, 1-R_0] \) for some \( R_0 \in (\lambda R, 1/2] \).

\textbf{Proof.} Since \( \mu \) is even and mean zero over \( \mathbb{R} \), it is clear that \( \rho_\circ \) is even and has \( \int_\mathbb{T} \rho_\circ[\mu](x) \, dx = 1 \). It follows from the expression of \( \mu_d \) and that \( \rho_\circ_d \) has the stated form. Combining the expression of \( \mu_c \) and the fact that \( |\mu'_c(x)| \lesssim |x|^{-3} \) for large \( |x| \), one can see that \( \rho_\circ_c \) is Hölder continuous with exponent \( 1/2 \). For \( x \notin B \) (when considered as a subset of \( \mathbb{R} \)), it is clear that \( -1 + \mu_c(x) \) is \( C^2 \) and \( |\mu''_c(x)| \lesssim |x|^{-4} \) for large \( |x| \) and \( \rho''_c(x) < 0 \), therefore we \( \rho_\circ_c \) is \( C^2 \) and

\[ \rho_\circ_c''(x-j) < 0, \quad x \in \mathbb{T} \backslash B. \]  

(6.4)
For \( \mu \) of Type II and III, in \((-\lambda, \lambda)\) and \((\lambda, 1 - \lambda)\) by the previous discussion, we have \( \rho_0 = \rho_{0,c} \). By Proposition 4.11, \( \sum_{j \in \mathbb{Z}, j \neq 0} \mu(x - j) < 0 \), therefore
\[
\operatorname{supp}(\rho_{0,c})_+ \subseteq \operatorname{supp}(1 + \mu(x) \cdot \chi_{[-1/2,1/2]})_+.
\] (6.5)
We separate the discussion depending on the size of \( \lambda R \). If \( \lambda R \leq 1/2 \), then
\[
\operatorname{supp}(1 + \mu(x) \chi_{[-1/2,1/2]})_+ = [-\lambda L, \lambda L] \cup [\lambda R, 1 - \lambda R],
\] (6.6)
where \([-\lambda L, \lambda L]\) is replaced with \( \emptyset \) if \( L = 0 \). Then it follows from \( \rho''_{0,c} < 0 \) that \( \operatorname{supp}(\rho_{0,c})_+ \) consists at most two possibly empty symmetric intervals, therefore must be \([-L_0, L_0]\) with \( L_0 \in [0, \lambda L) \) and \([R_0, 1 - R_0]\) with \( R_0 \in (\lambda R, 1/2] \). If \( \lambda R > 1/2 \), then
\[
\operatorname{supp}(1 + \mu(x) \chi_{[-1/2,1/2]})_+ = [-\lambda L, \lambda L],
\] (6.7)
and it is replaced with \( \emptyset \) if \( L = 0 \). Notice that \( R + L < 2 \) by Lemma 4.10 therefore \( |\lambda R - (-\lambda L)| < 1 \) when \( \lambda < 1/2 \), thus \( \lambda R \) as a point in \( \mathbb{T} \) does not lie in \([-\lambda L, \lambda L]\). Therefore we again have \( \rho''_{0,c} < 0 \) on \([-\lambda L, \lambda L]\), and the statement follows. \( \square \)

Next we establish the key connection between the functionals \( \tilde{H} \) and \( D \) over \( \mathbb{R} \) and the functionals \( H \) and \( D \) over \( \mathbb{T} \). Note that \( \rho_0 \) is not necessarily a measure but only a signed measure over \( \mathbb{T} \). Therefore we extend the functionals \( H \) by defining
\[
H[\rho] = -\inf_{x \in \mathbb{T}} (W \ast \rho),
\] (6.8)
for arbitrary signed measures \( \rho \) over \( \mathbb{T} \).

**Proposition 6.2.** Given \( \mu \) an admissible distribution over \( \mathbb{R} \) and \( \rho_0 = \rho_0[\mu] \). Let \( m = m(R, L(R)) \) be given by (4.20) for \( \mu \) of Type II and III and \( \lambda \) the scaling factor of \( \mu \). Assume \( \lambda \leq 1 \) for \( \mu \) of type I and \( \lambda \leq 1/2 \), \( \lambda m < \frac{1}{2} \) for \( \mu \) of type II or III. Then we have
\[
\tilde{H}[\mu] = -\inf_{x \in \mathbb{T}} (W \ast \rho_0) = H[\rho_0].
\] (6.9)
Moreover, \((W \ast \rho_0)(x) = H[\rho_0]\) for \( x \in \operatorname{supp}(\rho_{0,c})_+ \). On the other hand,
\[
\tilde{D}[\mu] > \int_{[-\lambda, \lambda]} ((\rho_0)_+ - 1) \, dx.
\] (6.10)

**Proof.** Firstly we observe
\[
\int_{[-\lambda, \lambda]} ((\rho_0)_+ - 1) \, dx < \int_{[-\lambda, \lambda]} (\max\{1 + \mu(x), 0\} - 1) \, dx = \int_{[-\lambda, \lambda]} \mu \, dx = \tilde{D}[\mu].
\] (6.11)
We then focus on the functional \( H \). By definition of \( \rho_{0,c} \), we obtain
\[
\hat{\rho}_0(k) = \begin{cases} 1, & k = 0 \\ F[\mu](k), & k \in \mathbb{Z}, k \neq 0 \end{cases}
\] (6.12)
using the mean-zero property \( \hat{\mu}(0) = 0 \). Here \( \hat{\rho}_0 \) is the Fourier coefficients over \( \mathbb{T} \) and \( F[\mu] \) is the Fourier transform over \( \mathbb{R} \). Notice that
\[
F[\hat{W}](\xi) = \frac{1}{|\xi|}, \xi \neq 0, \quad \hat{W}(k) = \frac{1}{|k|}, k \neq 0,
\] (6.13)
and \( \hat{W}(0) = 0 \), therefore
\[
F[\hat{W} \ast \mu](\xi) = \frac{F[\mu](\xi)}{|\xi|} \quad \text{for} \ \xi \neq 0, \quad F[\hat{W} \ast \mu](0) = \int_{\mathbb{R}} (\hat{W} \ast \mu) \, dx = \tilde{H}[\mu].
\] (6.14)
We denote \( \Lambda(x) := \sum_{j \in \mathbb{Z}} \delta(x - j) \) for \( x \in \mathbb{R} \). By Poisson summation formula, we have \( F[\Lambda](\xi) = \Lambda(\xi) \). Therefore
\[
F[\hat{W} \ast \mu \ast \Lambda](\xi) = F[\hat{W} \ast \mu] \cdot \Lambda(\xi) = \sum_{0 \neq j \in \mathbb{Z}} \frac{F[\mu](j)}{|j|} \delta(\xi - j) + \tilde{H}[\mu] \delta(\xi).
\] (6.15)
Now we compare with $W * \rho_o$ where
\[ W * \rho_o(k) = \frac{\hat{\mu}(k)}{|k|} \quad \text{for} \ k \neq 0, \quad W * \rho_o(0) = 0, \] (6.16)
we obtain by taking Fourier inversion
\[ (W * \rho_o)(x) + \tilde{\mathcal{H}}[\mu] = (W * \mu * \Lambda)(x) = (\tilde{W} * \mu) \mathcal{Z}(x). \] (6.17)

Recall in Proposition 4.11 that $\mu - \mu_d < 0$ and $\tilde{W} * \mu > 0$. Therefore in order to prove (6.9), it suffices to show that $\text{supp}(W * \mu) \mathcal{Z} \not= \emptyset$. By Remark 4.9 $\tilde{W} * \mu$ obtains its minimal value 0 in $\text{supp} \mu_c$, and therefore $\text{supp}(\tilde{W} * \mu) \subset \{x : \mu = -1\}$. It follows from the assumption on $\lambda$ that in all cases \( \int \mu \mu_d < 1 \). By the mean zero property of $\mu$, we see that $|\text{supp}(\tilde{W} * \mu)| < \int \mu \mu_d < 1$. Therefore we show (6.9).

If $\lambda \mu < 1/2$, then $(\tilde{W} * \mu) \mathcal{Z}$ is supported on $\lambda L < |x| < \lambda \mu$, therefore $W * \rho_o$ obtains its minimum exactly on $[-\lambda L, \lambda \mu] \cup [\lambda \mu, 1 - \lambda \mu]$ which contains $\text{supp}(\rho_{o,c})_+$. If $\lambda \mu \geq 1/2$, then similarly with Proposition 6.1 we know that $\lambda \mu$ does not lie in $[-\lambda L, \lambda \mu]$. Therefore $(\tilde{W} * \mu) \mathcal{Z}$ is zero on $[-\lambda L, \lambda \mu]$ which contains $\text{supp}(\rho_{o,c})_+$. Therefore we show that $W * \rho_o$ obtains minimal value $\mathcal{H}[^{\rho_o}]$ on $\text{supp}(\rho_{o,c})_+$.

\[ \square \]

### 6.2. A Comparison Principle via Convexity

In this section, our main goal is to establish the following comparison principle between energy minimizers associated with different external potentials. The proof of this principle essentially takes advantage of the convexity of log potential.

**Proposition 6.3.** Given $0 < M < \frac{1}{2}$, $m > 0$, and two external potentials over $\mathcal{T}$
\[ U_o = W * m(\delta_M + \delta_{-M}), \quad U_2 = U_o + U_* \] (6.18)
where $U_*$ is $C^1(\mathbb{T})$ is even. Let $m_1, m_2 \geq 0$, and $\rho_o$ and $\rho_2$ be the energy minimizer for $U_o$ and $U_2$ in $\mathcal{M}_{m_1, m_2}$ (c.f. (3.46)) respectively. If
\[ U'_o(x) < 0, \quad \forall x \in (0, \frac{1}{2}) \cap \text{supp} \rho_o, \] (6.19)
and $\rho_o$ and $\rho_2$ are Hölder continuous functions, then
\[ (W * \rho_o)(0) > (W * \rho_2)(0), \quad (W * \rho_o)(\frac{1}{2}) < (W * \rho_2)(\frac{1}{2}). \] (6.20)

We first give some preparations.

**Lemma 6.4.** Let $u$ be Hölder continuous on $\mathcal{T}$ with exponent $\beta$. Then its Hilbert transform $H[u]$ is defined everywhere over $\mathcal{T}$ and is Hölder continuous with exponent $\beta_1$ for any $0 < \beta_1 < \beta$.

**Proof.** Recall that the kernel for Hilbert transform over $\mathcal{T}$ is exactly $W'$, and it is an odd function. Therefore
\[ H[u](x) = \text{p.v.} \int_\mathcal{T} W'(y)u(x - y) \, dy = \int_\mathcal{T} W'(y)(u(x - y) - u(x)) \, dy. \] (6.21)
Here the last integrand is integrable because $|W'(y)| \lesssim |y|^{-1}$ near $y = 0$ and $|u(x - y) - u(x)| \lesssim C|y|^{\beta}$. Therefore $H[u](x)$ is defined everywhere.

To show the Hölder continuity, we take $x_1 < x_2$ and denote $\epsilon = x_2 - x_1 > 0$. Then $|H[u](x_2) - H[u](x_1)|$ is bounded since
\[ \int_{|y| < \epsilon} \left( |W'(y)(u(x_2 - y) - u(x_2))| + |W'(y)(u(x_1 - y) - u(x_1))| \right) \, dy \leq C \epsilon^{\beta}, \] (6.22)
\[ \int_{|y| > \epsilon} W'(y)(|u(x_2 - y) - u(x_2)| + |u(x_1 - y) - u(x_1)|) \, dy \leq C \epsilon^{\beta} \int_{|y| > \epsilon} |W'(y)| \, dy \leq C \epsilon^{\beta_1} \] (6.23)
for any $\beta_1 < \beta$. This finishes the proof. \[ \square \]
Let $m_0 > 0$, and $\rho \in M_{m_0}$ be even. Define its cumulative function as
\[
m[\rho](x) = \int_{[0,x]} \rho(y) \, dy, \quad x \in [0, \frac{1}{2}].
\] (6.24)

It is clear that $m[\rho](0) = 0$ and $m[\rho]\left(\frac{1}{2}\right) = \frac{m_0}{2}$. When $\rho$ is Hölder continuous, we also define the inverse function $X[\rho](m)$ for $m \in [0, m_0/2]$ so that $m[X[\rho](m)] = m$. It is clear that $X[\rho]$ is strictly increasing and piece-wise continuous. We will write $m(x)$ and $X(m)$ in short when there is no confusion.

**Lemma 6.5.** Let $m_0 > 0$ and $\rho \in M_{m_0}$ be even and Hölder continuous. Let $m(x)$ be the cumulative function for $\rho$ and $X(m)$ be its inverse function. Then we have the change-of-variable formula
\[
(W \ast \rho)(x) = \int_0^{m_0/2} (W(x - X(m)) + W(x + X(m))) \, dm
\] (6.25)
and
\[
(W' \ast \rho)(x) = \text{p.v.} \int_0^{m_0/2} (W'(x - X(m)) + W'(x + X(m))) \, dm
\] (6.26)
for $x \in [0, 1/2]$.

**Proof.** Since $\rho$ is Hölder continuous, both $W' \ast \rho$ and $W \ast \rho$ are well-defined everywhere by Lemma 6.4 and $X(m)$ is guaranteed to be strictly increasing and piece-wise continuous. By symmetry of $\rho$ and a substitution $y = X(m)$, we get
\[
(W \ast \rho)(x) = \int_0^{1/2} (W(x - y) + W(x + y)) \rho(y) \, dy
\] (6.27)
\[
= \int_0^{m_0/2} (W(x - X(m)) + W(x + X(m))) \, dm.
\]
We can consider $W' \ast \rho$ similarly, and it suffices to prove
\[
\text{p.v.} \int_0^{1/2} W'(x - y) \rho(y) \, dy = \text{p.v.} \int_0^{m_0/2} W'(x - X(m)) \, dm.
\] (6.28)
Without loss of generality, we can assume $x \in \text{supp} \rho$ and $\rho(x) > 0$, since otherwise p.v. can be removed. Denote $M_0 = m(x)$. Then by previous analysis, we obtain that
\[
\int_{[0,m_0/2]\setminus(M_0 - \epsilon, M_0 + \epsilon)} W'(x - X(m)) \, dm = \int_{[0,\rho(M_0 - \epsilon)]\cup[\rho(M_0 + \epsilon), 1/2]} W'(x - y) \rho(y) \, dy,
\] (6.29)
therefore it suffices to show that
\[
\int_{[x+(x-X(M_0-\epsilon)), X(M_0+\epsilon)]} W'(x - y) \rho(y) \, dy \rightarrow 0, \text{ as } \epsilon \rightarrow 0.
\] (6.30)
By the Hölder continuity of $\rho$, we get $\rho(x \pm \epsilon) = \rho(x) + O(\epsilon^\alpha)$. Therefore when $\epsilon$ is small enough, $|X(M_0 \pm \epsilon) - X(M_0)| \lesssim \epsilon$. The above limit then easily follows. \qed

Now we are ready to give the following comparison principle, which is the key to proving Proposition 6.3. We will compare two measures $\rho_0$ and $\rho_1$. For the notation, we will write $m_0$ for $m[\rho_0]$ and $X_0$ for $X[\rho_0]$. Similarly for $\rho_1$.

**Lemma 6.6.** Let $\rho_0$ and $\rho_1$ be in $M_{m_0}$ that are Hölder continuous and even. If
\[
m_0(x_0) < m_1(x_0)
\] (6.31)
for some $x_0 \in (0, 1/2)$, then there exists $0 < x_2 < x_\delta \leq 1/2$ and $x_0 \in \text{supp} \rho_0$ and $x_2 \in \text{supp} \rho_1$ such that
\[
m_0(x_0) = m_0(x_2), \quad (W' \ast \rho_0)(x_0) \geq (W' \ast \rho_1)(x_2).
\] (6.32)
Proof. For convenience, we will define $X_1(m)$ to be the smallest $x \in [0, 1/2]$ such that $m_1(x) = m$, and $X_2(m)$ to be the largest $x \in [0, 1/2]$ such that $m_0(x) = m$. Then $X_2$ is lower-semicontinuous and $X_1$ is upper-semicontinuous. By the assumption (6.31), we see that

$$\sup_{m \in [0, m_0/2]} (X_1(m) - X_2(m)) > 0.$$ (6.33)

This supremum can be achieved, say at $m_{**} \in [0, m_0/2]$, since $X_1 - X_2$ is upper-semicontinuous, and it is also the maximum of the difference. We then denote $x_1 = X_1(m_{**})$ and $x_2 = X_2(m_{**})$. They clearly satisfy $x_1 \in supp \rho_2$ and $x_2 \in supp \rho_1$, and $x_1 < x_2$, and $m_0(x_2) = m_0(x_2) = m_{**}(x_2)$. So it suffices to prove $(W' * \rho_2)(x_1) - (W' * \rho_1)(x_1) \geq 0$.

By Lemma 6.6, we can write $(W' * \rho_2)(x_1) - (W' * \rho_1)(x_1)$ as

$$p.v. \int_0^{m_0/2} (W'(x_1 - X_1(m)) + W'(x_1 + X_2(m))) - (W'(x_1 - X_1(m)) + W'(x_1 + X_2(m))) \, dm, \quad (6.34)$$

where the integrand is

$$\int_{x_1 - X_1(m)}^{x_1 + X_2(m)} W''(z) \, dz + \int_{x_1 + X_2(m)}^{x_1 + X_1(m)} W''(z) \, dz, \quad (6.35)$$

for any $m \neq m_{**}$.

It follows from the definition of $m_{**}$ that $x_1 - X_1(m) \leq x_2 - X_2(m)$. And one can check that in both integrals the domain does not contain $z = 0$. Therefore if $x_2 + X_1(m) \leq x_2 + X_2(m)$ then the conclusion follows from the positivity of $W''$. Suppose not, we must have $X_1(m) - X_2(m) < -(x_2 - x_1) < 0$, then we have

$$m_{**} = \left( \int_{x_1 - X_1(m)}^{x_1 - X_1(m)} + \int_{x_1 - X_1(m)}^{x_2 + X_1(m)} + \int_{x_1 + X_2(m)}^{x_1 + X_1(m)} + \int_{x_1 + X_2(m)}^{x_2 + X_1(m)} \right) W''(z) \, dz. \quad (6.36)$$

We can again show that $z = 0$ is not in the domain of any of these integrals: trivially true when $m < m_{**}$ and use $X_2(m) < X_1(m)$ for $m > m_{**}$. Now it is clear that the first and third integral are positive, and the second and fourth integral can combine as

$$\int_{x_1 - X_1(m)}^{x_2 + X_1(m)} W''(z) \, dz + \int_{x_1 + X_2(m)}^{x_1 + X_1(m)} W''(z) \, dz = \int_{X_1(m)}^{x_1 + X_2(m)} (W''(x_2 - z) - W''(x_2 + z)) \, dz. \quad (6.37)$$

In the last integral, we have $z$ and $x_3$ both in $[0, 1/2]$. Then it follows from the fact that $W''(x) = \pi/\sin^2 \pi x$ is even and decreasing in $(0, 1/2]$ that the integrand is always positive. We thus finish proving $(W' * \rho_2)(x_1) \geq (W' * \rho_1)(x_1)$. \hfill \Box

Now we are ready to prove the main proposition in this section.

Proof of Proposition 6.3. Recall the notation that for external potential $U_3$, we obtain $\rho_3 \in \mathcal{M}_{m_{**}}$ as the energy minimizer as proved in Proposition 3.8, and the generated potential is $V_3' := U_3 + W * \rho_3$. By Proposition 3.8, we have $V_3'(x) = 0$ on supp($\rho_3$). We denote the cumulative function $m_0$ for $\rho_3$. It follows from the assumption that $m_0(M) = m_1/2$. Similarly everything holds also for $U_3'$.

We claim that

$$m_0(x) \geq m_2(x), \quad 0 \leq x \leq 1/2.$$ (6.38)

Suppose not, then we apply Lemma 6.6 to get $x_1$ and $x_2$ satisfying (6.32). Since $V_3' = W' * \rho_3 + U_3' = 0$ on supp($\rho_3$) and similarly for $\rho_1$, (6.32) then implies

$$U_3'(x_2) \geq U_3'(x_1). \quad (6.39)$$

On the other hand,

$$U_3'(x_2) - U_3'(x_2) = (U_3'(x_2) - U_3'(x_2)) + (U_3'(x_1) - U_3'(x_2)) = \int_{x_1}^{x_2} U_3''(x) \, dx - U_3'(x_2) > 0. \quad (6.40)$$
Here the first term is positive since $U'' > 0$ by the expression of $U_0$ and $M \notin [x_1, x_3]$ since $m_0(M) = m_0(M) = m_1/2$. The second term is positive since $-U'(x_1) > 0$ by the assumption. Therefore we get a contradiction and prove the claim (6.38).

Finally, applying Lemma 4.7 with $X = \frac{1}{2}$, we get $(W * \rho_2)(0) > (W * \rho_2)(0)$, and the other conclusion $(W * \rho_2)(\frac{1}{2}) < (W * \rho_2)(\frac{1}{2})$ can be obtained similarly. □

6.3. Comparison between Minimizers. In this section, our main goal is to compare the value of $G$ for $\rho \in M$ over $\mathbb{T}$ with the value of $\tilde{G}$ for admissible distributions over $R$, so that we prove our main result $G \geq 1/2$ in Theorem 1.1.

Recall that in Theorem 5.1 and Proposition 3.8, we have shown that the unique minimizer of $G$ for $\rho \in M_{D>2}$ must be the energy minimizer of $E$ (together with the Dirac masses $m(\delta_M + \delta_{-M})$) where the external potential is in the form of $U = W * m(\delta_M + \delta_{-M})$ form some $m \in (0, 1/2]$ and $M \in [0, 1/2]$. We will compare $\rho$ with $\rho_0$ constructed via periodization. By description of $\rho_{o,d}$ in Proposition 6.1, we can find a unique $\rho_0$ with $\rho_{o,d} = m(\delta_M + \delta_{-M})$: if $M = 0$, then we have $\mu$ of Type I and $\lambda = 2m$; if $M \neq 0$, then we have $\mu$ of Type II or III with $\lambda = M$, and $R$ is uniquely determined by $m(R, L(R)) = m/\lambda$, since $m(R, L(R)) = D$ is increasing in $R$ as $L(R)$ is decreasing in $R$ by Proposition 4.11. Our main theorem for this section is the following comparison theorem. It follows directly from the following theorem, together with Theorem 5.1, that $G[\rho] \geq 1/2$ for $\rho \in M$.

**Theorem 6.7.** Let $0 < d < 1$. Let $\rho = m(\delta_M + \delta_{-M}) + \rho_1$ be an even minimizer of $G$ in $M_{D>2}$ given in Theorem 5.1. Let $\mu$ be the unique admissible distribution with the associated $\rho_{o,d} = m(\delta_M + \delta_{-M})$. Assume $M > 0$, then we have $\lambda = M$ and

$$H[\rho] \geq \tilde{H}[\rho], \quad D[\rho] \leq \tilde{D}[\mu]. \quad (6.41)$$

**Proof.** It is clear that $\lambda = M$ as explained above. It suffices to prove the inequality in (6.41).

Let $\rho_0$ be associated with $\mu$ as in (6.42).

We firstly study $H$. By Proposition 6.2, we have $H[\rho_0] = \tilde{H}[\rho]$, therefore it suffices to compare $H[\rho_0]$ and $H[\rho]$. By Proposition 6.1, we can write

$$\rho_o = m(\delta_M + \delta_{-M}) + \rho_{o,J} + \rho_{o,K} + \rho_{o,-} \quad (6.42)$$

where $\rho_{o,J}$ and $\rho_{o,K}$ are nonnegative (possibly identically zero) and supported on $J_o = [R_o, 1 - R_o]$ and $K_o = [-L_o, L_o]$ respectively, and $\rho_{o,-}$ is nonpositive, supported on $(J_o \cup K_o)^c$. It follows from Proposition 3.8 and Proposition 6.2 that $\rho_{o,J} + \rho_{o,K}$ is the unique minimizer of $E_U$ in $M_{m_0}$ where

$$m_0 = 1 - 2m - \int \rho_{o,-}(x) \, dx, \quad U = W * (m(\delta_M + \delta_{-M}) + \rho_{o,-}), \quad (6.43)$$

since $V_U[\rho_{o,J} + \rho_{o,K}] = U + W * (\rho_{o,J} + \rho_{o,K}) = W * \rho_o$ takes minimal value on $\text{supp}(\rho_{o,J} + \rho_{o,K}) = \text{supp}(\rho_{o,c})$. It then follows from Proposition 3.8 that $\rho_{o,J} + \rho_{o,K}$ is also the unique maximizer of ess inf $V_U$, therefore

$$-H[\rho] = \text{ess inf} (W * \rho) = \text{ess inf} V_U[\rho_1 - \rho_{o,-}] \leq \text{ess inf} (W * \rho_o) = -H[\rho_o] = -\tilde{H}[\mu]. \quad (6.44)$$

Next we study $D$. By Proposition 6.2, it suffices to prove

$$D[\rho] \leq \int_{[-M,M]} ((\rho_o)_+ - 1) \, dx. \quad (6.45)$$

If $\int_{[-x]} ((\rho_o)_+ - 1) \, dx \leq 0$, then

$$\int_{[-M,M]} ((\rho_o)_+ - 1) \, dx \geq \int_T (\rho - 1) \, dx + (1 - 2M)$$

$$= 1 - 2M = \int_T \rho \, dx - \int_{[-M,M]} 1 \, dx \geq \int_{[-M,M]} (\rho - 1) \geq D[\rho]. \quad (6.46)$$
Here the second inequality we use the above assumption \( \int_{\mathbb{T}} (\rho_{\circ, J} + \rho_{\circ, -}) \, dx \leq 0 \). Therefore we assume \( \int_{\mathbb{T}} (\rho_{\circ, J} + \rho_{\circ, -}) \, dx > 0 \) for the rest of the proof. This in particular implies that \( J \neq \emptyset \) and \( MR < 1/2 \) by Proposition \([6.4]\). Let \( x_J \in J_{\circ} \) be the unique number in \((0, 1/2)\) such that
\[
\int_{R_0 \leq |x| \leq x_J} \rho_{\circ, J} \, dx + \int_{\mathbb{T}} \rho_{\circ, -} \, dx = 0. \tag{6.47}
\]

We will formulate energy minimization problems for \( \rho_{\circ} \), by specifying external potentials \( U_1 \) and \( U_5 \) and their corresponding minimizer \( \rho_{\circ} \) and \( \rho_{\circ} \). For small \( \epsilon > 0 \) and \( r \geq 0 \), define a cutoff function
\[
\phi_{r, \epsilon}(x) = \max \left(0, 1 - \frac{1}{\epsilon} \right \text{dist} \left(x, \{y \in [-1/2, 1/2] : |y| > x_J + r\}\right),
\]
where \( \text{dist} \) denotes the distance function on \( \mathbb{T} \). Combined with \([6.47]\), for each \( \epsilon \), there exists a unique \( r = r(\epsilon) \in (0, \epsilon) \) such that
\[
\int_{\mathbb{T}} \rho_{\circ, J} (\chi_{J_\epsilon} - \phi_{r, \epsilon}) \, dx + \int_{\mathbb{T}} \rho_{\circ, -} \, dx = 0. \tag{6.49}
\]
We thus write \( \phi_{\epsilon} \) in short for \( \phi_{r(\epsilon), \epsilon} \). Then we define
\[
U_2 = W \ast \left( m(\delta_M + \delta_{-M}) + \rho_{\circ, J} \cdot (\chi_{J_\epsilon} - \phi_{\epsilon}) + \rho_{\circ, -}\right), \tag{6.50}
\]
and
\[
\rho_{\ast} = \rho_{\circ, J} \phi_{\epsilon} + \rho_{\circ, -}. \tag{6.51}
\]
By definition, \( \rho_{\ast} \in \mathcal{M}_{1-2m} \) and is the unique minimizer of \( \mathcal{E}_{U_1} \) since \( V_{U_1}[\rho_{\ast}] = W \ast \rho_{\ast} \) obtains minimal value on \( \text{supp} \rho_{\ast} \). Meanwhile it is also the unique minimizer in \( \mathcal{M}_{m_1, m_2} \) where
\[
m_1 = \int_{K_{\circ}} \rho_{\circ} \, dx, \quad m_2 = 1 - 2m - m_1. \tag{6.52}
\]
Next we define
\[
U_5 = W \ast \left( m(\delta_M + \delta_{-M})\right), \tag{6.53}
\]
and let \( \rho_{\circ} \) be the unique minimizer in \( \mathcal{M}_{m_1, m_2} \) for \( \mathcal{E}_{U_1} \). It is clear that
\[
U_\ast := U_2 - U_5 = W \ast (\rho_{\circ, J} (\chi_{J_\epsilon} - \phi_{\epsilon}) + \rho_{\circ, -}), \tag{6.54}
\]
is \( C^1 \) since \( \rho_{\circ, \epsilon} \) is Hölder continuous. We will verify \([6.19]\) in Lemma \([6.8]\). Then by Lemma \([6.3]\) to get
\[
(W \ast \rho_{\ast})(0) > (W \ast \rho_2)(0), \quad (W \ast \rho_5)(\frac{1}{2}) > (W \ast \rho_5)(\frac{1}{2}). \tag{6.55}
\]
By the construction of \( U_1 \) and \( W(x)' < 0 \) for \( x \in (0, 1/2) \), we have
\[
U_5(0) < U_5(0), \quad U_5(\frac{1}{2}) > U_5(\frac{1}{2}). \tag{6.56}
\]
Therefore
\[
(W \ast \rho_5)(0) + U_5(0) > (W \ast \rho_5)(0) + U_5(0) \geq (W \ast \rho_5)(\frac{1}{2}) + U_5(\frac{1}{2}) > (W \ast \rho_5)(\frac{1}{2}) + U_5(\frac{1}{2}). \tag{6.57}
\]
Here the second inequality is a consequence of \( \rho_{\ast} \) being an energy minimizer in \( \mathcal{M}_{1-2m} \), together with the fact that \( 1/2 \in \text{supp} \rho_{\ast} \). There \( \rho_5 + m(\delta_M + \delta_{-M}) \) must be of Type II in Proposition \([4.5]\). Notice that we can assume \( 0 \in \text{supp} \rho \) since otherwise \( \text{supp} \rho \cap (-M, M) = \text{supp} \rho \) is trivial. It follows from Corollary \([3.10]\) that \( (W \ast \rho)(0) \leq (W \ast \rho)(1/2) \). By Proposition \([4.6]\), \( (W \ast \rho)(0) - (W \ast \rho)(1/2) \) is increasing in \( m_1 = \int_{(-M, M)} \rho \, dx \), therefore
\[
\int_{(-M, M)} \rho_5 \, dx \geq \int_{(-M, M)} \rho \, dx. \tag{6.58}
\]
Combined with the fact that
\[
\int_{(-M, M)} (\rho_5 +) \, dx = m_1 = \int_{(-M, M)} \rho \, dx, \tag{6.59}
\]
and that $D[\rho] = \int_{[-M,M]} \rho \, dx$, we then obtain (6.45).

We now verify (6.19) for the constructed potential $U_4$ and $U_5$ in Theorem 6.7.

**Lemma 6.8.** Given $U_5$ and $U_4$ defined in (6.55) and (6.50). The potential $U_* := U_4 - U_5$ satisfies (6.19) if $\epsilon > 0$ is small enough.

**Proof.** We write $U_* = W * F(x)$ where

$$F(x) := \rho_0, J(x, \phi) + \rho_0, - = \begin{cases} 
\rho_0, -, & 0 \leq |x| \leq R_0 \\
\rho_0, J, & R_0 < |x| \leq x_j + r - \epsilon \\
\rho_0, J, \frac{x_j + r - x}{\epsilon}, & x_j + r - \epsilon < |x| \leq x_j + r \\
0, & x_j + r < |x| \leq \frac{1}{2}
\end{cases} \tag{6.60}
$$

Here $r = r(\epsilon)$ is in $(0, \epsilon)$ and $F(x)$ has mean-zero $F(x) \leq 0$ on $\{0 \leq |x| \leq R_0\}$ and $F(x) \geq 0$ on the complement. Our goal is to show that $(W * F)' < 0$ on $\{x_j + r - \epsilon \leq x < 1/2\}$ and $0 < x \leq L_0$.

First notice that for any $0 < x < y < 1/2$ and $z \in (0, x) \cup (y, 1/2)$ we have

$$W'(z - y) + W'(z + y) - W'(z - x) - W'(z + x) = -\int_{z-x}^{z+y} W''(u) \, du + \int_{z+x}^{z+y} W''(u) \, du = \int_{x}^{y} (-W''(z - u) + W''(z + u)) \, du < 0,$$

similar to the proof of (6.37). Then due to the even property and the signs of $F$, it is clear that an integration of (6.61) gives $(W * F)' < 0$ on $\{x_j + r - \epsilon \leq x < 1/2\}$ and $0 < x \leq K_0$.

We then focus on $x_j + r - \epsilon \leq x_j + r$. Then we claim that

$$F(2x_0 - x) \geq F(x), \quad \forall x \in [x_0, x_j + r]$$

for $\epsilon$ small enough. In fact, Proposition 6.4 shows that $\rho_0$ is smooth near $x_0$ with $\rho_0(x_0) > 0$. In particular,

$$\rho_0(2x_0 - x) \geq \rho_0(x_0) - (\rho_0'(x_0) + 1)(x - x_0), \quad \rho_0(x) \leq \rho_0(x_0) + (\rho_0'(x_0) + 1)(x - x_0)$$

Therefore, considering the possibility of $2x_0 - x$ lying in the second or third piece of (6.60), we have

$$F(2x_0 - x) - F(x) \geq \left(\rho_0(2x_0 - x) - (\rho_0'(x_0) + 1)(x - x_0)\right) \min\left\{1, \frac{x_j + r - (2x_0 - x)}{\epsilon}\right\}$$

$$- \left(\rho_0(x) - (\rho_0'(x_0) + 1)(x - x_0)\right) \frac{x_j + r - x}{\epsilon}$$

$$\geq \frac{1}{\epsilon} \rho_0(x_0) \left(\min\{\epsilon, x_j + r - (2x_0 - x)\} - (x_j + r - x)\right) - 2\rho_0'(x_0) + 1 \mid (x - x_0).$$

Notice that $(x_j + r - (2x_0 - x)) - (x_j + r - x) = 2(x - x_0)$ and $\epsilon - (x_j + r - x) \geq (x_j + r - x_0) - (x_j + r - x) = x - x_0$. Therefore the last quantity above is nonnegative if $\epsilon$ is small enough, which proves (6.62).

Then we define a function $G$ by

$$G(x) := \begin{cases} 
\rho_0, -, & 0 \leq |x| \leq R_G \\
F(2x_0 - x), & 2x_0 - (x_j + r) < |x| \leq x_0 \\
F(x), & x_0 < |x| \leq x_j + r \\
0, & \text{otherwise.}
\end{cases} \tag{6.65}
$$

Here $R_G \in (0, R_0)$ is determined by $\int_{x_0} G \, dx = 0$, which is possible since the positive parts of $G$ are below $F$, by (6.62). Then $F - G$ is supported on $\{|x| \leq x_0\}$ with the same sign properties as $F$, and we may apply (6.61) to show that $(W * (F - G))(x_0) > 0$, and in fact, bounded from below uniformly in $\epsilon$ and $x_0$. Since $G$ is symmetric around $x_0$ in a small neighborhood of $x_0$, this neighborhood makes no contribution to $(W * G)(x_0)$, and other parts only contribute $O(\epsilon)$ to
(W * G)(x_0) since they are away from x_0 with total mass O(ε). Therefore we get the positivity of (W * F)(x_0) for all x_J + r - ε ≤ x_0 ≤ x_J + r if ε is small enough. 

7. From Continuum to Discrete

In this chapter we finalize the proof of Theorem 1.4 on the minimization problem of G for measures. Then we show that it implies Theorem 1.1 via a construction of polynomials whose roots distribution approximates the minimizing distribution over T. Finally based on our proof of Theorem 1.1 we prove Theorem 1.2 on giving a sharp bound of the number of signed real roots for an arbitrary complex polynomial.

7.1. Proof of Main Theorem. In this section, we collect all results we prove before and deduce the main theorem.

Proof of Theorem 1.1 and Theorem 1.4. Recall that we first extend the functional D and H from the set of discrete probability measures

\[ \mathcal{M}_{\text{emp}} := \{ \rho \in \mathcal{M} : \rho = \sum_{j=1}^{N} c_j \delta(x - x_j), \quad N \in \mathbb{N}, \ c_j \in \mathbb{R}_{\geq 0}, \ x_j \in \mathbb{T} \}, \tag{7.1} \]

to all probability measures \( \mathcal{M} \) on T. We then show in Theorem 3.1 that the minimizer of \( \mathcal{G} \) in \( \mathcal{M}_{D \geq d} \) must be in the form of \( \rho = m(\delta_M + \delta_{-M}) + \rho_1 \) where \( \rho_1 \) is the sediment distribution in \( \mathcal{M}_{1-2m} \) w.r.t. \( U = W * m(\delta_M + \delta_{-M}) \). Depending on the size of M and m, we have constructed the sediment distributions in Proposition 4.4 (\( M = 0 \)) and 4.5 (\( M \neq 0 \)) and Proposition 4.6. We then show that \( \mathcal{G}[\rho] > 1/2 \) for sediment \( \rho \) with \( M \neq 0 \) by combining Theorem 5.1 and Theorem 6.7.

We now compute the value of \( \mathcal{G}[\rho] \) for sediment \( \rho \) with \( M = 0 \). In Proposition 4.4 we construct \( \rho = \rho_{1,m}(x) \in \mathcal{M} \) parametrized by \( m \). By expression of \( \rho \), we have \( D[\rho] = 2m \) is taken at the origin since \( \rho(x) < 1 \) for \( x \neq 0 \). On the other hand, it follows from the construction that \( W * \rho \) is stationary. By Lemma 4.3 by letting \( C_1 = 0 \), we obtain

\[ (W * \rho_1)'(x) = -\pi \frac{\sqrt{-(\sin^2 \pi x - (2m)^2)}}{\sin \pi x} \chi_{|x| \leq \frac{1}{2} \sin^{-1} 2m} \tag{7.2} \]

Due to the sign of \( W * \rho_1(x) \), we see that \( H[\rho] = -(W * \rho)(1/2) \). We can compute the value using mean-zero property of \( W * \rho \)

\[ (W * \rho_1)(\frac{1}{2}) = \frac{1}{1 - 2 \sin^{-1} 2m} \int_0^{\sin^{-1} 2m} W * \rho_1 \, dx \]

\[ = \frac{1}{1 - 2 \sin^{-1} 2m} \left( \frac{\sin^{-1} 2m}{\pi} - (W * \rho_1)(1/2) - \int_0^{\sin^{-1} 2m} W * \rho_1'(x) \, dx \right) \tag{7.3} \]

where the last equality follows from integration by parts and the fact that \( (W * \rho_1)(1/2) = (W * \rho_1)(\sin^{-1} 2m) \). It then follows from (7.3) and (7.2) that

\[ -(W * \rho_1)(\frac{1}{2}) = -2 \int_0^{\frac{1}{2} \sin^{-1} 2m} (W * \rho_1)'(x) \, dx = 2\pi \int_0^{\frac{1}{2} \sin^{-1} 2m} x \sqrt{\frac{4m^2}{\sin^2 \pi x} - 1} \, dx \]

\[ = \pi \int_0^{\frac{1}{2} \sin^{-1} 2m} \frac{1}{\pi} \sin^{-1} (2my) \sqrt{\frac{1}{y^2} - 1} \cdot \frac{2m}{\pi \sqrt{1 - (2my)^2}} \, dy \tag{7.4} \]

\[ = \frac{8m^2}{\pi} \int_0^{1} \sqrt{1 - y^2} \cdot \frac{\sin^{-1} (2my)}{2my \sqrt{1 - (2my)^2}} \, dy > 2m^2 \].
Therefore we prove the inequality in Theorem 1.4. One can also evaluate the limit \( \lim_{m \to \infty} (W \ast \rho_i)(\frac{1}{2})/m^2 = 2 \), thus

\[
\lim_{m \to \infty} G[\rho_i,m] = \frac{1}{2}.
\] (7.5)

Therefore we also show that \( \sqrt{2} \) sharp in Theorem 1.4 thus finish proving Theorem 1.4. Since \( \mathcal{M}_{\text{emp}} \subset \mathcal{M} \), we also prove the inequality in Theorem 1.4.

It now suffices to prove that Theorem 1.3 is sharp. We will do so by constructing \( \rho_i \) in

\[
\mathcal{M}_{\text{emp-rat}} = \left\{ \rho \in \mathcal{M} : \rho = \sum_{j=1}^{N} c_j \delta(x - x_j), N \in \mathbb{N}, c_j \in \mathbb{Q}_{\geq 0}, x_j \in \mathbb{T} \right\},
\] (7.6)

the set of empirical measures with rational coefficients, such that \( G[\rho_i] < 1/2 + \epsilon \). For each \( \rho = \rho_{i,m} = 2m\delta + \rho_{i,c} \in \mathcal{M} \), we claim that there exists \( \{\rho_n\} \subset \mathcal{M}_{\text{emp}} \) such that \( \rho_n \to \rho \) and \( \limsup_{n \to \infty} \mathcal{H}[\rho_n] \leq \mathcal{H}[\rho] \). For each \( n \), we define

\[
\rho_n = 2m\delta + \sum_{j=0}^{n^{-1}} \left( m_{j,1}\delta(x - \frac{j}{n}) + m_{j,2}\delta(x - \frac{j+1}{n}) \right),
\] (7.7)

where \( m_{j,1}, m_{j,2} \geq 0 \) are determined by the moment conditions

\[
\int_{x/n}^{(x+1)/n} \left( m_{j,1}\delta(y - \frac{j}{n}) + m_{j,2}\delta(y - \frac{j+1}{n}) - \rho_{i,c}(y) \right) dy = 0, \quad k, 0, 1.
\] (7.8)

The weak convergence of \( \{\rho_n\} \) to \( \rho \) is clear. Similar to the proof of (3.27) in Lemma 3.4, we may show that

\[
(W \ast (m_{j,1}\delta(-\frac{j}{n}) + m_{j,2}\delta(\frac{j+1}{n}) - \rho_{i,c})(\cdot)) \geq 0, \quad \forall x \notin [j/n, (j+1)/n].
\] (7.9)

Using the convexity of \( W \). Therefore applying (7.9) to those \( j \) with \( x \notin [j/n, (j+1)/n] \), we have

\[
(W \ast (\rho_n - \rho))(x) \geq (W \ast \left( m_{j,x,1}\delta(-\frac{j_x}{n}) + m_{j,x,2}\delta(-\frac{j_x+1}{n}) - \rho_{i,c}\chi_{[j_x/n, (j_x+1)/n]} \right))(x),
\] (10.10)

where \( j_x - \text{th interval contains } x \). For large \( n \), we have \( (W \ast \delta)(x) > 0 \) for \( |x| < 1/n \) since \( W \) is positive near \( 0 \). We can also bound the other term using \( \rho_{i,c} \leq 1 \) and \( W = -\log |2 \sin \pi x| \),

\[
|W \ast (\rho_{i,c}\chi_{[j_x/n, (j_x+1)/n]})| \leq \sup_{a \in \mathbb{T}} \int_{a}^{a+1/n} |W| dx \lesssim \frac{\log n}{n}.
\] (7.11)

Therefore we obtain

\[
(W \ast \rho_n)(x) - (W \ast \rho)(x) \geq -C \frac{\log n}{n},
\] (7.12)

which implies

\[
\mathcal{H}[\rho_n] \leq \mathcal{H}[\rho] + C \frac{\log n}{n}.
\] (7.13)

and therefore \( \lim_{n \to \infty} \mathcal{H}[\rho_n] \leq \mathcal{H}[\rho] \). Combining with Lemma 3.2, we have that \( \lim_{m \to \infty} \mathcal{D}[\rho_i,m] = \mathcal{D}[\rho] \) and \( \lim_{n \to \infty} \mathcal{H}[\rho_i] = \mathcal{H}[\rho] \), and therefore \( \lim_{n \to \infty} \mathcal{G}[\rho_i,m] = \mathcal{G}[\rho] \).

Therefore for each \( \epsilon > 0 \), we can find \( \rho = \rho_{i,m} \) such that \( \mathcal{G}[\rho] < 1/2 + \epsilon \). For this \( \rho \), we can construct \( \rho_{i,n} \) as above so that \( \mathcal{G}[\rho_{i,n}] < 1/2 + 2\epsilon \) for \( n \) large enough. For a \( \rho_{\text{emp}} = \sum_{j=1}^{N} c_j \delta(x - x_j) \), \( N \in \mathbb{N} \in \mathcal{M}_{\text{emp}} \), we can view \( \mathcal{G}[\rho_{\text{emp}}] \) as a function of \( \bar{c} = (c_1, \ldots, c_N) \) and indeed a continuous function in terms of \( \bar{c} \). Therefore, by replacing each \( c_j \) by a nearby rational number while keeping \( \sum_{j=1}^{N} c_j = 1 \), one can find a \( \rho'_i \in \mathcal{M}_{\text{emp-rat}} \) with \( \mathcal{G}[\rho'_i] > \frac{1}{2} + 3\epsilon \). Since \( \epsilon \) is arbitrary, we finish proving the sharpness of the constant \( \sqrt{2} \) in Theorem 1.1.

**Remark 7.1.** Notice that we actually show that \( \mathcal{G}[\rho] \) is strictly larger than \( 1/2 \). Indeed, by Theorem 5.7 we see that \( \mathcal{G}[\rho] \) cannot equal to \( 1/2 \) for \( \rho \) with \( M > 0 \), and we have just computed in the proof above that \( \mathcal{G}[\rho] > 1/2 \) for \( \rho \) with \( M = 0 \). Therefore \( 1/2 \) cannot be achieved for any \( \rho \in \mathcal{M} \), although we have constructed a family of \( \rho_m \) where \( \mathcal{G}[\rho_m] \) can be arbitrarily close to \( 1/2 \).

It then also follows that \( 1/2 \) cannot be achieved for any polynomial.
7.2. Application towards Real Roots. In this section, we give the proof for Theorem 1.2. After we prove Theorem 1.1, we can deduce Theorem 1.2 as a consequence. We can again extend the discrete question on polynomials to a continuous question about probability measures. For each \( \rho \in \mathcal{M} \), we define a functional \( \mathcal{R}[\rho] := \int_{\{0\}} \rho \, dx = \int_{\{0\}} (\rho - 1) \, dx \). It is easy to see that if \( \rho_f = \frac{1}{n} \sum_j \theta_j \) is the empirical measure from a degree \( n \) polynomial \( f(z) \), then \( \mathcal{R}[\rho_f] = N_+(f) / n \).

**Proof of Theorem 1.2.** It follows from the definition of \( \mathcal{D} \) that
\[
\mathcal{R}[\rho] \leq \mathcal{D}[\rho] \leq \sqrt{2} \cdot \sqrt{\mathcal{H}[\rho]}.
\]
(7.14)

This implies that for \( \rho = \rho_f \) that
\[
N_+(f) \leq \sqrt{2} \cdot \sqrt{\mathcal{H}[f]} \cdot n.
\]
(7.15)

Therefore it suffices to prove the inequality is sharp.

Notice that in the proof of Theorem 1.1 we have constructed \( \rho_{1,m} \) such that \( \mathcal{G}[\rho_{1,m}] < 1/2 + \epsilon \) for any \( \epsilon > 0 \). By the expression of \( \rho_{1,m} \) we see that \( \mathcal{D}[\rho_{1,m}] = \mathcal{R}[\rho_{1,m}] \), therefore we also have for these \( \rho_{1,m} \) that \( \mathcal{H}[\rho_{1,m}] / \mathcal{R}[\rho_{1,m}]^2 < 1/2 + \epsilon \). We then construct \( \rho_n \rightarrow \rho_{1,m} \) in the same way to approximate \( \rho = \rho_m \). Since \( \lim_{n \rightarrow \infty} \mathcal{D}[\rho_n] = 2m = \mathcal{R}[\rho_n] \), we also have \( \lim_{n \rightarrow \infty} \mathcal{H}[\rho_n] / \mathcal{R}[\rho_n]^2 = 1/2 \). Therefore we can choose \( \rho_n \) such that \( \mathcal{H}[\rho_n] / \mathcal{R}[\rho_n]^2 < 1/2 + 2\epsilon \). Finally the construction for \( \rho_n \) is the same since \( \mathcal{R} \) is also continuous in \( \mathcal{C} \) when \( \rho_{\text{emp}} = \sum_{j=1}^n \delta(x - x_j) \). Therefore we can find \( \rho_0 \) with \( \mathcal{H}[\rho_0] / \mathcal{R}[\rho_0]^2 < 1/2 + 3\epsilon \). Since \( \epsilon \) is arbitrary, we finish proving the sharpness of constant \( \sqrt{2} \).

The upper bound for \( N_0(f) \) is exactly the same since \( N_\theta(f(z)) = N_+(f(z \cdot e^{-2\pi i})) \) and \( \mathcal{H}[f(z)] = \mathcal{H}[f(z \cdot e^{-2\pi i})] \).

\[\square\]

8. Formulation in Harmonic Functions

In his 1952 work \cite{Gan52}, Ganelius formulates a question in harmonic functions and uses it to improve the constant in the original Erdős–Turán inequality proved by \cite{ET50}. This approach of harmonic functions has been further developed by Mignotte in \cite{Mig92}. In this section, our goal is to show that our sharp version of Erdős–Turán inequality in turn implies a sharp upper bound for harmonic functions in Ganelius’ formulation.

**Theorem 8.1** (Ganelius, 1952). Let \( f(z) = u(z) + iv(z) \) be an analytic function in \( |z| < 1 \) with \( f(0) = 0 \). Suppose \( u(z) < H \) and \( \frac{\partial^m}{\partial z^m}(z) < K \) in \( |z| < 1 \) where \( H, K > 0 \), then there exists \( C > 0 \) such that
\[
|v(z_1) - v(z_2)| \leq C \sqrt{H} K, \quad \text{for } |z_1|, |z_2| < 1.
\]
(8.1)

Moreover the constant \( C \) can be taken to be \( \sqrt{2\pi \sqrt{\pi} / k} \approx 4.64 \) where \( k = \sum_{m \geq 0} (-1)^{m-1}(2m + 1)^{-2} \) is the Catalan constant. \[\square\]

We will prove the following improvement with a sharp constant.

**Theorem 8.2.** Let \( f(z) = u(z) + iv(z) \) be an analytic function in \( |z| < 1 \) with \( f(0) = 0 \). Suppose \( u(z) \leq H \) and \( \frac{\partial^m}{\partial z^m}(z) \leq K \) in \( |z| < 1 \) where \( H, K > 0 \), then
\[
|v(z_1) - v(z_2)| \leq \sqrt{2\pi \sqrt{H} K}, \quad \text{for } |z_1|, |z_2| < 1.
\]
(8.2)

Moreover, \( \sqrt{2\pi} \) is the sharp constant for this inequality.

**Proof.** In order to prove inequality (8.2), we first note that it suffices to prove (8.2) for \( |z| = 1 \) in the case where \( f(z) \) that is analytic in \( |z| < 1 + \epsilon \) and \( u \leq H \) and \( \frac{\partial^m}{\partial z^m}(z) \leq K \). Indeed, if \( |z_i| < 1 - \epsilon \) for \( i = 1, 2 \), we can consider \( g(z) = f(z(1 - \epsilon)) \) instead. We still have the bound \( u_0 \leq H \) and \( \frac{\partial^m}{\partial z^m}(z) \leq K(1 - \epsilon) \leq K \). Now since \( f(z) \) is analytic on \( |z| < 1 + \epsilon \), \( u \) and \( v \) are both

\[\text{Notice that } \theta \text{ is taken to be in } [0, 1] \text{ in this current formulation whereas in } \cite{Gan52} \text{ and } \cite{Mig92} \theta \text{ is taken to be in } [0, 2\pi]. \text{ This results in a change of } \sqrt{2\pi} \text{ in the constant } C.\]
harmonic functions on $|z| < 1 + \epsilon$. The (8.2) for $z_i$ and $f$ then follows from that for $z_i/(1 - \epsilon)$ and $g$. By maximal value principle, $\sup_{|z_i|, |z_j| \leq 1} |\tilde{\vartheta}(z_i) - \tilde{\vartheta}(z_j)|$ is achieved at $|z_1|, |z_2| = 1$. Meanwhile we can also assume $K = 1$ without loss of generality by multiplying $f$ by $1/K$.

Denote the restriction of $u$ and $v$ on $|z| = 1$ as $\tilde{u}(\theta)$ and $\tilde{v}(\theta)$. We now define

$$\rho(\theta) = 1 - \tilde{v}'(\theta).$$

(8.3)

Then $\rho \in \mathcal{M}$ since $\int_T \rho(\theta) \, d\theta = 1$ and $\rho(\theta) > 0$ by $\frac{\partial v}{\partial n}(z) \leq 1$. Given $f(0) = 0$, it is a standard property of Hilbert transform on $T$ that

$$\tilde{u} = \frac{1}{\pi} \text{p.v.} W' \ast \tilde{v} = \frac{1}{\pi} W \ast \tilde{v}' = -\frac{1}{\pi} W \ast \rho.$$  

(8.4)

Therefore, $W \ast \rho \geq -\pi H$ and $\mathcal{H}[\rho] \leq \pi H$. By Theorem 1.4 we have $\mathcal{D}[\rho] \leq \sqrt{2} \cdot \sqrt{\mathcal{H}[\rho]}$, thus

$$\sqrt{H} \geq \sqrt{\mathcal{H}[\rho]}/\pi \geq \frac{1}{\sqrt{2\pi}} \sup_I (\rho - 1) \, dx = \frac{1}{\sqrt{2\pi}} \sup_{a,b \in T} (\tilde{v}(a) - \tilde{v}(b)).$$

(8.5)

which proves the (8.2).

Then we show that the constant in (8.2) is sharp. By the proof of Theorem 1.4 for any $\epsilon > 0$, we may take $\rho_{1,n} \in \mathcal{M}$ as given by (4.36) for some $m > 0$ such that $\frac{\mathcal{H}[\rho_{1,n}]}{\mathcal{H}[\rho]} < \frac{1}{2} + \epsilon$. Proposition 4.4 shows that $\text{ess inf}(W \ast \rho_{1,m}) = -\mathcal{H}[\rho_{1,m}]$ is achieved on an interval $[\frac{1}{2} \sin^{-1} 2m, 1 - \frac{1}{2} \sin^{-1} 2m]$. Therefore, by taking convolution with a compactly supported mollifier $\rho$, we obtain a nonnegative smooth function $\rho = \phi \ast \rho_{1,m} \in \mathcal{M}$ with $\mathcal{H}[\rho] = \mathcal{H}[\rho_{1,n}]$ since $W \ast \rho = \phi \ast (W \ast \rho_{1,m})$. Also, one can choose $\phi$ so that $\mathcal{D}[\rho]$ is arbitrarily close to $\mathcal{D}[\rho_{1,n}]$ by Lemma 3.2 and this guarantees we can find continuous $\rho$ such that $\frac{\mathcal{H}[\rho]}{\mathcal{D}[\rho]} < \frac{1}{2} + \epsilon$. Now we define

$$\tilde{v}(\theta) = \int_0^\theta (1 - \rho(t)) \, dt - c_\rho, \quad \tilde{u}(\theta) = \frac{1}{\pi} \text{p.v.} (W' \ast \tilde{v})(\theta) = -\frac{1}{\pi} (W \ast \rho)(\theta),$$

(8.6)

where $c_\rho$ is a constant that makes $\int_T \tilde{v}(\theta) \, d\theta = 0$. Here $\tilde{v}$, $\tilde{u}$ are both smooth. Therefore, we may construct an analytic function $f = \tilde{u} + i \tilde{v}$ in $|z| < 1$ by Poisson integral

$$f(r e^{i 2\pi \theta}) = \int_T P_r(\theta - t)(\tilde{u}(t) + i \tilde{v}(t)) \, dt, \quad P_r(\theta) = \frac{1 - r^2}{1 - 2r \cos(2\pi \theta) + r^2}.$$  

(8.7)

and $f$ is continuous on $|z| \leq 1$. Clearly $f(0) = 0$ because $\tilde{u}, \tilde{v}$ are mean-zero. By the harmonic property of $u$, we see that

$$\sup_{|z| < 1} u(z) = \sup_{|z| = 1} u(z) = -\frac{1}{\pi} \inf (W \ast \rho) = \frac{1}{\pi} \mathcal{H}[\rho].$$

(8.8)

Now using $v_r(\theta) = (P_r \ast \tilde{v})(\theta)$, we have $\partial v/\partial \theta = P_r \ast \tilde{v}'$. Again the harmonic property of $P_r \ast \tilde{v}'$ implies

$$\sup_{|z| < 1} \partial v/\partial \theta(z) = \sup_{|z| = 1} \partial v/\partial \theta(z) = \sup_{\theta \in T} (1 - \rho(\theta)) \leq 1.$$  

(8.9)

Therefore $f$ satisfies the assumptions of this theorem with $H = \frac{1}{2} \mathcal{H}[\rho]$ and $K = 1$. On the other hand, since $v$ is harmonic on $|z| < 1$ and continuous on $|z| \leq 1$,

$$\sup_{|z|, |z| < 1} |v(z_1) - v(z_2)| = \sup_{a,b \in T} (\tilde{v}(a) - \tilde{v}(b)) = \sup_{I} \int_I (\rho - 1) \, dx = \mathcal{D}[\rho].$$

(8.10)

Therefore we find $f$ such that

$$\sup_{|z_1|, |z_2| < 1} |v(z_1) - v(z_2)| \geq \sqrt{\pi H} / \sqrt{1/2 + \epsilon}.$$  

(8.11)

Since $\epsilon$ is arbitrary, this shows the sharpness of the constant in (8.2). □
Remark 8.3. By taking the difference with \( v(0) \), the inequality (8.1) and (8.2) in both theorems imply that

\[
|v(z)| \leq C\sqrt{\frac{1}{(1-x^2)k}}, \quad \text{for } |z| < 1, \tag{8.12}
\]

with the same constant \( C \), i.e. \( C = \sqrt{2\pi} \sqrt{\frac{1}{k}} \) and \( C = \sqrt{2\pi} \) respectively. However, the constant \( \sqrt{2\pi} \) in (8.12) is not necessarily sharp.

9. Acknowledgement

The second author would like to thank Theresa Anderson, Frank Thorne and Trevor Wooley for organizing the American Institute of Mathematics (AIM) workshop Arithmetic Statistics, Discrete Restriction, and Fourier Analysis in 2021, and Micah B. Milinovich and Emanuel Carneiro for introducing this problem to our knowledge. The second author would like to thank Emanuel Carneiro, Mithun Das, Alexandra Florea, Angel V. Kumchev, Amita Malik, Micah B. Milinovich and Caroline Turnage-Butterbaugh for helpful conversations.

10. Appendix: Continuity of Potential

We list several results on the continuity of the generated potential \( V = W * \rho \). Recall that a function \( f \) is lower semicontinuous at \( x = a \in \mathbb{T} \) if

\[
\liminf_{x \to a} f(x) \geq f(a). \tag{10.1}
\]

Proposition 10.1. Assume \( W : \mathbb{T} \to (-\infty, \infty) \) satisfies (H1)-(H4). For \( \rho \in \mathcal{M} \), denote \( \mathbf{V} = W * \rho \).

(i) The generated potential \( V \) is lower semicontinuous and is \( C^2 \) on \( \mathbb{T} \setminus \text{supp} \rho \).
(ii) There exists a constant \( C > 0 \) such that \( V''(x) \geq C \) at every \( x \notin \text{supp} \rho \).
(iii) Let \( (x_1, x_2) \subseteq (\text{supp} \rho)^c \) be an interval with endpoints \( x_1, x_2 \in \text{supp} \rho \). Then \( V \) is right continuous at \( x_1 \) and left continuous at \( x_2 \).

Proof. Proof of (i): The lower semicontinuity of \( V \) for general \( W \) can be found in [BCLR13, Lemma 2] and for \( W = -\ln|2\sin(\pi x)| \) is automatic. For the sake of completeness, we include the proof here. The continuity of \( W \) away from 0, together with (H3), implies that \( W \) is bounded from below, say, by \(-C_1\). By including the possibility of \( \infty \) value, we have \( \lim_{x \to x_0} W(x) = W(x_0) \) for any \( x_0 \in \mathbb{T} \). Therefore, for any \( x \in \mathbb{T} \) and sequence \( \{x_n\} \) with \( \lim_{n \to \infty} x_n = x \),

\[
\begin{align*}
V(x) + C_1 & = \int_{\mathbb{T}} (W(x-y) + C_1)\rho(y) \, dy = \int_{\mathbb{T}} \lim_{n \to \infty} (W(x_n-y) + C_1)\rho(y) \, dy \\
& \leq \liminf_{n \to \infty} \int_{\mathbb{T}} (W(x_n-y) + C_1)\rho(y) \, dy = \liminf_{n \to \infty} V(x_n) + C_1. \tag{10.2}
\end{align*}
\]

The inequality uses Fatou’s lemma on the nonnegative functions \( W(x_n-y) + C_1 \). The lower semicontinuity of \( V \) then follows.

Proof of (ii): By (H4), \( W \) is \( C^2 \) on \( \mathbb{T} \setminus \{0\} \) with \( W''(y) \geq C_W > 0 \) for any \( y \in \mathbb{T} \setminus \{0\} \). If \( x \notin \text{supp} \rho \), then there exists \( \epsilon > 0 \) such that \( (x-\epsilon, x+\epsilon) \notin \text{supp} \rho \), and

\[
V(x) = \int_{\mathbb{T}} W(x-y)\rho(y) \, dy = \int_{\mathbb{T}\setminus(x-\epsilon, x+\epsilon)} W(x-y)\rho(y) \, dy \tag{10.3}
\]

This shows that \( V \) is \( C^2 \) in \( (x-\epsilon, x+\epsilon) \) since \( W(x-y) \) is \( C^2 \) on the domain of integral. Also, for

\[
V''(x) = \int_{\mathbb{T}\setminus(x-\epsilon, x+\epsilon)} W''(x-y)\rho(y) \, dy \geq C_W \int_{\mathbb{T}\setminus(x_0-\epsilon, x_0+\epsilon)} \rho(y) \, dy = C_W > 0. \tag{10.4}
\]
Proof of (iii): By reflection around \((x_1 + x_2)/2\), it suffices to prove that \(V\) is right continuous at \(x_1\). Also, since we already know that \(V\) is lower semicontinuous, it suffices to prove: for any \(\epsilon > 0\), there exists \(\alpha > 0\) such that

\[
V(y) < V(x_1) + \epsilon, \quad \forall y \in (x_1, x_1 + \alpha).
\]

(10.5)

Also, it suffices to work with the case \(V(x_1) < \infty\). First notice that \((x_1, x_2)\) is an interval in \(\mathbb{T}\), and therefore we can take the representative \(x_1 < x_2 < x_1 + 1\). We will take \(\alpha = \frac{x_2 - x_1}{2}\). Since \(\text{supp} \rho \cap (x_1, x_2) = \emptyset\), we may write

\[
V(y) = \int_{[x_2-1,x_1]} W(y-z)\rho(z) \, dz,
\]

(10.6)

where \([x_2-1,x_1] = (x_1, x_2)^c\) when considered as an interval of \(\mathbb{T}\). Then

\[
V(y) - V(x_1) = \int_{[x_2-1,x_1]} (W(y-z) - W(x_1-z))\rho(z) \, dz = \int_{[x_2-1,x_1]} \int_{x_1-z}^{y-z} W'(u) \, du \rho(z) \, dz,
\]

(10.7)

where we dropped the point \(z = x_1\) in the integral because \(V(x_1) < \infty\) does not allow \(\rho\) to have a Dirac mass at \(x_1\). It then follows from the monotonicity of \(W'\) that

\[
V(y) - V(x_1) \leq -W'(\frac{x_2 - x_1}{2})(y - x_1),
\]

(10.8)

therefore when \(\alpha\) is small enough, we have \(V(y) - V(x_1) < \epsilon\).

\[\square\]

11. Appendix: Continuity of Energy

In this part, we will study properties of the energy functional \(\mathcal{E}\), defined in (3.33). In particular, we will prove that \(\mathcal{E}\) is continuous with respect to mollification. While doing so, we also give a version of Paserval’s identity based on some assumptions of \(W\).

Proposition 11.1. Assume \(W\) satisfies (H1)-(H5) and \(U\) has the form (3.32). Let \(\rho_i\) for \(i = 1, 2\) and \(\rho\) be probability measures on \(\mathbb{T}\). If \(\mathcal{E}[\rho] < \infty\), then

\[
\lim_{\alpha \to 0^+} \mathcal{E}[\rho * \psi_{\alpha}] = \mathcal{E}[\rho].
\]

(11.1)

If \(\mathcal{E}[\rho_i] < \infty\), then

\[
\int_{\mathbb{T}} (W * \rho_1) \cdot \rho_2 \, dx = \sum_{k \in \mathbb{Z}} \hat{W}(k) \hat{\rho}_1(k) \hat{\rho}_2(k).
\]

(11.2)

Proof. We first prove (11.1) in the case \(U = 0\). By assumption, \(\inf W = -C_0\) with \(C_0 > 0\). To prove (11.1), it suffices to prove

\[
\lim_{\alpha \to 0^+} \int_{\mathbb{T}} (W_1 * \psi_{\alpha} * \rho)(x)(\psi_{\alpha} * \rho)(x) \, dx = \int_{\mathbb{T}} W_1(x-y) \rho(y) \, dy \rho(x) \, dx,
\]

(11.3)

where \(W_1 = W + 2C_0\) is bounded from below by \(C_0\). Since \(\psi_{\alpha}\) is even, we obtain

\[
\int_{\mathbb{T}} (W_1 * \psi_{\alpha} * \rho)(x)(\psi_{\alpha} * \rho)(x) \, dx = \int_{\mathbb{T}} (W_1 * \psi_{\alpha} * \rho)(x) \rho(x) \, dx
\]

(11.4)

where \(\Psi_{\alpha} = \psi_{\alpha} * \psi_{\alpha}\). The assumption \(\mathcal{E}[\rho] < \infty\) implies \(\int_{\mathbb{T}} W_1(x-y) \rho(y) \, dy \rho(x) \, dx < \infty\). Therefore the measure of the line \(x = y\) is 0 since \(W_1(0) = \infty\). By (H1) \(W_1\) is continuous on \(\mathbb{T} \setminus \{0\}\), then \(\lim_{\alpha \to 0^+} (W_1 * \Psi_{\alpha})(x-y) = W_1(x-y)\) for any \(x \neq y\), and therefore this convergence holds almost everywhere with respect to the measure \(\rho(x)\rho(y)\) on \(\mathbb{T}^2\).

Notice that \(\psi_{\alpha}(x)\) is a positive linear combination of the characteristic functions \(\chi_{[-r,r]}\) with \(r > 0\), and same for \(\Psi_{\alpha}\). Combining with the assumption (H5) (which is equivalent to \((W_1 * \frac{1}{2\pi} \chi_{[-r,r]})(x) \leq C_1 W_1(x))\), we see that

\[
(W_1 * \Psi_{\alpha})(x) \leq C_1 W_1(x),
\]

(11.5)
for any $0 < a < 1/2$ and $x \in \mathbb{T}$. Therefore, the RHS integral of (11.4) is dominated by $C_1 \iint W_1(x - y)\rho(y)\,dy\rho(x)\,dx < \infty$. Combined with the convergence $\lim_{a \to 0^+}(W_1 * \Psi_a)(x - y) = W_1(x - y)$ for almost everywhere with respect to the measure $\rho(x)\rho(y)$, the dominated convergence theorem shows that

$$\lim_{a \to 0^+} \iint (W_1 * \Psi_a)(x - y)\rho(y)\,dy\rho(x)\,dx = \iint W_1(x - y)\rho(y)\,dy\rho(x)\,dx.$$  \tag{11.6}$$

which finishes the proof of (11.3).

Next we prove (11.1) for general $U$ and $E$. Since $U$ is bounded from below, the finiteness of $E[\rho]$ implies $\iint W(x - y)\rho(y)\,dy\rho(x)\,dx < \infty$. We have shown the convergence of $W$-term in $E_U$ in $U = 0$ case. Therefore, it suffices to show that

$$\lim_{a \to 0^+} \int U(x)(\rho * \psi_a)(x)\,dx = \int U(x)\rho(x)\,dx,$$  \tag{11.7}$$

for $U = W * \rho_U^+, U = W * \rho_U^-$ or $U = W * \delta = W$, using the expression of $U$ in (3.32). For the first two cases, we first observe

$$\int U(x)(\rho * \psi_a)(x)\,dx = \int (U * \psi_a)(x)\rho(x)\,dx,$$  \tag{11.8}$$

and then continuity of $U$ implies the uniform convergence of $U * \psi_a$ to $U$ on $\mathbb{T}$ as $a \to 0^+$. For the case $U = W$, we again have

$$\int W(x)(\rho * \psi_a)(x)\,dx = \int (W * \psi_a)(x)\rho(x)\,dx.$$  \tag{11.9}$$

Notice that $E[\rho] < \infty$ implies that $\int W\rho\,dx = \int U\rho\,dx < \infty$ since $W$ is bounded from below. Using (11.5) with $\Psi_a$ replaced by $\psi_a$, we see that $\lim_{a \to 0^+} \int (W * \psi_a)(x)\rho(x)\,dx = \int W\rho\,dx$ by dominated convergence.

Finally we prove (11.2). We first treat the case $\rho_1 = \rho_2 = \rho$. We first notice that for any $0 < a < 1/2$,

$$\int (W_1 * \psi_a * \rho)(x)(\psi_a * \rho)(x)\,dx = \sum_{k \in \mathbb{Z}} W_1(k)|\hat{\psi}(ak)|^2|\hat{\rho}(k)|^2,$$  \tag{11.10}$$

by Plancherel formula, since $W_1 * \psi_a * \rho$ and $\psi_a * \rho$ are both continuous. By (11.1), the LHS of (11.10) converges to $\iint \hat{W}_1(x - y)\hat{\rho}(y)\,d\rho(y)\,dx$.

To analyze the RHS of (11.10), we show that $\sum_{k \in \mathbb{Z}} W_1(k)|\hat{\rho}(k)|^2$ is finite. First notice that since $\hat{\psi}(0) = 1$ and $\hat{\psi}(\xi)$ is a smooth even function, we have

$$\lim_{a \to 0^+} |\hat{\psi}(ak)|^2 = 1, \quad \text{uniformly for } k \in [-K, K],$$  \tag{11.11}$$

for any $K \in \mathbb{Z}$. Therefore

$$\sum_{k \in \mathbb{Z}, |k| \leq K} W_1(k)|\hat{\rho}(k)|^2 = \lim_{a \to 0^+} \sum_{k \in \mathbb{Z}, |k| \leq K} W_1(k)|\hat{\psi}(ak)|^2|\hat{\rho}(k)|^2$$

$$\leq \lim_{a \to 0^+} \sum_{k \in \mathbb{Z}} W_1(k)|\hat{\psi}(ak)|^2|\hat{\rho}(k)|^2$$

$$= \iint W_1(x - y)\rho(y)\,dy\rho(x)\,dx < \infty.$$  \tag{11.12}$$

The first inequality uses the positivity of $\hat{W}_1$ and $|\hat{\psi}|^2$, and the last equality uses (11.3) and (11.10). Therefore the RHS of (11.10) is dominated by $\sum_{k \in \mathbb{Z}} W_1(k)|\hat{\rho}(k)|^2$ since $|\hat{\psi}(ak)| \leq 1$ for any $a$ and $k$. Then we see that the RHS of (11.10) converges to $\sum_{k \in \mathbb{Z}} W_1(k)|\hat{\rho}(k)|^2$. 

For the general case with possibly \( \rho_1 \neq \rho_2 \), we use the bilinear property

\[
2 \iint W(x-y)\rho_1(y) \, dy \, \rho_2(x) \, dx = \iint W(x-y)(\rho_1(y) + \rho_2(y)) \, dy(\rho_1(x) + \rho_2(x)) \, dx
\]

(11.13)

and the RHS of (11.2) can be written similarly. By assuming \( \rho_0 \), then

\[
W
\]

Notice that since \( \rho_0 \), then \( E[\rho_1 + \rho_2] < \infty \). Suppose not, then \( f(W_1 * \rho) \rho \, dx = \infty \). We can define \( W_1^A(x) := \min\{W_1(x), A\} \) for \( A > 0 \), then

\[
\lim_{A \to \infty} \int (W_1^A * \rho) \, dx = \infty,
\]

(11.14)

Therefore, \( E[\rho_1] < \infty \) implies the RHS of (11.10) for \( \rho = \rho_1 + \rho_2 \) is uniformly bounded as \( a \to 0^+ \).

Therefore we find a contradiction. Then the conclusion follows from the previous case applied to \( \rho_1, \rho_2, \rho_1 + \rho_2 \).

\[ \square \]
