BIG CATEGORIES, BIG SPECTRA

SCOTT BALCHIN AND GREG STEVENSON

Abstract. We introduce two new topological invariants of a rigidly-compactly generated tensor-triangulated category and study their associated support theories and relation to existing technology. The first, the smashing spectrum, is produced by proving that the frame of smashing ideals is always spatial, and is equipped with a surjective morphism to the Balmer spectrum which detects the failure of the telescope conjecture. The second, the big spectrum, results from taking the entire collection of localizing ideals seriously and considering prime localizing ideals. Although there are, in principle, a proper class of localizing ideals, we are able to prove the existence of at least one big prime lying over every Balmer prime. We conclude with a pair of examples illustrating our constructions.

1. Introduction

There are, by now, many paths through the landscape of mathematics which pass through the forest of tt-geometry. Information freely travels along well-worn trails between algebraic geometry, topology, representation theory, and the theory of operator algebras. This has been made possible by a concerted effort to domesticate this formerly wild land using tools like the Balmer spectrum of an essentially small tensor-triangulated category (henceforth a small tt-category) [Bal05] and Rickard idempotents for rigidly-compactly generated tt-categories [BF11] (affectionately known as ‘big tt-categories’).

However, many bastions of wilderness still remain, inhabited by bandersnatches and other such beasts, (and no vorpal blade to slay them). For instance, we have made essentially no inroads into understanding big tt-categories where the telescope conjecture fails. Our existing methods are somehow reliant on every coproduct preserving monoidal localization being a finite localization, i.e. corresponding to a localizing ideal generated...
by compact objects. Indeed, the evidence, e.g. [Ste13, Theorem 7.15] and [BHS21b, Theorem 9.11], suggests that approaches based on the spectrum of the compacts are doomed to failure in such cases.

The aim of this paper is to shine a light on some dark corners of the forest. We introduce two new spaces associated to a big tt-category: the smashing spectrum and the big spectrum. These spaces refine the spectrum of the compact objects and are better adapted to cases where the telescope conjecture fails. Our expectation is that the corresponding notions of support can be used to classify localizations in greater generality.

Let us now draw a rough map of the new regions available to us. Any rigidly-compactly generated tt-category $\mathcal{T}$ has a set $\mathcal{S}(\mathcal{T})$ of smashing tensor ideals, i.e. localizing ideals whose localization functor is given by tensoring with some idempotent object. These smashing tensor ideals form a lattice under inclusion, and it was shown in [BKS20] that this lattice is a frame—the motivation was to use tools from pointless topology to study $\mathcal{T}$.

The first main result of this paper is a continuation of this work: we prove in Theorem 3.2.8 that the frame $\mathcal{S}(\mathcal{T})$ is in fact spatial. Stone duality then affords us passage to our first space, the smashing spectrum $\text{Spc}^s(\mathcal{T})$, together with the expected functoriality and a natural smashing support $\text{Supp}^s$. This space refines $\text{Spc}^c$, where $\mathcal{T}^c$ denotes the subcategory of compact objects, as in the following theorem which summarizes some highlights from Sections 3 and 5.

**Theorem.** The space $\text{Spc}^s(\mathcal{T})$ has points given by prime smashing ideals. It is quasi-compact with a basis of quasi-compact open subsets and is equipped with a surjective quasi-compact map

$$\psi: \text{Spc}^s(\mathcal{T}) \to (\text{Spc}^c)''$$

defined by $\psi(S) = S \cap \mathcal{T}^c$ where $(\text{Spc}^c)''$ is the Hochster dual of $\text{Spc}^c$. This map is compatible with supports in the sense that $\psi^{-1}\text{Supp}^s t = \text{Supp}^s t$ for every $t \in \mathcal{T}^c$. Moreover, $\psi$ is a homeomorphism if and only if the telescope conjecture holds for tensor ideals.

One benefit of the smashing support is that it is inherently defined for arbitrary objects of $\mathcal{T}$, with no topological assumptions on the smashing spectrum. Alas, this inherent support is analogous to taking supports of cohomology and so is not well adapted to studying general objects. To address this we introduce in Section 3.3 an analogue of the small support of Foxby [Fox79] (along the lines of the support theory of Balmer and Favi [BF11]). This support has good properties when every point of the smashing spectrum is locally closed, which is emerging as a key condition in the current approach to big tt-geometry, and we make a preliminary analysis.

Our second and even more tantalizing proposal is to move away entirely from bootstrapping from compact objects and attempt to grapple directly with the whole collection of localizing ideals. This approach has the potential to produce, in full generality, a space analogous to $\text{Spc}^c$ which always classifies radical localizing ideals.

However, one runs into immediate difficulties: the upper bound of a chain of proper localizing subcategories need not be proper, so our friend Zorn forsakes us, and we no longer know we are working with a set of subcategories. Nonetheless, we can consider prime localizing tensor ideals (see Definition 4.1.1) and the collection $\text{SPC} \mathcal{T}$ of such, which we call the big spectrum. It comes with a notion of support which, in the examples we understand, is sufficiently fine to distinguish big objects and, crucially, is defined without imposing additional topological hypotheses.

While we do not know, in general, that $\text{SPC} \mathcal{T}$ forms a set, we prove in Theorem 5.2.4 the existence of big primes for any big tt-category.
Theorem. Given $p \in \text{Spc} T^c$ there exists a big prime $P$ such that $P \cap T^c = p$.

This proceeds via a rather suggestive connection between homological primes and big primes which warrants further exploration and could be relevant in the hunt for $tt$-residue fields.

We close the paper with two examples demonstrating our offering in action. In Section 6 we return to a familiar friend, the derived category of a commutative noetherian ring. The telescope conjecture holds, so the smashing spectrum reduces to the usual one. We describe the smashing primes and prove that the refined smashing support recovers Foxby’s small support. A complete description of the big spectrum is also given—again it is in natural bijection with points of the corresponding affine scheme and the associated support theory (which we emphasize again is defined without topological restriction) recovers the small support.

In the final section we examine a case where the telescope conjecture fails. We see concretely that the smashing spectrum is a finer invariant than the homological and Balmer spectra, and that the refined smashing support detects more than its counterpart valued in the spectrum of the compacts.

2. Preliminaries

Hypotheses. Throughout $(\mathcal{T}, \otimes, 1)$ will denote a rigidly-compactly generated tensor-triangulated category. In particular, $\mathcal{T}$ admits all small coproducts, the compact and rigid objects coincide, and they moreover form an essentially small subcategory $\mathcal{T}^c$ which generates $\mathcal{T}$ as a localizing category. We will refer to such a $\mathcal{T}$ as a big tt-category.

Warning. Throughout we shall denote by $\text{Supp}(\cdot)$, with appropriate decoration, the ‘native’ support theory associated to some space, e.g. Balmer’s support of compact objects or the (big) smashing support of Definition 3.2.11. We reserve the notation $\text{supp}(\cdot)$, and its variants, for the refinement of this support in terms of certain idempotent objects, and call it the small support. This reflects the originals in this genre, namely the sheaf theoretic support and the small support of Foxby for bounded complexes of flat modules [Fox79].

The warning is that this differs from what can be found in, for example, the work of Balmer–Favi [BF11] where the opposite convention is used.

Let us briefly recapitulate the two current topological invariants that we have available to us when working with a big tt-category, namely the Balmer and homological spectra.

2.1. The Balmer spectrum. Associated to any big tt-category $\mathcal{T}$ we have the Balmer spectrum $\text{Spc}(\mathcal{T}^c)$ which is the set of prime thick tensor ideals of $\mathcal{T}^c$ (i.e. thick subcategories closed under tensoring and such that if $a \otimes b \in P$ then $a \in P$ or $b \in P$) [Bal05]. For $x \in \mathcal{T}^c$ the support of $x$ is

$$\text{Supp}(x) = \{P \in \text{Spc}(\mathcal{T}^c) \mid x \notin P\},$$

and we take these as a basis of closed subsets for $\text{Spc}(\mathcal{T}^c)$. A key point is that the Balmer spectrum is in fact a spectral space, that is sober and with a basis of quasi-compact opens closed under finite intersection. Under certain technical hypotheses one can extend the support to a theory valid for all objects of $\mathcal{T}$, which we call the small support and denote by $\text{supp}$. We refer the reader to [BF11] for details.

More relevant to the material in the present paper will be the lattice-theoretic point of view (for a refresher on terminology we refer to [Joh82]). Denote by $\mathcal{T}(\mathcal{T}^c)$ the lattice of thick tensor ideals of $\mathcal{T}^c$. This lattice is a frame, which is moreover coherent [KPT17]
Theorem 3.1.9] and so, a fortiori it is spatial, i.e. isomorphic to the lattice of open subsets of some space.

Stone duality then gives rise to a spectral space $\text{Spec}(\mathcal{T}(\mathcal{T}^c))$ whose points are the meet-prime elements of $\mathcal{T}(\mathcal{T}^c)$ and whose lattice of opens is isomorphic to $\mathcal{T}(\mathcal{T}^c)$. The primes here coincide with those introduced by Balmer: there is a canonical bijection $\text{Spec}(\mathcal{T}(\mathcal{T}^c)) \cong \text{Spec}(\mathcal{T}^c)$. To relate the topologies, one first takes the Hochster dual of $\text{Spec}(\mathcal{T}(\mathcal{T}^c))$, denoted $\text{Spec}(\mathcal{T}(\mathcal{T}^c))^\vee$, whose open subsets are generated by the closed subsets of $\text{Spec}(\mathcal{T}(\mathcal{T}^c))$ with quasi-compact open complements (see for example [DST19]). By [KP17 Corollary 3.4.2] there is then a homeomorphism $\text{Spec}(\mathcal{T}(\mathcal{T}^c))^\vee \cong \text{Spc}(\mathcal{T}^c)$.

2.2. The homological spectrum. We denote by $\text{Mod} \mathcal{T}^c$ the category of additive functors $(\mathcal{T}^c)^{\text{op}} \rightarrow \text{Ab}$. This is a Grothendieck category and is equipped, via Day convolution, with a closed symmetric monoidal structure. We denote by $\text{mod} \mathcal{T}^c$ the (abelian) subcategory of finitely presented objects. We have the usual Yoneda embedding \( \mathcal{T}^c \hookrightarrow \text{mod} \mathcal{T}^c \) which can be extended to the restricted Yoneda functor \( \mathcal{T}^c \rightarrow \text{Mod} \mathcal{T}^c \) by mapping \( x \in \mathcal{T}^c \) to \( \hat{x} \) via

\[
\hat{x} : (\mathcal{T}^c)^{\text{op}} \rightarrow \text{Ab} \quad \hat{x}(-) = \text{Hom}_{\mathcal{T}}(-, x).
\]

This restricted Yoneda is a conservative, (co)product preserving, and monoidal homological functor which fits into a commutative diagram

\[
\begin{array}{ccc}
\mathcal{T}^c & \xrightarrow{h} & \text{mod} \mathcal{T}^c \\
\downarrow \hspace{1cm} \downarrow & & \downarrow \\
\mathcal{T} & \xrightarrow{h} & \text{Mod} \mathcal{T}^c.
\end{array}
\]

We refer the reader to the appendix of [BKS20] and to [BKS19] for more details on this construction and the module category in general.

A homological prime for $\mathcal{T}^c$ is defined to be a maximal proper Serre $\otimes$-ideal $\mathcal{B} \subset \text{mod} \mathcal{T}^c$. The homological residue field, $h_{\mathcal{B}}$, corresponding to a homological prime $\mathcal{B}$ is constructed via the composite

\[
h_{\mathcal{B}} = Q_{\mathcal{B}} \circ h : \quad \mathcal{T} \xrightarrow{h} \text{Mod} \mathcal{T}^c \xrightarrow{Q_{\mathcal{B}}} \text{Mod} \mathcal{T}^c \xrightarrow{\mathcal{B}^-} .
\]

Here, $h : \mathcal{T} \rightarrow \text{Mod} \mathcal{T}^c$ is the restricted Yoneda as defined above, $\mathcal{B}^-$ is the localizing subcategory in $\text{Mod} \mathcal{T}^c$ generated by $\mathcal{B}$, and the quotient is the usual Gabriel quotient.

By assumption $\mathcal{T}^c$ is essentially small. Hence $\text{mod} \mathcal{T}^c$ is also essentially small and so admits only a set of Serre subcategories. In particular, there is only a set of homological primes which we denote by $\text{Spc}^h(\mathcal{T}^c)$:

\[
\text{Spc}^h(\mathcal{T}^c) = \{ \mathcal{B} \subset \text{mod} \mathcal{T}^c \mid \mathcal{B} \text{ is a homological prime} \}.
\]

We equip this set with the topology generated by the closed subsets $\text{Supp}^h(x)$ for all $x \in \mathcal{T}^c$:

\[
\text{Supp}^h(x) := \{ \mathcal{B} \in \text{Spc}^h(\mathcal{T}^c) \mid \hat{x} \notin \mathcal{B} \} = \left\{ \mathcal{B} \in \text{Spc}^h(\mathcal{T}^c) \mid \exists \mathcal{B} \neq 0 \text{ in } \text{Mod} \mathcal{T}^c \right\}.
\]

We call $\text{Spc}^h(\mathcal{T}^c)$ along with this topology the homological spectrum.

For every $\mathcal{B} \in \text{Spc}^h(\mathcal{T}^c)$ its preimage in $\mathcal{T}^c$ under the Yoneda embedding

\[
\phi(\mathcal{B}) = h^{-1}(\mathcal{B}) \cap \mathcal{T}^c = \{ x \in \mathcal{T}^c \mid \hat{x} \in \mathcal{B} \}
\]
is a Balmer prime ideal in $\mathbb{T}^c$. As such, there is a surjective (and continuous) map $\phi : \text{Spc}^b(\mathbb{T}^c) \to \text{Spc}(\mathbb{T}^c)$ [Bal20a, 3.1]. This can also be seen by using the fact that the Balmer support of the compact objects is the terminal support theory [Bal05, Theorem 3.2].

A lattice theoretic interpretation of the homological spectrum does not appear in the literature, and it is unclear if such a perspective can exist. Indeed, it is not even known if the homological spectral is $T_0$ in general (if it is $T_0$, then it will be homeomorphic to $\text{Spc}(\mathbb{T}^c)$ via the comparison map $\phi$ [BHS21a]).

3. The smashing spectrum

Throughout this section we will make extensive use of the yoga of smashing ideals and their associated idempotents. We refer to [BF11] for the core techniques and to [BKS20] for preliminaries on right (and dually left) idempotents in a symmetric monoidal category.

Let $\mathbb{T}$ be a big tt-category. We denote by $S(\mathbb{T})$ the collection of smashing tensor ideals. This collection forms a set (this was originally proved by Krause [Kra00]) and is naturally ordered by inclusion. It is a complete lattice where finite meets are given by intersection and joins are given, as usual for such lattices, by taking the localizing subcategory generated by the union (see [BKS20, Remark 5.12] and Lemma 3.2.4 below). It was shown in [BKS20] that $S(\mathbb{T})$ is not only a complete lattice but a frame i.e. finite meets distribute over arbitrary joins.

Reminder 3.1.1. We remind ourselves of the following diagram of isomorphisms from [BKS20, Remark 4.9]

$$
\begin{align*}
\{\text{smashing } \otimes \text{-ideals}\} & \xrightarrow{h^{-1}(\mathcal{B}) \leftrightarrow \mathcal{B}} \{\text{localiz. } \otimes \text{-ideals } \mathcal{B} \subseteq \text{Mod } \mathbb{T}^c \text{ s.t. } \mathcal{B} = (\mathcal{B}^{fp})^- \text{ and s.t. } \mathcal{J} = \{f \in \mathbb{T}^c \mid \text{im}(f) \in \mathcal{B}\} \text{ equals } \mathcal{J}^2\} \\
\{\text{right-idempotents } 1 \to F \text{ in } \mathbb{T}\} & \xrightarrow{h} \{\text{flat right-idempotents } 1 \to F \text{ in } \text{Mod } \mathbb{T}^c\} \\
{\mathcal{B}^{fp}} & \xrightarrow{\text{maps from char } \mathcal{B}} \{\text{flat right-idempotents } 1 \to F \text{ in } \text{Mod } \mathbb{T}^c\}
\end{align*}
$$

Here $\mathcal{B}^{fp}$ denotes the full subcategory of finitely presented objects of $\mathcal{B}$ and $\mathcal{B} = (\mathcal{B}^{fp})^-$ denotes its completion under colimits in $\text{Mod } \mathbb{T}^c$, i.e. the smallest localizing subcategory containing $\mathcal{B}^{fp}$.

These isomorphisms all respect the orderings and so are lattice isomorphisms. As such we will regularly abuse notation and identify idempotents with their image in the module category. For a right idempotent $F$ we set $\text{Ker}(h(F) \otimes -) = \mathcal{B}_F$ as in the righthand vertical map above.

3.2. The frame $S(\mathbb{T})$ is spatial. Let $\mathbb{T}$ be a big tt-category. In this section we show the frame $S(\mathbb{T})$ of smashing ideals is always spatial. This allows us, via Stone duality, to pass to a space—the smashing spectrum—without any loss of information. We will then go on to make a preliminary analysis of this space and associated notions of support, both big and small, as well as discussing the finitely presented objects in $S(\mathbb{T})$ with a view toward coherence.

We start with a few preliminary facts about smashing ideals.

Lemma 3.2.1. Let $\{S_i \mid i \in I\}$ be a chain of smashing ideals with corresponding left idempotents $\{E_i \mid i \in I\}$. Then the flat left idempotent in $\text{Mod } \mathbb{T}^c$ corresponding to
\( S = \bigvee_i S_i \) is \( E = \operatorname{colim}_i E_i \). Similarly, if \( F_i \) are the corresponding right idempotents for the \( S_i \) then \( \operatorname{colim}_i F_i \) is the right idempotent for \( S \).

**Proof.** Let us start by making sense of the claimed colimit. If \( i < j \) in \( I \) then \( S_i \subseteq S_j \) and so \( E_i \otimes E_j \cong E_i \). The structure maps for the colimit are then given by tensoring \( \varepsilon_i : E_i \to 1 \) with \( E_j \) and using the above isomorphism to obtain a map \( E_i \to E_j \).

As filtered colimits in \( \text{Mod} T^e \) are exact, and the tensor product commutes with colimits, the colimit \( E \) is still flat. The universal property of the colimit determines a morphism \( \varepsilon : E \to 1 \) and one verifies readily that \( E \) is a left idempotent.

Since \( E \otimes E_i \cong E_i \) we see that \( \operatorname{im}(E \otimes -) \) contains each \( S_i \) and hence contains \( S \). On the other hand, if \( E' \) is the left idempotent corresponding to the join \( S \) then \( E' \otimes E_i \cong E_i \) and the colimit formula yields \( E' \otimes E \cong E \). It follows that \( \operatorname{im}(E \otimes -) \subseteq S \) and so \( E \cong E' \).

One can prove the statement for right idempotents similarly (see also Remark 3.2.2).

**Remark 3.2.2.** Since \( I \) is linearly ordered any tensor product \( F_i \otimes \ldots \otimes F_{i_r} \) with \( i_r \in I \) is isomorphic to \( F_j \) where \( j = \max\{i_1, \ldots, i_r\} \). By [BKS20, Proposition 5.2] we can write \( F = \operatorname{colim}_j F_j \) where \( J \) runs over the finite subsets of \( I \) and \( F_j = \otimes_{i \in J} F_i \). It follows that, by collapsing the indexing set to a final subset to eliminate redundancy, we can write \( F = \operatorname{colim}_i F_i \).

**Lemma 3.2.3.** Let \( \{M_i \mid i \in I\} \) be a chain of Serre subcategories of \( \text{mod} T^e \). Then

\[
\operatorname{serre}(\bigvee_i M_i) = \bigvee_i M_i
\]

i.e. the union is already a Serre subcategory. In particular, if

\[
M \in \bigvee_i M_i = \operatorname{serre}(\bigvee_i M_i)
\]

then there is a \( j \in I \) such that \( M \in M_j \).

**Proof.** Let \( M' \to M \to M'' \) be a short exact sequence in \( \text{mod} T^e \). Suppose that \( M' \) and \( M'' \) lie in \( M = \bigvee_i M_i \). We can pick a sufficiently large \( j \) such that \( M' \) and \( M'' \) lie in \( M_j \). Then, since \( M_j \) is Serre, we have \( M_j \subseteq M \). As \( M_j \) is contained in \( M \) we thus see \( M \in M_j \). A similar argument shows that if \( M \in M_j \) then \( M' \) and \( M'' \) are in \( M \) and so it is a Serre subcategory as claimed.

**Lemma 3.2.4.** Let \( \{S_i \mid i \in I\} \) be a set of smashing ideals with corresponding right idempotents \( \{F_i \mid i \in I\} \) and join \( S \) with right idempotent \( F \). Then \( B_F \) is the smallest localizing Serre subcategory containing \( \bigvee_i B_{F_i} \).

**Proof.** Let us denote by \( \mathcal{M} \) the localizing Serre subcategory generated by the \( B_{F_i} \). It is evident that \( \mathcal{M} \subseteq B_F \).

Any localizing Serre subcategory of \( \text{Mod} T^e \) is determined by the class of injective objects in its right perpendicular category. Thus it is sufficient to show these classes for \( \mathcal{M} \) and \( B_F \), which we denote by \( I_{\mathcal{M}} \) and \( I_{B_F} \) respectively, agree. Observe that

\[
I_{\mathcal{M}} = \bigcap_i I_{B_{F_i}} \quad \text{and} \quad I_{B_F} \subseteq I_{\mathcal{M}}
\]

the former by construction and the latter since \( \mathcal{M} \subseteq B_F \).

Suppose that \( J \in I_{\mathcal{M}} \). Then, using the description of \( F \) as a colimit from [BKS20, Proposition 5.2], we see \( J \otimes F \cong J \) since \( J \) is flat and \( J \otimes E_i \cong 0 \) for each of the left idempotents \( E_i \) corresponding to the \( S_i \). It follows, again by flatness of \( J \), that \( E \otimes J \cong 0 \) where \( E \) is the left idempotent for \( S \). This implies that \( J \in I_{B_F} \) and so \( I_{B_F} = I_{\mathcal{M}} \) as desired.
Lemma 3.2.5. Let \{S_i \mid i \in I\} be a chain of smashing ideals with corresponding right idempotents \{F_i \mid i \in I\} and join \(S\) with right idempotent \(F\). If \(M \in \text{mod } T^c\) satisfies \(M \otimes F \cong 0\) then there is an \(i \in I\) such that \(M \otimes F_i \cong 0\).

Proof. By Lemma 3.2.4, the localizing Serre ideal \(B_F\) of \(\text{Mod } T^c\) is generated by \(\cup_i B_{F_i}\).

The top-left of Reminder 3.1.4 reminds us that each \(B_{F_i}\) is generated by its subcategory of finitely presented objects \(B_{F_i}^{fp}\). In particular \(B_F\) is generated by \(\cup_i B_{F_i}^{fp}\). We now use that \(I\) is a chain: Lemma 3.2.3 tells us that this union is already a Serre subcategory and so must be \(B_{F_i}^{fp}\) (which in turn determines \(B_F\) by closing under filtered colimits).

Thus, if \(M \in B_{F_i}^{fp}\) then there is an \(i \in I\) such that \(M \in B_{F_i}^{fp}\), i.e. \(F_i \otimes M \cong 0\). \(\square\)

Lemma 3.2.6. Let \(S\) be a smashing ideal with right idempotent \(F\) and \(M \in \text{mod } T^c\) a finitely presented module such that \(M \notin B_F\). Then there is a (maximal) meet-prime smashing ideal \(P\) with right idempotent \(H\) such that \(S \subseteq P\) and \(M \notin B_H\).

Proof. Consider the set \(Z\) of smashing ideals \(R\) of \(T\) such that \(S \subseteq R\) and \(M \notin B_G\) where \(G\) is the right idempotent corresponding to \(R\). This set is not empty as it contains \(S\). Our aim, of course, is to show that any chain in \(Z\) has an upper bound and thus produce a meet-prime via Zorn’s lemma.

So, let \{\(R_i \mid i \in I\}\} be a chain of smashing ideals with corresponding right idempotents \{\(G_i \mid i \in I\}\} and join \(R\) with right idempotent \(G\). We suppose that the \(R_i\) all lie in \(Z\) and will show that \(R \in Z\). It is clear that \(S \subseteq R\). If \(M \in B_G\) then, by Lemma 3.2.6, \(M \in B_{G_i}\) for some \(i\) which is exactly what we have prohibited and so \(M \notin B_G\). Hence \(R \in Z\) showing that every chain in \(Z\) has an upper bound. By Zorn’s Lemma \(Z\) contains a maximal element \(P\).

We now show that \(P\) is meet-prime. Suppose that \(S_1\) and \(S_2\) are smashing ideals such that \(S_1 \wedge S_2 \subseteq P\). The lattice of smashing ideals is distributive (even a frame by [BKS20]) so we compute that

\[ P = P \lor (S_1 \wedge S_2) = (P \lor S_1) \wedge (P \lor S_2). \]

Now \(P \lor S_i\) certainly contains \(S\) for \(i = 1, 2\), so if \(P \subseteq P \lor S_i\) then we must have \(M \in B_{F_i}\), where \(F_i\) is the right idempotent for \(P \lor S_i\), by maximality of \(P\) in \(Z\). Thus if neither \(S_1\) nor \(S_2\) is contained in \(P\) we have

\[ M \in B_{F_1} \cap B_{F_2} = B_{F_1} \wedge B_{F_2} = B_{F_1 \wedge F_2} = B_H \]

which is a contradiction (recall that \(H\) is the right idempotent for \(P\)). Hence at least one of the \(S_i\) is contained in \(P\) showing that \(P\) is meet-prime. \(\square\)

Remark 3.2.7. Since it will be useful for producing meet-prime smashing ideals with certain properties let us mention a slight variant of the lemma. Let \(S\) be a smashing ideal with right idempotent \(F\) and \(M \subseteq \text{mod } T^c\) a set of finitely presented modules such that \(M \otimes M \subseteq M\) and \(M \cap B_F = \emptyset\).

Then there is a (maximal) meet-prime smashing ideal \(P\) with right idempotent \(H\) such that \(S \subseteq P\) and \(M \cap B_H = \emptyset\).

The invocation of a maximal smashing ideal \(P\) containing \(S\) and not meeting \(M\) proceeds in an identical fashion to the above. One only runs into a problem when considering the \(P \lor S_i\) to show \(P\) is meet-prime. One notes, as above, that this ideal contains \(S\) for \(i = 1, 2\), but if \(P \subseteq P \lor S_i\) for \(i = 1, 2\) then we only see that there exist \(M_1, M_2 \in M\) with \(M_i \in B_{F_i}\). We are rescued by the assumption that \(M\) is tensor multiplicative so \(M = M_1 \otimes M_2 \in M\) lies in \(B_{F_1} \cap B_{F_2}\) and we reach the desired contradiction since \(M \notin P\).

This version is more awkward in some situations as one needs to make sure \(0 \notin M\) which can already fail to be obvious even if one works with \(M = \{M^{\otimes i} \mid i \geq 1\}\), i.e. only cares about a single object.
Theorem 3.2.8. The frame $\mathcal{S}(\mathcal{T})$ of smashing tensor ideals of $\mathcal{T}$ is spatial.

Proof. Suppose that $\mathcal{S}_1 \not\subseteq \mathcal{S}_2$ are smashing ideals. Then $\mathcal{B}_{F_1} \not\subseteq \mathcal{B}_{F_2}$ where $F_i$ are the associated right idempotents. Since the $\mathcal{B}_{F_i}$ are determined by their finitely presented objects there is an $M \in \mathcal{B}_{F_1}^P$ such that $M \notin \mathcal{B}_{F_2}^P$. By Lemma 3.2.6 there is a meet-prime $\mathcal{P}$, with right idempotent $H$, such that $\mathcal{S}_2 \subseteq \mathcal{P}$ and $M \notin \mathcal{B}_H$. This shows $\mathcal{B}_{F_1} \not\subseteq \mathcal{B}_H$ and so $\mathcal{S}_1 \not\subseteq \mathcal{P}$. The point $p: \mathcal{S}(\mathcal{T}) \to \{0,1\}$ corresponding to $\mathcal{P}$ thus satisfies $p(\mathcal{S}_1) = 1$ and $p(\mathcal{S}_2) = 0$ which shows $\mathcal{S}(\mathcal{T})$ is spatial. □

Remark 3.2.9. Rose Wagstaffe, in her thesis [Wag21], gives an independent proof that the frame of smashing ideals is spatial using model theoretic techniques. In fact these techniques provide an alternative, and elegant, proof of the fact that $\mathcal{S}(\mathcal{T})$ is a frame.

Definition 3.2.10. It follows from Theorem 3.2.8 that there is a Sober space $\text{Spc}^s(\mathcal{T})$, the **smashing spectrum** of $\mathcal{T}$, which is dual to $\mathcal{S}(\mathcal{T})$ via Stone duality.

The points of $\text{Spc}^s(\mathcal{T})$ are in bijection with meet-prime smashing ideals of $\mathcal{T}$ and the lattice of open subsets of $\text{Spc}^s(\mathcal{T})$ is isomorphic to $\mathcal{S}(\mathcal{T})$. We will silently make these identifications when convenient. Given a smashing subcategory $\mathcal{S}$ we denote by $U_{\mathcal{S}}$ the corresponding open subset of $\text{Spc}^s(\mathcal{T})$ and its closed complement by $V_{\mathcal{S}}$.

Going through the usual motions we arrive at our first new notion of support.

Definition 3.2.11. The **smashing support** of an object $X \in \mathcal{T}$ is

$$\text{Supp}^s X = \{ \mathcal{P} \in \text{Spc}^s(\mathcal{T}) \mid X \notin \mathcal{P} \}.$$ 

Remark 3.2.12. Let $x \in \mathcal{T}^c$ be a compact object. Then $\mathcal{S} = \text{loc}^\otimes(x)$ is a smashing ideal. The corresponding open subset of $\text{Spc}^s(\mathcal{T})$ is

$$U_{\mathcal{S}} = \{ \mathcal{P} \in \text{Spc}^s(\mathcal{T}) \mid \mathcal{S} \not\subseteq \mathcal{P} \} = \{ \mathcal{P} \in \text{Spc}^s(\mathcal{T}) \mid x \notin \mathcal{P} \}.$$ 

Thus it is natural to define the support of $x$ to be this open subset. Definition 3.2.11 is motivated by extending this observation to arbitrary objects.

Warning 3.2.13. In the case of the Balmer spectrum, the topology is generated by the supports of compact objects. This is not necessarily the case for the smashing spectrum. We expect trouble when the telescope conjecture fails for $\mathcal{T}$, and we find it; we refer the reader to Remark 7.2.1 for an explicit example.

Remark 3.2.14. Denoting by $\mathcal{P}_x$ the right idempotent associated to a meet-prime smashing ideal $\mathcal{P}$ we have

$$\text{Supp}^s X = \{ \mathcal{P} \in \text{Spc}^s(\mathcal{T}) \mid X \otimes \mathcal{P} \neq 0 \}.$$ 

Lemma 3.2.15. The smashing support satisfies the following properties:

1. $\text{Supp}^s(0) = \emptyset$ and $\text{Supp}^s(1) = \text{Spc}^s(\mathcal{T})$;
2. $\text{Supp}^s \bigsqcup X_i = \bigcup_i \text{Supp}^s X_i$;
3. $\text{Supp}^s \Sigma X = \text{Supp}^s X$;
4. for any triangle $X \to Y \to Z$ we have $\text{Supp}^s Y \subseteq \text{Supp}^s X \cup \text{Supp}^s Z$;
5. $\text{Supp}^s X \otimes Y \subseteq \text{Supp}^s X \cap \text{Supp}^s Y$;
6. if $x,y \in \mathcal{T}^c$ then $\text{Supp}^s x \otimes y = \text{Supp}^s x \cap \text{Supp}^s y$.

Proof. Properties (1)-(4) follow in a straightforward way from the fact that prime smashing ideals are localizing subcategories. Property (5) is an immediate consequence of the fact that they are ideals.

For (6) we need to show the reverse inclusion of (5). Since $x$ and $y$ are compact they generate smashing ideals $S_x = \text{loc}^\otimes(x)$ and $S_y = \text{loc}^\otimes(y)$. If $\mathcal{P} \in \text{Supp}^s x \cap \text{Supp}^s y$, i.e.
We define the Rickard idempotent at $x \notin \mathcal{P}$ and $y \notin \mathcal{P}$ then $\mathcal{S}_x \not\subseteq \mathcal{P}$ and $\mathcal{S}_y \not\subseteq \mathcal{P}$. As $\mathcal{P}$ is meet-prime it follows that $\mathcal{S}_x \cap \mathcal{S}_y \not\subseteq \mathcal{P}$, and the claim then follows from Lemma 3.2.16 which tells us that $\mathcal{S}_x \cap \mathcal{S}_y = \mathcal{S}_{x \otimes y}$ so $x \otimes y \not\notin \mathcal{P}$.

**Lemma 3.2.16.** If $\mathcal{S}$ and $\mathcal{R}$ are smashing ideals then $\mathcal{S} \cap \mathcal{R} = \mathcal{S} \otimes \mathcal{R}$. Moreover, if $\mathcal{S} = \text{loc}(\mathcal{S}^c)$ and $\mathcal{R} = \text{loc}(\mathcal{R}^c)$ then $\mathcal{S} \cap \mathcal{R} = \text{loc}(\mathcal{S}^c \cap \mathcal{R}^c) = \text{loc}(\mathcal{S}^c \otimes \mathcal{R}^c)$.

**Proof.** Let $E_\mathcal{S}$ and $E_\mathcal{R}$ denote the corresponding left idempotents, so that $\mathcal{S} = \text{loc}\langle E_\mathcal{S} \rangle$ and similarly for $\mathcal{R}$. Then, by [Ste13] Lemma 3.12 we have

$$\mathcal{S} \otimes \mathcal{R} = \text{loc}\langle E_\mathcal{S} \otimes E_\mathcal{R} \rangle$$

and the latter is equal to $\mathcal{S} \cap \mathcal{R}$.

For the second statement suppose that $\mathcal{S}$ and $\mathcal{R}$ are generated by compact objects. Then, again using [Ste13] Lemma 3.12, we have

$$\mathcal{S} \cap \mathcal{R} = \mathcal{S} \otimes \mathcal{R} = \text{loc}\langle \mathcal{S}^c \rangle \otimes \text{loc}\langle \mathcal{R}^c \rangle = \text{loc}\langle \mathcal{S}^c \otimes \mathcal{R}^c \rangle.$$

**Remark 3.2.17.** Recall that we are assuming that $\mathcal{T}^c$ is rigid and so $\mathcal{S}^c \otimes \mathcal{R}^c = \mathcal{S}^c \cap \mathcal{R}^c$.

3.3. **Small smashing support.** The notion of support defined in the previous section, while natural from the point of pointless topology, is not refined enough for effectively dealing with non-compact objects (cf. Lemma 3.3.1). Since the dream is, at least in some examples (but unfortunately not all, cf. Remark 3.1.7), to capture general localizing phenomena we need an analogue of the small support of Foxby [Fox79] (as extended in the work of several others, [BF11] being most relevant to us here).

We will end up using a similar approach to that of [BF11]. Given a smashing ideal $\mathcal{S}$ let us denote by $E_\mathcal{S}$ and $F_\mathcal{S}$ the associated left and right idempotents. For $X \in \mathcal{T}$ considering $X \otimes F_p$ cuts us down to $\mathcal{T}/\mathcal{P}$ i.e. to considering the smashing ideals in the interval $[\mathcal{P}, \mathcal{T}]$. The primes in this interval give the closure $V(\mathcal{P})$ of $\mathcal{P}$ in $\text{Spc}^c(\mathcal{T})$. The problem is that simply looking here won’t detect if $X$ really lives ‘further down’ because if $\mathcal{P} \subseteq Q$ and $X \otimes F_Q \neq 0$ then necessarily this is the case for $X \otimes F_P$. In other words, perhaps $P \in \text{Supp}^a X$ is an artifact of $Q \in \text{Supp}^a X$ and not immanent.

We thus want to ensure that for $\mathcal{P}$ to be in the support of $X$ that $X$ is ‘essential’ in $\mathcal{T}/\mathcal{P}$, i.e. it doesn’t come from a further localization. As in other versions of big tt-geometry we need hypotheses on the spectrum to get our way.

**Remark 3.3.1.** We do not know, in general, if $\mathcal{S}(\mathcal{T})$ is a coherent frame (but see Section 3.3 for some partial results) and so it isn’t clear we can take its Hochster dual to work with Thomason subsets as is traditional e.g. for $\text{Spc}^{c}(\mathcal{T})$. As such we will be interested in open subsets as opposed to the Thomason subsets which are used in [BF11].

**Definition 3.3.2.** Suppose that $\mathcal{P}$, viewed as a point of $\text{Spc}^c(\mathcal{T})$, is locally closed, i.e. there is some open subset $U_\mathcal{S}$ (recall every open has this form), such that $\{\mathcal{P}\} = U_\mathcal{S} \cap V_\mathcal{P}$. We define the Rickard idempotent at $\mathcal{P}$ by

$$\Gamma_\mathcal{P} = E_\mathcal{S} \otimes F_p.$$

**Remark 3.3.3.** The object $\Gamma_\mathcal{P}$ is not zero and we will prove it. Write $\{\mathcal{P}\} = U_\mathcal{S} \cap V_\mathcal{P}$ so $\Gamma_\mathcal{P} = E_\mathcal{S} \otimes F_p$. This is zero if and only if $E_\mathcal{S} \in \mathcal{P}$ which is equivalent to $\mathcal{S} \subseteq \mathcal{P}$. This would mean the point corresponding to $\mathcal{P}$ sent $\mathcal{S}$ to 0 i.e. $\mathcal{P} \notin U_\mathcal{S}$ which is nonsense.

**Definition 3.3.4.** A space $A$ is $T_D$ if every point of $A$ is locally closed.
Definition 3.3.5. Suppose that $\text{Spc}^\circ(T)$ is $T_D$. Then the small smashing support of an object $X \in T$ is
\[
\text{supp}^s X = \{ P \in \text{Spc}^\circ(T) \mid \Gamma_P \otimes X \neq 0 \}.
\]

Remark 3.3.6. It is clear from the definition that the analogues of Lemma 3.2.1 (1)-(5) hold for the small smashing support.

The notion of support we get doesn’t depend on any choices we made regarding the $\Gamma_P$.

Lemma 3.3.7. Let $A, B, C$ and $D$ be smashing smashing ideals. If
\[
U_A \cap V_B = U_C \cap V_D \text{ then } E_A \otimes F_B \cong E_C \otimes F_D.
\]

Proof. We can split the proof into steps by first varying the open set and then varying the closed set. The proof of [BF11, Lemma 7.4] mutatis mutandis applies to show these statements (their proof refers to two other results in their paper, but one is a general statement about idempotents and the other is baked into our setting so there is no problem).

Moreover, if $P$ is locally closed so one can isolate $\{ P \}$ via a closed and open subset then we can always assume that the closed subset involved is $V_P$, so our definition of $\Gamma_P$ using $F_P$ is not restrictive.

Lemma 3.3.8. Suppose that $S$ and $R$ are smashing smashing ideals such that $U_S \cap V_R = \{ P \}$ i.e. $P$ is locally closed. Then $U_S \cap V_R = \{ P \}$.

Proof. Let $R$ and $S$ be as in the statement. We have $P \in V_R$ and hence the closure of $P$ is contained in $V_R$. The closure of $P$ is precisely $V_P$, so $V_P \subseteq V_R$ and it follows that $U_S \cap V_R = \{ P \}$.

Lemma 3.3.9. Suppose that $\text{Spc}^\circ(T)$ is $T_D$. For any $X \in T$ we have
\[
\text{supp}^s X \subseteq \text{Supp}^s X
\]
with equality if $X$ is compact.

Proof. Suppose that $P \in \text{supp}^s X$. Then necessarily $F_P \otimes X \neq 0$ and so $P \in \text{Supp}^s X$.

Now take $t \in T^c$ and let $P$ be a smashing prime with $t \notin P$ i.e. $F_P \otimes t \neq 0$ in $T/P$. Pick $S$ such that $U_S \cap V_P = \{ P \}$. Because $P$ is smashing $t \otimes F_P$ is compact in $T/P$ and since $P$ is prime any two non-zero smashing ideals of $T/P$ have non-zero intersection. The final preparatory observation we need is that the left idempotent for $S_P$ in $T/P$ is $E_S \otimes F_P$. With this in mind we consider, in $T/P$,
\[
\text{loc}^\otimes(t \otimes F_P) \cap \frac{S \vee P}{P} = \text{loc}^\otimes(E_S \otimes F_P \otimes t)
\]
and see that it is zero if and only if $E_S \otimes F_P \otimes t$ is zero. We have assumed $t \otimes F_P \neq 0$ and $S_P \neq 0$ (since $S \nsubseteq P$) so this intersection cannot vanish. Hence $P \in \text{supp}^s t$ as desired.

Remark 3.3.10. The topological condition is a familiar one, but in disguise. Indeed, (remembering that we are in the Hochster dual setting) a spectral space $A$ has the property that each of its points can be written as the intersection of a Thomason subset and the complement of a Thomason subset if and only if the Hochster dual $A^\vee$ is $T_D$.

Note that it is possible to isolate the property of being $T_D$ using a more lattice theoretic formalism as we now describe. For a lattice $L$, we say that an element $b$ immediately precedes $a$ if $b < a$ and if $b < c \leq a$ then we necessarily have $c = a$. A slicing filter of a lattice $L$ is a prime filter $F$ such that there exist $a, b$ with $b \notin F \ni a$, and $b$ immediately
preceding $a$ in $L$. One can then show, as in [PP12], that a $T_0$-space is $T_D$ if and only if each $N(x) = \{ U \in \mathcal{O}(X) \mid x \in U \}$ is a slicing filter.

**Remark 3.3.11.** Bazzoni and Štovíček have computed the frame $\mathcal{S}(D(R))$ for $R$ a valuation domain [BS17 Theorem 5.23]. It is given by certain subchains of the poset of intervals $[i, p]$ in $\text{Spec} \, R$ where $i^2 = i$.

It seems likely that there is enough freedom in this formalism to produce examples where $\text{Spc}^s(D(R))$ is not $T_D$, and so one shouldn’t expect this condition to come for free.

We conclude our musings on supports in the abstract by studying the small supports of left and right idempotents.

**Lemma 3.3.12.** Let $S$ be a smashing ideal with left and right idempotents $E_S$ and $F_S$. If $P \subseteq U_S$ is locally closed then $\Gamma_P \otimes E_S \neq 0$ and $\Gamma_P \otimes F_S = 0$.

**Proof.** Let $R$ be a smashing ideal such that $\{P\} = U_R \cap V_P$. Our interest is in $E_S \otimes \Gamma_P = E_S \otimes E_R \otimes F_P$. The idempotent $E_S \otimes E_R$ corresponds to $S \cap R$ i.e. to the open subset $U_S \cap U_R$. By assumption $P$ lies in both of these opens and so

$$\{P\} = U_R \cap V_P = U_R \cap U_S \cap V_P.$$

By Lemma 3.3.11 we deduce that

$$\Gamma_P = E_R \otimes F_P \cong E_R \otimes E_S \otimes F_P.$$

It follows that $E_S \otimes \Gamma_P$ is non-zero and, in fact, that $\Gamma_P$ lies in $S$ so $\Gamma_P \otimes F_S = 0$. □

**Proposition 3.3.13.** Suppose that $\text{Spc}^s(T)$ is $T_D$. Let $S$ be a smashing ideal of $T$. Then $\text{supp}^s E_S = U_S$ and $\text{supp}^s F_S = V_S$.

**Proof.** Let $S$ be a smashing ideal. By Lemma 3.3.12 we have $U_S \subseteq \text{supp}^s E_S$. If $P \in \text{supp}^s E_S$ then, in particular, $E_S \otimes F_P \neq 0$. Hence $E_S \not\subseteq P$, i.e. $S \not\subseteq P$ and so $P \in U_S$. This proves the claimed equality.

Similarly, we have shown in the last lemma that $\text{supp}^s F_S \subseteq V_S$. If $P \in V_S$ then we have just shown that $E_S \otimes \Gamma_P = 0$. It follows that $F_S \otimes \Gamma_P \cong \Gamma_P$ and so $P \in \text{supp}^s F_S$. □

**Remark 3.3.14.** It follows that if we topologize $\text{Spc}^s(T)$ by generating the open subsets from the small supports of objects of $T$ we get a topology that is finer than the Skula topology whose opens are generated by the open and closed subsets of $\text{Spc}^s(T)$, i.e. by the subsets $U_S$ and $V_S$ for $S \in \mathcal{S}(T)$.

Continuing to assume that $\text{Spc}^s(T)$ is $T_D$, the Skula topology on it is discrete and so the two possibilities discussed above coincide. The message we receive is that if the small support can classify localizing ideals (which can fail, see Remark 5.1.7) then it should be via the powerset of $\text{Spc}^s(T)$ and this would be equivalent to obtaining all localizing ideals by joins and meets of smashing ideals and their right perpendiculars.

### 3.4 Functoriality of the smashing spectrum

We now discuss functoriality of the construction. Suppose that $F \colon T \rightarrow U$ is an exact and coproduct preserving monoidal functor between big tt-categories. That $T$ and $U$ are rigidly-compactly generated and $F$ is monoidal conspire to guarantee that $F$ preserves compact objects.

**Lemma 3.4.1.** If $S$ is a smashing subcategory of $T$ with left idempotent $E$ then $F(E)$ is a left idempotent in $U$ and the associated smashing subcategory of $U$ is $\text{loc}^c(FS)$. The analogous statement holds for right idempotents.
Proof. Applying $F$ to $\varepsilon : E \to 1_T$ and using the inverse of $1_U \sim \to F(1_T)$ gives the structure map for $F(E)$. One checks easily that this makes $F(E)$ into a left idempotent. The associated smashing subcategory is $\text{loc}^\otimes(F(E))$, and it remains to note that if $X \in \text{loc}^\otimes(E)$ then $F(X) \in \text{loc}^\otimes(F(E))$ (e.g. apply [Ste13, Lemma 3.8]). \hfill \square

Proposition 3.4.2. The functor $F$ induces a morphism of frames $f : S(T) \to S(U)$. In particular, there is a continuous map $\text{Spc}^a(U) \to \text{Spc}^a(T)$.

Proof. The induced morphism $f$ is defined by sending $S$ to $\text{loc}^\otimes(FS)$ as in the previous lemma. If $S_i$ for $i = 1, 2$ are smashing subcategories with associated left idempotents $E_i$ then $S_1 \cap S_2$ corresponds to the left idempotent $E_1 \otimes E_2$. Thus, identifying the lattices of smashing ideals and left idempotents, we have

$$f(E_1 \land E_2) = f(E_1 \otimes E_2) = F(E_1) \otimes F(E_2) = F(E_1 \land F(E_2) = f(E_1) \land f(E_2)$$

and so $f$ preserves finite joins.

Thus $f$ is a map of frames. The existence of the continuous map on the associated spectra is automatic. \hfill \square

Remark 3.4.3. If $F : T \to U$ is an exact and coproduct preserving monoidal functor between big $\mathbf{tt}$-categories it is not necessarily true that $F^{-1}$ sends smashing ideals to smashing ideals, and so one cannot describe the induced map on smashing spectra as in the same way as for the Balmer spectrum.

We give a concrete example of this phenomenon.

Example 3.4.4. Consider the derived base change functor $\pi : D(\mathbb{Z}) \to D(\mathbb{F}_p)$ for a prime $p$. Then $0$ is the unique prime smashing ideal of $D(\mathbb{F}_p)$. We have

$$\pi^{-1}(0) = \text{Ker} \pi = \text{loc}(\{\mathbb{Q}\} \cup \{\mathbb{F}_q \mid q \neq p\})$$

which is not smashing (its support is not specialization closed). The induced map

$$\text{Spec} \mathbb{F}_p = \text{Spc}^a(D(\mathbb{F}_p)) \to \text{Spc}^a(D(\mathbb{Z})) = \text{Spec} \mathbb{Z}$$

sends $0$ to $D_{\mathbb{Z}(p)}(\mathbb{Z})$ the smashing prime corresponding to $p$; see Section 6 for further details.
3.5. Finitely presented smashing subcategories. So far we know that \( S(T) \) is a spatial frame and \( \text{Spc}^s(T) \) is Sober. It is natural to ask when \( S(T) \) is a coherent frame, i.e. when \( \text{Spc}^s(T) \) is a spectral space.

We will use some facts from \([Kra05]\). A Serre subcategory \( B \) of \( \text{mod} \ T^c \) is perfect if the right adjoint to the localization functor \( \text{Mod} \ T^c \rightarrow \text{Mod} \ T^c/B \) is exact. This is equivalent to asking that the localization functor preserves projectives, which implies that the quotient is a module category. Krause proves (sans tensor, but adding it causes no issues) that the lattice \( S(T) \) is isomorphic to the lattice of perfect Serre tensor ideals of \( \text{mod} \ T^c \).

**Notation 3.5.1.** Given a set \( \mathcal{X} \) of objects of \( \text{mod} \ T^c \) we denote by \( \langle \mathcal{X} \rangle \) the smallest perfect Serre tensor ideal of \( \text{mod} \ T^c \) containing \( \mathcal{X} \).

**Remark 3.5.2.** It is not a priori clear that such a smallest perfect Serre tensor ideal exists. However, this is the case. One can see this, for instance, by using the bijection of \([Kra05]\) identifying perfect Serre ideals with exact ideals and then observing that it’s clear from the characterization of \([Kra05\text{ Corollary 12.6]}\) that an intersection of exact ideals is exact.

By \([Kra05\text{ Lemma 8.7]}\) the join of a family of perfect Serre ideals is just their join as Serre ideals, i.e. the smallest Serre ideal containing a family of perfect Serre ideals is perfect. We will repeatedly use this fact without further mention.

We begin with a general lemma about Serre ideals.

**Lemma 3.5.3.** Given a set \( \mathcal{X} \) of objects of \( \text{mod} \ T^c \) and \( M \in \text{serre}^\otimes(\mathcal{X}) \) there exist \( N_1, \ldots, N_n \) in \( \mathcal{X} \) such that \( M \in \text{serre}^\otimes(\mathcal{N}_1, \ldots, \mathcal{N}_n) \).

**Proof.** We will construct \( \mathcal{B} = \text{serre}^\otimes(\mathcal{X}) \) inductively. First observe that a Serre subcategory is an ideal if and only if it is closed under tensoring with representable functors: any finitely presented \( L \) is a quotient of some \( t \in T^c \) and the tensor product is right exact so \( L \otimes N \) is a factor of \( t \otimes N \). Thus if we set \( \mathcal{X}' = \{ t \otimes N \mid t \in T^c, N \in \mathcal{X} \} \) we have \( \mathcal{B} = \text{serre}(\mathcal{X}) \) and we reduce to checking the claim without worrying about the tensor product. Indeed, if we find the \( \mathcal{N}_i' \) in \( \mathcal{X}' \) they are of the form \( t_i \otimes N_i \) for \( N_i \in \mathcal{X} \) and so the statement is proved. Let us then consider ourselves to have replaced \( \mathcal{X} \) with \( \mathcal{X}' \).

We set \( \mathcal{B}_0 = \mathcal{X} \) and inductively define \( \mathcal{B}_{r+1} \) to be the class of subobjects, quotients, and extensions of objects of \( \mathcal{B}_r \) (it would be aesthetically more pleasant to add finite sums all at once, but would make life slightly harder). Then \( \cup_i \mathcal{B}_i \subseteq \text{serre}(\mathcal{X}) \) is closed under subobjects, quotients, and extensions and so must be \( \mathcal{B} \).

Now suppose that \( M \in \text{serre}(\mathcal{X}) = \mathcal{B} = \cup_i \mathcal{B}_i \). Then \( M \in \mathcal{B}_r \) for some \( r \geq 0 \). We can now trace backward. By construction there is either \( L_1 \) and \( L_2 \) in \( \mathcal{B}_{r-1} \) giving \( M \) by extension or \( M \) is a subobject or quotient of some \( L \in \mathcal{B}_{r-1} \). We then continue exhibiting reasons for the relevant objects to be in each layer, decreasing the index as we go, and obtain \( N_1, \ldots, N_n \in \mathcal{X} \) such that \( M \in \text{serre}(N_1, \ldots, N_n) \).

\[ \square \]

**Proposition 3.5.4.** A smashing subcategory \( S \), with right idempotent \( F \), is finitely presented in the lattice \( S(T) \) if and only if there is an \( M \in \text{mod} T^c \) such that \( B^\text{fp}_F = \langle M \rangle \).

**Proof.** Let us first suppose that \( S \in S(T) \) is finitely presented. Then

\[
B^\text{fp}_F = \bigcup_{N \in B^\text{fp}_F} \langle N \rangle \quad \text{that is} \quad S = \bigvee_{N \in B^\text{fp}_F} S_N
\]
where $S_N$ is the smashing ideal corresponding to $\langle N \rangle$. Since $S$ is finitely presented there exist $N_1, \ldots, N_r$ such that $S = \vee_{i=1}^r S_{N_i}$. Hence

$$B_{F}^{\text{fp}} = \bigvee_{i=1}^r \langle N \rangle = \langle N_1 \oplus \cdots \oplus N_r \rangle$$

as required.

For the converse let us suppose that $B_{F}^{\text{fp}} = \langle M \rangle$. Then $S \subseteq \vee \lambda S_\lambda$ is equivalent to $\langle M \rangle = B_{F}^{\text{fp}} \subseteq \bigvee \lambda B_{F_\lambda}^{\text{fp}}$. But then $\langle M \rangle$, the smallest perfect Serre ideal containing $M$, must also lie in this join and so $S \subseteq \vee_{i=1}^n S_{\lambda_i}$. □

**Corollary 3.5.5.** The maximal smashing ideal $T$ is finitely presented and every smashing ideal is a join of finitely presented ones.

**Proof.** The first claim is clear from the Proposition as the right idempotent for $T$ is 0 and $B_{0}^{\text{fp}} = \text{mod } T^c = \langle 1 \rangle$.

For the second claim it is enough to note that for any smashing ideal $S$ with right idempotent $F$ in $T$ we have

$$B_{F} = \bigvee_{N \in B_{F}} \langle N \rangle$$

and so $S = \bigvee_{N \in B_{F}} S_N$

where $S_N$ is the finitely presented smashing ideal corresponding to $\langle N \rangle$. □

This already gives us useful information about the smashing spectrum.

**Corollary 3.5.6.** The smashing spectrum $\text{Spc}^s(T)$ is quasi-compact and has a basis of quasi-compact open subsets.

**Proof.** As $S(T)$ is spatial we have $S \subseteq S'$ if and only if $U_S \subseteq U_S'$ and $S$ is finitely presented if and only if the corresponding open subset $U_S$ is quasi-compact. Corollary 3.5.5 then translates to the desired facts. □

**Remark 3.5.7.** A more highbrow way of phrasing the proof is that $S(T)$ is isomorphic to the lattice of open subsets of $\text{Spc}^s(T)$. An open subset is finitely presented in this lattice if and only if it is quasi-compact.

All we are missing for $\text{Spc}^s(T)$ to be spectral is that intersections of quasi-compact opens are quasi-compact. Equivalently, to show that $S(T)$ is a coherent frame we would need to check that binary meets of finitely presented smashing ideals are finitely presented. The difficulty is that we do not have a good explicit description of how to generate $\langle M \rangle$ from $M \in \text{mod } T^c$.

4. The big spectrum

In this section we will introduce yet another space associated to a big tt-category $T$. Let us begin with a very naive definition which has, perhaps because of this extreme naïveté, not yet been considered in the literature.
Definition 4.1.1. We call a proper localizing ideal $P$ of $T$ prime (or a big prime (ideal) to emphasize the size) if it is radical, i.e. if $X^\otimes n \in P$ then $X \in P$, and whenever $I \cap J \subseteq P$ for radical localizing ideals $I$ and $J$ we have $I \subseteq P$ or $J \subseteq P$. In other words, $P$ is meet-prime with respect to radical localizing ideals.

Remark 4.1.2. Our life would be much easier if we simply defined these to be localizing ideals $P$ such that containing $X \otimes Y$ forced either $X$ or $Y$ to lie in $P$. The problem with this definition is that, following the philosophy of the essentially small case rather than the form, we should work with meet-prime radical ideals. If it turns out that, due to the presence of infinite coproducts, these definitions do not coincide that would be something we would need to reckon with eventually no matter what.

These satisfy the ‘ideal version’ of the expected commutative algebra style property.

Notation 4.1.3. For a localizing ideal $I$ we denote its radical by $\sqrt{I}$, which is the smallest radical localizing ideal containing it. For localizing ideals $I$ and $J$ we denote by $I \otimes J$ the smallest localizing subcategory containing all objects $I \otimes J$ for $I \in I$ and $J \in J$.

Lemma 4.1.4. For radical localizing ideals $I$ and $J$ we have

$$I \cap J = \sqrt{I \otimes J}.$$ 

Proof. Since $I$ and $J$ are ideals, if $I \in I$ and $J \in J$ then $I \otimes J \in I \cap J$. Thus $I \otimes J \subseteq I \cap J$. Since $I$ and $J$ are radical so is $I \cap J$ and hence $\sqrt{I \otimes J} \subseteq I \cap J$.

If $K \in I \cap J$ then $K \otimes K \in I \otimes J$ and so $K$ lies in $\sqrt{I \otimes J}$, which proves the reverse containment and hence equality. □

Lemma 4.1.5. Suppose that $I$ and $J$ are radical localizing ideals of $T$ and $P$ is a big prime. Then $I \otimes J \subseteq P$ implies that at least one of $I$ or $J$ is contained in $P$.

Proof. Since $P$ is prime and hence radical by definition we have that $I \otimes J \subseteq P$ if and only if $\sqrt{I \otimes J}$ is contained in $P$. Thus if $I \otimes J$ is contained in $P$ so is its radical, which is $I \cap J$ by Lemma 4.1.4. The conclusion then follows from primeness of $P$. □

Remark 4.1.6. Ideally this would, as in commutative algebra and the tt-geometry of small tt-categories, be equivalent to the statement that $X \otimes Y \in P$ if and only if at least one of $X$ or $Y$ lies in $P$. The issue is that the presence of infinite coproducts makes taking the radical a much more complicated process (cf. the example that follows).

Example 4.1.7. Let $k$ be a field, let $n_i$ be a sequence of natural numbers with each $n_i \geq 2$, and consider the truncated polynomial ring

$$\Lambda = k[x_i \mid i \in \mathbb{N}]/(x_i^{n_i} \mid i \in \mathbb{N}).$$

By [DP98] Theorem B for any $n \geq 1$ there exists an object $X_n \in D(\Lambda)$ such that $X^\otimes n \neq 0$ but $X^\otimes n+1 \cong 0$. It follows that

$$N = \{X \in D(\Lambda) \mid X^\otimes i \cong 0 \text{ for some } i \in \mathbb{N}\}$$

is not a localizing ideal. It is closed under suspensions, summands, and cones but not coproducts: the object $\bigsqcup_n X_n$ is not tensor nilpotent and so does not lie in $N$.

One can of course close under coproducts, adding such sums of nilpotents, but then there is no obvious reason for the result to be closed under cones. Once we add cones there is no obvious reason for the result to be radical. We continue in this fashion and the process does not obviously ever terminate (even proceeding transfinitely and taking unions at limit ordinals, as these unions might not be closed under coproducts).
Lemma 4.1.8. Suppose that every localizing ideal of \( T \) is radical. Then \( P \) is a big prime if and only if whenever \( X \otimes Y \in P \) one of \( X \) or \( Y \) lies in \( P \).

Proof. Suppose that \( P \) is a big prime and \( X \otimes Y \in P \). Then, using Lemma 4.1.4 and the fact that radicals are free, we see

\[
\text{loc}^\otimes(X) \cap \text{loc}^\otimes(Y) = \text{loc}^\otimes(X \otimes Y) \subseteq P
\]

(the second equality via [Ste13, Lemma 3.11]) and so \( X \in P \) or \( Y \in P \).

On the other hand, suppose that \( P \) satisfies the objectwise condition. It is automatically radical by assumption. Let us be given \( I \cap J \subseteq P \) for localizing ideals \( I \) and \( J \) and say \( I \nsubseteq P \).

Pick an \( X \in I \) with \( X \not\in P \). Then for \( Y \in J \) we have

\[
X \otimes Y \in I \cap J \subseteq P
\]

and so, since \( X \not\in P \), we have \( Y \in P \). This shows \( J \subseteq P \) as required. \( \square \)

Definition 4.1.9. We denote by \( \text{SPC}_T \) the collection of big prime ideals of \( T \), and call it the big spectrum. We define the big support of an object \( X \in T \) by

\[
\text{SUPP} \ X = \{ P \in \text{SPC}_T \mid X \not\in P \}
\]

and ‘topologize’ \( \text{SPC}_T \) (see the remark below) by declaring these subsets to be closed and taking the topology they generate.

Remark 4.1.10. There be dragons here. We do not know that \( \text{SPC}_T \) forms a set in general, and so it is potentially an abuse of the usual terminology to call it a space.

Remark 4.1.11. One could equally well topologize \( \text{SPC}_T \) by only looking at the big support of \( \alpha \)-compact objects for some regular cardinal \( \alpha \). This gives a family of topologies, which become increasingly fine, that seem worthy of investigation. A particular case of interest, which will occur in the sequel, is to take \( \alpha = \aleph_0 \).

The big support satisfies the properties one would expect and, at least when one doesn’t need to deal with radicals, we also get the tensor product property.

Lemma 4.1.12. The big support satisfies the following properties:

1. \( \text{SUPP}(0) = \emptyset \) and \( \text{SUPP}(1) = \text{SPC}_T \);
2. \( \text{SUPP} \prod_i X_i = \bigcup_i \text{SUPP} X_i \);
3. \( \text{SUPP} \Sigma X = \text{SUPP} X \);
4. for any triangle \( X \to Y \to Z \) we have \( \text{SUPP} Y \subseteq \text{SUPP} X \cup \text{SUPP} Z \);
5. \( \text{SUPP} X \otimes Y \subseteq \text{SUPP} X \cap \text{SUPP} Y \);
6. if every localizing ideal is radical then \( \text{SUPP} X \otimes Y = \text{SUPP} X \cap \text{SUPP} Y \).

Proof. The usual results with the usual proof; property (6) follows immediately from Lemma 4.1.8. \( \square \)

5. Comparison maps

There is some work to do in order to situate \( \text{Spc}^a(T) \) and \( \text{SPC}_T \) in the landscape: we need to describe their relation to \( \text{Spc}^c(T) \), the premier, and to the plucky newcomer \( \text{Spc}^h(T^c) \), the homological spectrum of \( [\text{Bal20a}] \), both of which we recalled in Section 2.

The comparison is, in some sense, a little facile. Our interest in our new toys is the hope that they can be used to classify (more of the) localizing tensor ideals in situations where the telescope conjecture fails or where \( T \) is not ‘sufficiently noetherian’ (whatever that might mean). We already know that \( \text{Spc} \) and \( \text{Spc}^h \) are not up to this task. Nonetheless
there are canonical morphisms comparing these spaces and it is instructive, and computationally beneficial, to explore them.

5.1. **The smashing spectrum.** Suppose that $K^e$ is a thick ideal of $T^e$. Then we may inflate it to $K = \text{loc}(K^e)$. By results of Miller and Neeman the localizing subcategory $K$ is a tensor ideal and satisfies $K \cap T^e = K^e$, justifying the notation (a convenient reference for these facts is \[BF11\] Theorem 4.1]). On the other hand, given a smashing ideal $S$ of $T$ we may form $S^e = S \cap T^e$ and this is a tensor ideal of $T^e$.

Let us denote the lattice of thick tensor ideals of $T^e$ by $T(T^e)$. Inflation gives a map of posets $f: T(T^e) \rightarrow S(T)$ and intersection with compacts gives a poset map $g: S(T) \rightarrow T(T^e)$.

**Lemma 5.1.1.** The poset map $f$ is a morphism of frames with right adjoint $g$ and $gf = 1$.

*Proof.* By construction $f$ preserves arbitrary joins. Suppose that $K^e_i$ for $i = 1, 2$ are thick ideals of compacts. Then $f(K^e_1 \cap K^e_2)$ is clearly contained in $f(K^e_1 \cap fK^e_2)$. For the reverse containment we note that, letting $E_i$ denote the respective left idempotents, $E_i \in \text{loc}(K^e_i)$ implies that $E_1 \otimes E_2$, the idempotent for $fK^e_1 \cap fK^e_2$, lies in

$$\text{loc}(K^e_1) \otimes \text{loc}(K^e_2) = \text{loc}(K^e_1 \otimes K^e_2)$$

where this equality is \[Ste13\] Lemma 3.11]. Thus $E_1 \otimes E_2$, and hence $fK^e_1 \cap fK^e_2$, is contained in $f(K^e_1 \cap K^e_2)$.

We have noted above that, by work of Neeman, $\text{loc}(K^e) \cap T^e = K^e$ i.e. $gf = 1$. Finally, suppose that $K^e \in T(T^e)$ and $S \in S(T)$. Then $fK^e \subseteq S$ if and only if $K^e \subseteq S$ and only if $K^e \subseteq S = gS$, which proves that $f \dashv g$. □

Recall that for a spectral space $X$ we denote by $X^\vee$ the Hochster dual of $X$. This is the space with the same points and whose open subsets are generated by the closed subsets of $X$ with quasi-compact open complement.

**Theorem 5.1.2.** There is a continuous map $\psi: \text{Spc}^e(T) \rightarrow (\text{Spc} T^e)^\vee$ given by $\psi(P) = P^c$ such that

$$\psi^{-1} \text{Supp } t = \text{Supp }^s t$$

for all $t \in T^e$.

*Proof.* The map $\psi$ is given by $\text{Spec}(f)$, i.e. by Stone duality, and is automatically continuous. An exercise in unwinding this construction shows that it sends a smashing prime $P$ to $\psi(P) = g(P) = P^c$.

Suppose that $t$ is compact. By definition, $P \in \text{Supp }^s t$ means that $t \notin P$, i.e. $t \notin P^c$. This says precisely that $t \notin \psi(P)$. We have shown that

$$\psi^{-1} \text{Supp } t = \{P \mid t \notin \psi(P)\} = \{P \mid t \notin P^c\} = \{P \mid t \notin P\} = \text{Supp }^s t$$

as claimed. □

**Remark 5.1.3.** It is not in general true that $\psi$ is compatible with the small support of arbitrary objects, see Remark \[7.2.2\].

**Corollary 5.1.4.** The morphism $\psi$ is quasi-compact i.e. if $W \subseteq (\text{Spc } T^e)^\vee$ is a quasi-compact open subset then $\psi^{-1}(W)$ is quasi-compact.

*Proof.* Suppose that $W \subseteq (\text{Spc } T^e)^\vee$ is a quasi-compact open subset. This translates to $W$ being a closed subset of $\text{Spc } T^e$ with quasi-compact open complement. By \[Bal05\] Proposition 2.14] there is a compact object $t \in T^e$ such that $W = \text{Supp } t$. Hence $\psi^{-1}(W) = \text{Supp }^s t$ and we reduce to showing the latter is quasi-compact.
We have
\[ \text{Supp}^a t = \{ P \in \text{Spc}^a(T) \mid t \not\in P \} = \{ P \in \text{Spc}^a(T) \mid \text{loc}^a(t) \not\in P \} = U_{\text{loc}^a(t)}. \]

The open \( U_{\text{loc}^a(t)} \) is quasi-compact if and only if \( \text{loc}^a(t) \in \mathcal{S}(T) \) is a finitely presented object. The latter statement follows from Proposition 3.5.4 by noting that the corresponding perfect Serre ideal of \( \text{mod} T^c \) is generated by \( T^c(-, t) \).

**Proposition 5.1.5.** The comparison map \( \psi \) is surjective.

**Proof.** Let \( p \in \text{Spc} \mathcal{T}^c \) be given. We consider the smashing ideal \( \text{loc}(p) \) and the set of finitely presented projective \( T^c \)-modules
\[ \mathcal{M} = \{ T(-, t) \mid t \in T^c \text{ and } t \not\in p \}. \]

The set \( \mathcal{M} \) is tensor multiplicative since \( p \) is prime: if \( t, s \in \mathcal{M} \) and \( T(-, t) \otimes T(-, s) = T(-, t \otimes s) \) is not in \( \mathcal{M} \) then \( t \otimes s \) is in \( p \) so one of \( t \) or \( s \) lies in \( p \) which is excluded by assumption. We can thus apply the variant of Lemma 3.2.6 described in Remark 3.2.7 to produce a smashing prime \( P \) such that \( \text{loc}(p) \subseteq P \) and \( \mathcal{M} \) intersects the corresponding Serre ideal trivially, i.e.
\[ P \cap \{ t \in T^c \mid t \not\in p \} = \emptyset. \]

It follows that \( \psi(P) = P^c = p \).

**Corollary 5.1.6.** The comparison map \( \psi \) is a homeomorphism if and only if the telescope conjecture for smashing ideals holds, i.e. if every smashing ideal is generated by compact objects.

**Proof.** As Stone duality is an equivalence of categories the map \( \psi \) is a homeomorphism if and only if the maps \( f \) and \( g \) of Lemma 5.1.1 are inverse lattice isomorphisms between \( \mathcal{S}(T) \) and \( \mathcal{T}(T^c) \). This is the case precisely if the telescope conjecture holds.

**Remark 5.1.7.** We learn from the Corollary that there are cases in which the smashing spectrum is insufficient for the purposes of understanding localizing ideals. For instance, it is shown in \cite{BS17} that the telescope conjecture holds for \( R = \prod_R k \), where \( k \) is a field, and so \( \psi \) is a homeomorphism. But, as shown in \cite{Ste14} there are exotic localizing ideals, i.e. ideals which are not determined by their support.

**Remark 5.1.8.** If one knew that \( \text{Spc}^a(T) \) were in fact a spectral space, then one could give more streamlined proofs of some of the results in this section. In particular, consider the Hochster dual \( \text{Spc}^a(T)^{\vee} \) and note that that this space along with the support theory \( \text{Supp}^a \) provides a support datum for \( T^c \) via Lemma 3.2.14. As such, by \cite[Theorem 3.2]{Bal05}, we obtain the existence of the continuous map \( \psi \) and the compatibility with \( \text{Supp}^a \).

**Remark 5.1.9.** Let us record another interesting consequence that we would be afforded if \( \text{Spc}^a(T) \) were spectral. In the seminal work of Hochster it is shown that spectral spaces are exactly those spaces that can be realized as Spec(\( R \)) for \( R \) a commutative ring \cite{Hoc09}. The proof of this is achieved by constructing for any spectral space \( X \) a ring \( R_X \) such that Spec(\( R_X \)) \( \cong X \). However, this construction is not functorial.

One is then led to study those subcategories of the category of spectral spaces such that Spec admits a section. In his proof Hochster critically uses the fact that Spec admits an inverse on the subcategory consisting of two spectral spaces \( X, X' \) and a given spectral map \( f: X \rightarrow X' \) between them. In particular, one could lift the spectral map \( \psi: \text{Spc}^a(T)^{\vee} \rightarrow \text{Spc}(T^c) \) to a ring map for all big tt-categories.
5.2. Primes, primes, and primes. Let us now discuss how to compare the remaining notions of prime ideal, i.e. smashing, big, and homological.

Given $B \in \text{Spc}^h(\mathcal{T}^e)$, with associated pure injective $I_B$ (we change the usual notation slightly to avoid conflict with left idempotents), Balmer tells us in [Bal20a, Theorem 3.11] that

$$B' = \ker[-, I_B] = \{M \in \text{Mod} \mathcal{T}^e \mid [M, I_B] = 0\},$$

where $[-, -]$ denotes the internal hom in $\text{Mod} \mathcal{T}$, is the unique maximal localizing Serre ideal containing $B$.

Lemma 5.2.1. Suppose that $B \in \text{Spc}^h(\mathcal{T}^e)$ and let $B'$ be the unique maximal localizing Serre ideal containing $B$. Then $h^{-1}B'$ is a big prime in $\mathcal{T}$.

Proof. First of all, since $B'$ is a localizing subcategory of $\text{Mod} \mathcal{T}^e$ closed under the induced suspension, it follows from the fact that $h$ is cohomological, coproduct preserving, and compatible with suspension that $h^{-1}B'$ is localizing in $\mathcal{T}$. Similarly, since $h$ is monoidal it follows that $h^{-1}B'$ is an ideal.

Next let us check that $P = h^{-1}B'$ is radical. Suppose $X \otimes n \in P$, i.e. $hX \otimes n \in B'$. This is the same as saying $B \not\subseteq \supp hX$. By the tensor product formula [Bal20a, Theorem 4.5] the homological supports of $X \otimes n$ and $X$ agree, so $B$ is not in the support of $X$, i.e. $hX \in B'$ and so $X \in P$.

Finally, we must check $P$ satisfies the primeness condition. To this end let $I$ and $J$ be radical localizing ideals with $I \otimes J \subseteq P$ (we can work with this condition by Lemma 4.1.4). Suppose that $I \not\subseteq P$ and pick some $X$ witnessing this fact. Thus $hX \not\in B'$ and so $hX$, its image in $\text{Mod} \mathcal{T}^e/B'$, is also non-zero. The object $hX$ is flat and so $\ker(- \otimes hX)$ is a proper localizing Serre ideal of $\text{Mod} \mathcal{T}^e/B'$. By maximality of $B'$ it must thus be trivial, i.e. $hX \otimes (-)$ kills no non-zero object. But for every $Y \in J$ we know that $hX \otimes hY \cong h(X \otimes Y) \in B'$ and so $hX \otimes hY \cong 0$ in the quotient. Thus $hY \cong 0$ i.e. $hY \in B'$ and so $Y \in P$. Hence $P$ is a big prime. \qed

Proposition 5.2.2. The assignment $B \mapsto B' \mapsto h^{-1}B'$ defines a comparison map

$$\chi: \text{Spc}^h(\mathcal{T}^e) \to \text{SPC} \mathcal{T}$$

such that $\chi^{-1}\supp x = \supp^h x$ for every compact object $x$. In particular, $\chi$ is continuous when the big spectrum is topologized via the supports of compact objects.

Proof. The map $\chi$ is well defined by Lemma 5.2.1. For a compact object $x$ we have

$$\chi^{-1}\supp x = \chi^{-1}\{P \in \text{SPC} \mathcal{T} \mid x \not\in P\}$$

$$= \{B \mid x \not\in h^{-1}B'\}$$

$$= \{B \mid hx \not\in B'\}$$

$$= \{B \mid hx \not\in B\}$$

$$= \supp^h x.$$  

It follows that $\chi$ is continuous as the $\supp x$ are the basic closed subsets for the chosen topology on the big spectrum. \qed

Remark 5.2.3. We lack the examples to predict how this map might behave in general. We would hazard the (very speculative and particularly baseless) guess that there should be a comparison map in the other direction (of which $\chi$ would like to be a section—see Proposition 5.2.5 for a vague step in this direction).
What we have shown is also enough to guarantee at least as many big primes as small ones.

**Theorem 5.2.4.** Given $p \in \text{Spc} T^c$ there exists a big prime $P$ such that $p = P^c$.

*Proof.* By [Bal20b, Corollary 3.9] there is a homological prime $B$ in $\text{mod} T^c$ such that $p = h^{-1}B$. Passing to the unique localizing Serre ideal $B'$ containing $B$ we get a big prime $P = h^{-1}B'$ by Lemma 5.2.1. By [Bal20a, Theorem 3.11] $B' \cap \text{mod} T^c = B$ and so

\[ P^c = h^{-1}B' \cap T^c = h^{-1}(B' \cap h^{-1}(\text{mod} T^c)) = h^{-1}(B' \cap \text{mod} T^c) = h^{-1}B = p. \]

□

**Proposition 5.2.5.** Suppose that every localizing ideal of $T$ is radical and let $P \in \text{SPC} T$. Then $P^c = P \cap T^c$ lies in $\text{Spc} T^c$. In particular there is a comparison map (of sets) $\omega: \text{SPC} T \rightarrow \text{Spc} T^c$ fitting into a commutative triangle

\[
\begin{array}{ccc}
\text{Spc} h(T^c) & \overset{\phi}{\rightarrow} & \text{Spc} T^c \\
\downarrow{\chi} & & \downarrow{\omega} \\
\text{SPC} T & &
\end{array}
\]

*Proof.* By Lemma 5.1.8 a localizing ideal $P$ is a big prime if and only if $X \otimes Y \in P$ implies at least one of $X$ or $Y$ lies in $P$. Thus if $a$ and $b$ are compact objects of $T$ such that $a \otimes b \in P^c$ we must have, without loss of generality, $a \in P$. Since $a$ is compact it lies in $P^c$ and so $P^c$ is a prime thick tensor ideal in the sense of Balmer.

To see the triangle commutes we just compute that, for a homological prime $B$ contained in its unique maximal localizing Serre ideal $B'$, we have

\[ \phi(B) = h^{-1}B = h^{-1}B' \cap T^c = \omega(h^{-1}B') = \omega \chi B \]

analogously to the computation in Theorem 5.2.4. □

6. **An example: commutative noetherian rings**

In this section we discuss, in an example we understand somewhat well, the behaviour of the objects we have defined.

**Remark 6.1.1.** We stick here to the derived category of a commutative noetherian ring, but many parts easily generalize to any example with nice enough spectrum for the local-to-global principle to hold (replacing residue fields by $\Gamma P$’s), and it all generalizes when we know the classification of localizing ideals in terms of $\text{Spc} T^c$. The choice to use residue fields is really aesthetic.

Throughout we fix $R$ a commutative noetherian ring. All functors are taken to be derived, and equality sometimes means isomorphism. Let us begin by reminding ourselves of some details to fix notation.

Let $p$ be a prime ideal of $R$. We set, as usual, $\mathcal{V}(p) = \{p\}$ and $Z(p) = \{q \in \text{Spec} R \mid p \notin \mathcal{V}(q)\}$.

There is a corresponding prime ideal in $D^{\text{perf}}(R)$, namely

\[ D^{\text{perf}}_{Z(p)}(R) = \{ E \in D^{\text{perf}}(R) \mid \text{supp} E \subseteq Z(p) \} = \{ E \in D^{\text{perf}}(R) \mid E_p = 0 \}. \]

This gives an inclusion reversing bijection between $\text{Spec} R$ and $\text{Spc} D^{\text{perf}}(R)$. 
We know, by the work of Neeman \[\text{Nee92}\], that localizing ideals of \(D(R)\) are in bijection with subsets of \(\text{Spec } R\) and that the telescope conjecture holds.

By \[\text{Bal20b, Corollary 5.11}\] the comparison map \(\text{Spc}^hD_{\text{perf}}(R) \to \text{Spc}D_{\text{perf}}(R)\) is a bijection, i.e. there is a unique homological prime associated to each prime ideal of \(R\). The homological prime associated to \(p\) is given by the kernel of the functor

\[
\text{mod } D_{\text{perf}}(R) \to \text{mod } D_{\text{perf}}(k(p))
\]

induced by \(R \to k(p)\).

Now let us describe the big and smashing primes for \(D(R)\) and then make a systematic comparison.

6.2. Big primes. We know that there are only a set of localizing subcategories in \(D(R)\), that every localizing subcategory is an ideal, and that every ideal is radical. So (although some things break) we can comfortably look at prime localizing ideals and by Lemma 4.1.8 we can define these as either meet-prime localizing subcategories or as objectwise prime with respect to the tensor product.

**Lemma 6.2.1.** Let \(P\) be a prime localizing ideal of \(D(R)\). Then there is a unique \(p \in \text{Spec } R\) such that \(k(p) / p \in P\), i.e.

\[
P = \text{loc}(k(q) \mid q \neq p).
\]

In particular, the primes are the maximal proper localizing subcategories. This sets up a bijection \(\text{Spec } R \cong \text{SPC } D(R)\).

**Proof.** If \(p \neq q\) then \(k(p) \otimes k(q) = 0\) and so at least one of \(k(p)\) or \(k(q)\) lies in \(P\). In other words there is at most one \(p\) such that \(k(p) \notin P\). We know the residue fields generate \(D(R)\) so as \(P\) is proper there is exactly one such \(p\). The remaining statements follow: the first by the classification of localizing subcategories and the second immediately. \(\square\)

The corresponding notion of support is

\[
\text{SUPP } X = \{P \in \text{SPC } D(R) \mid X \notin P\} = \{p \in \text{Spec } R \mid k(p) \otimes X \neq 0\},
\]

which recovers Foxby’s small support, aka the Balmer-Favi notion of support under the identification \(\text{Spc } D_{\text{perf}}(R) \cong \text{SPC } D(R)\). There are two extremal ways to topologise \(\text{SPC } D(R)\). One is to take as a basis of closed subsets the supports of the compact objects and this yields a homeomorphism to \(\text{Spc } D_{\text{perf}}(R)\) and \(\text{Spec } R\). The other is to take as a basis the supports of arbitrary objects of \(D(R)\) which gives the discrete topology on \(\text{SPC } D(R)\) and a bijection between closed subsets and localizing ideals. See Section 6.5 for some remarks on what happens in between.

**Lemma 6.2.2.** For a prime \(p \in \text{Spec } R\) with corresponding small prime \(p\) and big prime \(P\) we have

\[
P \cap D_{\text{perf}}(R) = p
\]

with the latter being an equality if and only if \(p\) is a generic point.

**Proof.** We compute that

\[
P \cap D_{\text{perf}}(R) = \{E \in D_{\text{perf}}(R) \mid \text{supp } E \subseteq \text{Spec } R \setminus \{p\}\}
\]

\[
= \{E \in D_{\text{perf}}(R) \mid \text{supp } E \subseteq Z(p)\}
\]

\[
= D_{\text{perf}}^Z(p)(R)
\]

\[
= p
\]
where the second equality is given by the fact that the support of a compact is closed, and so if it fails to contain \( p \) it cannot contain any prime specializing to \( p \).

We see that \( \text{loc}(p) \subseteq \mathcal{P} \). This is an equality precisely if \( \mathcal{Z}(p) = \text{Spec} \mathcal{R} \setminus \{p\} \), i.e. if and only if \( p \) is the unique prime specializing to \( p \); this is precisely the statement that \( p \) is generic. \( \square \)

6.3. Smashing primes. Now let us turn to the characterization of smashing primes. The telescope conjecture holds and so by Corollary 5.1.6 the comparison map

\[
\psi : \text{Spc}^h(D(R)) \longrightarrow (\text{Spc} D^\text{perf}(R))^\vee
\]

is a homeomorphism and it identifies the smashing and usual support for compact objects. From this bijection (and the further identification of \( \text{Spc} D^\text{perf}(R) \) with \( \text{Spec} \mathcal{R} \)) we see that the meet-prime smashing ideals are precisely the \( D\mathcal{Z}(p)(R) \) for \( p \in \text{Spec} \mathcal{R} \).

Now let us discuss the support of a general object. It turns out that the smashing support is not granular enough to deal with arbitrary objects.

**Lemma 6.3.1.** Let \( X \) be an object of \( D(R) \). Then \( \text{Supp}^s X \) is the specialization closure of \( \text{supp} X \).

**Proof.** Using the identification of the smashing spectrum with \( \text{Spec} \mathcal{R} \) we compute that

\[
\text{Supp}^s X = \{ p \in \text{Spec} \mathcal{R} \mid X \not\subseteq D\mathcal{Z}(p)(R) \} = \{ p \in \text{Spec} \mathcal{R} \mid \text{supp} X \not\subseteq \mathcal{Z}(p) \}
\]

which is precisely the set of specializations of points in \( \text{supp} X \). \( \square \)

However, since \( \text{Spec} \mathcal{R} \) is noetherian the dual space \( (\text{Spec} \mathcal{R})^\vee \) is \( T_D \) so we can work with the small smashing support of Definition 3.3.5 and it does the job.

**Lemma 6.3.2.** Treating the bijection \( \psi \) as an identification we have, for \( X \in D(R) \), an equality

\[
\text{supp}^s X = \text{supp} X.
\]

In particular, the small smashing support classifies localizing subcategories of \( D(R) \).

**Proof.** Given \( p \in \text{Spec} \mathcal{R} \) the subset \( \mathcal{V}(p) \) is open in \( \text{Spc}^h D(R) \) and \( \mathcal{P} \), the corresponding smashing prime, is maximal in it (remember if \( p \subseteq q \) then \( \mathcal{Z}(p) \supseteq \mathcal{Z}(q) \)). Thus we may compute \( \Gamma_p \) as

\[
\Gamma_p = E_{\mathcal{D}(\mathcal{V}(p))(R)} \otimes F_p = \Gamma_{\mathcal{V}(p)} R \otimes R_p = \Gamma_p R.
\]

This identifies the idempotents computing the two notions of support and so they agree. \( \square \)

6.4. Comparisons. Let us now to summarise how to move between these four equivalent setups. We already have comparison maps

\[
\phi : \text{Spc}^h(D^\text{perf}(R)) \longrightarrow \text{Spc} D^\text{perf}(R) \quad \text{and} \quad \psi : \text{Spc}^s(D(R)) \longrightarrow (\text{Spc} D^\text{perf}(R))^\vee
\]

which are given by \( \phi(B) = h^{-1}B \cap D^\text{perf}(R) \) and \( \psi(P) = P \cap D^\text{perf}(R) \). We know that these are both homeomorphisms. We also have a map

\[
\text{SPC} D(R) \longrightarrow \text{Spc} D^\text{perf}(R) \quad Q \mapsto Q \cap D^\text{perf}(R)
\]

which is continuous in either topology on the big spectrum, and a homeomorphism if we topologize it via supports of perfect complexes.

We also understand very explicitly how to move from homological primes to big primes. By Proposition 5.2.2 there is a comparison map \( \chi : \text{Spc}^h(D^\text{perf}(R)) \longrightarrow \text{SPC} D(R) \).
Lemma 6.4.1. The comparison map $\chi$ is a homeomorphism for the topology on the big spectrum generated by supports of compacts. The homological prime $B$ corresponding to $k(p)$ is sent to

$$\chi(B) = \text{Ker}(k(p) \otimes -) = \text{loc}(k(q) \mid q \neq p).$$

Proof. This is an exercise in unwinding the definitions and applying [Bal20b, Corollary 5.11] to relate the homological primes to the kernels of the base change functors associated to the residue fields.

We see that all four spaces are homeomorphic and all notions of support coincide (apart from the usual big/small distinction). This is indicative of the situations in which we have a classification, i.e. where all things are as tame as one could hope for.

6.5. Topologies on the big spectrum. We now briefly discuss the content of Remark 4.1.11. For the sake of convenience we will frequently identify $\text{SPC}_D(R)$ and $\text{Spec } R$ as discussed in Section 6.2. Given a regular cardinal $\alpha$ let us denote by $\tau_\alpha$ the topology on $\text{SPC}_D(R)$ obtained by generating the closed subsets via the collection

$$\{\text{SUPP } X \mid X \in D(R)^\alpha\}$$

where $D(R)^\alpha$ denotes the full subcategory of $\alpha$-compact objects, and by $\tau_\infty$ the topology generated by taking supports of arbitrary objects.

We have already seen that $\tau_{\aleph_0}$ gives the usual topology on $\text{SPC}_D(R) \cong \text{Spec } R$. At the other extreme, the topology $\tau_\infty$ is discrete: for any subset $W$ we have

$$\text{SUPP } \bigoplus_{p \in W} k(p) = W.$$  

We note that in $\tau_\alpha$ any union of fewer than $\alpha$ closed subsets is still closed—this topology is what one might call $\alpha$-Alexandroff.

As a first approximation one can understand this metamorphosis from the Zariski to the discrete topology in terms of the cardinality of $R$.

Lemma 6.5.1. If $V$ is a closed subset of $\text{Spec } R$ then the corresponding left idempotent $\Gamma_V R$ is $\aleph_1$-compact.

Proof. For $r \in R$ the stable Koszul complex $K_\infty(r) = R \rightarrow R_r$, where the map is the canonical one and the complex lives in degrees 0 and 1, gives an explicit representative for $\Gamma_{V(r)} R$. We have

$$K_\infty(r) = \text{hocolim}_i K(r^i)$$

where $K(r^i)$ is the usual Koszul complex on $r^i$, and so we see $K_\infty(r)$ is a countable homotopy colimit of compacts and hence is $\aleph_1$-compact.

For the general case one can write $V = V(I)$ and, choosing generators $I = (r_1, \ldots, r_n)$, we have

$$\Gamma_V R \cong K_\infty(r_1, \ldots, r_n) = K_\infty(r_1) \otimes \cdots \otimes K_\infty(r_n).$$

One sees easily from what we have already shown that this is $\aleph_1$-compact, for instance by using that $D(R)^{\aleph_1}$ is closed under countable homotopy colimits.

For a regular cardinal $\alpha$ we denote by $\alpha^+$ its successor.

Lemma 6.5.2. Let $p \in \text{Spec } R$ be a prime ideal such that $S = R \setminus p$ has cardinality $\alpha$. Then $R_p$ is $\alpha^+$-presentable as a module and $\alpha^+$-compact in $D(R)$.
Proof. We can write $R_p$ as a filtered colimit of copies of $R$ with index set $S$. Thus $R_p$ is $\alpha^+$-presentable and so, for instance by appealing to [Kra15, Theorem 5.10], is $\alpha^+$-compact in $\mathcal{D}(R)$.

Remark 6.5.3. We note that, quite frequently, this bound is far from optimal.

Proposition 6.5.4. Let $p \in \text{Spec } R$ be a prime ideal such that $S = R \setminus p$ has cardinality $\alpha \geq \aleph_0$. Then $\Gamma_p R$ is $\alpha^+$-compact, and so $\{p\}$ is closed in $\tau_{\alpha^+}$. In particular, if $\alpha \geq \max\{|R|, |\text{Spec } R|\}$ then $\tau_{\alpha^+}$ is the discrete topology on $\text{Spec } R$.

Proof. By Lemma 6.5.2 $R_p$ is $\alpha^+$-compact and by Lemma 6.5.1 so is $\Gamma_{V(p)} R$. Hence $\Gamma_p R = R_p \otimes \Gamma_{V(p)} R$ is also $\alpha^+$-compact. It has support precisely $\{p\}$ and so this subset is closed in $\tau_{\alpha^+}$. The second statement follows as, by assumption on $\alpha$, any set $W$ of primes is $\alpha^+$-small and each $\Gamma_p R$ is $\alpha^+$-compact so $W = \text{SUPP } \bigoplus_{p \in W} \Gamma_p R$ is closed in $\tau_{\alpha^+}$.

\[\square\]

7. An example: no telescope here

Let $(A, m, k)$ be a non-Noetherian rank 1 valuation domain, e.g. we could take for $A$ the perfection of $\mathbb{F}_p[[x]]$. The corresponding scheme $\text{Spec } A$ has underlying space

\[\begin{array}{c}
(0) \\
m \\
\end{array}\]

as for a discrete valuation ring. The maximal ideal $m$ is flat with $m^2 = m$ and so $m \to A$ is a left idempotent in $\mathcal{D}(A)$. This gives rise to a non-finite smashing localization

$\text{loc}(m) \to \mathcal{D}(A) \to \mathcal{D}(k)$.

7.2. The smashing spectrum. All smashing subcategories of $\mathcal{D}(A)$ are known by [BS17] and fit into the following picture, where $Q$ denotes the function field of $A$: 

\[
\begin{array}{c}
\mathcal{D}(A) \\
\text{loc}(m) \\
\text{loc}(Q/m) \\
0 \\
\end{array}
\]

\[
\begin{array}{c}
\mathcal{D}(A) \\
\text{loc}(m) \\
\text{loc}(Q/m) \\
0 \\
\end{array}
\]
This frame is finite and so is not only spatial but is a coherent frame. We see that the meet-prime smashing ideals are $P = \text{loc}(m)$, $Q = D_m(A)$, and 0. The open subsets of $\text{Sp}^s D(A)$ are

$$U_0 = \emptyset, U_{\text{loc}(Q/m)} = \{0\}, U_{\text{loc}(m)} = \{0, Q\}, U_{D_m(A)} = \{0, P\}, \text{ and } U_{D(A)} = \text{Sp}^s D(A).$$

Thus the smashing spectrum is

$$P \bullet Q \bullet 0$$

where $P$ and $Q$ are closed points and 0 is open (remember that we are in the Hochster dual picture and so to compare with $\text{Spec} A$ we should dualize to get a local space with two generic points).

Next let us turn to describing the small support. The points $P$ and $Q$ are closed and so $\Gamma_P = k$ and $\Gamma_Q = Q$ are the corresponding right idempotents. The open point 0 is generic, so $V_0 = \text{Sp}^s D(A)$ and we can write $\{0\} = U_{\text{loc}(Q/m)} \cap V_0$ yielding

$$\Gamma_0 = Q/m.$$  

Thus, for instance, if $a \in A$ is a non-zero divisor then the small (and big) support of the perfect complex $A/(a)$ is

$$\text{supp}_s A/(a) = \{P, 0\} = U_{D_m(A)}.$$  

We note this is not a closed subset (again one should expect it to be open, as it is, rather than closed since we are in the Hochster dual picture to $\text{Sp}c$).

**Remark 7.2.1.** If one topologizes the smashing spectrum only using the supports of compact objects then one does not get the correct space. Indeed, by compatibility with suspension and cones we have for perfect complexes $t, s \in D^{\text{perf}}(A)$ that

$$\text{thick}(t) = \text{thick}(s) \implies \text{Supp}_s t = \text{Supp}_s s$$

(or use Theorem 5.1.2). Thus the possible smashing supports of objects of $D^{\text{perf}}(A)$ are

$$\emptyset, \text{Sp}^s D(A), \text{ and } \{P, 0\}$$

and the corresponding space is not even Sober.

**Remark 7.2.2.** In this example the small smashing support is not compatible with the comparison map $\psi$. We have $\text{supp} m = \text{Sp}c D^{\text{perf}}(A)$ but

$$\text{supp}_s m = U_{\text{loc}(m)} = \{0, Q\} \subset \text{Sp}^s D(A) = \psi^{-1}(\text{Sp}c D^{\text{perf}}(A))^\vee,$$

where the first equality is Proposition 3.3.13.

**Remark 7.2.3.** By assigning some notion of dimension to points of the Balmer spectrum one can, at least when the dual is $T_D$, use the corresponding filtration to decompose the category $T$ into pieces supported at individual primes. This has been done by various authors, with varying levels of sophistication used in reconstructing $T$ from said pieces.

In the cases where the telescope conjecture fails, such as in the current example, one may instead consider decomposing the category $T$ over the smashing spectrum. This gives a finer decomposition.
For instance, let us meditate briefly on the case of $\mathcal{D}(A)$, as considered above. Working with the spectrum of the compacts we get the recollement corresponding to the triangle
$$\Gamma_m A \to A \to Q$$
i.e. the gluing of $\text{Spec} A$ from the generic point and the formal scheme at the closed point. On the other hand, when working with the smashing spectrum, this refines to the recollement corresponding to the triangle
$$\Sigma^{-1}Q/m \to A \to Q \times k.$$
In some sense we have ‘gone deeper’ than the closed point and the residue field has emerged as generic information.

More generally, now we know $\text{Spc}^s(T)$ exists as a space, we can apply much of the machinery that has already been developed for the Balmer spectrum, for instance [Bal07, Ste17, BG20], to produce such refined decompositions more generally.

### 7.3. Big primes.

One gets all known localizing subcategories from $\text{Spc}^s D(A)$ by looking at arbitrary subsets, i.e. in terms of the small smashing support, but there is currently no classification of localizing ideals. Given this (we don’t even know there is a set of localizing subcategories) $\text{SPC} D(A)$ is a bit more delicate. For instance, what we have in the noetherian setting doesn’t generalize naively:

$$\text{loc}(k \oplus Q) = \mathcal{D}(k) \times \mathcal{D}(Q) \subset \mathcal{D}(A).$$

It would be very interesting to compute $\text{SPC} \mathcal{D}(A)$, or at least some of it, in this example. We know at least two primes through the following easy lemma.

**Lemma 7.3.1.** Suppose $L$ is a localizing ideal in a big tt-category $T$. Then $L$ is prime if and only if $T/L$ is meet-local in the sense that if $I \cap J = 0$ for radical localizing ideals in $T/L$ then $I = 0$ or $J = 0$. In particular, if $T/L$ is tt-minimal, i.e. $L$ is a maximal ideal, then $L$ is prime.

Since $\mathcal{D}(k)$ and $\mathcal{D}(Q)$ are minimal it follows that $\text{loc}(m)$ and $\mathcal{D}^\text{perf}_{\{m\}}(A)$ are big primes, lying over 0 and $\mathcal{D}^\text{perf}_{\{m\}}(A)$ respectively. One is tempted to suspect that $\text{loc}(Q \oplus k)$ is also maximal and hence prime, but we don’t know this.
