GEOMETRIC SYZYGY CONJECTURE IN POSITIVE CHARACTERISTIC

YI WEI

Abstract. We study the syzygies of canonical curves of even genus $g = 2k$ over an algebraically closed field $\mathbb{F}$ with $\text{char}(\mathbb{F}) = p > 0$. For $p \geq \frac{k+4}{2} = k+2$, we prove a structure theorem for the last syzygy space. As a corollary, this gives a new proof of Green’s Conjecture for general canonical curves of even genus in positive characteristic. Assuming $p > 2k$, we prove Geometric Syzygy Conjecture for a general smooth curve of even genus $g = 2k$.

1. Introduction

Throughout this paper, $\mathbb{F}$ is any algebraically closed field with characteristic $p > 0$. A pair $(X, L)$ of a K3 surface $X$ and line bundle $L$ is called polarized K3 surface of degree $2d$ if $L$ is ample and $L^2 = 2d$. The pair $(X, L)$ is primitively polarized if, further, $L$ is primitive. Over any algebraically closed field, there exist primitively polarized K3 surfaces $(X, L)$ of degree $2g - 2$ for any $g \geq 3$. [Huy16 §II, Thm 4.2]

Assume $\text{char}(\mathbb{F}) \neq 2$. Let $(X, L)$ be any primitively polarized K3 surface over $\mathbb{F}$ of even genus $g = 2k \geq 4$, i.e. degree $2g - 2$. A general member $C \in |L|$ is irreducible and smooth of genus $g$. [Huy16 §II, Cor 3.6]. Moreover, the hyperplane restriction theorem [Gre84] implies the equality of Koszul cohomologies

\[(1) \quad K_{k,1}(C, \omega_C) = K_{k,1}(X, L)\]

whenever $C$ is a smooth and connected hyperplane section of a K3 surface $X$.

To any pair $(C, A)$ consisting of a smooth curve $C \in |L|$ and a base-point free line bundle $A \in W^1_k(C)$ with $h^0(A) = 2$, one associates a rank 2 Lazarsfeld-Mukai bundle $E = E_{C,A}$ on $X$. [Laz86]. The dual bundle $E^\vee$ fits into the exact sequence

\[0 \to E^\vee \to H^0(C, A) \otimes \mathcal{O}_X \to i_*A \to 0,\]

where $i : C \hookrightarrow X$ is the inclusion. The vector bundle $E$ has numerical invariants $c_1(E) = \text{det}(E) = L$, $c_2(E) = k + 1; h^0(E) = k + 2, h^1(E) = h^2(E) = 0, h^0(E^\vee) = h^1(E^\vee) = 0$. A general section $s \in H^0(E)$ gives a general zero-dimensional $Z(s)$ on a general curve $C \in |L|$ with $\deg Z(s) = k + 1$. Moreover, all $g_{k+1}^1$'s on curves arise as sections of $E$. Our first result is the following.

Main Theorem 1.1. Fix an algebraically closed field $\mathbb{F}$ with $\text{char}(\mathbb{F}) = p > 0$. Let $(X, L)$ be a general element in any component of the moduli space of primitively polarized K3 surfaces of even genus $g = 2k \geq 4$ over $\mathbb{F}$. Assume $p \geq k + 2$. Let $E$ be the rank two Lazarsfeld-Mukai bundle defined above. For any nonzero $s \in H^0(E)$, the space $K_{k-1,1}(X, L, H^0(L \otimes I_{Z(s)}))$ is a one-dimensional subspace of $K_{k-1,1}(X, L)$. The morphism

\[\psi : \mathbb{P}(H^0(E)) \to \mathbb{P}(K_{k-1,1}(X, L))\]

\[[s] \mapsto [K_{k-1,1}(X, L, H^0(L \otimes I_{Z(s)}))]\]

is the Veronese embedding of degree $k - 2$.

In particular, $\psi$ induces a natural isomorphism $\text{Sym}^{k-2}H^0(X, E) \simeq K_{k-1,1}(X, L)$. 

1
Note that the above theorem implies $K_{k,1}(X, L) = 0$ by standard dimension computations. [Far17, §IV.1]. Hence $K_{k,1}(C, \omega_C) = 0$ by (1). It is well-known that this single vanishing suffices to prove Green’s conjecture for a general canonical curve.

**Corollary 1.1** (Green’s Conjecture in positive characteristic). Let $\mathbb{F}$ be any algebraically closed field with $\text{char}(\mathbb{F}) = p > 0$. Let $C$ be a general curve over $\mathbb{F}$ of even genus $g = 2k$ for $k \geq 2$. Assume $p \geq \frac{g+4}{2} = k + 2$. Then $K_{k,1}(C, \omega_C) = 0$.

Corollary 1.1 is first proved in [AFP+18, Thm 1.2] with full generality, i.e. including the case of odd genus. The authors used totally different method which turned out to be quite a technical proof. Our approach is considerably simple, based on [Kem20, Thm 0.2], which used only homological algebra. But note that the effective lower bound of the characteristic $p$ we give is almost identical as that given in [AFP+18, Thm 1.2], which is $\frac{g+2}{2}$.

**Remark 1.1.** (i) Main Theorem 1.1 in characteristic zero is proved in [Kem20 Thm 0.2], where K3 surface $(X, L)$ is assumed to have $\text{Pic}(X) = \mathbb{Z}[L]$, indeed a general case in characteristic zero. Kemény’s proof makes essential use of the property $\text{Pic}(X) = \mathbb{Z}[L]$, which could be a huge issue in positive characteristic. In particular, the Tate conjecture implies that any K3 surface over $\mathbb{F}_p$ has even Picard number [Huy16 §XVII. Cor 2.9].

(ii) The existence of such a base-point free line bundle $A \in W_{k+1}^1(C)$ with $h^0(A) = 2$ on a general smooth curve $C \in |L|$ for a general primitively polarized K3 surface $(X, L)$ is guaranteed by the following proposition, for which the proof is saved until Section 3. (One simply sets $r = 1, d = k + 1, g = 2k$)

**Proposition 1.1.** Fix an algebraically closed field $\mathbb{F}$ with $\text{char}(\mathbb{F}) \neq 2$. Let $(X, L)$ be a general member of any component of the moduli space of primitively polarized K3 surfaces over $\mathbb{F}$ of genus $g$ for $g \geq 3$. Let $r, d$ be such integers that the Brill-Noether number $\rho(r, d, g) = 0$. Consider the Brill-Noether loci $W_d^r(C)$ for a general smooth curve $C \in |L|$, then each $A \in W_d^r(C)$ has $h^0(A) = r + 1$ and $A$ base-point free.

For any polarized variety $(X, L)$, a natural question is whether one can find a spanning set of the spaces $K_{p,1}(X, L)$ consisting of elements of low rank. Here one defines the rank of a syzygy $\alpha \in K_{p,1}(X, L)$ as the minimum dimension of the subspace $V \subseteq H^0(X, L)$ such that $\alpha \in K_{p,1}(X, L; V)$, i.e. $\alpha$ is represented by an element of $\bigwedge^p V \otimes H^0(X, L)$, [Bot07].

For a general primitively polarized K3 surface $(X, L)$ of even genus $g = 2k$, we will show that, any non-zero section $s \in H^0(E)$ is regular i.e. the zero locus $Z(s) \subseteq X$ is zero-dimensional, and $h^0(X, L \otimes I_Z(s)) = k + 1$. If we restrict the subspaces $K_{k-1,1}(X, L; H^0(L \otimes I_Z(s))) \subseteq K_{k-1,1}(X, L)$ to a curve $C \in |L|$ containing the locus $Z(s)$, then $K_{k-1,1}(X, L; H^0(L \otimes I_Z(s)))$ restricts to

$$K_{k-1,1}(C, \omega_C; H^0(\omega_C \otimes A^{-1})) \subseteq K_{k-1,1}(C, \omega_C),$$

where $A \in W_{k+1}^1(C)$ is the line bundle associated to the divisor $Z(s) \subseteq C$. In particular, the rank $k + 1$ syzygies $\alpha \in K_{k-1,1}(X, L; H^0(L \otimes I_Z(s)))$ drop rank by one when restricted to $C$.

Following a similar strategy to the proof of [Kem20 Cor 0.4] and with a slightly different assumption on the lower bound of $\text{char}(\mathbb{F}) = p > 0$, Main Theorem 1.1 combined with an observation of Voisin [Voi02, Prop 7], implies the Geometric Syzygy Conjectures for even genus in positive characteristic.

**Main Theorem 1.2** (Geometric Syzygy Conjecture for Even Genus). Fix an algebraically closed field $\mathbb{F}$ with $\text{char}(\mathbb{F}) = p > 0$. Let $C$ be a general curve over $\mathbb{F}$ of even genus $g = 2k$ for $k \geq 2$. Assume $p > 2k$. Then $K_{k-1,1}(C, \omega_C)$ is generated by syzygies of lowest possible rank $k$. More precisely, $K_{k-1,1}(C, \omega_C)$ is generated by the rank $k$ syzygies

$$\alpha \in K_{k-1,1}(C, \omega_C; H^0(\omega_C \otimes A^{-1})), \quad A \in W_{k+1}^1(C).$$
Remark 1.2. The inclusions of $H^0(\omega_C \otimes A^{-1}) \hookrightarrow H^0(\omega_C)$ are parameterized by sections $H^0(A)$. And so are $K_{k-1,1}(C, \omega_C; H^0(\omega_C \otimes A^{-1})) \hookrightarrow K_{k-1,1}(C, \omega_C)$. Different sections in $H^0(A)$ give different subspaces $K_{k-1,1}(C, \omega_C; H^0(\omega_C \otimes A^{-1}))$ of $K_{k-1,1}(C, \omega_C)$. One may need multiple sections to have enough such subspaces of $K_{k-1,1}(C, \omega_C)$. The above theorem asserts that those subspaces generate $K_{k-1,1}(C, \omega_C)$. Since $K_{k-1,1}(C, \omega_C)$ is finite dimensional, one needs only finitely many rank $k$ syzygies to generate $K_{k-1,1}(C, \omega_C)$.

Main Theorem is proved by two steps. We first adapt Thm 0.2 under generalized assumptions as follows.

Proposition 1.2. Let $(X, L)$ be a primitively polarized K3 surface of even genus $g = 2k$ for $k \geq 2$ over an algebraically closed field $\mathbb{F}$. Assume $\text{char}(\mathbb{F}) = p \geq \frac{9+4}{2} = k+2$. Assume on a smooth curve $C \subseteq |L|$, there exists a line bundle $A \in W_{k+1}^1(C)$ with $h^0(A) = 2$ and $A$ base-point free. Let $E$ be a rank $2$ Lazarsfeld-Mukai bundle associated to such a pair $(C, A)$. If any non-zero $s \in H^0(E)$ is regular, i.e. the vanishing locus $Z(s)$ is zero-dimensional, then the space $K_{k-1,1}(X, L; H^0(L \otimes I_{Z(s)}))$ is a one-dimensional subspace of $K_{k-1,1}(X, L)$. The morphism

$$\psi: \mathbb{P}(H^0(E)) \rightarrow \mathbb{P}(K_{k-1,1}(X, L))$$

is the Veronese embedding of degree $k-2$.

In particular, $\psi$ induces a natural isomorphism $\text{Sym}^{k-2}H^0(X, E) \simeq K_{k-1,1}(X, L)$.

Remark 1.3. (i) If $\text{Pic}(X) = \mathbb{Z}[L]$, then every non-zero section $s \in H^0(E)$ is regular. Indeed, if $Z(s)$ is one-dimensional for some non-zero $s$, then $H^0(E(-D)) \neq 0$ for some effective divisor $D$, which has to be a multiple of $L$, i.e. $E(-D) = E(-mL)$ for some positive $m$. However, $H^0(E(-mL)) \subseteq H^0(E(-L))$ and $E(-L) \simeq E^\vee$ with $h^0(E^\vee) = 0$. A contradiction.

(ii) Let $Z \subseteq X \times \mathbb{P}(H^0(E))$ be the reduced closed subvariety defined by $\{(x, s) | s(x) = 0\}$. If any non-zero section $s \in H^0(E)$ is regular, then $Z$ is locally complete intersection, hence Cohen-Macaulay. By miracle flatness theorem, the second projection $Z \rightarrow \mathbb{P}(H^0(E))$ is finite and flat. The converse is clear.

Secondly, we conclude by a deformation type argument. The main tool we use is Ogus’s Theorem as follows. A brief sketch of the proof of this theorem is provided in Appendix A.

Theorem 1.1 ([Ogu79]). Let $\mathbb{F}$ be an algebraically closed field with $\text{char}(\mathbb{F}) = p > 0$. Let $(\mathcal{X}/T, \mathcal{L})$ be a versal $\mathbb{F}$-deformation of a primitively polarized K3 surface $(X, L)$ of degree $2d$, with $(L) \subseteq \text{Pic}(X)$ a direct summand. Then the geometric generic fiber $(X_\tau, \mathcal{L}_\tau)$ is ordinary with degree $2d$, and $\text{Pic}(X_\tau)$ is generated by $\mathcal{L}_\tau$.

We consider a versal $\mathbb{F}$-deformation of an arbitrary primitively polarized K3 surface $(X, L)$ over $\mathbb{F}$ with degree $2g - 2$ and construct a universal Lazarsfeld-Mukai bundle associated to it in Section 3. We will show that a general primitively polarized K3 surface $(X, L)$ satisfies the assumption of Proposition 1.2, i.e. any non-zero section $s \in H^0(E)$ is regular. By generic flatness theorem and flat base change, it suffices to prove the case for the geometric generic fiber $(X_\tau, \mathcal{L}_\tau)$. Note that the geometric generic fiber $(X_\tau, \mathcal{L}_\tau)$ has Picard number one, which easily satisfies the assumption. (see Remark 1.3 (i))

Acknowledgements. I thank Michael Kemeny for generous ideas and numerous discussions. We thank J. Rathmann for explaining Ogus’s results, and how to apply them.

Support for this research was provided by the University of Wisconsin–Madison Office of the Vice Chancellor for Research and Graduate Education with funding from the Wisconsin Alumni Research Foundation.
2. Preliminaries

2.1. Koszul Cohomology. Let \( V \) be a vector space and denote \( S_V := \bigoplus_{d \geq 0} \text{Sym}^d(V) \) symmetric tensor algebra associated to \( V \). Let \( M \) be a graded \( S_V \)-module, one defines Koszul cohomology \( K_{p,q}(M,V) \) as the middle cohomology of

\[
\bigwedge^{p+1} V \otimes M_{q-1} \to \bigwedge^p V \otimes M_q \to \bigwedge^{p-1} V \otimes M_{q+1}.
\]

Mark Green first used Koszul cohomology to study projective geometry. Let \( X \) be a projective variety, \( L \) a line bundle and \( F \) a coherent sheaf. We define a graded \( S_L := S_{H^0(X,L)} \)-module

\[
\Gamma_X(F,L) := \bigoplus_{q \in \mathbb{Z}} H^0(X,L^{\otimes q} \otimes F).
\]

Denote \( K_{p,q}(X,F,L) := K_{p,q}(\Gamma_X(F,L),H^0(X,L)) \). For any subspace \( W \subseteq H^0(X,L) \), we may regard \( \Gamma_X(O_X,L) \) as a \( S_W \)-module. Denote \( K_{p,q}(X,F,L;W) := K_{p,q}(\Gamma_X(F,L),W) \). If \( F = O_X \), we simplify the notions \( K_{p,q}(X,F,L) \) as \( K_{p,q}(X,L) \) and \( K_{p,q}(X,F,L;W) \) as \( K_{p,q}(X,L;W) \).

2.2. Lazarsfeld-Mukai Bundle. In [Laz86], Lazarsfeld first introduced such vector bundle \( E = E_{C,A} \) on a K3 surface \( X \) associated to a pair \((C,A)\), where \( C \) is a smooth curve lying on \( X \), and \( A \) a base-point free line bundle on \( C \) with \( h^0(A) = r + 1 \) and \( \deg A = d \). As mentioned in the Introduction, \( E^\vee \) fits into an exact sequence

\[
0 \to E^\vee \to H^0(C,A) \otimes O_X \to i_*A \to 0,
\]

where \( i : C \hookrightarrow X \) is the inclusion. Dualizing it gives

\[
(2) \quad 0 \to H^0(C,A)^* \otimes O_X \to E \to i_*(\omega_C \otimes A^{-1}) \to 0.
\]

As computed in [Laz86], \( E \) is a vector bundle of rank \( r + 1 \), and \( c_1(E) = O_X(C), c_2(E) = d; h^0(E) = h^0(A) + h^1(A), h^1(E) = h^2(E) = 0, h^0(E^\vee) = h^1(E^\vee) = 0 \). Moreover \( \chi(E \otimes E^*) = 2h^0(E \otimes E^*) - h^1(E \otimes E^*) = 2 - 2\rho(A) \) where \( \rho(A) = g(C) - h^0(A) \cdot h^1(A) \).

This paper focuses on the case when \( d = k + 1 \) and \( r = 1 \), and \( C \subseteq |L| \) for an ample line bundle on \( X \). Hence the Lazarsfeld-Mukai bundle is of rank \( 2 \). By the relation between Chern classes and degeneracy locus of sections of a vector bundle. A general section \( s \in H^0(E) \) gives a general zero-dimensional \( Z(s) \) on a general curve \( C \in |L| \) with \( \deg Z(s) = k + 1 \). Thus, we have the following exact sequence

\[
0 \to O_X \xrightarrow{s} E \xrightarrow{\Lambda s} I_{Z(s)} \otimes L \to 0.
\]

Take another \( s' \in H^0(E) \) independent of \( s \) such that their degeneracy locus is \( C \), then the above exact sequence adapts to

\[
(3) \quad 0 \to \langle s, s' \rangle \otimes O_X \to E \to i_*(\omega_C \otimes O_C(-Z(s))) \to 0.
\]

Denote \( O_C(Z(s)) \) as \( A \), then the above exact sequence implies \( h^0(\omega_C \otimes A^{-1}) = h^1(A) = k \). Dualizing it gives

\[
0 \to E^\vee \to \langle s, s' \rangle^* \otimes O_X \to i_*A \to 0.
\]

Hence \( \deg(A) = c_2(E) = k + 1 \). By Riemann-Roch theorem, \( h^0(A) = 2 \). Compare (2) and (3), we may identify \( H^0(C,A) \cong \langle s, s' \rangle^* \). Therefore \( A \) is base-point free. In a word, for a non-zero regular section \( s \in H^0(E) \), i.e. \( Z(s) \) is zero-dimensional, and it is associated to a base-point free line bundle \( A \in W_{k+1}^1(C) \) for a curve \( C \subseteq |L| \) containing \( Z(s) \).
2.3. Brill-Noether Theory. Classical Brill-Noether theory concerns special divisors on a smooth curve $C$ of genus $g$ over an algebraically closed field $\mathbb{F}$. For given integers $r, d$, one defines the Brill-Noether number $\rho(r, d, g) = g - (r + 1)(r - d + g)$. Define Brill-Noether loci

$$W^r_d(C) := \{ \text{line bundle } A \text{ on } C \mid \deg(A) = d, h^0(A) \geq r + 1 \}. $$

Let $G^r_d(C) := \{(V, A) \mid r + 1 \text{ dimensional subspace } V \subseteq H^0(A), A \in W^r_d(C)\}$ i.e. parametrize all linear systems of degree $d$ and dimension $r$ on $C$. Brill-Noether asserts that for a general curve $C$, (1) if $\rho < 0$, then $W^r_d(C)$ hence $G^r_d(C)$ is empty; (2) if $\rho \geq 0$, then $G^r_d(C)$ hence $W^r_d(C)$ is not empty.

When $\mathbb{F} = \mathbb{C}$, Lazarsfeld \cite{Laz86} showed that, if $\text{Pic}(X) = \mathbb{Z}[L]$, then any smooth member $C$ in $|L|$ is general in the Brill-Noether sense. Moreover, a curve $C$ is called to satisfy Petri’s condition, if the map $H^0(A) \otimes H^0(\omega_C \otimes A^*) \to H^0(\omega_C)$ is injective for any line bundle $A$ on $C$. Gieseker proved that a general curve satisfies Petri’s condition, which refines the Brill-Noether theory of the loci $W^r_d(C)$. \cite{ACGH85}, §IV In fact, Lazarsfeld \cite{Laz86} even proves that a general smooth member of $C \in |L|$ is Petri general. In his elegant proof, he essentially used the generic smoothness theorem in characteristic 0, which can be a huge problem in positive characteristic.

By Theorem 1.1 we may assume $(X, L)$ is a polarized K3 surface over some algebraically closed field $\mathbb{F}$ such that $\text{Pic}(X) = \mathbb{Z}[L]$. By a similar argument of \cite{Laz86} Cor 1.3, any Lazarsfeld-Mukai bundle associated to a prescribed pair $(C, A)$ is simple, hence $\chi(E \otimes E^*) = 2 - 2\rho(A) = 2h^0(E \otimes E^*) - h^1(E \otimes E^*) \leq 2$, i.e. $\rho(A) \geq 0$. One can further prove that, for any smooth member $C \in |L|$ and every line bundle $A$ on $C$, $\rho(A) \geq 0$. \cite{Laz86} Cor 1.4 i.e. any smooth curve $C \in |L|$ is Brill-Noether general.

2.4. Green’s Conjecture. Green’s Conjecture on syzygies of canonical curves asserts that one can read off existence of special linear series on an algebraic curve, by looking at the syzygies of its canonical embedding. Precisely, if $C$ is a smooth projective curve of genus $g$, let $K_{p,q}(C, \omega_C)$ denote the $(p, q)$-th Koszul cohomology group of the canonical bundle $\omega_C$ and $\text{Cliff}(C)$ be the Clifford index of $C$, then Green \cite{Gre84} conjectured the following:

$$K_{p,2}(C, \omega_C) = 0, \quad \forall p < p' \iff \text{Cliff}(C) > p'$$

In the case of even genus $g = 2k$, a single vanishing $K_{k,1}(C, \omega_C) = 0$ suffices to prove Green’s Conjecture for a general canonical curve. In \cite{Vo102}, Voisin studied curves lying on a polarized K3 surface $(X, L)$ of even genus $g = 2k$ with $\text{Pic}(X) = \mathbb{Z}[L]$. As mentioned in the Introduction, for $\text{char}(\mathbb{F}) \neq 2$, the hyperplane restriction theorem \cite{Gre84} implies

$$K_{k,1}(C, \omega_C) = K_{k,1}(X, L)$$

whenever $C$ is a smooth and connected (i.e. general) hyperplane section of $L$ on $X$ (note that $L|_C = \omega_C$ in this case). Indeed, the above identity holds true under the hypothesis that $H^1(X, qL) = 0$ for all $q \geq 0$. Although Kodaira-Ramanujam vanishing theorem fails in positive characteristic in general, it does hold for an ample line bundle $L$ on K3 surfaces, \cite{Huy16}, §II. Prop 3.1.

Main Theorem 1.1 implies in particular that, for a general primitively polarized K3 surface $(X, L)$, we have $\text{Sym}^{k-2}H^0(X, E) \simeq K_{k-1,1}(X, L)$ and so $\dim K_{k-1,1}(X, L) = \binom{2k-2}{k-2}$. This implies that $K_{k,1}(X, L) = 0$ by standard dimension computations, \cite{Far17}, §IV.1. Therefore, one deduces Corollary 1.1 i.e. Green’s Conjecture for general canonical curves of even genus in positive characteristic.

Now we proceed to prove Proposition 1.2. Let $\mathbb{F}$ be an algebraically closed field with $\text{char}(\mathbb{F}) = p$, we have a natural isomorphism

$$(\text{Sym}^j F)^\vee \simeq \text{Sym}^j F^\vee, \quad \text{for } 1 \leq j \leq p - 1$$
for any vector bundle $F$ on an algebraic $\mathbb{F}$-variety $X$. Indeed, $\left(\text{Sym}^j F^\vee\right)^\vee$ is naturally isomorphic to the divided algebra

$$D^j F := \{ x \in F^{\otimes j} \mid \sigma(x) = x, \text{ for all } \sigma \in S_j \}$$

and we define an isomorphism

$$D^j F \to \text{Sym}^j F$$

\[ x \mapsto \frac{1}{j!} \sum_{\sigma \in S_j} \sigma(x) \]

Note that this isomorphism fails to be defined for $j \geq p$.

Moreover, let $0 \to F_1 \to F_2 \to F_3 \to 0$ be an exact sequence of vector bundles on $X$. Provided, $1 \leq j \leq p - 1$, there are two long exact sequences, [ABW82, Ch. V];

\[ \cdots \to \bigwedge^{j-2} F_2 \otimes \text{Sym}^{2}(F_1) \to \bigwedge^{j-1} F_2 \otimes F_1 \to \bigwedge^{j} F_2 \to \bigwedge^{j} F_3 \to 0, \]

\[ \cdots \to \text{Sym}^{j-2} F_2 \otimes \bigwedge^{2} F_1 \to \text{Sym}^{j-1} F_2 \otimes F_1 \to \text{Sym}^{j} F_2 \to \text{Sym}^{j} F_3 \to 0. \]

Note that the first exact sequence above involves the isomorphism from divided to symmetric products and hence needs the assumption $j \leq p - 1$ (the second exact sequence remains true without this assumption). Further, provided $j \leq p - 1$, we may dualize the sequence $0 \to F_1 \to F_2 \to F_3 \to 0$, obtain the second exact sequence and dualize again, obtaining an exact sequence

\[ 0 \to \text{Sym}^{j} F_1 \to \text{Sym}^{j} F_2 \to \text{Sym}^{j-1} F_2 \otimes F_3 \to \text{Sym}^{j-2} F_2 \otimes \bigwedge^{2} F_3 \to \cdots \]

Proof of Proposition 1.2. One applies the universal secant sheaves approach to prove the proposition, [Kem20] §1.2. The whole computation carries out essentially the same. There are only two things to check out.

(i) The highest symmetric power of vector bundles [Kem20] uses is $\text{Sym}^{k+1}$. This is why we set the bound $p \geq \frac{g+4}{2} = k + 2$.

(ii) All the sheaves appearing in the universal secant sheaves construction should be locally free.

In particular, we only have to check [Kem20] Lem 1.1. This also follows from our assumption that any non-zero $s \in H^0(E)$ is regular, i.e. $Z \to \mathbb{P}(H^0(E))$ is finite and flat. (see Remark 1.3.(ii))

3. Universal Construction

To apply Lazarsfeld-Mukai bundle method, a K3 surface of Picard number one is preferred. While it may be impossible to start with a required one over the original field $\mathbb{F}$, Theorem [1.1] suggests us to pay attention to a smooth family of primitively polarized K3 surfaces and consider the geometric generic fiber. Thus, we prove Main Theorem [1.1] by the approach of universal Lazarsfeld-Mukai bundle construction for a smooth family of primitively polarized K3 surfaces $(X, \mathcal{L}) \to T$.

**Definition 1.** A smooth family of primitively polarized K3 surfaces of degree $2g - 2$ is a smooth projective morphism of $\mathbb{F}$-varieties $\pi : (X, \mathcal{L}) \to T$ with an ample line bundle $\mathcal{L}$ on $X$, such that for every $t \in T$, each fiber $(X_t, \mathcal{L}_t)$ is a primitively polarized K3 surfaces of degree $2g - 2$. 

\[ \square \]
**Lemma 3.1.** Assume \( \text{char}(\mathbb{F}) \neq 2 \). Let \( \pi : (\mathcal{X}, \mathcal{L}) \to \mathcal{T} \) be a smooth family of primitively polarized K3 surfaces of degree \( 2g - 2 \). Up to a base change to some non-empty Zariski open of \( \mathcal{T} \), there exists an embedded smooth family of curves

\[
\begin{array}{ccc}
\mathcal{C} & \xrightarrow{i} & \mathcal{X} \\
\pi|_{\mathcal{C}} & \downarrow & \pi \\
\mathcal{T} & \to & 
\end{array}
\]

such that for every \( t \in \mathcal{T} \), \( C_t \subseteq X_t \) is a smooth curve of genus \( g \) with \( \mathcal{O}_{X_t}(C_t) \cong \mathcal{L}_t \). We may interchangeably use the notion \((\mathcal{X}, \mathcal{C}) \to \mathcal{T}\) as a smooth family of primitively polarized K3 surfaces with degree \( 2g - 2 \).

**Proof.** By reducing to an irreducible component, we may assume \( \mathcal{T} \) to be irreducible. Since for every \( t \in \mathcal{T} \), \( \dim H^0(X_t, \mathcal{L}_t) = g + 1 \), then \( \pi_* \mathcal{L} \) is a locally free sheaves on \( \mathcal{T} \) by Grauert’s theorem. Consider the projective bundle \( \mathbb{P}(\pi_* \mathcal{L}) \to \mathcal{T} \), there is a universal family

\[
\begin{array}{ccc}
\mathcal{C} & \xrightarrow{i} & \mathbb{P}(\pi_* \mathcal{L}) \\
p|_{\mathcal{C}} & \downarrow & p \\
\mathbb{P}(\pi_* \mathcal{L}) & \to & 
\end{array}
\]

where \( \mathcal{C} := \{(x, [s]_t) \in \mathcal{X}_x \times_{\mathcal{T}} \mathbb{P}(\pi_* \mathcal{L}) \mid x \in V([s]_t) \subseteq X_t \text{ for } [s]_t \in H^0(X_t, \mathcal{L}_t) \text{ and } t \in \mathcal{T} \} \) i.e. the fiber of \([s]_t \in \mathbb{P}(\pi_* \mathcal{L})\) along \( p|_{\mathcal{C}} \) is just the vanishing set of \([s]_t \in H^0(X_t, \mathcal{L}_t)\) in \( X_t \). Denote it as \( C|_{[s]_t} \subseteq X_t \), it is a curve of arithmetic genus \( g \) (possibly singular).

A general member \( C_t \in |\mathcal{L}_t| \) is smooth. After restricting to a non-empty Zariski open of \( \mathbb{P}(\pi_* \mathcal{L}) \), one may assume each fiber \( C|_[s]_t \) is smooth. Moreover, choose a local section of \( \mathbb{P}(\pi_* \mathcal{L}) \to \mathcal{T} \) over some non-empty open \( \mathcal{T}' \) of \( \mathcal{T} \), i.e. \( s : \mathcal{T}' \to \mathbb{P}(\pi_* \mathcal{L}) \), the pullback of the above diagram by the base change to \( \mathcal{T}' \to \mathbb{P}(\pi_* \mathcal{L}) \) gives us the following diagram, satisfying all the assumptions.

\[
\begin{array}{ccc}
\mathcal{C}' & \xrightarrow{i} & \mathcal{X}' \\
\pi'|_{\mathcal{C}'} & \downarrow & \pi' \\
\mathcal{T}' & \to & \mathcal{T}
\end{array}
\]

\( \square \)

**Lemma 3.2.** Let \( \pi : \mathcal{C} \to \mathcal{T} \) be a smooth family of genus \( g \) curves. Assume the geometric generic fiber \( C_\mathcal{T} \) is Brill-Noether general. Let \( r, d \) be such integers such that the Brill-Noether number \( \rho(r, d, g) = 0 \). Then up to a base change to an étale open of \( \mathcal{T} \), there exists a line bundle \( \mathcal{A} \) on \( \mathcal{C} \), such that for every \( t \in \mathcal{T} \), \( \mathcal{A}_t \in W^r_d(C_t) \) with \( h^0(C_t, \mathcal{A}_t) = r + 1 \) and \( \mathcal{A}_t \) base-point free.

**Proof.** Without loss of generality, we may assume \( \pi : \mathcal{C} \to \mathcal{T} \) admits a section, since any smooth family admits an étale local section. Let \( \mathcal{Pic}^d_{\mathcal{C}/\mathcal{T}} \) be the relative Picard scheme with degree \( d \) associated to \( \pi : \mathcal{C} \to \mathcal{T} \). The Brill-Noether variety \( W^r_d(\pi) \subseteq \mathcal{Pic}^d_{\mathcal{C}/\mathcal{T}} \) associated to \( \pi : \mathcal{C} \to \mathcal{T} \) is a \( \mathcal{T} \)-scheme representing the functor (see [ACG11 §XXI.3])

\[
\begin{array}{ccc}
\text{Sch}/\mathcal{T} & \to & \text{Sets} \\
\mathcal{S} & \mapsto & \{[\mathcal{L}] \in \mathcal{Pic}^d_{\mathcal{C}/\mathcal{T}}(\mathcal{S}) \mid \text{the Fitting-rank}(R^1_{ps,s}\mathcal{L}) \geq g - d + r\}
\end{array}
\]

where \( p_S : \mathcal{C} \times_{\mathcal{T}} \mathcal{S} \to \mathcal{S} \) is the projection. More precisely, set-theoretically,

\[
\text{supp}(W^r_d(\pi)) = \{(t, L) \mid t \in \mathcal{T}, L \in \mathcal{Pic}^d(C_t) \text{ such that } L \in W^r_d(C_t)\}.
\]
Since \( \rho \geq 0 \) implies \( W^r_d(C) \neq \emptyset \) for every curve \( C \), the \( \mathcal{T} \) points \( W^r_d(\pi)(\mathcal{T}) \neq \emptyset \). Choose any \( \mathcal{A} \in W^r_d(\pi)(\mathcal{T}) \), i.e. for every \( t \in \mathcal{T} \), \( \mathcal{A}_t \in W^r_d(C_t) \) i.e. \( h^0(C_t, \mathcal{A}_t) \geq r + 1 \). By assumption, the geometric generic fiber \( C_\pi \) is Brill-Noether general with \( \rho(r, d, g) = 0 \).

Claim. For any \( \mathcal{A} \in W^r_d(C_\pi) \) over the original fiber \( C_\pi \), we have
\[
\begin{cases}
    h^0(\mathcal{A}) = r + 1, & \text{in particular,} \\
    \mathcal{A} \text{ is base-point free} & \mathcal{A}_t \text{ is base-point free}
\end{cases}
\]
Indeed, denote \( \overline{\mathcal{A}} \) as the pullback of \( \mathcal{A} \) by \( C_\pi \rightarrow C_\pi \). By flat base change, we have \( H^0(C_\pi, \overline{\mathcal{A}}) = H^0(C_\pi, \mathcal{A}) \otimes_{\mathcal{O}(\pi)} \overline{\mathcal{A}} \). If \( h^0(\mathcal{A}) = h^0(\overline{\mathcal{A}}) \geq r + 2 \), then \( W^{r+1}_d(C_\pi) \neq \emptyset \), but it contradicts with \( \rho(r + 1, d, g) < 0 \) as \( C_\pi \) is Brill-Noether general. Moreover, as the field extension is faithfully flat, if \( \mathcal{A} \) is not base-point free, equivalently \( \mathcal{A} \) globally generated, so is \( \overline{\mathcal{A}} \). Take the base-point free part \( \overline{\mathcal{A}}_b \) (i.e. \( \text{im}(H^0(\overline{\mathcal{A}}) \otimes \mathcal{O}_{C_\pi} \rightarrow \overline{\mathcal{A}}) \)), whose degree is strictly less than that of \( \overline{\mathcal{A}} \) but with the same global sections. Hence \( W^{r+1}_d(C_\pi) \neq \emptyset \) for some \( p > 0 \), but it contradicts with \( \rho(r, d - p, g) < 0 \).

Finally, by the upper semi-continuity of the function \( t \mapsto h^0(C_t, \mathcal{A}_t) \) and base-point freeness being an open condition, we may shrink the base again to get the required property: there exists a line bundle \( \mathcal{A} \) on \( C \) such that for every \( t \in \mathcal{T} \), \( \mathcal{A}_t \in W^r_d(C_t) \) with \( h^0(C_t, \mathcal{A}_t) = r + 1 \) and \( \mathcal{A}_t \) base-point free.

\[ \square \]

With the argument in the above lemma, we are ready to prove Proposition 1.1.

Proof of Proposition 1.1. For any primitively polarized K3 surface \((X, L)\) of degree \(2g - 2\) over an algebraically closed field \( \mathbb{F} \). Let \( \pi : (X, \mathcal{L}) \rightarrow \mathcal{T} \) be a smooth versal \( \mathbb{F} \) deformation of \((X, L)\), i.e. smooth family of primitively polarized K3 surfaces (see in the proof 3 of Theorem 1.1) with line bundle \( \mathcal{L} \) of (relative) degree \(2g - 2\). The geometric generic fiber \((X_\pi, \mathcal{L}_\pi)\) has \( \text{Pic}(X_\pi) = \mathbb{Z}[\mathcal{L}_\pi] \). In particular, any smooth \( C_\pi \in |\mathcal{L}_\pi| \) is Brill-Noether general.

Similar in the proof of Lemma 3.1 with a focus on an open dense “smooth” part \( \mathbb{P}(H^0(\pi_* \mathcal{L}))_s \) whose points are those \((t, [s]_t)\) such that \([s]_t \) defines a smooth curve \( C \in |\mathcal{L}_t| \). There is a universal family
\[
\begin{array}{ccc}
    \mathcal{C} & \longrightarrow & \mathcal{X}_\mathbb{P} := \mathcal{X} \times_{\mathcal{T}} \mathbb{P}(\pi_* \mathcal{L})_s \\
    p|_{\mathcal{C}} & \downarrow & \mathbb{P}(\pi_* \mathcal{L})_s \\
    \mathbb{P}(\pi_* \mathcal{L})_s & \overset{p}{\longrightarrow} & \mathbb{P}(\pi_* \mathcal{L})_s
\end{array}
\]
such that the fiber over the point \((t, [s]_t) \in \mathbb{P}(\pi_* \mathcal{L})_s \) along \( p|_{\mathcal{C}} \) is the smooth curve \( C_{[s]_t} \subseteq X_t \) defined by section \([s]_t \in H^0(\mathcal{L}_t)\).

Claim. For a general fiber \((X_t, L_t)\) over \( \mathcal{T} \) and a general smooth curve \( C \in |L_t| \), i.e. a general fiber over \( \mathbb{P}(\pi_* \mathcal{L})_s \), each \( \mathcal{A} \in W^r_d(C) \) has (i) \( h^0(\mathcal{A}) = r + 1 \) and (ii) \( \mathcal{A} \) base-point free.

If (i) fails for a general fiber, consider the related Brill-Noether variety \( W^r_d(C) \) associated to the smooth family of curves \( p|_C : C \rightarrow \mathbb{P}(\pi_* \mathcal{L})_s \), then \( \text{supp}(W^{r+1}_d(p|_C)) \) is not supported on any divisor of \( \mathbb{P}(\pi_* \mathcal{L})_s \), hence also contains the generic points of \( \mathbb{P}(\pi_* \mathcal{L})_s \) (maybe reducible). But as the Brill-Noether number \( \rho(r, d, g) = 0 \), by the claim in the proof of Lemma 3.2 those generic fibers, which are all over the generic point \( \tau \in \mathcal{T} \), are geometrically Brill-Noether general. Hence they do not admit any line bundle with \( h^0(\mathcal{A}) \geq r + 2 \). A contradiction.

Similarly, if (ii) fails for a general fiber, consider the related Brill-Noether variety \( W^{r-i}_d(p|_C) \) for \( 0 < i < d \), then at least for some \( i \), \( \text{supp}(W^{r-i}_d(p|_C)) \) is not supported on any divisor of \( \mathbb{P}(\pi_* \mathcal{L})_s \), hence also contains the generic points of \( \mathbb{P}(\pi_* \mathcal{L})_s \). A contradiction by the same reason as above.

\[ \square \]
Let \( \pi : (X, C) \to T \) be a smooth family of primitively polarized K3 surfaces of degree \( 2g - 2 \). Let \( i : C \hookrightarrow X \) denote the closed embedding. Assume \( A \) is a line bundle \( A \) over \( C \) such that \( A_t \in W^r_d(C_t) \) and for every \( t \in T \), \( h^0(C_t, A_t) = r + 1 \) and \( A_t \) base-point free. By Grauert’s theorem, one easily see that \( \pi|_{C, s} A = \pi_s i_s A \) is a locally free sheaf on \( T \) of rank \( r + 1 \). We construct a universal Lazarsfeld-Mukai bundle \( E \) on \( X \) associated to the line bundle \( A \) on \( C \) by the following steps. Take the kernel \( F \) of the natural surjective evaluation map \( \pi^* \pi_s i_s A \to i_s A \) to fit into an exact sequence

\[
0 \to F \to \pi^* \pi_s i_s A \to i_s A \to 0.
\]

**Remark 3.1.** The natural map \( \pi^* \pi_s i_s A \to i_s A \) being surjective means \( i_s A \) is globally generated along fibers, i.e. for any \( t \in T \), \( H^0(C_t, A_t) \otimes_{\kappa(t)} O_{X_t} \to i_{t,s} A_t \), which is true under our assumption.

**Proposition 3.1.** Let \( \pi : (X, C) \to T \) and \( A \) defined as above. Denote the associated line bundle \( L = O_X(C) \). Then

(i) The kernel \( F \) is a locally free sheaf of rank \( r + 1 \) on \( X \). Its dual \( F^\vee \) is denoted as the universal Lazarsfeld-Mukai bundle \( E \) for \( \pi : (X, C) \to T \) associated to the line bundle \( A \) on \( C \). We have \( \det(E) = L \).

(ii) For every \( t \in T \), the following pullback of the exact sequence (4) along the fiber \( X_t \) is exact.

\[
0 \to F_t \to H^0(C_t, A_t) \otimes_{\kappa(t)} O_{X_t} \to i_{t,s} A_t \to 0
\]

where \( i_t : C_t \hookrightarrow X_t \) denotes the closed embedding. In particular, \( \xi_t := F_t^\vee \) is the Lazarsfeld-Mukai bundle associated to a pair \( (C_t, A_t) \) on \( X_t \). Moreover, it satisfies the following numerical invariants: \( \det(F_t) = L_t = O_{X_t}(C_t), h^0(E_t) = h^0(A_t) + h^1(A_t), h^1(E_t) = h^2(E_t) = 0 \).

**Proof.** For (i), note that \( C \subseteq X \) is a divisor, \( i_s A \) being locally isomorphic to \( i_s O_C \), has homological dimension 1 over \( O_X \). Hence \( F \) is locally free. It is clear that \( E = F^\vee \) has rank \( r + 1 \). As the map \( F \to \pi^* i_s A \) drops rank along \( C, \det(F) = O_X(-C) \), i.e. \( \det(E) = L \).

For (ii), by applying \( j^* \) to the sequence (4), where \( j : X_t \hookrightarrow X \) denotes the embedding above any point \( t \in T \), we have

\[
\text{Tor}_1^{\mathcal{O}_X}(j^{-1} i_s A, O_{X_t}) \to F_t \to \pi_t|_{C, s} A_t \otimes_{\kappa(t)} O_{X_t} \to i_{t,s} A_t \to 0.
\]

In fact, \( i_s A \) is a flat sheaf of \( O_X \)-module since flatness is a local property and \( i_s O_C \) is a flat sheaf of \( O_X \)-module. Also, \( j^{-1} \) is exact. This implies \( \text{Tor}_1^{\mathcal{O}_X}(j^{-1} i_s A, O_{X_t}) = 0 \). In addition, by proper base change theorem, we have the natural isomorphism \( \pi|_{C,s} A \otimes \kappa(t) \cong H^0(C_t, A_t) \). Hence, we obtain the exact sequence (5).

\[
0 \to H^0(C_t, A_t) \otimes_{\kappa(t)} O_{X_t} \to E_t \to i_{t,s}(\omega_{C_t} \otimes A_t^\vee) \to 0
\]

Then \( h^0(E_t) = h^0(A_t) + h^1(A_t) \). Other numerical invariants are similarly computed in [Laz86]. \( \square \)

Now we are going to use the construction of universal Lazarsfeld-Mukai bundle for a smooth versal deformation of K3 surfaces to prove Main Theorem (1).

**Proof of Main Theorem [1]** For any primitively polarized K3 surface \( (X, L) \) of genus \( g = 2k \) over \( \mathbb{P} \). Let \( \pi : (X, C) \to T \) be a smooth versal \( \mathbb{P} \)-deformation of \( (X, L) \), of which the geometric generic fiber \( (X_T, L_T) \) has Pic\( (X_T) = \mathbb{Z}[L_T] \). Since the Brill-Noether number \( \rho(1, k + 1, 2k) = 0 \), according to Lemma [3.2] by passing to an étale open of \( T \), one may assume \( A \) to be a line bundle on \( C \), flat over \( T \), such that for every \( t \in T \), \( A_t \in W^{k+1}_{k+1}(C_t) \) with \( h^0(C_t, A_t) = 2 \) and \( A_t \) base-point free. Let \( E \) be the rank 2 universal Lazarsfeld-Mukai bundle over \( X \) associated to the line bundle \( A \) on \( C \). In particular, for every \( t \in T \), \( h^1(A_t) = k \) by Riemann-Roch theorem, hence \( h^0(E_t) = h^0(A_t) + h^1(A_t) = k + 2 \). By Grauert’s theorem, \( \pi_s E \) is a locally free sheaf of rank \( k + 2 \) on \( T \).

Consider the projective bundle \( \varphi : \mathbb{P}(\pi_* E) \to T \). Any point \( p \in \mathbb{P}(\pi_* E) \) can be identified with \( (t, [s])/t \) for some \( t \in T \) and \( [s]_t \in \mathbb{P}(H^0(E_t)) \). Take the fiber product with \( \pi : X \to T \) to form a
smooth family of K3 surfaces $X_p := X \times \mathbb{P}(\pi_*, \mathcal{E}) \to \mathbb{P}(\pi_*, \mathcal{E})$. Without too much abuse of notions, we still denote the pullback of $\mathcal{L}$ (resp. $\mathcal{E}$) to $X_p$ as $\mathcal{L}$ (resp. $\mathcal{E}$). Above any point $p = (t, [s]_t) \in \mathbb{P}(\pi_*, \mathcal{E})$, denote the fiber $X_p \subseteq X_p$. Note that we have natural isomorphism of fibers $(X_p, \mathcal{L}_p, \mathcal{E}_p) \simeq (X_t, \mathcal{L}_t, \mathcal{E}_t)$.

Define the reduced closed subvariety $Z \subseteq X_p$ on the closed set

$$Z = \{(x, [s]_t) \in X \times \mathbb{P}(\pi_*, \mathcal{E}) | x \in V([s]_t) \subseteq X_t \text{ for } [s]_t \in \mathbb{P}(\pi_*, \mathcal{E})\}.$$ 

For any point $p = (t, [s]_t) \in \mathbb{P}(\pi_*, \mathcal{E})$, we have $Z_p = \{x \in X_p \simeq X_t | s(x) = 0\}$. On the other hand, for any point $t \in T$, denote the projection $Z \to \mathbb{P}(\pi_*, \mathcal{E})$ under the base change $\mathbb{P}(\mathcal{H}_t^0(\mathcal{E}_t)) \to \mathbb{P}(\mathcal{E}_t)$ as $Z_t \subseteq X_t \times \mathbb{P}(\mathcal{H}_t^0(\mathcal{E}_t)) \to \mathbb{P}(\mathcal{H}_t^0(\mathcal{E}_t))$. Since the geometric generic fiber $(X_T, \mathcal{L}_T)$ has Picard number one, $Z_T \to \mathbb{P}(\mathcal{H}_t^0(\mathcal{E}_t))$ is finite and flat. (see Remark 1.3(iii)). As the field extension is faithfully flat, $Z_T \to \mathbb{P}(\mathcal{H}_t^0(\mathcal{E}_t))$ is also flat.

By generic flatness theorem, we may choose a non-empty Zariski open set of $U \to \mathbb{P}(\pi_*, \mathcal{E})$ such that $Z|_U$ is flat over $U$. May assume $U$ contains the whole generic fiber $\mathbb{P}(\mathcal{H}_t^0(\mathcal{E}_t)) \subset \mathbb{P}(\pi_*, \mathcal{E})$ as $Z_t \to \mathbb{P}(\mathcal{H}_t^0(\mathcal{E}_t))$ is flat. Since $\varphi : \mathbb{P}(\pi_*, \mathcal{E}) \to T$ is proper and surjective, the image of the complement of $U$ under $\varphi$ is a proper closed subset of $T$ avoiding the generic point $\tau \in T$. By possibly shrinking $U \subseteq \mathbb{P}(\pi_*, \mathcal{E})$, we may take open $V \subseteq T$ such that $\varphi|_U : \varphi^{-1}(V) = U \subseteq \mathbb{P}(\pi_*, \mathcal{E}) \to V \subseteq T$ is surjective. Then one easily sees that for any $t \in V \subseteq T$, $Z_t \to \mathbb{P}(\mathcal{H}_t^0(\mathcal{E}_t))$ is flat and proper. Moreover, since over the generic point $\tau$, $Z_\tau \to \mathbb{P}(\mathcal{H}_t^0(\mathcal{E}_t))$ is a surjection between two projective varieties of the same dimension $k + 1$, the map is quasi-finite. It follows that $Z_t \to \mathbb{P}(\mathcal{H}_t^0(\mathcal{E}_t))$ is also quasi-finite, hence finite, for any $t \in V$. Now it is clear that, for any closed point $t \in V \subseteq T$, $(X_t, \mathcal{L}_t)$ satisfies the assumption of Proposition 1.2. Therefore, we prove that a general primitively polarized K3 surface $(X, L)$ satisfies the expected properties. 

\[ \text{Proposition 3.2.} \]

Let $(X, L)$ be a general primitively polarized K3 surface of even genus $g = 2k$. For a general smooth curve $C \in |L|$, let $A \in W^1_{k+1}(C)$ with $h^0(A) = 2$ and base-point free. Let $E$ be the rank 2 Lazarsfeld-Mukai bundle associated to such a pair $(C, A)$. We have a well-defined finite surjective map $d : \text{Gr}_2(\mathcal{H}_t^0(E)) \to |L|$ with degree $\frac{k}{2k} \binom{2k}{k}$. Moreover, the fiber $d^{-1}(C)$ over a general smooth curve $C \in |L|$ may be identified naturally with Brill-Noether loci $W^1_{k+1}(C)$.

\[ \text{Proof.} \]

The existence of such line bundle $A$ over a general smooth curve $C \in |L|$ is guaranteed by Proposition 1.1. Taking degree 2 wedge power of $\mathcal{H}_t^0(E) \otimes \mathcal{O}_X \to E$ gives $\bigwedge^2 \mathcal{H}_t^0(E) \otimes \mathcal{O}_X \to \bigwedge^2 E = L$. Taking the global section gives

$$\det : \bigwedge^2 \mathcal{H}_t^0(E) \to \mathcal{H}_t^0(L).$$

A rational map $d : \text{Gr}_2(\mathcal{H}_t^0(E)) \to |L|$ is given by taking a general two dimensional subspace $W \subseteq \mathcal{H}_t^0(E)$ to the degeneracy locus of the evaluation map $W \otimes \mathcal{O}_X \overset{ev}{\to} E$, which is given by a section of $L$ via taking degree 2 wedge power of $ev$

$$s : \mathcal{O}_X \simeq \bigwedge^2 W \otimes \mathcal{O}_X \overset{\bigwedge^2 ev}{\to} \bigwedge^2 E = L.$$ 

To sum up, we have the following commutative diagram

\[ \text{Gr}_2(\mathcal{H}_t^0(E)) \xrightarrow{\text{Plücker embedding}} \mathbb{P}(\bigwedge^2 \mathcal{H}_t^0(E)) \]

\[ d \]

\[ \to \]

\[ \mathbb{P}(\det) \]

\[ |L| \]

Let $|L|_{gs}$ denote the open dense subset of $|L|$ contained by the locus of irreducible smooth curves. Consider a relative Brill-Noether variety $p : W^1_{k+1}(|L|_{gs}) \to |L|_{gs}$. By Proposition 1.1, we may further shrink $|L|_{gs}$ if necessary, to assume that, for any curve $C \in |L|_{gs}$, each $A \in W^1_{k+1}(C)$ has
$h^0(C, A) = 2$ and $A$ base point free. Define a morphism $\psi : W_{k+1}^1(|L|_{gs}) \to \text{Gr}_2(H^0(E))$ as follows. Given $A \in W_{k+1}^1(C)$, we associate it to $[H^0(C, A)^*] \in \text{Gr}_2(H^0(E))$ via the following exact sequence

$$0 \to H^0(C, A)^* \otimes O_X \xrightarrow{\text{ev}} E \to i_*(\omega_C \otimes A^{-1}) \to 0.$$ 

The map $\text{ev}$ drops rank along $C$, hence the vanishing locus of the corresponding section $s : O_X \to \bigwedge^2 E = L$ is exactly $C$. That is to say, we have a commutative diagram

$$\begin{array}{c}
W_{k+1}^1(|L|_{gs}) \\
p \\
\downarrow \psi \\
\bigwedge^2 |L|_{gs} \\
d \\
\bigwedge^0 |L|_{gs} \subseteq \text{Gr}_2(H^0(E))
\end{array}$$

On the other hand, for any $[W] \in \text{Gr}_2(H^0(E))$ such that $d(W) = C \in |L|_{gs}$, the cokernel is a rank one torsion free sheaf supported on $C$, i.e. a line bundle on $C$. We may write as the following where $A$ is some line bundle on $C$.

$$0 \to W \otimes O_X \to E \to i_*(\omega_C \otimes A^{-1}) \to 0.$$ 

This gives $h^0(\omega_C \otimes A^{-1}) = k$. Dualizing it gives

$$0 \to E^\vee \to W^* \otimes O_X \to i_* A \to 0.$$ 

Hence $\text{deg}(A) = c_2(E) = k + 1$. By Riemann-Roch, $h^0(\lambda) = 2$. This identifies $W = H^0(C, A)^*$ and $A$ is base-point free, i.e. $A \in W_{k+1}^1(C)$. This process gives an inverse of $\psi$, which identifies $d^{-1}(C) \simeq W_{k+1}^1(C)$ for $C \in |L|_{gs}$.

Let $\pi : (X, C) \to T$ be a versal $\mathbb{F}$-deformation of arbitrary primitive polarized K3 surface. Over the geometric generic fiber, $\text{Pic}(X_\mathbb{F}) = \mathbb{Z}[L_\mathbb{F}]$. By Lemma 5.2 and Proposition 5.1 we may further assume that there is a line bundle $\mathcal{A}$ on $C$ such that for every $t \in T$, $\mathcal{A}_t \in W_{k+1}^1(C_t)$ and $h^0(C_t, \mathcal{A}_t) = 2$ with $\mathcal{A}_t$ base-point free, and $\mathcal{E}$ is the rank 2 universal Lazarsfeld-Mukai bundle associated to the pair $(C, \mathcal{A})$. Let $\pi^* \pi_* \mathcal{E} \to \mathcal{E}$ be the natural evaluation map, taking the degree 2 wedge power gives

$$\bigwedge^2 \pi^* \pi_* \mathcal{E} = \pi^* \bigwedge^2 \pi_* \mathcal{E} \to \text{det} \mathcal{E} = \mathcal{L}.$$ 

Hence after pushing forward to $T$ and by projection formula, we have the determinant map of vector bundles over $T$

$$\text{det} : \pi_* \pi^* \bigwedge^2 \pi_* \mathcal{E} = \pi_* \mathcal{O}_X \otimes \bigwedge^2 \pi_* \mathcal{E} \to \pi_* \mathcal{L},$$

where $\pi_* \mathcal{O}_X$ is a line bundle over $T$ by Grauert’s theorem. Take the stalk at $t \in T$, the determinant map reduces to

$$\text{det}_{t} : \bigwedge^0 H^0(\mathcal{E}_t) \to H^0(\mathcal{L}_t).$$

Consider the induced map between the associated projective bundles and a related Grassmannian bundle over $T$. Note that the projective bundle is insensitive to a twist by a line bundle, i.e. $\mathbb{P}(\mathcal{E}) = \mathbb{P}(\mathcal{E} \otimes \mathcal{L})$ for any line bundle $\mathcal{L}$ and vector bundle $\mathcal{E}$. We have the following commutative diagram of $T$-schemes

$$\begin{array}{ccc}
\text{Gr}_2(\pi_* \mathcal{E}) & \xleftarrow{\text{Plücker embedding}} & \mathbb{P}(\bigwedge^2 \pi_* \mathcal{E}) \\
\downarrow d & & \downarrow \pi_* \mathcal{L} \\
\mathbb{P}(\text{det}) & \xrightarrow{\text{Plücker embedding}} & \mathbb{P}(\mathcal{E})
\end{array}$$
Over each point \( t \in \mathcal{T} \), the above diagram reduces to the following:

\[
\begin{align*}
\text{Gr}_2(H^0(\mathcal{E})) & \xrightarrow{\text{Plücker embedding}} \mathbb{P} (\wedge^2 H^0(\mathcal{E})) \\
|\mathcal{L}_t| & \rightarrow |\mathcal{L}_t| \\
d_{|\mathcal{L}_t|} & \rightarrow \mathbb{P} (\det |\mathcal{X}_t|)
\end{align*}
\]

Over the geometric generic fiber, \( \text{Pic}(X_\tau) = \mathbb{Z} [\mathcal{L}_\tau] \). It implies the determinant map \( \det |\mathcal{X}_\tau : \wedge^2 H^0(\mathcal{E}_\tau) : H^0(\mathcal{L}_\tau) \) does not vanish on any element of rank 2. \([\text{Voi02}] \) proof of equ (3.18)). Hence it defines a regular map \( d_{|\mathcal{X}_\tau} : \text{Gr}_2(H^0(\mathcal{E}_\tau)) \rightarrow |\mathcal{L}_\tau| \). It is clearly dominant. Moreover, it is finite since both are projective varieties with the same dimension 2\( k \).

It follows from flat base change that over the generic fiber, we have a well-defined surjective regular map \( d_{|\mathcal{X}_\tau} : \text{Gr}_2(H^0(\mathcal{E}_\tau)) \rightarrow |\mathcal{L}_\tau| \), which is finite as well by the same reason as above. Note that there is a largest dense open \( U \) of \( \text{Gr}_2(H^0(\pi_* \mathcal{E})) \) where the rational map \( d : \text{Gr}_2(H^0(\pi_* \mathcal{E})) \rightarrow \mathbb{P}(\pi_* \mathcal{L}) \) is defined. Apparently, \( U \) contains the whole generic fiber \( \text{Gr}_2(H^0(\mathcal{E}_\tau)) \). Since the Grassmanian bundle \( \varphi : \text{Gr}_2(\pi_* \mathcal{E}) \rightarrow \mathcal{T} \) is proper and surjective, the image of the complement of \( U \) under \( \varphi \) is a proper closed subset \( \mathcal{S} \) of \( \mathcal{T} \) avoiding the generic point \( \tau \). Let \( V = \mathcal{T} \setminus \mathcal{S} \) be a non-empty open, then \( d \) is a regular map on \( \varphi^{-1}(V) \subseteq U \subseteq \text{Gr}_2(\pi_* \mathcal{E}) \), i.e., over each fiber \( t \in V \subseteq \mathcal{T} \), \( d_{|\mathcal{X}_t} : \text{Gr}_2(H^0(\mathcal{E}_t)) \rightarrow |\mathcal{L}_t| \) is regular. As the map \( d_{|\mathcal{X}_t} : \text{Gr}_2(H^0(\mathcal{E}_t)) \rightarrow |\mathcal{L}_t| \) over the generic fiber is finite, finiteness being an open condition, implies over a general fiber \( X_t, d_{|\mathcal{X}_t} : \text{Gr}_2(H^0(\mathcal{E}_t)) \rightarrow |\mathcal{L}_t| \) is finite. In particular, it implies \( d_{|\mathcal{X}_t} \) is surjective as well. Therefore, one may shrink \( V \) if necessary to show that a general \((X,L)\) satisfies the prescribed property.

Now we proceed to compute the degree of the finite surjective map \( d : \text{Gr}_2(H^0(E)) \rightarrow |L| \) for a general \((X,L)\). To ease the notation, let \( Z = \text{Gr}(2,H^0(E)) \) and \( Y = |L| \). Note that the finite map \( d : Z \rightarrow Y \) between two smooth schemes is automatically flat. Assume its degree is \( n \). Now for any \( y \in Y \), the fiber \( d^{-1}(y) = Z_y \) is a finite subscheme of \( Z \), and \( O(Z_y) \) is a finite dimensional \( k \)-vector space with \( \text{dim}_k O(Z_y) = n \). \([\text{Liu02}] \) p.176] In fact, \( Z_y \) is a complete intersection of hyperplane sections of \( \text{Gr}(2,H^0(E)) \) in the space \( \mathbb{P}(\wedge^2 H^0(E)). \) \([\text{Voi02}] \) p.29] Moreover, the number of hyperplane sections \( \text{dim } \wedge^2 H^2(E) - \text{dim } H^0(L) = (k+2)/2 - (2k+1) = \text{codim}(X, \mathbb{P}(\wedge^2 H^0(E))) \) has the expected intersection dimension. Hence, the degree of the finite map \( n = \text{dim}_k O(Z_y) \) coincides with the degree of the Grassmannian \( \text{Gr}(2,H^0(E)) \) via its Plücker embedding. A formula for its degree can be found in \([\text{Har92}] \) p.247

\[
\deg \text{Gr}(2,k+2) = (2k)! \prod_{i=0}^{1} \frac{i!}{(k+i)!} = \frac{(2k)!}{k!(k+1)!} = \frac{1}{k+1} \binom{2k}{k}.
\]

\[ \square \]

It is well-known that Main Theorem \([\text{I}2]\) combined with an observation of Voisin, implies Main Theorem \([\text{I}3]\), see the unpublished \([\text{Bot01}] \) §XI.

**Proof of Main Theorem \([\text{I}2]\)** Let \((X,L)\) be a general primitively polarized K3 surface with even genus, such that the regular map \( d : \text{Gr}(2,H^0(E)) \rightarrow |L| \) is surjective and finite with degree \( \frac{1}{k+1} (2k)! \). By assumption \( p > 2k \), hence coprime to the degree \( \frac{1}{k+1} (2k)! \). It follows that the corresponding extension of function fields is separable. By generic smoothness for a generically separable map (see Appendix B), for a general smooth \( C \in |L| \), the fiber \( d^{-1}(C) \simeq W^1_{k+1}(C) \) is reduced. Note that \( A \in W^1_{k+1}(C) \) is mapped to \([H^0(A)^*] \in \text{Gr}_2(H^0(E)). \)

By \([\text{Voi02}] \) Prop 7, the spaces \( \text{Sym}^{k-2} H^0(A)^* \), for \( A \in W^1_{k+1}(C) \) generate \( \text{Sym}^{k-2} H^0(E) \). Each \( H^0(A)^* \) corresponds to a line \( T_A \) in \( \mathbb{P}(H^0(E)) \). A section \([t]_A \in H^0(A)^* \subseteq H^0(E) \) corresponds to a
point $[t]_A$ sitting on the line $T_A$, whose image under
\[ \psi : \mathbb{P}(H^0(E)) \to \mathbb{P}(K_{k-1,1}(X, L)) \]
is $[K_{k-1,1}(X, L; H^0(L \otimes I_Z([t]_A)))]$. (see Proposition 1.2) Let the set
\[ T := \bigcup_{A \in W_{k+1}^1(C)} T_A \]
be the union of lines. The image of $T$ under $\psi$ is non-degenerate. \[\text{[Bot01 Thm 11.2]}\] This implies $K_{k-1,1}(X, L)$ is generated by the subspaces $K_{k-1,1}(X, L; H^0(L \otimes I_Z(s)))$, where $Z(s)$ given by a non-zero regular $s \in H^0(E)$ corresponds to a line bundle $A \in W_{k+1}^1(C)$ on a fixed curve $C$. (see Section 2.2) After restricting to $C$, such spaces are identified with subspaces of the form
\[ K_{k-1,1}(C, \omega_C; H^0(\omega_C \otimes A^{-1})) \subseteq K_{k-1,1}(C, \omega_C), \quad A \in W_{k+1}^1(C) \]
under the isomorphism $K_{k-1,1}(X, L) \simeq K_{k-1,1}(C, \omega_C)$. This completes the proof. \[\square\]

**Appendix A. Ogus’s Theorem**

**A.1. Spectral Sequences.** Assume $X$ is smooth, proper variety over a field $F$ with char$(F) = p > 0$, and additionally:

(A.1.1) The Hodge-Frölicher spectral sequence: $E_1^{p,q} = H^q(X, \Omega^p_{\text{dR}}) \Rightarrow H^{p+q}(X/F)$ degenerates at $E_1$ page.

(A.1.2) The conjugate spectral sequence: $E_2^{p,q} = H^q(X, H^q(\Omega^\bullet_X)) \Rightarrow H^{p+q}(X/F)$ degenerates at $E_2$ page.

(A.2) The crystalline cohomology groups $H^r_{\text{cris}}(X/W(F))$ are torsion free.

**Remark 1.** The Cartier operator induces a (Frobenius inverse linear) isomorphism $C : H^q(\Omega^\bullet_{\text{dR}}) \to \Omega^q_{\text{dR}}$, hence an isomorphism $H^q(H^q(\Omega^\bullet_{\text{dR}})) \to H^q(\Omega^q_{\text{dR}})$. It follows that (A.1.1) is equivalent to (A.1.2). Moreover, if they are equivalent, one can view $C$ as an isomorphism
\[ C : \text{gr}^p_{\text{F}_{\text{dR}}} H^{p+q}(X/F) \to \text{gr}^q_{\text{Hodge}} H^{p+q}(X/F). \]
Recall that $X/F$ satisfies assumption (A.1) and (A.2) if $X$ has a smooth lifting $\tilde{X}/W(F)$ with $H^q(\tilde{X}, \Omega^p_{\tilde{X}/W(F)})$ torsion free. In particular when $X$ is a K3 surface. \[\text{[DI81]}\]

**Remark 2.**

(i) A K3 surface $X/F$ is called *ordinary* if the Frobenius endomorphism induces an isomorphism on $H^2(X, \mathcal{O}_X)$. It is ordinary if two filtrations on $H^2_{\text{dR}}(X/F)$ satisfies $F^2_{\text{con}} \cap F^2_{\text{Hodge}} = 0$. For ordinary K3 surface, the map $\text{Im} : \text{Pic}(X) \otimes K \to H^1(X, \Omega^1_X) \subseteq H^2_{\text{dR}}(X/F)$ is injective. \[\text{[Ogu79 Rmk 1.9]}\]

(ii) A K3 surface $X/F$ is called *superspecial* if two filtrations induced by two spectral sequences on $H^2_{\text{dR}}(X/F)$ coincides, i.e. iff $F^2_{\text{con}} = F^2_{\text{Hodge}}$.

**A.2. Deformations and Obstructions.** We discuss some problems of deformation theory, and the obstruction of prolonging an ample line bundle in a family. Assume $f : \mathcal{X} \to \mathcal{T}$ is a smooth proper family of (possible formal) schemes, satisfies:

(A.2.1) The higher direct image $R^nf_*\mathcal{O}_{\mathcal{X}/\mathcal{T}}$ is locally free $\mathcal{O}_{\mathcal{T}}$-modules.

(A.2.2) The (relative) Hodge-Frölicher spectral sequence degenerates at $E_1$ page.

**Classical Obstruction Theory.** If $\mathcal{S} \subset \mathcal{T}$ is defined by a square zero ideal $\mathcal{I}$, and $\mathcal{L}$ is a line bundle on $\mathcal{X}_\mathcal{S} = \mathcal{X} \times_\mathcal{T} \mathcal{S}$, then the obstruction $\sigma_\mathcal{T}(\mathcal{L})$ to prolonging $\mathcal{L}$ to $\mathcal{X}$ lies in $H^2(\mathcal{X}_\mathcal{S}, \mathcal{O}_\mathcal{S}) \otimes \mathcal{I} \simeq$
$H^2(\mathcal{X}, f^*(\mathcal{I}))$, where $o_{\mathcal{T}}(\mathcal{L})$ is defined to be the image of $\mathcal{L}$ under the natural coboundary arising from the exact sequence:

$$0 \to f^*(\mathcal{I}) \xrightarrow{\epsilon} \mathcal{O}_\mathcal{X}^* \to \mathcal{O}_{\mathcal{X}_S}^* \to 0.$$ 

where $\epsilon(\alpha) = 1 + \alpha$.

**Deligne’s Generalization and Crystalline Interpretation.** Instead of assuming $\mathcal{T}^2 = 0$, suppose $\mathcal{I}$ admits a nilpotent PD structure $\gamma$, and use $\gamma$ to define an exact sequence:

$$0 \to f^*(\mathcal{I}) \xrightarrow{\epsilon_\gamma} \mathcal{O}_\mathcal{X}^* \to \mathcal{O}_{\mathcal{X}_S}^* \to 0$$

where $\epsilon_\gamma(\alpha) = \sum_0^{\infty} \gamma_n(\alpha)$. The coboundary of $\mathcal{L}$ is an element $o_{\mathcal{T}, \gamma}(\mathcal{L})$ of $H^2(\mathcal{X}, f^*(\mathcal{I}))$ can be identified in the following way: the crystalline Chern class of $\mathcal{L}$ gives us a global section of $R^2f_{S, \text{cris}}\mathcal{O}_{\mathcal{X}_S/\mathbb{Z}_p}$ on $(\mathcal{S}_{\text{cris}}/\mathbb{Z}_p)$, and the PD structure $\gamma$ enables us to evaluate $c_1(\mathcal{L})$ on the object $(\mathcal{T}, \mathcal{I}, \gamma)$ of $\text{Cris}(\mathcal{S}/\mathbb{Z}_p)$. Furthermore, the lifting $\mathcal{X}'$ of $\mathcal{X}_S$ provides us with an isomorphism: 

$$(R^2f_{S, \text{cris}}\mathcal{O}_{\mathcal{X}_S/\mathbb{Z}_p})(\mathcal{T}, \mathcal{I}, \gamma) \simeq H^2_{\text{dR}}(\mathcal{X}/\mathcal{T}),$$

which is where we view $c_1(\mathcal{L})_{\mathcal{T}, \gamma}$. Since the image of $\pi : c_1(\mathcal{L}) \to H^2_{\text{dR}}(\mathcal{X}_S/S)$ lies in $F^1_{\text{Hodge}}H^2_{\text{dR}}(\mathcal{X}_S/S)$, i.e. the first level of the Hodge filtration, the image of $c_1(\mathcal{L})_{\mathcal{T}, \gamma}$ in $H^2(\mathcal{X}, \mathcal{O}_\mathcal{X})$ in fact lies in $H^2(\mathcal{X}, f^*(\mathcal{I}))$. In a word, the obstruction $o_{\mathcal{T}, \gamma}(\mathcal{L})$ can be described by the first (crystalline) Chern class $c_1(\mathcal{L})_{\mathcal{T}, \gamma}$.

**Remark 3.**

(i) Suppose $\mathcal{S} = \text{Spec } \mathcal{F}$, $\mathcal{T} = \text{Spf } \mathcal{F}[t_1, \ldots, t_n]$, and that the crystalline Chern class $c_1(L) \in H^2_{\text{cris}}(\mathcal{X}_S/W)$ prolongs to a horizontal section of $H^2_{\text{cris}}(\mathcal{X}/W[t_1, \ldots, t_n])$. Then $L$ prolongs to $\mathcal{X}'$.

(ii) The first order obstruction $o(L) \in H^2(\mathcal{X}_0, \mathcal{O}_{\mathcal{X}_0}) \otimes \mathfrak{m}/\mathfrak{m}^2$ is simply the cup product of the Hodge Chern class $\pi_{\text{Hodge}}(c_1(L)) \in H^1(\mathcal{X}_0, \Omega^1_{\mathcal{X}_0})$ with the Kodaira-Spencer class $\tau \in H^1(\mathcal{X}_0, T_{\mathcal{X}_0/\mathcal{F}}) \otimes \mathfrak{m}/\mathfrak{m}^2$. In particular, if $c_1(L)$ lies in $F^2_{\text{Hodge}}$, this obstruction vanishes.

Now we apply the above deformation theory to K3 surfaces over positive characteristic fields. The versal formal $\mathcal{F}$-deformation $f : \mathcal{X} \to \mathcal{S}$ of a K3 surface $\mathcal{X}_0/\mathcal{F}$ lies over $\mathcal{S} = \text{Spf } \mathcal{F}[t_1, \ldots, t_{20}]$ with $R^nf_*\Omega^1_{\mathcal{X}/\mathcal{S}}$ locally free $\mathcal{O}_\mathcal{S}$-modules. Applying Griffiths transversality on $R^nf_*\Omega^1_{\mathcal{X}/\mathcal{S}} \simeq H^2_{\text{dR}}(\mathcal{X}/\mathcal{S})$ gives us two isomorphisms:

\[
\nabla'[2] : T^1_{\mathcal{S}/\mathcal{F}} \simeq \text{Hom}(\text{gr}^2_FH^2_{\text{dR}}(\mathcal{X}/\mathcal{S}), \text{gr}^1_FH^2_{\text{dR}}(\mathcal{X}/\mathcal{S})) \\
\nabla'[1] : T^1_{\mathcal{S}/\mathcal{F}} \simeq \text{Hom}(\text{gr}^1_FH^2_{\text{dR}}(\mathcal{X}/\mathcal{S}), \text{gr}^0_FH^2_{\text{dR}}(\mathcal{X}/\mathcal{S}))
\]

induced by Gauss-Manin connection $\nabla$. Moreover, the versal formal $\mathcal{F}$-deformation $\mathcal{X}/\mathcal{S}$ satisfies the property that the (relative) Hodge-Fröhlicher spectral sequence degenerates at $E_1$ page. It simplifies the above two isomorphisms to the following:

\[
\nabla'[2] : T^1_{\mathcal{S}/\mathcal{F}} \simeq \text{Hom}(H^0(\mathcal{X}, \Omega^2_{\mathcal{X}/\mathcal{S}}), H^1(\mathcal{X}, \Omega^1_{\mathcal{X}/\mathcal{S}})) \\
\nabla'[1] : T^1_{\mathcal{S}/\mathcal{F}} \simeq \text{Hom}(H^1(\mathcal{X}, \Omega^1_{\mathcal{X}/\mathcal{S}}), H^2(\mathcal{X}, \mathcal{O}_\mathcal{X})).
\]

(6)

In fact, for any $D \in T^1_{\mathcal{S}/\mathcal{F}}$, $\nabla'[2](D)$ is the negative transpose of $\nabla'[1](D)$. And $\nabla$ in (6) gives an isomorphism

$$H^1(\mathcal{X}, \Omega^1_{\mathcal{X}/\mathcal{S}}) \simeq \Omega^1_{\mathcal{S}/\mathcal{F}} \otimes H^2(\mathcal{X}, \mathcal{O}_\mathcal{X}).$$

Evaluating at zero, it becomes an isomorphism

$$H^1(X_0, \Omega^1_{X_0/\mathcal{F}}) \to \mathfrak{m}/\mathfrak{m}^2 \otimes H^2(X_0, \mathcal{O}_{X_0}).$$

\[1\]Here $\pi_{\text{Hodge}}$ denotes the composition of $\pi$ with the projection of the first level filtration $F^1_{\text{Hodge}}H^2_{\text{dR}}(X_0/\mathcal{F})$ to $H^1(X_0, \Omega^1_{X_0}).$

\[2\]Griffiths transversality basically says $\nabla(F^p) \subset F^{p-1} \otimes \Omega_S$, where $F^p$ denotes the filtration for $R^nf_*(\mathcal{O}^*_\mathcal{X}/\mathcal{S}).$
One may choose a basis $\omega \in H^0(\mathcal{X}, \Omega^2_{\mathcal{X}/S})$, then $\nabla$ composed with cup product with $\omega$ induces an isomorphism:

$$\rho_\omega : H^1(\mathcal{X}, \Omega^1_{\mathcal{X}/S}) \to \Omega^1_{S/\mathbb{F}}.$$  

Evaluating at zero, it becomes an isomorphism $\rho_{\omega,0} : H^1(X_0, \Omega^1_{X_0/\mathbb{F}}) \to \mathfrak{m}/\mathfrak{m}^2$.

Now we discuss the formal deformation space of a primitively polarized K3 surface $(X_0, L_0)$. Recall that there is a maximal closed formal subscheme $\sum(L_0)$ over which $L_0$ can be prolonged. Moreover, $\sum(L_0)$ is defined by a single equation. In fact, since $L_0$ is not a multiple of any other ample line bundle, if $X_0$ is ordinary, then $\sum(L_0)$ is smooth of codimension one. In general, it is smooth unless $X_0$ is superspecial. In the superspecial case and char $p \neq 2$, $\sum(L_0)$ has an ordinary quadratic singularity. It turns out that $(X_0, L_0)$ is superspecial iff the first Chern class $c_1(L_0) \in F^2_{\text{Hodge}} H^2_{\text{dR}}(X_0/\mathbb{F}) = H^0(X_0, \Omega^2_{X_0})$.

**Remark 4.** (i) Combine the above argument with Remark 3.(ii), we may see that, for a primitively polarized ordinary K3 surface $(X_0, L_0)$, $\sum(L_0)$ is smooth of codimension one, defined by the vanishing of the image $\pi : c_1(L) \to H^1(\mathcal{X}, \Omega^1_{\mathcal{X}/S})$.

(ii) By Grothendieck existence theorem, the formal deformation space $\sum(L_0)$ is algebraizable.

Therefore, we end up with an honest smooth deformation of $(X_0, L_0)$ i.e. a smooth family of primitively polarized K3 surfaces over $\mathbb{F}$, with the dimension of the deformation space 19. In particular, the morphism of $\mathbb{F}$-universal deformation $\mathcal{X} \to \mathcal{T} = \sum(L_0)$ is projective.

Now we're ready to prove Theorem 1.1.

**Proof of Theorem 1.1.** After deleting some proper closed subset of $\mathcal{T}$, we may assume $(\mathcal{X}/\mathcal{T}, \mathcal{L})$ is a smooth family of ordinary primitively polarized K3 surfaces of degree $2g - 2$. Moreover, it's a versal deformation of $(X_t, \mathcal{L}_t)$ for every $t \in \mathcal{T}$, with $\mathcal{L}_t^2 = 2g - 2$ and $(\mathcal{L}_t) \subseteq \text{Pic}(X_t)$ a direct summand for every such $t$. (for a detailed argument, see [Ogu79 Thm 2.9]) The versality at each point $t \in \mathcal{T}$ implies that the map induced by Kodaira-Spencer:

$$H^1(X_t, \Omega^1_{X_t/\mathbb{F}})/\pi(c_1(\mathcal{L}_t)) \otimes K \to \mathfrak{m}_t/\mathfrak{m}_t^2 \otimes H^2(X_t, \mathcal{O}_{X_t})$$

is an isomorphism (by Griffiths transversality) for every point, and hence

$$H^1(\mathcal{X}, \Omega^1_{\mathcal{X}/\mathcal{T}})/\pi(c_1(\mathcal{L})) \otimes \mathcal{O}_{\mathcal{T}} \to \Omega^1_{\mathcal{T}/\mathbb{F}} \otimes H^2(\mathcal{X}, \mathcal{O}_{\mathcal{X}})$$

is also an isomorphism. This remains true if we replace $\mathcal{T}$ by Spec $\kappa(\tau)$, where $\tau$ is the generic point. The tangent space at the origin of Pic($X_\tau$)/$\kappa(\tau)$ identifies with $H^1(X_\tau, \mathcal{O}_{X_\tau}) = 0$, then Pic($X_\tau$) is étale $\kappa(\tau)$-scheme. For any purely inseparable extension $k/\kappa(\tau)$, Pic($X_k$) = Pic($X_\tau$) × Pic($\kappa(\tau)$) = Pic($X_\tau$). Hence after some separable extension, i.e. pass to some finite étale cover of $\mathcal{T}$, we may assume Pic($X_\tau$) = Pic($X_{\mathcal{T}}$). It’s clear that Im(Pic($X_\tau$)) $\otimes \kappa(\tau)$ forms a horizontal subspace of $H^2_{\text{dR}}(X_\tau/\kappa(\tau))$, hence killed by the above map. Counting dimensions, we see that Im(Pic($X_\tau$)$\otimes \kappa(\tau)$ has dimension one, and the same is true over $\kappa(\tau)$. But since $X_\tau$ is ordinary, the map is injective.

**Appendix B. Generic Smoothness**

Let $\mathbb{F}$ be any perfect field, e.g. any algebraically closed field or characteristic 0 field.

**Lemma 1.** Let $\pi : X \to Y$ be a dominant map of integral $\mathbb{F}$-varieties with an separably generated field extension $K(X)/K(Y)$ of function fields of $X$ and $Y$. Then there exists a non-empty (hence dense) open subset $U \subset X$, such that $\pi|_U$ is smooth.
Proof. Let $n = \dim X - \dim Y$, then $K(X)/K(Y)$ is a separably generated field extension with transcendental degree $n$ by assumption. Hence, the relative differential $\Omega_{X/Y}$ has rank $n$ at the generic point $\eta_X$. By upper semi-continuity, the coherent sheaf $\Omega_{X/Y}$ has constant rank $n$ over a non-empty open subset of $X$. Now a constant rank coherent sheaf on a reduced scheme implies locally free. Moreover, generic flatness guarantees there is a non-empty open over which $\Omega_{X/Y}$ is flat. Let $U \subset X$ be the intersection of those two opens, then $U$ satisfies the requirement. \hfill \Box

Remark 5. (i) Since $¥=\mathbb{F}$-variety $X$, the function field $K(X)/\mathbb{F}$ is a separably generated field extension. Then $\dim\mathbb{F}\Omega^1_{K(X)/\mathbb{F}} = \text{tr.deg}_{\mathbb{F}} K(X)$. Let $Y = \text{Spec} \mathbb{F}$, then the above lemma shows that any variety $X$ over $\mathbb{F}$ has an open dense subset over which $X$ is smooth.

(ii) The converse of the above lemma is also true, i.e. if $\pi$ is generically smooth on $X$, then the field extension of function fields is separably generated. Indeed, the composition of maps $X \xrightarrow{\pi} Y \xrightarrow{\pi} \text{Spec} \mathbb{F}$ gives an exact sequence of $\mathbb{F}$-vector spaces

$$\pi^* \Omega^1_{Y/\mathbb{F}} \to \Omega^1_{X/\mathbb{F}} \to \Omega^1_{X/Y} \to 0$$

Taking the stalk at the generic point induces an exact sequence of $\mathbb{F}$-vector spaces

$$\mathbb{F}^{\dim Y} \to \mathbb{F}^{\dim X} \to \Omega^1_{K(X)/K(Y)} \to 0$$

If $\pi$ is generically smooth on $X$, then the above exact sequence is exact on the left, i.e.

$$0 \to \mathbb{F}^{\dim Y} \to \mathbb{F}^{\dim X} \to \Omega^1_{K(X)/K(Y)} \to 0$$

which gives $\dim\mathbb{F}\Omega^1_{K(X)/K(Y)} = \dim X - \dim Y = \text{tr.deg}_{K(Y)} K(X)$, thus $K(X)/K(Y)$ is separably generated.

Lemma 2. Let $\pi : X \to Y$ be as above. Assume further that $X$ is smooth, then there exists a non-empty (hence dense) open subset $V \subset Y$, such that $\pi|_{f^{-1}(V)}$ is smooth.

Proof. The argument is completely local. By Remark 5(iii), without loss of generality, may assume $Y$ is smooth. Recall that for a morphism between two smooth varieties to be smooth, it suffices to check the induced map on tangent space $T_{\pi,x} : T_{x,X} \to T_{\pi(x),Y}$ is surjective for every closed point $x \in X$. Now define a locally closed subset $X_r$ of $X$ as follows

$$X_r := \{\text{closed point } x \in X \mid \text{rank} T_{\pi,x} \leq r\}$$

By Chevalley’s theorem, the image $\pi(X_r)$ is also constructible. Claim: $\dim \pi(X_r) \leq r$. We may choose an irreducible component of $X_r$ by $X$ and $\pi(X_r)$ by $Y$. By the above lemma, we are able to find a non-empty open $U \subset X$ such that $\pi|_{U}$ is smooth, i.e. for any $x \in U$, $T_{\pi,x} : T_{x,X} \to T_{\pi(x),Y}$ is surjective. Therefore, $\dim Y = \dim \pi(x) \leq \text{dim} T_{\pi(x)} \leq \text{rank} T_{\pi,x} \leq r$.

Now if $\dim Y = n$, by removing $\pi(X_{n-1})$ whose dimension is no greater than $n - 1$, we see that $\pi$ induces surjections on the corresponding tangent spaces. This completes the proof. \hfill \Box
