Higher semiadditive Grothendieck-Witt theory and the $K(1)$-local sphere

Shachar Carmeli Allen Yuan

Abstract

We develop a higher semiadditive version of Grothendieck-Witt theory. We then apply the theory in the case of a finite field to study the higher semiadditive structure of the $K(1)$-local sphere at the prime 2. As a further application, we compute and clarify certain power operations in the homotopy of the $K(1)$-local sphere.

1 Introduction

In chromatic homotopy theory, one studies the localization of the $\infty$-category of spectra at a Morava K-theory $K(n)$. One striking feature of these localizations, denoted $\text{Sp}_{K(n)}$, is the vanishing of Tate cohomology for finite groups:

**Theorem 1.0.1.** ([Hovey-Sadofsky [HS96], Greenlees-Sadofsky [GS96]]) Let $G$ be a finite group and $X \in \text{Sp}_{K(n)}^{BG}$ be a $K(n)$-local spectrum with $G$-action. Then the natural norm map

$$L_{K(n)}X^G \to X^hG$$

is an equivalence.

Theorem 1.0.1 was subsequently generalized to the telescopic localizations $\text{Sp}_{T(n)}$ by Kuhn [Kuhn04]. Hopkins and Lurie [HL13] gave the following insightful interpretation of this theorem: recall that if $\mathcal{C}$ is a semiadditive category, then for any finite set $T$ and $T$-tuple of elements $\{Y_t\}_{t \in T}$ of $\mathcal{C}$, there is a canonical isomorphism $\coprod_{t \in T} Y_t \simeq \prod_{t \in T} Y_t$. Theorem 1.0.1 asserts that an analogous statement is true in $\text{Sp}_{K(n)}$ with the groupoid $BG$ in the place of the finite set $T$; namely, by viewing $X$ as a functor $X : BG \to \text{Sp}_{K(n)}$, the theorem asserts that the colimit and the limit of $X$ are naturally equivalent.

Thus, $\text{Sp}_{K(n)}$ exhibits a “higher” form of semiadditivity, which Hopkins and Lurie [HL13] dub 1-semiadditivity: the idea is that a 0-semiadditive $\infty$-category is simply a semiadditive $\infty$-category, and for $m > 0$, an $m$-semiadditive $\infty$-category $\mathcal{D}$ should have the feature that for any $m$-finite space $A$ (that is, a space with finite homotopy groups concentrated in degrees 0 through $m$) and any diagram $f : A \to \mathcal{D}$, there is a canonical isomorphism

$$Nm_f : \lim_{\longrightarrow} f \xrightarrow{\sim} \lim_{\longleftarrow} f.$$

Hopkins and Lurie extend Theorem 1.0.1 by showing that $\text{Sp}_{K(n)}$ is $m$-semiadditive for each $m$. This was further generalized in work by the first author, Schlank, and Yanovski [CSY18], who proved the analogous statement for the telescopic localizations $\text{Sp}_{T(n)}$.

An important consequence of higher semiadditivity is that the objects in a higher semiadditive $\infty$-category acquire a rich algebraic structure. Namely, recall that any object $Y$ in a semiadditive category canonically acquires the structure of a commutative monoid; in particular, for any finite set $T$, there is a canonical addition map

$$\prod_T Y \simeq \coprod_T Y \to Y,$$

which exists because the semiadditive structure supplies an equivalence $\coprod_T Y \simeq \prod_T Y$. An object $X$ of an $m$-semiadditive $\infty$-category admits even more structure: one can sum not only over finite sets, but over any $m$-finite space $A$. More precisely, given such an $A$, there is a canonical higher addition map $f_A : X^A \to X$ given by the composite

$$X^A \simeq X \otimes A \to X \otimes \text{pt} \simeq X.$$
Here, the first map is (the inverse of) the equivalence resulting from the higher semiadditive structure, and the second map is induced by the map $A \to \text{pt}$.

**Remark 1.0.2.** The collection of these $f_A$ maps, together with corresponding restriction maps, endow $X$ with a structure known as an $m$-commutative monoid (with 0-commutative monoids being just ordinary commutative monoids). First described systematically by Harpaz [Har20], this $m$-commutative monoid structure for $X$ is captured by a functor

$$X^{(-)} : \text{Span}(S_m)^\text{op} \to \text{Sp}$$

given by $A \mapsto X^A$. Here, $\text{Span}(S_m)$ is the $\infty$-category of $m$-truncated $\pi$-finite spaces and spans. In fact, we will work in a $p$-typical setting, where one further restricts to $m$-truncated $\pi$-finite spaces with homotopy groups of $p$-power order. We refer the reader to Section 2 for a more careful discussion of ($p$-typical) $m$-commutative monoids.

### 1.1 Semiadditive cardinality

This paper is focused on one part of this $m$-commutative monoid structure:

**Definition 1.1.1 ([CSY20] Definition 2.1.5, [HL13] Notation 5.1.7).** Let $\mathcal{C}$ be an $m$-semiadditive $\infty$-category, let $X \in \mathcal{C}$ and let $A$ be an $m$-truncated $\pi$-finite space. Then let $|A|_X : X \to X$ be the endomorphism of $X$ defined by the composite

$$|A|_X : X \xrightarrow{\Delta_A} X^A \xrightarrow{f_A} X,$$

where $\Delta_A$ is the canonical diagonal map induced by $A \to \text{pt}$. As $X$ varies, these maps assemble to a natural transformation $|A| : \text{Id}_{\mathcal{C}} \to \text{Id}_{\mathcal{C}}$, which we will refer to as the *cardinality* of $A$.

This terminology is justified by the following example:

**Example 1.1.2.** In the special case where $A$ is discrete, the endomorphism $|A|$ is given by multiplication by the cardinality of the finite set $A$.

In fact, in the rational case, the cardinality of a $\pi$-finite space $A$ is a familiar invariant:

**Example 1.1.3.** In the $\infty$-category $\text{Sp}_Q$ of rational spectra (more generally, in any *semirational* $\infty$-category, cf. [CSY20, Example 2.2.2]), the cardinality of any $\pi$-finite space $A$ is given by the Baez-Dolan homotopy cardinality, which is the rational number

$$|A|_0 := \sum_{a \in \pi_0(A)} \prod_{n \geq 1} |\pi_n(A,a)|(-1)^n,$$

regarded as an element of $\pi_0(S_Q) \simeq Q$.

But the cardinalities of $\pi$-finite spaces determine canonical invariants in *any* higher semiadditive $\infty$-category. In particular, since $\text{Sp}_{K(n)}$ is $\infty$-semiadditive [HL13], any $\pi$-finite space $A$ determines
an element $|A|_{S_K(n)} \in \pi_0(S_{K(n)})$. In fact, by work of the first author, Schlank, and Yanovski [CSY18], the $\infty$-category $Sp_{T(n)}$ is also $\infty$-semiadditive. Moreover, the localization functor $L_{K(n)} : Sp_{T(n)} \to Sp_{K(n)}$ is colimit preserving, and therefore the natural map $S_{T(n)} \to S_{K(n)}$ sends $|A|_{S_{T(n)}}$ to $|A|_{S_{K(n)}}$. Hence, not only do the cardinalities of $\pi$-finite spaces determine canonical elements $|A| \in \pi_0(S_{K(n)})$, but such elements admit canonical lifts to elements $|A| \in \pi_0(S_{T(n)})$. In particular, although it is difficult in general to construct elements in the homotopy groups of the $\text{telecopically}$ localized spheres $S_{T(n)}$, the cardinalities provide a family of such elements. One may then wonder which elements in $\pi_0(S_{K(n)})$ arise in this manner.

**Example 1.1.4** (Example 2.2.4 [CSY20]). In the $\infty$-category $\text{Mod}_{E_n}(Sp_{K(n)})$ of $K(n)$-local modules over a height $n$ Lubin-Tate theory $E_n$, one has the explicit formula

$$|B^k C_p| = p^{\binom{n-1}{k}}.$$ 

In other words, under the natural map $S_{T(n)} \to E_n$, $|B^k C_p|$ is sent to the integer $p^{\binom{n-1}{k}}$. Given this, it is natural to ask if the cardinalities $|A|$ produce interesting elements in the homotopy of $S_{T(n)}$, or if they are always just rational numbers such as the ones given in Example 1.1.4.

A consequence of our main result is that the cardinalities of $\pi$-finite spaces can produce non-rational elements in the $K(n)$ or $T(n)$-local spheres. In fact, we compute (for all primes $p$) the $K(1)$-local cardinalities of all $\pi$-finite spaces $A$ with $p$-power torsion homotopy groups, and we show that at the prime 2, the cardinality of $BC_2$ produces an element of $\pi_0(S_{K(1)})$ which is not a 2-adic integer.

### 1.2 Statement of results

#### 1.2.1 $K(1)$-local cardinalities

In order to state our results, we recall some facts about the $K(1)$-local sphere, many of which date back to the work of Adams on the image of $J$; the reader is referred to [Hop14, §1, §2] and [Hen17, §6] for more details.

Let $p$ be a prime and let $S_{K(1)}$ denote the $K(1)$-local sphere at the prime $p$. Then $S_{K(1)}$ fits into a cofiber sequence

$$S_{K(1)} \to K \xrightarrow{\psi^g - 1} K$$

where $K$ denotes $KU_p^\wedge$ for $p$ odd and $KO_2^\wedge$ for $p = 2$, and $\psi^g$ denotes an Adams operation corresponding to a topological generator $g \in \mathbb{Z}_p^\times$ if $p$ odd and $g \in \mathbb{Z}_2^\times/\{\pm 1\}$ if $p = 2$. From this fiber sequence we can extract the ring structure of $\pi_0 S_{K(1)}$. Note first that if $\eta \in \pi_1 KO$ is the Hopf element, then $\psi^g(\eta) = \eta$. Then, by the long exact sequence of homotopy groups associated with (1), we get

$$\pi_0 S_{K(1)} \cong \begin{cases} \mathbb{Z}_p & \text{if } p \text{ is odd}, \\ \mathbb{Z}_2 \oplus \mathbb{Z}/2 \cdot \varepsilon & \text{if } p = 2. \end{cases}$$

Here, $\delta : \pi_1 KO_2^\wedge \to \pi_0 S_{K(1)}$ is the boundary map and

$$\varepsilon = \delta(\eta) = \eta \cdot \zeta$$
where $\zeta = \delta(1) \in \pi_{-1} S^1_{K(1)}$. Since, again from the long exact sequence, $\pi_{-2} S^1_{K(1)} = 0$, we deduce that $\zeta^2 = 0$ and hence $\varepsilon^2 = 0$. Therefore, we obtain the following ring structure for $\pi_0 S^1_{K(1)}$:

$$\pi_0 S^1_{K(1)} \cong \begin{cases} 
\mathbb{Z}_p & \text{if } p \text{ is odd}, \\
\mathbb{Z}_2[\varepsilon]/(\varepsilon^2, 2\varepsilon) & \text{if } p = 2.
\end{cases}$$

(2)

Our main result, which is proven as Theorem 5.1.1, is:

**Theorem A.** Let $p$ be a prime, let $S^1_{K(1)}$ denote the $K(1)$-local sphere at the prime $p$, and let $A$ be a connected $\pi$-finite space with $p$-power torsion homotopy groups. Then

$$|A|_{S^1_{K(1)}} = \begin{cases} 
1 & \text{if } p \text{ is odd}, \\
1 + \log_2(|A|_0) \cdot \varepsilon & \text{if } p = 2,
\end{cases}$$

where $|A|_0$ denotes the homotopy cardinality of Example 1.1.3. In particular,

$$|BC_p|_{S^1_{K(1)}} = \begin{cases} 
1 & \text{if } p \text{ is odd}, \\
1 + \varepsilon & \text{if } p = 2.
\end{cases}$$

Theorem A also determines $|A|_X : X \to X$ for general $X \in \text{Sp}^1_{K(1)}$ as multiplication by $|A|_{S^1_{K(1)}}$. In fact, the most essential content of the theorem is the computation of $|BC_2|$ in the $S^1_{K(1)}$ at the prime 2. This is because of the following two remarks:

**Remark 1.2.1.** For all primes $p$, the computation of the cardinalities for spaces as in Theorem A reduces to the computation of $|BC_p|_{S^1_{K(1)}}$ via formal properties of higher semiadditivity (cf. Theorem 5.1.1 for the reduction).

**Remark 1.2.2.** The map of rings $S^1_{K(1)} \to KU^\wedge_p$ induces a ring map

$$\pi_0 S^1_{K(1)} \to \pi_0 KU^\wedge_p \cong \mathbb{Z}_p.$$  

(3)

This map arises as the endomorphisms of the unit of the colimit preserving functor

$$- \otimes_{S^1_{K(1)}} KU^\wedge_p : \text{Sp}^1_{K(1)} \to \text{Mod}_{KU^\wedge_p}(\text{Sp}^1_{K(1)}),$$

and thus, for any $\pi$-finite space $A$, it sends $|A| \in \pi_0 S^1_{K(1)}$ to $|A| \in \pi_0 KU^\wedge_p$.

In the case when the prime $p$ is odd, the map (3) is an isomorphism. It follows that since $|BC_p|_{KU^\wedge_p} = 1$ (in $\text{Mod}_{KU^\wedge_p}(\text{Sp}^1_{K(1)})$) by Example 1.1.4, we also have $|BC_p|_{S^1_{K(1)}} = 1$.

On the other hand, when $p = 2$, the map of (3) is the map

$$\mathbb{Z}_2[\varepsilon]/(\varepsilon^2, 2\varepsilon) \to \mathbb{Z}_2,$$

given by the formula $a + b\varepsilon \mapsto a$. Since this map is not injective, the fact that $|BC_2| = 1$ in $\text{Mod}_{KU^\wedge_2}(\text{Sp}^1_{K(1)})$ does not imply the same statement in $\text{Sp}^1_{K(1)}$. In particular, both 1 and $1 + \varepsilon$ in $\pi_0 S^1_{K(1)}$ map to 1 $\in \pi_0 KU^\wedge_2$. The majority of the paper is dedicated to showing that in fact $|BC_2|_{S^1_{K(1)}} = 1 + \varepsilon \in \pi_0 S^1_{K(1)}$.
1.2.2 Higher semiadditive Grothendieck-Witt theory

The proof of Theorem A is inspired by the following: at an odd prime $p$, it follows from work of Quillen that one may identify $S_{K(1)}$ as the $K(1)$-local algebraic $K$-theory of a finite field $\mathbb{F}_\ell$, where $\ell$ is prime such that $\ell \in \mathbb{Z}_p^\times$ is a topological generator. At the prime $p = 2$, one may consider a more sophisticated variant of this construction: instead of finite dimensional $\mathbb{F}_\ell$-vector spaces, one may consider the groupoid $Q\mathcal{F}(\mathbb{F}_\ell)$ of pairs $(V, b)$ where $V$ is a finite dimensional $\mathbb{F}_\ell$-vector space and $b$ is a non-degenerate symmetric bilinear form on $V$. The group completion spectrum of $Q\mathcal{F}(\mathbb{F}_\ell)$ is known as the Grothendieck-Witt theory of $\mathbb{F}_\ell$, denoted $GW(\mathbb{F}_\ell)$ (cf. Section 2.2 for a more detailed discussion). It follows essentially from work of Friedlander that one has the following:

**Theorem 1.2.3** (Friedlander [Fri76]). Let $\ell \equiv 3, 5 \pmod{8}$ and let $S_{K(1)}$ denote the $K(1)$-local sphere at the prime $p = 2$. Then there is an equivalence of spectra

$$L_{K(1)}GW(\mathbb{F}_\ell) \simeq S_{K(1)}.$$  

Our strategy to prove Theorem A is to model the higher semiadditive structure on $S_{K(1)}$ as the effect on $K$-theory of certain explicit operations on symmetric bilinear forms. This will allow us to compute the operation $|BC_2|_{S_{K(1)}} : S_{K(1)} \to S_{K(1)}$ in terms of a certain concrete map

$$Q\mathcal{F}(\mathbb{F}_\ell) \to Q\mathcal{F}^{BC_2}(\mathbb{F}_\ell) \xrightarrow{f_{BC_2}} Q\mathcal{F}(\mathbb{F}_\ell).$$

Here, $Q\mathcal{F}^{BC_2}$ denotes the $C_2$-equivariant analog of $Q\mathcal{F}$, and the first map regards a symmetric bilinear form as a $C_2$-equivariant symmetric bilinear form with respect to the trivial action.

More precisely, for every commutative algebra $\mathcal{C}$ in $p$-typically $m$-semiadditive $\infty$-categories (in the sense of [CSY20, Definition 3.1.1]), we define a spectrum $GW(\mathcal{C})$, the Grothendieck-Witt spectrum of $\mathcal{C}$. Moreover, we show that this construction is compatible with higher semiadditivity in the following sense (cf. Section 2 for notations and Definition 3.2.8 for a more precise statement):

**Theorem B** (Higher semiadditive Grothendieck-Witt theory). Let $\mathcal{C}$ be a commutative algebra in $p$-typical $m$-semiadditive $\infty$-categories. Then $GW(\mathcal{C})$ extends canonically to a functor

$$GW^{(-)}(\mathcal{C}) : \text{Span}(S_m^{(p)})^{\text{op}} \to \text{Sp}$$

such that $GW^{(pt)}(\mathcal{C}) \simeq GW(\mathcal{C})$. Here, $S_m^{(p)}$ denotes $m$-truncated spaces whose homotopy groups are finite of $p$-power order.

In the case when $\mathcal{C}$ is the category of finite dimensional $\mathbb{F}_\ell$-vector spaces and $m = 1$, the value of the functor $GW^{(-)}(\mathbb{F}_\ell) := GW^{(-)}(\mathcal{C})$ at a groupoid $BG$ is the Grothendieck-Witt spectrum of $G$-equivariant symmetric bilinear forms over $\mathbb{F}_\ell$. One can think of this theorem as endowing these various equivariant theories of symmetric bilinear forms with coherent pullback and pushforward maps. On the other hand, since $\text{Sp}_{K(1)}$ is $\infty$-semiadditive, any $K(1)$-local spectrum $X$ extends to an $m$-commutative monoid

$$X^{(-)} : \text{Span}(S_m^{(p)})^{\text{op}} \to \text{Sp}_{K(1)}$$
given by \( A \mapsto X^A \). The following theorem asserts that, for \( X = S_{K(1)} \) (at the prime \( p = 2 \)), this \( m \)-commutative monoid structure can be understood in terms of the higher semiadditive Grothendieck-Witt theory of Theorem B.

**Theorem C.** Let \( \ell \equiv 3, 5 \pmod{8} \) be a prime, let \( GW(\mathbb{F}_\ell) \) be as in Theorem B (with \( p = 2 \)), and let \( S_{K(1)} \) denote the \( K(1) \)-local sphere at the prime 2. Then there is a canonical equivalence

\[
L_{K(1)}GW(\mathbb{F}_\ell) \simeq S_{K(1)}^{(-)}
\]

of functors \( \text{Span}(S_1)_{\text{op}} \to \text{Sp}_{K(1)} \).

In other words, Friedlander’s equivalence \( L_{K(1)}GW(\mathbb{F}_\ell) \simeq S_{K(1)} \) extends to an equivalence of (2-typical) 1-commutative monoids. We prove Theorem C in Section 4, and use it to compute \( |BC_2|_{S_{K(1)}} \) in Theorem 5.1.1, thus finishing the proof of Theorem A.

### 1.2.3 Computational consequences in \( S_{K(1)} \)

As an application of Theorem A, we finish the paper by computing certain well-known operations in \( \pi_0 S_{K(1)} \): namely, the power operations \( \theta \) (first defined by McClure [BMMS86, §IX], [Hop14]) and \( \delta_p \) (appearing in the work of Schlank, Yanovski, and the first author [CSY18]), and the \( K(1) \)-local logarithm \( \log_{K(1)} \) of Rezk [Rez06].

**Remark 1.2.4.** These operations are completely computed in the literature in the case of an odd prime \( p \) (this is elementary for the power operations \( \delta_p \) and \( \theta_p \), and done by Rezk in the case of \( \log_{K(1)} \)). In the case \( p = 2 \), there are additional ambiguities related to the torsion in \( \pi_0 S_{K(1)} \), and the authors were not able to find a reference for complete computations of these operations, though they may be known to experts. For the sake of completeness and convenience to the reader, we state the following results for all primes \( p \).

**Theorem 1.2.5.** Let \( p \) be a prime and let \( S_{K(1)} \) denote the \( K(1) \)-local sphere at \( p \). Then for \( p \) odd and \( x \in \pi_0 S_{K(1)} \cong \mathbb{Z}_p \), we have

\[
\delta_p(x) = \theta(x) = \frac{x - x^p}{p}.
\]

For \( p = 2 \) and an element \( r + d\varepsilon \in \pi_0 S_{K(1)} \cong \mathbb{Z}_2[\varepsilon]/(2\varepsilon, \varepsilon^2) \),

\[
\delta_2(r + d\varepsilon) = \theta(r + d\varepsilon) + d\varepsilon = \frac{r - r^2}{2} + rd\varepsilon.
\]

**Theorem 1.2.6.** Let \( \log_p : 1 + p\mathbb{Z}_p \to \mathbb{Z}_p \) denote the \( p \)-adic logarithm.

- For an odd prime \( p \), the Rezk logarithm is given on \( (\pi_0 S_{K(1)})^\times \cong \mathbb{Z}_p^\times \) by the formula

\[
\log_{K(1)}(x) = \frac{1}{p} \log_p(x^{p-1}).
\]
• For $p = 2$, the Rezk logarithm is given on $(\pi_0 S_{K(1)})^\times \simeq (\mathbb{Z}_2[\varepsilon]/(2\varepsilon, \varepsilon^2))^\times \simeq \mathbb{Z}_2^\times \oplus \mathbb{Z}/2\mathbb{Z}$ by the formula
\[
\log_{K(1)}(r + d\varepsilon) = \frac{1}{2} \log_2(r) + \frac{r - 1}{2} \varepsilon.
\]

This follows from work of Rezk [Rez06, Theorem 1.9] when $p$ is odd and up to torsion when $p = 2$; additionally, work of Clausen [Cla17] computes the $p = 2$ case on the $\mathbb{Z}_2^\times$ component in the source. We extend the result to all of $(\pi_0 S_{K(1)})^\times$ using Theorem A and an observation of T. Schlank that $|BC_2|_{S_{K(1)}} \in (\pi_0 S_{K(1)})^\times$ is always a strict unit, that is, the image of 1 under a spectrum map $\mathbb{Z} \to gl_1 S_{K(1)}$.

Outline of paper

In §2, we review some preliminaries. In §3, we construct a higher semiadditive refinement of Grothendieck-Witt theory, proving Theorem B; this section is technical and the details of the proof are not used elsewhere in the paper. In §4, we make the core argument of the paper and prove Theorem C. Finally, in §5, we complete the proof of Theorem A and deduce computations of operations on the $K(1)$-local sphere.

Acknowledgements

The authors would like to thank Clark Barwick, Jacob Lurie, Tomer Schlank, and Lior Yanovski for many valuable discussions that led to this work. They also thank Robert Burklund, Dustin Clausen, Peter Haine, Jeremy Hahn, Yonatan Harpaz, and Hadrian Heine for helpful discussions and correspondences, and Robert Burklund, Dustin Clausen, Shay Ben Moshe, Tomer Schlank, and Lior Yanovski for comments on a draft. The first author was partially supported by the Adams Fellowship of the Israeli Academy of Science, and by the Danish National Research Foundation through the Copenhagen Centre for Geometry and Topology (DNRF151). The second author was supported in part by NSF grant DMS-2002029.

2 Preliminaries

Here, we review some background on higher semiadditivity (Section 2.1) and Grothendieck-Witt theory (Section 2.2).

2.1 Higher commutative monoids and higher semiadditivity

We saw in the introduction (cf. Remark 1.0.2) that the objects in a higher semiadditive $\infty$-category admit additional algebraic structure: in particular, for any $X$ in an $m$-semiadditive $\infty$-category and any $m$-finite space $A$, there is a natural map
\[
f_A : X^A \to X
\]

\[
f_A : X^A \to X
\]
which can be thought of as implementing “$A$-fold addition,” by analogy to the case when $A$ is a finite set. The $f_A$ maps, as $A$ ranges over $m$-finite spaces, fit together into an algebraic structure known as an $m$-commutative monoid, first formalized by Harpaz [Har20]. In this section, we define $m$-commutative monoids and their variants, and review some of the theory of higher semiadditive $\infty$-categories from this perspective.

### 2.1.1 Higher commutative monoids

For our applications to Grothendieck-Witt theory, it will be convenient to work in a $p$-typical setting, where all homotopy groups are $p$-groups:

**Definition 2.1.1.** We say that a $\pi$-finite space is $p$-typical if all its homotopy groups are of $p$-power order. We denote by $S_m^{(p)}$ the $\infty$-category of $m$-truncated $p$-typical $\pi$-finite spaces: that is, spaces $A$ with finitely many connected components, such that $\pi_i(A, a)$ is a finite $p$-group for all $i > 0$ and $a \in A$, and vanishes for $i > m$.

The notion of a $p$-typical $m$-commutative monoid is defined using the $\infty$-category of spans $\text{Span}(S_m^{(p)})$ [Bar17, §5]. Informally, its objects are $m$-truncated $p$-typical $\pi$-finite spaces, and a morphism between two such spaces $A$ and $B$ is a third space $C \in S_m^{(p)}$ together with a pair of maps $A \leftarrow C \rightarrow B$.

**Remark 2.1.2.** When $m = 0$, $\text{Span}(S_m^{(p)})$ is simply the 2-category $\text{Span}(\text{Fin})$ of spans of finite sets.

Recall that for a category $\mathcal{C}$ with products, a commutative monoid in $\mathcal{C}$ is a product preserving functor from $\text{Span}(\text{Fin})^\text{op}$ to $\mathcal{C}$. By analogy, we have:

**Definition 2.1.3** (Definition 5.10 [Har20]). Let $\mathcal{C} \in \text{Cat}_\infty$. A $p$-typical $m$-commutative pre-monoid in $\mathcal{C}$ is a functor $M : \text{Span}(S_m^{(p)})^\text{op} \to \mathcal{C}$. We say that $M$ is a $p$-typical $m$-commutative monoid if it additionally satisfies the following Segal-type condition:

\[(*) \text{ For every } A \in S_m^{(p)}, \text{ the maps } \{a^* : M(A) \to M(\text{pt})\}_{a \in A} \text{ induced from the point embeddings } a : \text{pt} \to A \text{ exhibit } M(A) \text{ as the limit of the constant } A\text{-shaped diagram on the value } M(\text{pt}).\]

We denote by

$$\text{CMon}_m^{(p)}(\mathcal{C}) \subseteq \text{PMon}_m^{(p)}(\mathcal{C}) \simeq \text{Fun}(\text{Span}(S_m^{(p)})^\text{op}, \mathcal{C})$$

the $\infty$-category of $p$-typical $m$-commutative pre-monoids and the full subcategory of $p$-typical $m$-commutative monoids in it. If $\mathcal{C}$ admits $S_m^{(p)}$-limits, then, as in [Har20, Proposition 5.14], we have

$$\text{CMon}_m^{(p)}(\mathcal{C}) \simeq \text{Fun}^{S_m^{(p)}}(\text{Span}(S_m^{(p)})^\text{op}, \mathcal{C}).$$

Here, $\text{Fun}^{S_m^{(p)}}$ denotes functors which preserve limits indexed by spaces in $S_m^{(p)}$.

**Remark 2.1.4.** Informally, a $p$-typical $m$-commutative pre-monoid consists of restriction maps

$$f^* : M(B) \to M(A)$$
for \( f: A \to B \in S_m^{(p)} \), and push-forward, or integration, maps

\[
\int f : M(A) \to M(B).
\]

The functoriality in spans encodes Fubini and base-change type compatibilities of the restriction and integration maps, as in [CSY18, Proposition 3.1.13 & Corollary 3.1.14]. In the special case where \( M \) is a \( p \)-typically \( m \)-commutative monoid, and denoting \( M(\text{pt}) \) again by \( M \), we can view the above as an integration of \( M \)-valued functions on \( A \) along the map \( f: A \to B \).

**Remark 2.1.5.** We can view a 1-commutative pre-monoid \( M \) as a \((p\text{-typical})\) global equivariant object in \( \mathcal{C} \) (in the sense of [Sch18]) endowed with extra “exotic transfer,” or “deflation” maps along morphisms of groupoids with non-discrete fibers. In this language, the property of being a \((p\text{-typical})\) \( m \)-commutative monoid corresponds to the property of being Borel-complete.

### 2.1.2 From higher commutative monoids to higher semiadditivity

By work of Harpaz, the notion of a higher semiadditive \( \infty \)-category can be formulated in terms of higher commutative monoids. We review this formulation here, leading up to the key fact (Corollary 2.1.9) that objects in a \((p\text{-typical})\) \( m \)-semiadditive \( \infty \)-category admit a unique structure of a \((p\text{-typical})\) \( m \)-commutative monoid.

**Notation 2.1.6.** Denote by \( \text{Cat}_{S_m^{(p)}} \) the (non-full) subcategory of \( \text{Cat}_\infty \) consisting of \( \infty \)-categories which admit \( S_m^{(p)} \)-colimits, and functors preserving \( S_m^{(p)} \)-colimits between them. We denote by \( \text{Cat}_{\infty}^{\otimes_{p-m}} \subseteq \text{Cat}_{S_m^{(p)}} \) the full subcategory spanned by the \( p \)-typically \( m \)-semiadditive \( \infty \)-categories (cf. [CSY20, Definition 3.1.1] and Proposition 2.1.8).

**Remark 2.1.7.** Recall that \( \mathcal{C} \) is \((p\text{-typically})\) \( m \)-semiadditive if, for every map of spaces \( f: A \to B \) with \((p\text{-typical})\) \( m \)-truncated \( \pi \)-finite fibers, the norm map

\[
\text{Nm}_f : f_! \to f_*
\]

between functors \( \mathcal{C}^A \to \mathcal{C}^B \) (which is defined inductively) is an isomorphism [HL13, §4]. For us, it will be convenient to use an alternative definition due to Yonatan Harpaz, that we shall now present.

The \( \infty \)-category \( \text{Cat}_{S_m^{(p)}} \) admits a canonical symmetric monoidal structure via the Lurie tensor product (see [Lur16, Corollary 4.8.1.4]) which we denote by \( \otimes \), with respect to which \( S_m^{(p)} \) is the unit. In this setting, Harpaz has given the following beautiful characterization of higher semiadditivity:

**Proposition 2.1.8.**

1. The \( \infty \)-category \( \text{Span}(S_m^{(p)}) \) is an idempotent algebra in \( \text{Cat}_{S_m^{(p)}} \).

2. The modules over \( \text{Span}(S_m^{(p)}) \) in \( \text{Cat}_{S_m^{(p)}} \) are exactly the \( p \)-typically \( m \)-semiadditive \( \infty \)-categories; that is, we have

\[
\text{Mod}_{\text{Span}(S_m^{(p)})}(\text{Cat}_{S_m^{(p)}}) \simeq \text{Cat}_{\infty}^{\otimes_{p-m}} \subseteq \text{Cat}_{S_m^{(p)}}.
\]
For an $\infty$-category $\mathcal{C} \in \text{Cat}_\mathcal{S}(p)_m$, one has an equivalence $\mathcal{C} \otimes \text{Span}(\mathcal{S}_m^{(p)}) \simeq \text{CMon}_m^{(p)}(\mathcal{C})$.

The non-$p$-typical case is discussed in [Har20, §5.1]. The proof for the $p$-typical case is identical.

Roughly, the first two parts of the proposition articulate a sense in which the $\infty$-category

$$\text{Span}(\mathcal{S}_m^{(p)}) \in \text{CAlg}(\text{Cat}_\mathcal{S}(p)_m)$$

is universal among $p$-typically $m$-semiadditive $\infty$-categories. Together with the third part, one has the following corollary which we will be critical to our arguments:

**Corollary 2.1.9.** Let $\mathcal{C} \in \text{Cat}_\infty^{(p)}_m$ be a $p$-typical $m$-semiadditive $\infty$-category. Then the forgetful functor $\text{CMon}_m^{(p)}(\mathcal{C}) \to \mathcal{C}$ is an equivalence. In other words, every object of $\mathcal{C}$ admits a unique structure of a $p$-typical $m$-commutative monoid in $\mathcal{C}$.

**Proof.** We deduce the corollary from the various parts of 2.1.8: by part (2), $\mathcal{C}$ is a module over $\text{Span}(\mathcal{S}_m^{(p)})$ in $\text{Cat}_\mathcal{S}(p)_m$. By (1), the unit map $\mathcal{C} \to \mathcal{C} \otimes \text{Span}(\mathcal{S}_m^{(p)}) \simeq \text{CMon}_m^{(p)}(\mathcal{C})$ is an isomorphism (see [Lur16, Proposition 4.8.2.10]). Therefore, the right adjoint of this unit map, which is the forgetful functor $\text{CMon}_m^{(p)}(\mathcal{C}) \to \mathcal{C}$, is an equivalence as well. 

We shall use the following notation for this unique structure:

**Definition 2.1.10.** Let $\mathcal{C} \in \text{Cat}_\infty^{(p)}_m$. For $X \in \mathcal{C}$ we denote by $X^{(-)} \in \text{CMon}_m^{(p)}(\mathcal{C})$ the unique $p$-typical $m$-commutative monoid in $\mathcal{C}$ whose underlying object is $X$.

**Example 2.1.11.** The $\infty$-categories $\text{Sp}_{K(n)}$ and $\text{Sp}_{T(n)}$ are $\infty$-semiadditive (i.e., $m$-semiadditive for every $m \geq 0$) [HL13, CSY18]. We obtain higher commutative monoids $\mathcal{S}_K^{(-)}_{K(n)} \in \text{CMon}_m^{(p)}(\text{Sp}_{K(n)})$, $\mathcal{S}_T^{(-)}_{T(n)} \in \text{CMon}_m^{(p)}(\text{Sp}_{T(n)})$.

This paper is dedicated to studying these higher commutative monoids in the case $n = 1$ (in which case they are same because the telescope conjecture holds at height 1, see, e.g., [Bou79, Theorem 4.1]).

### 2.1.3 Cardinalities

We saw in the introduction that if $M$ is an $m$-commutative monoid and $A$ is an $m$-finite space, then there is a natural endomorphism $|A|_M : M \to M$ known as the cardinality of $|A|$ (at $M$). In fact, one can give this definition more generally for a $p$-typical $m$-commutative pre-monoid:

**Definition 2.1.12.** (see [CSY20, Definition 2.1.5]) Let $\mathcal{C} \in \text{Cat}_\infty$ and let $M \in \text{PMon}_m^{(p)}(\mathcal{C})$. For $A \in \mathcal{S}_m^{(p)}$ we define the map $|A|_M : M(\text{pt}) \xrightarrow{\pi^*} M(A) \xrightarrow{\int} M(\text{pt})$, where $\pi : A \to \text{pt}$ is the terminal map. We refer to $|A|_M$ as the **cardinality** of $A$ at $M$. 

11
The cardinalities of $A$ on the various $M$’s assemble to a natural endomorphism of the functor $\text{ev}_{\text{pt}} : \text{PMon}^{(p)}_{m}(\mathcal{C}) \to \mathcal{C}$ which evaluates at $\text{pt} \in \text{Span}(S^{(p)}_{m})$. We shall denote this natural transformation simply by $|A|$. In particular, if $\mathcal{C}$ is $p$-typically $m$-semiadditive, we can restrict $|A|$ to a natural transformation of the identity functor of $\mathcal{C} \simeq \text{CMon}^{(p)}_{m}(\mathcal{C})$. These natural transformations are studied systematically in [CSY20] – in particular, one can show (see [CSY20, Remark 2.1.10(2)]) that if $\mathcal{C}$ is further symmetric monoidal and its tensor product distributes over $S^{(p)}_{m}$-colimits, then $|A|$, as a natural transformation of the identity functor of $\mathcal{C}$, is given by multiplication with the element $|A|_{1, \varphi} \in \pi_{0}\mathcal{C}$.

2.2 Classical Grothendieck-Witt theory

Let $S_{K(1)}$ denote the $K(1)$-local sphere at the prime 2. Fix a prime $\ell$ congruent to 3 or 5 modulo 8. The main construction of this paper is a model for the 2-typical 1-commutative monoid $S^{(-)}_{K(1)} \in \text{CMon}^{(2)}_{1}(\text{Sp}_{K(1)}) \simeq \text{Sp}_{K(1)}$ as the $K(1)$-localization of a 2-typical 1-commutative pre-monoid $GW^{(-)}(F_{\ell}) \in \text{PMon}^{(p)}_{m}(\text{Sp})$, whose underlying spectrum is the Grothendieck-Witt spectrum $GW(F_{\ell})$. Hence, we shall now recall the construction and basic properties of this spectrum.

**Definition 2.2.1.** For $\mathcal{C} \in \text{CAlg}(\text{Cat}^{\infty})$, we let $Q\mathcal{F}(\mathcal{C}) \in \text{CMon}(\mathcal{S})$ be the commutative monoid of pairs $(X, b)$ where $X \in \mathcal{C}$ and $b : X \otimes X \to 1$ is a non-degenerate symmetric bilinear form on $X$, with the monoid structure given by direct sum of symmetric bilinear forms.

The reader is referred to Definition 3.1.7 for a more rigorous definition. We remark that we will exclusively consider symmetric bilinear forms away from the prime 2, where they are interchangeable with quadratic forms.

The Grothendieck-Witt spectrum of $\mathcal{C}$ is obtained by applying group completion.

**Definition 2.2.2.** Let $\mathcal{C} \in \text{CAlg}(\text{Cat}^{\infty})$. The Grothendieck-Witt spectrum of $\mathcal{C}$ is the connective spectrum given by the group-completion

$$GW(\mathcal{C}) := Q\mathcal{F}(\mathcal{C})^{gp} \in \text{Sp}^{	ext{cn}}.$$ 

For an ordinary commutative ring $R$, we shall denote

$$Q\mathcal{F}(R) := Q\mathcal{F}(\text{Mod}_{R}(\text{Ab})).$$

and

$$GW(R) := GW(\text{Mod}_{R}(\text{Ab})).$$

For every invertible element $r \in R^{\times}$, we have an associated symmetric bilinear form

$$q_{r}(x \otimes y) = rxy,$$

and we denote the object $(R, q_{r}) \in Q\mathcal{F}(\mathcal{C})$ by $[r]$. By abuse of notation, we denote by $[r]$ also its class in $GW(R)$. We shall primarily be interested in the case where $R$ is a finite field of odd characteristic.
Example 2.2.3. Let $k$ be a finite field of characteristic not equal to 2. Then any symmetric bilinear form $(V,q) \in QF(k)$ can be diagonalized, and therefore splits as a sum

$$(V,q) = \sum_i [x_i]$$

for elements $x_i \in k^\times/(k^\times)^2$. Since $k$ is a finite field, this latter group is isomorphic to $\mathbb{Z}/2$, generated by a nonsquare class $r$. Moreover, the only relation is $2[r] = 2$, so $QF(k)$ is the free monoid on $[1]$ and $[r]$ subject to the relation $2[r] = 2$.

From this example, one can read off the 0-th Grothendieck-Witt group (see, e.g., [Lam05, Theorem 3.5]):

**Proposition 2.2.4.** Let $k$ be a finite field of odd characteristic. Then

$$\pi_0 GW(k) \simeq \mathbb{Z}[e]/(e^2, 2e),$$

where $e = [r] - [1]$ for $r \in k^\times$ a non-square.

3 Higher semiadditive Grothendieck-Witt theory

In the previous section, we saw that from any symmetric monoidal $\infty$-category $\mathcal{C}$, one can extract a spectrum $GW(\mathcal{C})$ known as the Grothendieck-Witt theory of $\mathcal{C}$. In this section, we enhance this construction to take higher semiadditivity into account: in particular, we show that if $\mathcal{C}$ is a $p$-typical symmetric monoidally $m$-semiadditive $\infty$-category (i.e., $\mathcal{C} \in CAlg(Cat_{\infty}^{(p,m)}))$, then $GW(\mathcal{C})$ naturally acquires the structure of a $p$-typical $m$-commutative pre-monoid

$$GW(\mathcal{C}) : \text{Span}(S_m^{(p)})^{op} \to \text{Sp}.$$  

Informally, the construction consists of the following data: for $A \in S_m^{(p)}$, we set

$$GW^A(\mathcal{C}) := GW(\mathcal{C}^A).$$

Then, for every map $f: A \to B \in S_m^{(p)}$, we provide maps

$$f^*: GW^B(\mathcal{C}) \to GW^A(\mathcal{C})$$

and

$$f_f: GW^A(\mathcal{C}) \to GW^B(\mathcal{C}).$$

Ignoring the symmetric bilinear forms, these maps are given by pre-composition with $f$ and left Kan extension along $f$, respectively. For a symmetric bilinear form $b: X \otimes X \to 1$ on a dualizable object $X \in \mathcal{C}^B$, we set

$$f^*b: f^*X \otimes f^*X \simeq f^*(X \otimes X) \xrightarrow{f^*b} f^*1_B \simeq 1_A.$$  

To specify $f_f$ on a symmetric bilinear form $b$, it will be easiest to specify its mate.
Construction 3.0.1. Let $f: A \to B \in \mathcal{S}_m^{(p)}$, let $\mathcal{C} \in \mathbf{CAlg}(\mathbf{Cat}_\infty^{\oplus \mathcal{M}})$, and let $(X, b) \in \mathcal{QF}(\mathcal{C}^A)$. Then $b$ determines a map

$$b^\vee: X \to \mathbb{D}(X),$$

which we call its mate, where $\mathbb{D}(X)$ denotes the (symmetric monoidal) dual of the dualizable object $X$. We then define the bilinear form

$$f_f b: f_! X \otimes f_! X \to 1_B$$

to be the mate of the composite

$$f_!(X) \xrightarrow{b^\vee} f_!(\mathbb{D}(X)) \xrightarrow{\text{Nm}} f_!(\mathbb{D}(X)) \simeq \mathbb{D}(f_!(X)).$$

Although it is not clear from this definition, it is a consequence of our results that this procedure defines a symmetric bilinear form. Our goal for the rest of this section is to show that these constructions, currently given at the level of individual maps in $\text{Span}(\mathcal{S}_m^{(p)})$, assemble into a functor $GW(-): \text{Span}(\mathcal{S}_m^{(p)})^{op} \to \text{Sp}$.

3.1 Semiadditive anti-involutions

Let $\mathcal{C}$ be a symmetric monoidal $\infty$-category. We saw above that the data of a symmetric bilinear form $b$ on a dualizable object $X \in \mathcal{C}$ can be encoded via its mate $b^\vee: X \to \mathbb{D}(X)$. In Section 3.1.1, we construct a categorical framework for organizing such data. In fact, we will work in a more general setting where $\mathbb{D}$ is replaced by any anti-involution $\iota: \mathcal{C} \xrightarrow{\sim} \mathcal{C}^{op}$ of $\mathcal{C}$ (cf. Definition 3.1.2). Given an anti-involution $\iota$ on $\mathcal{C}$, we will construct its $\infty$-category of fixed points $\Phi(\mathcal{C}, \iota)$: informally, an object of $\Phi(\mathcal{C}, \iota)$ is the data of an object $X \in \mathcal{C}$ together with an equivalence $X \xrightarrow{\sim} \iota(X)$.

In Section 3.1.2, we study the interaction of this construction with semiadditivity. In particular, we will see (Theorem 3.1.13) that if $\mathcal{C}$ is additionally $p$-typically $m$-semiadditive, then its $\infty$-category of fixed points $\Phi(\mathcal{C}, \iota)$ acquires the structure of a $p$-typical $m$-commutative monoid in $\mathbf{Cat}_\infty$.

3.1.1 Anti-involutions and their fixed points

Given an $\infty$-category $\mathcal{C}$, one can pass to its opposite $\infty$-category $\mathcal{C}^{op}$. The assignment $\mathcal{C} \mapsto \mathcal{C}^{op}$ defines an action of $C_2$ on the $\infty$-category $\mathbf{Cat}_\infty$.

Notation 3.1.1. Hereafter, we regard $\mathbf{Cat}_\infty$ as equipped with this $C_2$ action; for instance, $\mathbf{Cat}_\infty^{hC_2}$ will denote homotopy fixed points with respect to this action. We will also have reason to consider the $\infty$-category of functors from $BC_2$ to $\mathbf{Cat}_\infty$, and we will denote this functor category by $\mathbf{Cat}^{BC_2}_\infty$.

Definition 3.1.2. An $\infty$-category with anti-involution is an object of $\mathbf{Cat}_\infty^{hC_2}$. For an $\infty$-category $\mathcal{C}$, an anti-involution on $\mathcal{C}$ is a refinement of $\mathcal{C} \in \mathbf{Cat}_\infty$ to an object of $\mathbf{Cat}_\infty^{hC_2}$.

Concretely, an anti-involution on $\mathcal{C}$ is an anti-equivalence $\iota: \mathcal{C} \xrightarrow{\sim} \mathcal{C}^{op}$ together with a natural isomorphism $\iota^2 \xrightarrow{\sim} \text{Id}$ as well as higher coherence data. We will primarily be interested in the following prototypical example:
**Example 3.1.3.** Let $\mathcal{C}$ be a symmetric monoidal $\infty$-category. Then the full subcategory $\mathcal{C}^{\text{dbl}} \subseteq \mathcal{C}$ spanned by the dualizable objects admits a canonical anti-involution $\mathcal{D}: \mathcal{C}^{\text{dbl}} \xrightarrow{\sim} (\mathcal{C}^{\text{dbl}})^{\text{op}}$, given by taking the symmetric monoidal dual. This construction determines a functor

$$(\cdot)^{\text{dbl}}: \text{CAlg} (\text{Cat}_\infty) \to \text{Cat}_\infty^{hC_2}$$

(cf. [HLAS20, Theorem 5.11]).

We shall now construct the fixed points of a category with anti-involution. Recall that given an $\infty$-category $\mathcal{C}$, one can consider its twisted arrow $\infty$-category $\text{Tw}(\mathcal{C})$: informally, the objects of $\text{Tw}(\mathcal{C})$ are given by arrows $(X \to Y)$ in $\mathcal{C}$ and the morphisms from $(X \to Y)$ to $(X' \to Y')$ can be thought of as commutative squares

$$
\begin{array}{ccc}
X & \xrightarrow{f} & Y \\
\downarrow & & \uparrow \\
X' & \to & Y'.
\end{array}
$$

One can construct $\text{Tw}$ more formally as follows: let $\Delta$ denote the category of non-empty linearly ordered finite sets. The complete Segal space construction of Rezk [Rez01] determines a fully faithful embedding $\text{Cat}_\infty \hookrightarrow S^{\Delta^{\text{op}}}$ as presheaves of spaces on $\Delta$ satisfying a certain “complete Segal” condition [Lur09, Corollary 4.3.16].

The $\infty$-category $\Delta$ has an involution

$$(\cdot)^{\text{rev}}: \Delta \to \Delta,$$

which reverses the order of a totally ordered set, and precomposition with $(\cdot)^{\text{rev}}$ induces the $C_2$ action $(\cdot)^{\text{op}}$ of $\text{Cat}_\infty$. Additionally, the category $\Delta$ admits a monoidal structure by concatenation of linearly ordered sets, which we will denote by $\star$. One can then consider the functor

$$\text{Tw}: S^{\Delta^{\text{op}}} \to S^{\Delta^{\text{op}}}$$

given by

$$\text{Tw}(\mathcal{C})(I) = \mathcal{C}(I \star I^{\text{rev}}).$$

This functor takes complete Segal spaces to complete Segal spaces, so it restricts to an endofunctor of $\text{Cat}_\infty$ (c.f. [HMS20, Proposition A.2.3]): we denote this endofunctor also by

$$\text{Tw}: \text{Cat}_\infty \to \text{Cat}_\infty.$$

When the $\infty$-category $\mathcal{C}$ additionally comes equipped with an anti-involution $\iota$, the $\infty$-category $\text{Tw}(\mathcal{C})$ acquires a natural $C_2$ action given on objects by

$$(X \xrightarrow{f} Y) \mapsto (\iota(Y) \xrightarrow{\iota(f)} \iota(X)).$$

Moreover, this procedure is functorial:
Lemma 3.1.4. The functor $\text{Tw}: \text{Cat}_\infty \rightarrow \text{Cat}_\infty$ lifts to a functor

$$\text{Tw}: \text{Cat}_{hC_2} \rightarrow \text{Cat}_{BC_2}$$

together with a $C_2$-equivariant natural transformation $\text{Tw}(\mathcal{C}) \rightarrow \mathcal{C}^{\text{op}} \times \mathcal{C}$. Here, the $C_2$ action on the target is given by $(X,Y) \mapsto (\iota(Y),\iota(X))$.

Proof. To demonstrate the lemma, we note that there is a natural isomorphism $(I \ast I^{\text{rev}})^{\text{rev}} \cong I \ast I^{\text{rev}}$ in the ordinary category $\Delta$ and hence $\text{Tw}$ intertwines the involution $(-)^{\text{op}}$ of $\text{Cat}_\infty$ with the trivial involution of $\text{Cat}_\infty$. Consequently, it induces a functor between the corresponding fixed points

$$\text{Tw}: \text{Cat}_{hC_2} \rightarrow \text{Cat}_{BC_2}.$$ 

Moreover, the forgetful map $\text{Tw}(\mathcal{C}) \rightarrow \mathcal{C}^{\text{op}} \times \mathcal{C}$ is induced from the natural embeddings $I \hookrightarrow I \ast I^{\text{rev}}$ and $I^{\text{rev}} \hookrightarrow I \ast I^{\text{rev}}$, and so it is visibly equivariant. □

Let $(\mathcal{C},\iota) \in \text{Cat}_{hC_2}$ be an $\infty$-category with anti-involution. Then the above lemma produces a natural $C_2$-equivariant functor

$$\text{Tw}(\mathcal{C}) \rightarrow \mathcal{C} \times \mathcal{C}^{\text{op}}.$$ 

There is also a natural functor

$$\mathcal{C} \xrightarrow{(\text{Id},\iota)} \mathcal{C} \times \mathcal{C}^{\text{op}}$$

which is equivariant when the source, $\mathcal{C}$, is endowed with the trivial $C_2$-action.

Definition 3.1.5. We define the functor

$$\Phi^{\text{lax}}: \text{Cat}_{hC_2} \rightarrow \text{Cat}_{BC_2}$$

by the formula

$$\Phi^{\text{lax}}(\mathcal{C},\iota) = \mathcal{C} \times \mathcal{C} \times \mathcal{C}^{\text{op}} \text{Tw}(\mathcal{C}),$$

so that an object of $\Phi^{\text{lax}}(\mathcal{C},\iota)$ is a map $X \rightarrow \iota(X)$ in $\mathcal{C}$. We also define the functor

$$\Phi: \text{Cat}_{hC_2} \rightarrow \text{Cat}_{BC_2}$$

to be the full sub-functor $\Phi(\mathcal{C},\iota) \subseteq \Phi^{\text{lax}}(\mathcal{C},\iota)$ spanned by the isomorphisms $X \xrightarrow{\sim} \iota(X)$.

We may think of $\Phi^{\text{lax}}(\mathcal{C},\iota)$ and $\Phi(\mathcal{C},\iota)$ as the “lax fixed points” and “fixed points,” respectively, of $\iota$ acting on $\mathcal{C}$. While we are primarily interested in $\Phi$, it will be useful to treat these two functors in parallel.

Remark 3.1.6. We will often have reason to consider refinements of $\Phi$ and $\Phi^{\text{lax}}$ to semiadditive settings (cf. Theorem 3.1.13). To avoid cumbersome notation, we will often refer to these refinements simply as $\Phi$ or $\Phi^{\text{lax}}$, but we will be careful to specify the source and the target of the functors in these cases.

Using this language, we can now present a more formal definition of $QF(\mathcal{C})$. 16
Definition 3.1.7. For a symmetric monoidal ∞-category $C \in \text{CAlg}(\text{Cat}_\infty)$, we define $QF(C)$ by the formula

$$QF(C) \simeq \Phi(C^{\text{dbl}}, \mathbb{D})^{hC_2}.$$ 

By definition, an object of $\Phi(C^{\text{dbl}}, \mathbb{D})$ is a dualizable object $X \in C$ together with an isomorphism $X \xrightarrow{\sim} \mathbb{D}(X)$, which corresponds to a non-degenerate bilinear map $X \otimes X \to 1$. The group $C_2$ acts by swapping the two tensor factors, and so its fixed points are symmetric bilinear maps.

3.1.2 Anti-involutions and semi-additivity

Our aim now is to promote $\Phi(C, \iota)$ and $\Phi^{\text{lax}}(C, \iota)$ to $p$-typical $m$-commutative monoids when $C$ is $p$-typically $m$-semiadditive. This will essentially follow from the facts that these functors are compatible with the formation of $p$-typical $m$-commutative monoids (Lemma 3.1.8), and that every object of $(\text{Cat}_\infty^{\oplus -m})^{hC_2}$ admits a canonical such structure (Corollary 3.1.11).

To see that $\Phi$ and $\Phi^{\text{lax}}$ induce functors on $m$-commutative monoids, we show:

Lemma 3.1.8. The functors $\Phi : \text{Cat}_\infty^{hC_2} \to \text{Cat}_\infty^{BC_2}$ and $\Phi^{\text{lax}} : \text{Cat}_\infty^{hC_2} \to \text{Cat}_\infty^{BC_2}$ are limit preserving.

Proof. First, since the evaluation at the base-point functor $\text{Cat}_\infty^{BC_2} \to \text{Cat}_\infty$ is conservative and limit preserving, it suffices to verify the claim non-equivariantly.

To see that $\Phi^{\text{lax}}$ is limit preserving, it suffices to see that each of the three functors in the pullback $\phi^{\text{lax}} = \mathcal{C} \times \mathcal{C} \times \mathcal{C}^{\text{op}} \text{Tw}($preserves limits. The functors $\mathcal{C} \to \mathcal{C}$ and $\mathcal{C} \to \mathcal{C} \times \mathcal{C}^{\text{op}}$ are clearly limit preserving. The functor $\mathcal{C} \to \text{Tw}($preserves limits since it is given by pre-composition with a map $\Delta \to \Delta$ on $S^{\Delta^\text{op}}$, and the fully faithful embedding $\text{Cat}_\infty \to S^{\Delta^\text{op}}$ is conservative and limit preserving.

To deduce that $\Phi$ is limit preserving, it is enough to show that, for every (small) $\infty$-category $I$ and every $I$-shaped diagram $\{ (C_a, \iota_a) \}_{a \in I} \in \text{Cat}_\infty^{hC_2}$, the equivalence

$$\phi^{\text{lax}} \lim_{a \in I} (C_a, \iota_a) \simeq \lim_{a \in I} \phi^{\text{lax}} (C_a, \iota_a)$$

carries the full subcategory $\Phi \lim_{a \in I} (C_a, \iota_a)$ to $\Phi \lim_{a \in I} (C_a, \iota_a)$. Unwinding the definitions, this reduces to the fact that for every diagram $I \to \text{Cat}_\infty^{hC_2}$, a map

$$\{ X_a \}_{a \in I} \xrightarrow{\phi_a \mid a \in I} \{ \iota_a (X_a) \}_{a \in I} \in \lim_{a \in I} \mathcal{C}_a$$

is an isomorphism if and only if each $\phi_a$ is an isomorphism.

We now turn to the second ingredient in the refinement of $\Phi$: the higher commutative monoid structures on those $(C, \iota) \in \text{Cat}_\infty^{hC_2}$ for which $C$ is $p$-typically $m$-semiadditive. In fact, we shall package such pairs in a $p$-typically $m$-semiadditive $\infty$-category.
Proposition 3.1.9. The involution \((-)^{op}\) of \(\text{Cat}_\infty\) restricts to an involution of the (non-full) subcategory \(\text{Cat}^{\oplus_{p,m}}_\infty\) of \(\text{Cat}_\infty\).

Proof. Since \(\text{Cat}^{\oplus_{p,m}}_\infty\) is a subcategory of \(\text{Cat}_\infty\), it suffices to see that

1. If \(\mathcal{C} \in \text{Cat}^{\oplus_{p,m}}_\infty\), then \(\mathcal{C}^{op} \in \text{Cat}^{\oplus_{p,m}}_\infty\). This follows from [CSY20, Proposition 2.1.4(1)].

2. A functor \(F: \mathcal{C}_0 \to \mathcal{C}_1\) in \(\text{Cat}^{\oplus_{p,m}}_\infty\) preserves \(S_{m}^{(p)}\)-limits if and only if \(F^{op}: \mathcal{C}_0^{op} \to \mathcal{C}_1^{op}\) does. This is because a functor between \(p\)-typically \(m\)-semiadditive \(\infty\)-categories preserves \(S_{m}^{(p)}\)-limits if and only if it preserves \(S_{m}^{(p)}\)-limits ([CSY20, Proposition 2.1.8]).

In view of this result, the \(C_2\)-action on \(\text{Cat}_\infty\) by \((-)^{op}\) restricts to an action on the subcategory \(\text{Cat}^{\oplus_{p,m}}_\infty \subset \text{Cat}_\infty\) and we can form the \(\infty\)-category \((\text{Cat}^{\oplus_{p,m}}_\infty)^{hC_2}\) of \(p\)-typically \(m\)-semiadditive \(\infty\)-categories with anti-involution. We will now show that this category of homotopy fixed points is itself higher semiadditive.

Lemma 3.1.10. The inclusion of the (non-full) subcategory \(\hat{\text{Cat}}^{\oplus_{p,m}}_\infty \subset \hat{\text{Cat}}_\infty\) preserves limits. Here, \(\hat{-}\) indicates that one considers \(\infty\)-categories which are not necessarily small.

Proof. The inclusion of this subcategory may be factored as the composite

\[\text{Cat}^{\oplus_{p,m}}_\infty \to \text{Cat}^{S_{m}^{(p)}}_\infty \to \hat{\text{Cat}}_\infty,\]

where \(\text{Cat}^{S_{m}^{(p)}}_\infty\) denotes the \(\infty\)-category of \(\infty\)-categories admitting \(S_{m}^{(p)}\)-colimits together with functors preserving such colimits. It suffices to show that each of these inclusions is limit preserving. The first inclusion preserves limits because \(\hat{\text{Cat}}^{\oplus_{p,m}}_\infty\) can be identified as the category of modules \(\text{Mod}_{\text{Span}(S_m^{(p)})}(\text{Cat}^{S_{m}^{(p)}}_\infty)\) over the (idempotent) algebra \(\text{Span}(S_m^{(p)})\) ([Har20, Corollary 5.3]). On the other hand, the second inclusion \(\hat{\text{Cat}}^{S_{m}^{(p)}}_\infty \subset \hat{\text{Cat}}_\infty\) preserves limits because it admits a left adjoint, given by freely adding \(S_{m}^{(p)}\)-colimits (see [Lur17, Corollary 5.3.6.10]).

Corollary 3.1.11. The \(\infty\)-category \((\text{Cat}^{\oplus_{p,m}}_\infty)^{hC_2}\) is \(p\)-typically \(m\)-semiadditive and the canonical functor \((\text{Cat}^{\oplus_{p,m}}_\infty)^{hC_2} \to \hat{\text{Cat}}^{hC_2}_\infty\) is limit preserving.

Proof. By (the straightforward \(p\)-typical analog of) [CSY20, Proposition 2.2.11], the \(\infty\)-category \(\text{Cat}^{\oplus_{p,m}}_\infty\) is \(p\)-typically \(m\)-semiadditive. Combining Lemma 3.1.10 and Proposition 3.1.9, we deduce that \((\text{Cat}^{\oplus_{p,m}}_\infty)^{hC_2}\) is \(p\)-typically \(m\)-semiadditive.

It remains to show that the functor \((\text{Cat}^{\oplus_{p,m}}_\infty)^{hC_2} \to \hat{\text{Cat}}^{hC_2}_\infty\) is limit preserving. This is because the inclusion \(\text{Cat}^{\oplus_{p,m}}_\infty \to \hat{\text{Cat}}_\infty\) is limit preserving (by the small category analog of Lemma 3.1.10) and limit-preserving functors are closed under limits in \(\hat{\text{Cat}}_\infty\).

Let us illustrate this corollary more concretely:
Example 3.1.12. Let $\mathcal{C}$ be a $p$-typically $m$-semiadditive $\infty$-category. Then $\mathcal{C}$ acquires a canonical $p$-typical $m$-commutative monoid structure, which provides for any map $f : A \to B$ in $S_m^{(p)}$ an integration functor $\int_f = f^! : \mathcal{C}^A \to \mathcal{C}^B$ (given by left Kan extension). Now suppose $\mathcal{C}$ is equipped with an anti-involution $\iota$, so $(\mathcal{C}, \iota) \in (\text{Cat}_{\infty}^{\otimes p})^{h\mathcal{C}^2}$. Then one can build a diagram

$$
\begin{array}{ccc}
\mathcal{C}^A & \xrightarrow{f} & \mathcal{C}^B \\
\downarrow^\iota & & \downarrow^B \\
(\mathcal{C}^A)^{op} & \xrightarrow{(f^!)^{op}} & (\mathcal{C}^B)^{op}.
\end{array}
$$

Corollary 3.1.11 implies that since $(\text{Cat}_{\infty}^{\otimes p-m})^{h\mathcal{C}^2}$ is $p$-typically $m$-semiadditive, $(\mathcal{C}, \iota)$ acquires a canonical $m$-commutative monoid structure in $(\text{Cat}_{\infty}^{\otimes p-m})^{h\mathcal{C}^2}$. Part of such data is a witness to the commutativity of (4): unwinding the constructions, this homotopy can be expressed concretely by the formula

$$(f^!_*)^{op}_t A \simeq (f^!_*)^{op}_t A \simeq \iota^B f_1$$

where the first equivalence comes from the norm equivalence $f_1 \simeq f_*$ arising from the higher semiadditivity of $\mathcal{C}$, and the second comes from $\iota$ being an anti-involution.

We are now ready to define a higher semiadditive version of the functors $\Phi$ and $\Phi^{lax}$.

Theorem 3.1.13. The functors $\Phi : (\text{Cat}_{\infty}^{\otimes p-m})^{h\mathcal{C}^2} \to \text{Cat}_{\infty}^{BC_2}$ and $\Phi^{lax} : (\text{Cat}_{\infty}^{\otimes p-m})^{h\mathcal{C}^2} \to \text{Cat}_{\infty}^{BC_2}$ admit refinements to functors

$$(\text{Cat}_{\infty}^{\otimes p-m})^{h\mathcal{C}^2} \to \text{CMon}_m^{(p)}(\text{Cat}_{\infty})^{BC_2}.$$  

In other words, for $(\mathcal{C}, \iota)$ a $p$-typically $m$-semiadditive $\infty$-category with anti-involution, the $\infty$-categories $\Phi(\mathcal{C}, \iota)$ and $\Phi^{lax}(\mathcal{C}, \iota)$ are canonically $C_2$-equivariant $p$-typical $m$-commutative monoids in $\text{Cat}_{\infty}$.

Proof. We prove the result for $\Phi$, the proof for $\Phi^{lax}$ being completely analogous. Note that if $\mathcal{D}_0$ and $\mathcal{D}_1$ are $\infty$-categories which admit $S_m^{(p)}$-limits and $F : \mathcal{D}_0 \to \mathcal{D}_1$ is a $S_m^{(p)}$-limit preserving functor, then post-composition with $F$ induces a functor

$$(\text{CMon}_m^{(p)}(\mathcal{D}_0)) \to (\text{CMon}_m^{(p)}(\mathcal{D}_1)).$$

Indeed, the Segal condition involves only $S_m^{(p)}$-limits and hence $F$ preserves this condition. Consequently, by Lemma 3.1.8, the functor $\Phi : \text{Cat}_{\infty}^{h\mathcal{C}^2} \to \text{Cat}_{\infty}^{BC_2}$ induces a functor

$$(\text{CMon}_m^{(p)}(\text{Cat}_{\infty}^{h\mathcal{C}^2})) \to (\text{CMon}_m^{(p)}(\text{Cat}_{\infty}^{h\mathcal{C}^2})) \simeq (\text{CMon}_m^{(p)}(\text{Cat}_{\infty}^{BC_2})).$$

Similarly, by the second part of Corollary 3.1.11, the functor $(\text{Cat}_{\infty}^{\otimes p-m})^{h\mathcal{C}^2} \to \text{Cat}_{\infty}^{h\mathcal{C}^2}$ is limit-preserving and hence induces a functor

$$(\text{CMon}_m^{(p)}((\text{Cat}_{\infty}^{\otimes p-m})^{h\mathcal{C}^2})) \to (\text{CMon}_m^{(p)}(\text{Cat}_{\infty}^{h\mathcal{C}^2})).$$
Finally, by the first part of Corollary 3.1.11, \((\text{Cat}_{\infty}^{\oplus+p\cdot m})^{hC_2}\) is \(p\)-typically \(m\)-semidditive and hence we have a canonical equivalence
\[
(\text{Cat}_{\infty}^{\oplus+p\cdot m})^{hC_2} \cong \text{CMon}_m^{(p)}((\text{Cat}_{\infty}^{\oplus+p\cdot m})^{hC_2})
\]
(see Proposition 2.1.8). Composing these three functors we get the desired refinement.

By abuse of notation, we denote the resulting functors
\[
(\text{Cat}_{\infty}^{\oplus+p\cdot m})^{hC_2} \rightarrow \text{CMon}_m^{(p)}(\text{Cat}_{\infty}^{BC_2})^B
\]
again by \(\Phi\) and \(\Phi^{\text{lax}}\), so that if \(\mathcal{C}\) is \(p\)-typically \(m\)-semiadditive, then \(\Phi(\mathcal{C},\iota)\) and \(\Phi^{\text{lax}}(\mathcal{C},\iota)\) are higher commutative monoids in \(\text{Cat}_{\infty}^{BC_2}\).

We end this section with an explicit description of this higher commutative monoid structure on the level of objects.

**Proposition 3.1.14.** Let \((\mathcal{C},\iota) \in (\text{Cat}_{\infty}^{\oplus+p\cdot m})^{hC_2}\). For every map \(f : A \rightarrow B\) of \(p\)-typical \(m\)-finite spaces, the higher commutative monoid structure on \(\Phi^{\text{lax}}(\mathcal{C},\iota)\) provides a functor
\[
\int_f : \Phi^{\text{lax}}(\mathcal{C},\iota)^A \rightarrow \Phi^{\text{lax}}(\mathcal{C},\iota)^B.
\]

On an object \((\phi : X \rightarrow \iota(X)) \in \Phi^{\text{lax}}(\mathcal{C},\iota)^A\) (where \(X \in \mathcal{C}^A\) and \(\iota\) is applied pointwise), this functor is given by the formula
\[
\int_f (X \xrightarrow{\phi} \iota(X)) = (f_*X \xrightarrow{\psi} \iota(f_*X)) \in \Phi^{\text{lax}}(\mathcal{C},\iota)^B,
\]
where \(\psi\) is the composite
\[
f_*X \xrightarrow{f_*\phi} f_*\iota(X) \simeq \iota(f_*X) \xrightarrow{\iota(Nm^f)} \iota(f_*X).
\]

**Proof.** Recall that we have explained in Example 3.1.12 how any such \((\mathcal{C},\iota) \in (\text{Cat}_{\infty}^{\oplus+p\cdot m})^{hC_2}\) defines a higher commutative monoid in \((\text{Cat}_{\infty}^{\oplus+p\cdot m})^{hC_2}\). Then, the higher commutative monoid structure of \(\Phi^{\text{lax}}(\mathcal{C},\iota)\) is defined by applying the (limit preserving) functor given by
\[
\Phi^{\text{lax}}(\mathcal{C},\iota) = \mathcal{C} \times_{\mathcal{C} \times \mathcal{C}^{\text{op}}} \text{Tw}(\mathcal{C})
\]
to the above higher commutative monoid \((\mathcal{C},\iota) \in \text{CMon}_m^{(p)}((\text{Cat}_{\infty}^{\oplus+p\cdot m})^{hC_2})\). Here, we emphasize that the functor \(\mathcal{C} \rightarrow \mathcal{C} \times \mathcal{C}^{\text{op}}\) is given by \((\text{id},\iota)\).

Using this pullback, we find that the integration map \(\int_f\) on an object \((\phi : X \rightarrow \iota(X)) \in \Phi^{\text{lax}}(\mathcal{C},\iota)^A\) consists of the following collection of data:

1. The integration of \(X \in \mathcal{C}^A\), which is \(f_*X \in \mathcal{C}^B\).
2. The integration of the (twisted) arrow \((\phi : X \rightarrow \iota(X))\) in \(\mathcal{C}^A\), which is the (twisted) arrow \((f_*X \xrightarrow{f_*\phi} f_*\iota(X))\) in \(\mathcal{C}^B\).
(3) The identification of their corresponding images in \( \mathcal{C}^B \times (\mathcal{C}^B)^{\text{op}} \). Referring to the first two points, this amounts to identifying the pairs \((f_1X, \iota(f_1X))\) and \((f_1X, f_1(X))\). By definition, this uses the compatibility of \(f_1\) with \(\iota\) inherent in the higher commutative monoid structure of \((\mathcal{C}, \iota) \in \text{CMon}_m^{(p)}((\text{Cat}_{\infty}^{\otimes-p-m})^{hC_2})\). As explained in Example 3.1.12, this is given by the composite

\[
\iota_1(f_1X) \simeq \iota(f_1X) \xrightarrow{\iota(Nm_1)} \iota(f_1X).
\]

Putting together this data, we obtain the claimed formula. \(\square\)

**Remark 3.1.15.** Since the fully faithful embedding \(\Phi(\mathcal{C}, \iota) \subseteq \Phi^{\text{lax}}(\mathcal{C}, \iota)\) is compatible with the higher commutative monoid structure, the same formula applies for \(\Phi\) instead of \(\Phi^{\text{lax}}\).

### 3.1.3 Lax symmetric monoidal structure on \(\Phi\)

In the previous section, we defined a functor \(\Phi : (\text{Cat}_{\infty}^{\otimes-p-m})^{hC_2} \rightarrow \text{CMon}^{(p)}_m((\text{Cat}_{\infty}^{\otimes})^{hC_2})\) taking an \(m\)-semiadditive ∞-category \(\mathcal{C}\) with an anti-involution \(\iota : \mathcal{C} \rightarrow \mathcal{C}^{\text{op}}\) to its ∞-category of fixed points \(\Phi(\mathcal{C}, \iota)\), considered as a \((C_2\text{-equivariant})\) higher commutative monoid in categories. The purpose of this section is to endow \(\Phi\) with multiplicative structure: more precisely, we will describe symmetric monoidal structures on the source and target of \(\Phi\), and show that \(\Phi\) is lax symmetric monoidal with respect to these structures. In Section 3.2.4, this will be used to endow the Grothendieck-Witt spectrum of a higher semiadditive symmetric monoidal ∞-category with a ring structure.

Recall that \(\text{Cat}_{\infty}^{\otimes-p-m}\) admits a symmetric monoidal structure coming from the Lurie tensor product (cf. Section 2.1.2). We first show that this lifts to a symmetric monoidal structure on \((\text{Cat}_{\infty}^{\otimes-p-m})^{hC_2}\).

**Proposition 3.1.16.** The \(C_2\)-action on \(\text{Cat}_{\infty}^{\otimes-p-m}\) given by \(\mathcal{C} \mapsto \mathcal{C}^{\text{op}}\) lifts canonically to a symmetric monoidal action, that is, a \(C_2\)-action on \(\text{Cat}_{\infty}^{\otimes-p-m}\) considered as an object of \(\text{CAlg}(\text{Cat}_{\infty})\).

**Proof.** For this proof, we will use the standard notations from the theory of ∞-operads of [Lur16]. Let \(\text{Cat}_{\infty}^\otimes\) denote the ∞-operad corresponding to the Cartesian symmetric monoidal structure on \(\text{Cat}_{\infty}\). Then, the ∞-operad \((\text{Cat}_{\infty}^{\otimes-p-m})^\otimes\) corresponding to the symmetric monoidal ∞-category \(\text{Cat}_{\infty}^{\otimes-p-m}\) is given as the subcategory \((\text{Cat}_{\infty}^{\otimes-p-m})^\otimes \subset \text{Cat}_{\infty}^{\otimes}\) where (cf. [Lur16, Notation 4.8.1.2]):

1. The objects are the sequences \((\mathcal{C}_1, \mathcal{C}_2, \cdots, \mathcal{C}_k)\) where each \(\mathcal{C}_i \in \text{Cat}_{\infty}^{\otimes-p-m}\).
2. A morphism \((\mathcal{C}_1, \mathcal{C}_2, \cdots, \mathcal{C}_k) \rightarrow (\mathcal{D}_1, \mathcal{D}_2, \cdots, \mathcal{D}_j)\) covering \(\alpha : \{k\} \rightarrow \{j\}\) is in the subcategory \((\text{Cat}_{\infty}^{\otimes-p-m})^\otimes \subset \text{Cat}_{\infty}^{\otimes}\) iff each component functor

\[
\prod_{i \in \alpha^{-1}(\ell)} \mathcal{C}_i \rightarrow \mathcal{D}_\ell
\]

preserves \(S_m^{(p)}\)-colimits separately in each variable.

The \(C_2\)-action by \(\text{op}\) on \(\text{Cat}_{\infty}\) is symmetric monoidal, and thus induces a \(C_2\)-action on \(\text{Cat}_{\infty}^\otimes\). To see that this restricts to a symmetric monoidal action on \(\text{Cat}_{\infty}^{\otimes-p-m}\), it suffices to check that:
(1) The action map $\text{op} : \text{Cat}_\infty \otimes \to \text{Cat}_\infty \otimes$ preserves the subcategory $(\text{Cat}_{\infty}^{\otimes p-m})^\otimes$. This is true on objects because the opposite of a $p$-typically $m$-semiadditive $\infty$-category is $p$-typically $m$-
semiadditive. It follows for morphisms because functors between $p$-typically $m$-semiadditive $\infty$-categories preserve $S_m^{(p)}$-colimits if and only if they preserve $S^{(p)}_m$-limits.

(2) The resulting functor $\text{op} : (\text{Cat}_\infty^{\otimes p-m})^\otimes \to (\text{Cat}_\infty^{\otimes p-m})^\otimes$ sends coCartesian arrows to coCartesian arrows. This is immediate for the inert morphisms, and follows for the active morphisms again from the fact that functors between $p$-typically $m$-
semiadditive $\infty$-categories preserve $S_m^{(p)}$-colimits if and only if they preserve $S^{(p)}_m$-limits.

As a consequence of this result, we can regard the fixed points $(\text{Cat}_{\infty}^{\otimes p-m})^{hC_2}$ as taken within the $\infty$-category of symmetric monoidal $\infty$-categories; this equips $(\text{Cat}_{\infty}^{\otimes p-m})^{hC_2}$ with a symmetric monoidal structure.

Next, we turn our attention to the fixed point functor $\Phi$: we start by considering a closely related functor:

**Lemma 3.1.17.** Let $(\text{Cat}_{\infty}^{\otimes p-m})^{hC_2}$ be given a symmetric monoidal structure via Proposition 3.1.16, and regard $\text{Cat}_{\infty}^{BC_2}$ as having the Cartesian symmetric monoidal structure. Then there is a canonical lax symmetric monoidal structure on the composite

$$(\text{Cat}_{\infty}^{\otimes p-m})^{hC_2} \xrightarrow{j} \text{Cat}_{\infty}^{hC_2} \xrightarrow{\Phi} \text{Cat}_{\infty}^{BC_2},$$

where $j$ denotes the forgetful functor and $\Phi$ is the fixed point functor regarded as a functor $\text{Cat}_{\infty}^{hC_2} \to \text{Cat}_{\infty}^{BC_2}$.

**Proof.** This is because each functor in the composite admits a lax symmetric monoidal structure:

(1) By the proof of Proposition 3.1.16, the forgetful functor $\text{Cat}_{\infty}^{\otimes p-m} \to \text{Cat}_{\infty}$ extends to a $BC_2$-family of lax symmetric monoidal functors. Therefore, its limit, which is the functor $j$, acquires a lax symmetric monoidal structure.

(2) The functor $\Phi$ preserves limits by Lemma 3.1.8, and both the source and the target are given the Cartesian symmetric monoidal structure; thus, $\Phi$ is symmetric monoidal.

Hence, to endow the fixed points functor $\Phi : (\text{Cat}_{\infty}^{\otimes p-m})^{hC_2} \to \text{CMon}_{\infty}^{(p)}(\text{Cat}_{\infty})^{BC_2}$ with a lax symmetric monoidal structure, it remains to consider the effect of taking $m$-commutative monoids on lax symmetric monoidal functors.

The $\infty$-category $\text{Span}(S_m^{(p)})^{op}$ admits a symmetric monoidal structure given by the Cartesian product in $S_m^{(p)}$. Hence, for every presentably symmetric monoidal $\infty$-category $\mathcal{C}$, we can consider $\text{PMon}_{\infty}^{(p)}(\mathcal{C})$ as a symmetric monoidal $\infty$-category via Day convolution [Gla16].

22
Proposition 3.1.18. Let $\mathcal{C}$ be a presentably symmetric monoidal $\infty$-category. Then $\text{CMon}^p_m(\mathcal{C})$ is a symmetric monoidal localization of $\text{PMon}^p_m(\mathcal{C})$, and in particular, it admits a unique symmetric monoidal structure for which the localization functor $\text{PMon}^p_m(\mathcal{C}) \to \text{CMon}^p_m(\mathcal{C})$ is symmetric monoidal. Moreover, the equivalence $\text{CMon}^p_m(\mathcal{C}) \simeq \text{CMon}^p_m(S) \otimes \mathcal{C}$ is a symmetric monoidal equivalence.

Proof. This follows from [BMS21, Theorem 4.17]. □

Combining these results, we obtain

Theorem 3.1.19. The functor $\Phi : (\text{Cat}^\oplus_m)^{hC_2} \to \text{CMon}^p_m(\text{Cat}^B_m)$ is lax symmetric monoidal.

Proof. We can write $\Phi$ as a composite

$$(\text{Cat}^\oplus_m)^{hC_2} \xrightarrow{\sim} \text{CMon}^p_m((\text{Cat}^\oplus_m)^{hC_2}) \hookrightarrow \text{PMon}^p_m((\text{Cat}^\oplus_m)^{hC_2})$$

$$\hookrightarrow \text{PMon}^p_m(\text{Cat}^B_m) \xrightarrow{L} \text{CMon}^p_m(\text{Cat}^B_m),$$

where $L$ is the symmetric monoidal localization from Proposition 3.1.18 and $\Phi \circ (-)$ denotes post-composition with $\Phi$ regarded as a functor $(\text{Cat}^\oplus_m)^{hC_2} \to \text{Cat}^B_m$. We show, in order, that each map in this composite admits a lax symmetric monoidal structure.

- The equivalence

$$(\text{Cat}^\oplus_m)^{hC_2} \xrightarrow{\sim} \text{CMon}^p_m((\text{Cat}^\oplus_m)^{hC_2}) \simeq (\text{Cat}^\oplus_m)^{hC_2} \otimes \text{CMon}^p_m(S)$$

identifies with the tensor product of the identity functor of $(\text{Cat}^\oplus_m)^{hC_2}$ and the unit $S \to \text{CMon}^p_m(S)$. Hence, it is a symmetric monoidal equivalence by the second part of Proposition 3.1.18.

- The inclusion $\text{CMon}^p_m((\text{Cat}^\oplus_m)^{hC_2}) \hookrightarrow \text{PMon}^p_m((\text{Cat}^\oplus_m)^{hC_2})$ is the right adjoint of the symmetric monoidal localization $L$, and hence is canonically lax symmetric monoidal.

- For symmetric monoidal $\infty$-categories $\mathcal{A}$ and $\mathcal{B}$, the Day convolution symmetric monoidal structure on $\text{Fun}(\mathcal{A}, \mathcal{B})$ (when it exists) is functorial in post-composing with lax symmetric monoidal functors. Hence, by Lemma 3.1.17, the functor $\Phi \circ (-)$ is lax symmetric monoidal with respect to Day convolution.

- Finally, $L$ is a symmetric monoidal localization.
3.2 Grothendieck-Witt theory as a higher commutative monoid

We now refine GW to a functor valued in \( p \)-typical \( m \)-commutative pre-monoids. After some preliminaries on symmetric monoidal duality, we refine \( QF \) to take symmetric monoidally \( m \)-semiadditive categories to \( m \)-commutative monoids (Section 3.2.2). Then, we apply group completion to obtain the semiadditive form of GW in Section 3.2.3, and discuss the multiplicative structure in Section 3.2.4. Finally, in Section 3.2.5, we unwind the definition of the higher semiadditive structure on GW in the special case of vector spaces over a field.

3.2.1 Symmetric monoidal duality and semiadditivity

Let \( \mathcal{C} \) be a symmetric monoidal \( \infty \)-category. Then recall (Example 3.1.3) that one can extract the full subcategory \( \mathcal{C}^{\text{dbl}} \subset \mathcal{C} \) of dualizable objects. This subcategory admits a canonical anti-involution by symmetric monoidal duality, and so the assignment \( \mathcal{C} \mapsto \mathcal{C}^{\text{dbl}} \) determines a functor

\[
(-)^{\text{dbl}} : \text{CAlg}(\text{Cat}_{\infty}) \rightarrow \text{Cat}_{\infty}^{hC_2}.
\]

We will need a higher semiadditive version of this functor:

**Proposition 3.2.1.** The assignment \( \mathcal{C} \mapsto \mathcal{C}^{\text{dbl}} \) determines a functor

\[
(-)^{\text{dbl}} : \text{CAlg}(\text{Cat}_{\infty}^{\mathbb{P}, m}) \rightarrow (\text{Cat}_{\infty}^{\mathbb{P}, m})^{hC_2}.
\]

Moreover, this functor is lax symmetric monoidal with respect to the Lurie tensor product (cf. Proposition 3.1.16).

The proof, which is assembled at the end of this section, will proceed by factoring \((-)^{\text{dbl}}\) as a composite of several lax symmetric monoidal functors. Let \( \text{CAlg}(\text{Cat}_{\infty}^{\mathbb{P}, m})^{\text{rig}} \subset \text{CAlg}(\text{Cat}_{\infty}^{\mathbb{P}, m}) \) denote the full subcategory of rigid \( p \)-typical symmetric monoidally \( m \)-semiadditive categories – that is, those \( \mathcal{C} \in \text{CAlg}(\text{Cat}_{\infty}^{\mathbb{P}, m}) \) satisfying the condition that every object \( X \in \mathcal{C} \) is dualizable.

**Lemma 3.2.2.** The subcategory \( \text{CAlg}(\text{Cat}_{\infty}^{\mathbb{P}, m})^{\text{rig}} \subset \text{CAlg}(\text{Cat}_{\infty}^{\mathbb{P}, m}) \) is closed under the symmetric monoidal structure (given by the Lurie tensor product).

**Proof.** It suffices to show that if \( \mathcal{C}, \mathcal{D} \in \text{CAlg}(\text{Cat}_{\infty}^{\mathbb{P}, m})^{\text{rig}} \), then their tensor product \( \mathcal{C} \otimes \mathcal{D} \) is also rigid. Note that by construction ([Lur16, Proposition 4.8.1.10]), there is a symmetric monoidal functor \( \mathcal{C} \times \mathcal{D} \rightarrow \mathcal{C} \otimes \mathcal{D} \), and so any object in the image of \( \mathcal{C} \times \mathcal{D} \) is dualizable. But \( \mathcal{C} \otimes \mathcal{D} \) is generated under \( S_{m}^{(p)} \)-colimits by the image of \( \mathcal{C} \times \mathcal{D} \), so the lemma follows by noting that for categories in \( \text{CAlg}(\text{Cat}_{\infty}^{\mathbb{P}, m}) \), dualizable objects are closed under \( S_{m}^{(p)} \)-colimits [CSY21, Corollary 2.7].

It follows that \( \text{CAlg}(\text{Cat}_{\infty}^{\mathbb{P}, m})^{\text{rig}} \) inherits a symmetric monoidal structure under the tensor product.

\[\text{CSY21, Corollary 2.7}^{1}\]

\[\text{CSY21, Corollary 2.7}^{1}\]
Lemma 3.2.3. The assignment \( \mathcal{C} \mapsto \mathcal{C}^{\text{dbl}} \) determines a lax symmetric monoidal functor
\[
\text{CAlg}(\text{Cat}_{\infty}^{p\text{-}}) \to \text{CAlg}(\text{Cat}_{\infty}^{p\text{-}\text{rig}}).
\]

Proof. First we note:

(1) The \( \infty \)-category \( \text{CAlg}(\text{Cat}_{\infty}^{p\text{-}}) \) can be identified with the (non-full) subcategory of \( \text{CAlg}(\text{Cat}_{\infty}) \) spanned by \( p \)-typical \( m \)-semiadditive \( \infty \)-categories and functors which preserve \( S_m^{(p)} \)-colimits separately in each variable.

(2) There is a functor \( \text{CAlg}(\text{Cat}_{\infty}) \to \text{CAlg}(\text{Cat}_{\infty}^{\text{rig}}) \) by extracting dualizable objects.

Thus, to construct the functor \( \text{CAlg}(\text{Cat}_{\infty}^{p\text{-}}) \to \text{CAlg}(\text{Cat}_{\infty}^{p\text{-}\text{rig}}) \), it suffices to check that the functor of (2) restricts appropriately; in particular we check:

- For \( \mathcal{C} \in \text{CAlg}(\text{Cat}_{\infty}^{p\text{-}}) \), the \( \infty \)-category \( \mathcal{C}^{\text{dbl}} \) is also \( p \)-typically \( m \)-semiadditive. This is because \( \mathcal{C}^{\text{dbl}} \subseteq \mathcal{C} \) is closed under \( S_m^{(p)} \)-colimits [CSY21, Proposition 2.5].

- That for \( \mathcal{C}, \mathcal{D} \in \text{CAlg}(\text{Cat}_{\infty}^{p\text{-}}) \), a \( S_m^{(p)} \)-colimit preserving symmetric monoidal functor \( \mathcal{C} \to \mathcal{D} \) restricts to \( \mathcal{C}^{\text{dbl}} \to \mathcal{D}^{\text{dbl}} \) on the dualizable objects. This again follows from the fact that \( \mathcal{C}^{\text{dbl}} \) and \( \mathcal{D}^{\text{dbl}} \) are closed under \( S_m^{(p)} \)-colimits in \( \mathcal{C} \) and \( \mathcal{D} \) respectively.

It remains to see that this restricted functor is lax symmetric monoidal. But note that the symmetric monoidal structure on \( \text{CAlg}(\text{Cat}_{\infty}^{p\text{-}}) \) is coCartesian (because it is a category of commutative algebras), and the subcategory \( \text{CAlg}(\text{Cat}_{\infty}^{p\text{-}\text{rig}}) \) is closed under the monoidal structure by Lemma 3.2.2. Thus, the symmetric monoidal structure on \( \text{CAlg}(\text{Cat}_{\infty}^{p\text{-}\text{rig}}) \) is also coCartesian. Since the source \( \text{CAlg}(\text{Cat}_{\infty}^{p\text{-}}) \) of the functor is unital, it follows from [Lur16, Proposition 2.4.3.9] that the functor is lax symmetric monoidal.

We have seen that the construction \( \mathcal{C} \to \mathcal{C}^{\text{op}} \) defines a symmetric monoidal \( C_2 \)-action on \( \text{Cat}_{\infty} \), and that this endows the subcategory \( \text{Cat}_{\infty}^{p\text{-}} \subset \text{Cat}_{\infty} \) with a symmetric monoidal \( C_2 \)-action (cf. Proposition 3.1.16). It follows that \( \text{CAlg}(\text{Cat}_{\infty}^{p\text{-}}) \) also admits a \( C_2 \)-action by \( \mathcal{C} \mapsto \mathcal{C}^{\text{op}} \).

Lemma 3.2.4. The \( C_2 \)-action on \( \text{CAlg}(\text{Cat}_{\infty}^{p\text{-}}) \) by \( \mathcal{C} \mapsto \mathcal{C}^{\text{op}} \) restricts to a \( C_2 \)-action on the subcategory \( \text{CAlg}(\text{Cat}_{\infty}^{p\text{-}\text{rig}}) \), and this restricted action is trivial. Consequently, there is a lax symmetric monoidal functor
\[
\text{CAlg}(\text{Cat}_{\infty}^{p\text{-}\text{rig}}) \to (\text{CAlg}(\text{Cat}_{\infty}^{p\text{-}\text{rig}}) \text{rig})^{hC_2}.
\]

Proof. To restrict the action, it suffices to note that if \( \mathcal{C} \) is rigid, then \( \mathcal{C}^{\text{op}} \) is rigid. We have seen (e.g. in the proof of Lemma 3.2.3) that \( \text{CAlg}(\text{Cat}_{\infty}^{p\text{-}}) \subset \text{CAlg}(\text{Cat}_{\infty}) \) is the inclusion of a subcategory, and it follows from the construction of the \( C_2 \)-action (proof of Proposition 3.1.16) that this inclusion is \( C_2 \)-equivariant with respect to the \( \text{op} \) action. Hence, one also has that \( \text{CAlg}(\text{Cat}_{\infty}^{p\text{-}\text{rig}}) \subset \text{CAlg}(\text{Cat}_{\infty}) \text{rig} \) is a \( C_2 \)-equivariant inclusion of a subcategory; note further that on morphism spaces, this subcategory includes all equivalences. Combining this with [HLAS20, Theorem 5.11], which asserts that the \( C_2 \)-action on \( \text{CAlg}(\text{Cat}_{\infty}) \text{rig} \) is trivial, we conclude that the \( C_2 \)-action on \( \text{CAlg}(\text{Cat}_{\infty}^{p\text{-}\text{rig}}) \) is also trivial.
Now we can finish the proof of Proposition 3.2.1:

Proof of Proposition 3.2.1. We construct the desired functor \((-)^{dbl}\) as a composite

\[
\text{CAlg}(\text{Cat}^\oplus_{\infty}) \to \text{CAlg}(\text{Cat}^\oplus_{\infty}) \to \text{CAlg}(\text{Cat}^\oplus_{\infty}) \to \text{CAlg}(\text{Cat}^\oplus_{\infty}) \to \text{CAlg}(\text{Cat}^\oplus_{\infty}) \to \text{CAlg}(\text{Cat}^\oplus_{\infty}) \to \text{CAlg}(\text{Cat}^\oplus_{\infty})
\]

The first two functors, and their lax symmetric monoidality, are Lemma 3.2.3 and Lemma 3.2.4, respectively. The third functor exists and is symmetric monoidal because, by construction, one has a symmetric monoidal \(C_2\)-equivariant inclusion \(\text{CAlg}(\text{Cat}^\oplus_{\infty}) \to \text{CAlg}(\text{Cat}^\oplus_{\infty})\). Finally, the last functor is induced by the forgetful functor \(\text{CAlg}(\text{Cat}^\oplus_{\infty}) \to \text{Cat}^\oplus_{\infty}\), which is \(C_2\)-equivariantly symmetric monoidal by Proposition 3.1.16.

\[\square\]

### 3.2.2 Symmetric bilinear forms

We may now refine \(QF(\mathcal{E})\) to a higher commutative monoid.

**Definition 3.2.5.** Let \(QF(-) : \text{CAlg}(\text{Cat}^\oplus_{\infty}) \to \text{CMon}_{m}(\text{S})\) be the composite

\[
\text{CAlg}(\text{Cat}^\oplus_{\infty}) \xrightarrow{(-)^{dbl}} (\text{Cat}^\oplus_{\infty})^{hC_2} \xrightarrow{\Phi} \text{CMon}_{m}(\text{Cat}_{\infty})^{BC_2} \xrightarrow{(-)^{m}} \text{CMon}_{m}(\text{S}).
\]

In particular, a point of the space \(QF^A(\mathcal{E})\) is a pair \((X, b)\) where \(X \in \mathcal{E}^A\) and \(b\) is a non-degenerate symmetric bilinear form on \(X\), with respect to the point-wise tensor product of \(\mathcal{E}^A\). We also have the expected integration maps for \(QF(-)(\mathcal{E})\):

**Proposition 3.2.6.** Let \(\mathcal{E} \in \text{CAlg}(\text{Cat}^\oplus_{\infty})\) and let \(f : A \to B \in \text{S}(p)\). The map

\[I_f : QF^A(\mathcal{E}) \to QF^B(\mathcal{E})\]

agrees with the map constructed in Construction 3.0.1.

**Proof.** Since \(QF(-)(\mathcal{E}) \simeq \Phi(\mathcal{E}^{dbl}, \mathcal{D})^{hC_2}\) the claim follows immediately from Proposition 3.1.14. \[\square\]

### 3.2.3 From symmetric bilinear forms to Grothendieck-Witt theory

To produce the higher semiadditive version of Grothendieck-Witt theory from \(QF(-)(\mathcal{E})\), all that is left is to perform group completion level-wise. For this, we first need to promote the spaces \(QF^A(\mathcal{E})\) to commutative monoids in spaces in a way compatible with the higher commutative monoid structure of \(QF(-)(\mathcal{E})\). In fact, such an extension is automatic:

**Proposition 3.2.7.** For every \(m \geq 0\), there is a canonical equivalence

\[
\text{CMon}_{m}^{(p)}(\text{S}) \simeq \text{CMon}_{m}^{(p)}(\text{CMon}(\text{S})).
\]

26
Proof. We have $\text{CMon}^m(S) \simeq \text{CMon}(S)$, where $\otimes$ denotes the tensor product of presentable $\infty$-categories [Lur16, §4.8]. Since $\text{CMon}(S)$ is an idempotent algebra in $\text{Pr}$ classifying 0-semiadditivity (see, e.g., [CSY20, Proposition 5.3.1]), the result follows from the fact that for every $m \geq 0$, $\text{CMon}^m(S)$ is a semiadditive $\infty$-category.

Let $\Sigma^p : \text{CMon}(S) \to \text{Sp}$ denote the group completion functor.

**Definition 3.2.8.** For $m \geq 0$, define the functor $GW : \text{CAlg}(\text{Cat}^{\infty}_{\text{p}-m}) \to \text{PMon}^m(S)$ to be the composite

$$\text{CAlg}(\text{Cat}^{\infty}_{\text{p}-m}) \xrightarrow{QF} \text{CMon}^m(S) \simeq \text{CMon}^m(\text{CMon}(S)) \to \text{PMon}^m(S).$$

Namely, $GW^A(\mathcal{C})$ is the connective spectrum obtained from $QF^A(\mathcal{C}) \in \text{CMon}(S)$ via group-completion. Note that the summation operation in the monoid $QF^A(\mathcal{C})$, and hence in the spectrum $GW^A(\mathcal{C})$, is given by direct sum of symmetric bilinear forms.

**Remark 3.2.9.** Although $QF^A(\mathcal{C})$ is a $p$-typical $m$-commutative monoid, the functor $GW^A(\mathcal{C})$ need not satisfy the Segal condition in general, and hence it is only a $p$-typical $m$-commutative premonoid.

### 3.2.4 Multiplicative structure on GW

Recall that the $\infty$-category $\text{PMon}^m(S) = \text{Fun}(\text{Span}(S^{(p)}), \text{Sp})$ admits a symmetric monoidal structure given by Day convolution. In this section, we show that for every symmetric monoidal $p$-typically $m$-semiadditive $\infty$-category $\mathcal{C}$, the Grothendieck-Witt object $GW(\mathcal{C}) \in \text{PMon}^m(S)$ admits a canonical structure of a commutative (a.k.a. $E_\infty$-) algebra in $\text{PMon}^m(S)$. To accomplish this, we refer to Definition 3.2.8, in which the functor $GW : \text{CAlg}(\text{Cat}^{\infty}_{\text{p}-m}) \to \text{PMon}^m(S)$ is defined as a certain composite: we will show that each functor in the composite, and consequently $GW$ itself, is a lax symmetric monoidal functor.

**Proposition 3.2.10.** The functor

$$QF^A : \text{CAlg}(\text{Cat}^{\infty}_{\text{p}-m}) \to \text{CMon}^m(S)$$

of Definition 3.2.5 is lax symmetric monoidal.

**Proof.** We check that each functor in the composite of Definition 3.2.5 is lax symmetric monoidal.

1. The functor $(-)^{\text{dbl}}$ is lax symmetric monoidal by Proposition 3.2.1.
2. The functor $\Phi$ is lax symmetric monoidal by Theorem 3.1.19.
3. The functor $(-)^{hC2}$ is lax symmetric monoidal because it is right adjoint to the symmetric monoidal functor $\text{CMon}^m(\text{Cat}^\infty) \to \text{CMon}^m(\text{Cat}^\infty)^{BC2}$ which takes the constant functor on $BC2$.  

27
(4) The functor $(-)^\approx$ is lax symmetric monoidal because it is right adjoint to the symmetric monoidal inclusion $\text{CMon}^p_m(S) \subset \text{CMon}^p_m(\text{Cat}_\infty)$.

\[\text{Corollary 3.2.11.} \text{ The functor }\]
\[\text{GW}(-) : \text{CAlg}(\text{Cat}^p_{\infty}) \to \text{PMon}^p_m(\text{Sp})\]
\[\text{is lax symmetric monoidal. Hence, for any symmetric monoidal } p\text{-typically } m\text{-semiadditive } \infty\text{-category } \mathcal{C}, \text{ the spectrum } \text{GW}(\mathcal{C}) \text{ acquires a canonical structure of a commutative algebra in } \text{PMon}^p_m(\text{Sp}).\]

\[\text{Proof.} \text{ We check that the functors in Definition 3.2.8 are lax symmetric monoidal:}\]

(1) The functor $\mathcal{QF}(-)$ is lax symmetric monoidal by the previous proposition.

(2) The equivalence $\text{CMon}^p_m(S) \simeq \text{CMon}^p_m(\text{CMon}(S))$ is symmetric monoidal by combining (the proof of) Proposition 3.2.7 with Proposition 3.1.18.

(3) The inclusion $\text{CMon}^p_m(\text{CMon}(S)) \hookrightarrow \text{PMon}^p_m(\text{CMon}(S))$ is lax symmetric monoidal because it is right adjoint to a symmetric monoidal localization (cf. Proposition 3.1.18).

(4) The functor $(-)^{gp} : \text{CMon}(S) \to \text{Sp}$ is symmetric monoidal, and thus the functor $\text{PMon}^p_m(\text{CMon}(S)) \to \text{PMon}^p_m(\text{Sp})$ induced by post-composition is lax symmetric monoidal for the Day convolution structure.

\[\text{3.2.5 Grothendieck-Witt theory of fields}\]

We shall now specialize the above discussion to the case of the 2-typical 1-commutative pre-monoid $\text{GW}^{-1}(\text{Mod}_k(\text{Ab}))$ where $k$ is a field in which 2 is invertible. To ease notation, we abbreviate

\[\text{GW}^A(k) := \text{GW}^A(\text{Mod}_k(\text{Ab}))\]

in this case.

We shall now describe explicitly, in some cases, the integration maps for $\mathcal{QF}^{BG}(k)$ (and thus for $\text{GW}^{-1}(k)$).

\[\text{Proposition 3.2.12. Let } G \text{ be a finite group of order a power of } 2, \text{ let } k \text{ be a field of characteristic prime to } 2, \text{ and let } (V,b) \in \mathcal{QF}^{BG}(k) \text{ be a } G\text{-equivariant vector space equipped with an equivariant symmetric bilinear form. Then the map}\]

\[\int_{BG} : \mathcal{QF}^{BG}(k) \to \mathcal{QF}(k)\]

28
sends the pair \((V, b)\) to the pair \((V_G, f_{BG} b)\) where the symmetric bilinear form \(f_{BG} b\) is given by the formula

\[ f_{BG} b(\overline{u}, \overline{v}) = \sum_{g \in G} b(g v, u). \]

Here, \(\overline{u}, \overline{v} \in V_G\) denote the coinvariant classes of the vectors \(u, v \in V\).

**Proof.** Let \(b^\vee : V \to D\) be the mate of \(b\). Then, by Proposition 3.2.6, the map \((f_{BG} b)^\vee\) is given by

\[ (f_{BG} b)^\vee(\overline{u}) = b^\vee(Nm_{BG}(\overline{u})) = b^\vee(\sum_{g \in G} gu) \]

so that

\[ (f_{BG} b)(\overline{u}, \overline{v}) = (f_{BG} b^\vee(\overline{u})(\overline{v}) = (b^\vee(\sum_{g \in G} gu))(v) = \sum_{g \in G} b(gu, v). \]

\[ \square \]

**Notation 3.2.13.** For an integer \(r\) and group \(G\), let \([r]\) denote the object \((k, b_r) \in QF_{BG}(k)\), where \(k\) is the constant local system on \(BG\) with value \(k\) and \(b_r\) is the symmetric bilinear form given by \(b_r(x, y) = rxy\).

**Corollary 3.2.14.** For any 2-group \(G\), we have

\[ f_{BG}[r] = [|G| \cdot r] \in QF(k). \]

**Proof.** By Proposition 3.2.12 and the assumption that \(G\) acts trivially on \(k\), we have

\[ (f_{BG} b_r)(x, y) = \sum_{g \in G} b_r(gx, y) = \sum_{g \in G} b_r(x, y) = |G| \cdot b_r(x, y) = b_{|G| r}(x, y), \]

which is exactly the symmetric bilinear form on \(k\) corresponding to the object \([|G| \cdot r] \in QF(k)\). \(\square\)

### 4 \(K(1)\)-local Grothendieck-Witt theory of finite fields

Let \(S_{K(1)}\) denote the \(K(1)\)-local sphere at the prime 2. Recall that, in order to prove Theorem A, we aim to compute the element \(|BC_2| \in \pi_0(S_{K(1)})\). This element is defined in terms of the 1-commutative monoid structure on \(S_{K(1)}\), which is given by a functor

\[ S_{K(1)}^{(-)} : \text{Span}(G^{(2)}_1)^{op} \to \text{Sp}. \]

The goal of this section is to show that this functor can be understood in terms of the functor \(GW^{(-)}\) constructed in Section 3. In particular, we will show:
Theorem 4.0.1. Let $\ell \equiv 3, 5 \pmod{8}$ be a prime, and let

$$GW^{(-)}(\mathbb{F}_\ell) : \text{Span}(S_1^{(2)})^{\text{op}} \to \text{Sp}$$

denote the functor constructed in the previous section. Then there is a natural transformation of functors $GW^{(-)}(\mathbb{F}_\ell)^\wedge_2 \to S_{K(1)}^{(-)}$ which, pointwise, exhibits the source as the connective cover of the target.

We will deduce this theorem from the following more precise statement, which we prove at the end of the next section:

Proposition 4.0.2. Let $\ell$ be an odd prime. Then, the following statements hold:

1. The $K(1)$-localization map $GW^{(-)}(\mathbb{F}_\ell)^\wedge_2 \to L_{K(1)}GW^{(-)}(\mathbb{F}_\ell)$ pointwise exhibits the source as the connective cover of the target.

2. The functor $L_{K(1)}GW^{(-)}(\mathbb{F}_\ell)$ defines a 1-commutative monoid (i.e., satisfies the Segal condition).

3. If, in addition, $\ell \equiv 3, 5 \pmod{8}$, then there is an equivalence $L_{K(1)}GW^{(-)}(\mathbb{F}_\ell) \simeq S_{K(1)}^{(-)}$ of 1-commutative monoids.

The main input to this proposition is from work of Fiedorowicz-Hauschild-May [FHM82] in which they show that the spectra $GW^G(\mathbb{F}_\ell)$ can be understood in terms of equivariant real $K$-theory as the fixed points of an Adams operation (cf. Proposition 4.1.1). We will show that their description readily implies (1). For the second statement, we combine their description with the Atiyah-Segal completion theorem, which essentially says that equivariant real $K$-theory satisfies the Segal condition.

The last statement involves the theory of ambidexterity – in particular, the fact that any $K(1)$-local spectrum admits a unique 1-commutative monoid structure (Example 2.1.11). This means that, given (2), it suffices to identify the value of the functor $L_{K(1)}GW^{(-)}(\mathbb{F}_\ell)$ evaluated at a point as $S_{K(1)}^{(-)}$.

Remark 4.0.3. The (non-equivariant) identification $L_{K(1)}GW(\mathbb{F}_\ell) \simeq S_{K(1)}$ (for $\ell \equiv 3, 5 \pmod{8}$) goes back to work of Friedlander [Fri76]. The role of Fiedorowicz-Hauschild-May’s equivariant generalization of this identification in our story is that it allows us to additionally understand the 1-commutative pre-monoid structure on $GW^{(-)}(\mathbb{F}_\ell)$.

4.1 Relating $S_{K(1)}$ to GW

We now prove the various statements in Proposition 4.0.2. We begin by stating the results that we use from the work of Fiedorowicz-Hauschild-May [FHM82]. Note that the Frobenius automorphism $\varphi : \mathbb{F}_\ell \to \mathbb{F}_\ell$ induces a natural transformation

$$\varphi : GW^{(-)}(\mathbb{F}_\ell) \to GW^{(-)}(\mathbb{F}_\ell).$$

It turns out that this natural transformation models the Adams operations on equivariant real $K$-theory:
Proposition 4.1.1 ([FHM82], Section 8). Let \( \ell \) be an odd prime and let \( G \) be a 2-group. Then there is a commutative square of spectra

\[
\begin{array}{ccc}
GW^G(\mathbb{F}_\ell)^\wedge_2 & \xrightarrow{\varphi} & GW^G(\mathbb{F}_\ell)^\wedge_2 \\
\downarrow^{\beta^G} & & \downarrow^{\beta^G} \\
\tau_{\geq 0}(KO^G)^\wedge_2 & \xrightarrow{\psi^\ell} & \tau_{\geq 0}(KO^G)^\wedge_2
\end{array}
\]

in which the vertical maps \( \beta^G \) are equivalences. Here \( \psi^\ell \) denotes the \( \ell \)-th Adams operation.

Furthermore, the map from the connective cover of the fiber of \( 1 - \varphi \) to \( GW^G(\mathbb{F}_\ell)^\wedge_2 \) can be identified with the natural map \( GW^G(\mathbb{F}_\ell)^\wedge_2 \rightarrow GW^G(\mathbb{F}_\ell)^\wedge_2 \).

Proof. The vertical equivalences are the content of [FHM82, Theorem 0.3]. The commutativity of the square is demonstrated in [FHM82, Section 8], in the proof of Theorem 0.5, and the identification of the fiber is [FHM82, Theorem 8.1].

Remark 4.1.2. In fact, the equivalences \( \beta^G \) of Proposition 4.1.1 are shown to be compatible with restriction in \( G \) in the sense that they arise as the genuine \( G \)-fixed points of a genuine \( G \)-equivariant map [FHM82, Theorem 0.3]. In particular, there is a commutative square

\[
\begin{array}{ccc}
GW^G(\mathbb{F}_\ell)^\wedge_2 & \longrightarrow & (GW(\mathbb{F}_\ell)^hG)^\wedge_2 \\
\downarrow^{\beta^G} & & \downarrow^{\beta^hG} \\
\tau_{\geq 0}(KO^G)^\wedge_2 & \longrightarrow & \tau_{\geq 0}(KO^{hG})^\wedge_2
\end{array}
\]

for all 2-groups \( G \).

Together, Proposition 4.1.1 and Remark 4.1.2 imply that in order to check that the functor \( L_{K(1)}GW(-)(\mathbb{F}_\ell) \) defines a 1-commutative monoid (i.e., satisfies the Segal condition), it suffices to show the analogous statement for real equivariant \( K \)-theory.

Proposition 4.1.3 (Atiyah-Segal Completion Theorem, 2-complete form [AS69]). Let \( G \) be a 2-group. Then the natural map of spectra \( KO^G \rightarrow KO^{BG} \) is an equivalence after 2-completion.

Proof. By the usual Atiyah-Segal completion theorem [AS69], this map exhibits \( \pi_* (KO^{BG}) \) as the completion of the ring \( \pi_* (KO^G) \) at the augmentation ideal. Since \( G \) is a 2-group, the augmentation ideal defines the 2-adic topology (see [AT69, Proposition III.1.1]).

Corollary 4.1.4. The functor \( L_{K(1)}GW(-)(\mathbb{F}_\ell) : \text{Span}(S_1^{(2)})^{op} \rightarrow \text{Sp} \) satisfies the Segal condition. In other words, \( L_{K(1)}GW(-)(\mathbb{F}_\ell) \) defines a 2-typical 1-commutative monoid in \( K(1) \)-local spectra.
Proof. By Proposition 4.1.1 and Remark 4.1.2, it suffices to show that the natural map

$$\tau_{\geq 0}(\text{KO}^G_2)^{\wedge} \to (\text{KO}_2^G)^{BG}$$

is an equivalence after $K(1)$-localization for every 2-group $G$. But $(\text{KO}^G_2)^{\wedge}$ is $K(1)$-local and $K(1)$-localization is insensitive to connective cover, so the left-hand side localizes to $(\text{KO}^G_2)^{\wedge}$. Since $K(1)$-local spectra are closed under limits in $\mathcal{S}$, the right-hand side is unchanged by localization, and thus the conclusion follows from Proposition 4.1.3.

We now prove Proposition 4.0.2. The essential input is Corollary 2.1.9, which asserts that $K(1)$-local spectra admit an essentially unique 1-commutative monoid structure.

Proof of Proposition 4.0.2. Statement (1) follows directly from Proposition 4.1.1. By the functoriality of $GW(-)$ in the ring, the composite of the sequence

$$L_{K(1)}GW(-)(\mathbb{F}_\ell) \to L_{K(1)}GW(-)(\mathbb{F}_\ell) \xrightarrow{1-\varphi} L_{K(1)}GW(-)(\mathbb{F}_\ell)$$

is canonically nullhomotopic (where $\varphi$ is the natural transformation induced from the Frobenius map of $\mathbb{F}_\ell$); applying Proposition 4.1.1, we conclude that the sequence is a (pointwise) fiber sequence of functors. Therefore, by Corollary 4.1.4, we conclude that $L_{K(1)}GW(-)(\mathbb{F}_\ell)$ satisfies the Segal condition (which is statement (2)) and has underlying spectrum equivalent to the fiber of the map

$$1-\psi\ell: KO_2^\wedge \to KO_2^\wedge.$$

When $\ell \equiv 3, 5 \pmod{8}$, $\ell$ is a topological generator for $\mathbb{Z}_2^\wedge / \{\pm 1\} \simeq \mathbb{Z}_2$ and therefore this fiber is equivalent to $S_{K(1)}$ (see, for instance, [Hop14]). The conclusion of (3) then follows from Corollary 2.1.9.

### 4.1.1 The induced map on $\pi_0$

Theorem 4.0.1 roughly asserts that the 1-semiadditive structure of $S_{K(1)}$ can be understood in terms of the higher semiadditive Grothendieck-Witt theory of a finite field via a certain map of 1-commutative monoids $GW(-)(\mathbb{F}_\ell) \to S_{K(1)}$. In order to better translate between the two objects, we will compute $GW(\mathbb{F}_\ell) \to S_{K(1)}$ explicitly on $\pi_0$.

First, recall from Section 1.2.1 the equivalence

$$\pi_0 S_{K(1)} \simeq \mathbb{Z}_2[\epsilon]/(\epsilon^2, 2\epsilon),$$

where $\epsilon := \eta \cdot \zeta$. On the other hand, by Proposition 2.2.4, one has an isomorphism

$$\pi_0 GW(\mathbb{F}_\ell) \simeq \mathbb{Z}[e]/(e^2, 2e)$$

where $e$ represents the symmetric bilinear form $[r] - [1]$ for a nonsquare $r \in \mathbb{F}_\ell^\times$. 

32
Lemma 4.1.5. In the above notation, the ring map
\[ \mathbb{Z}[e]/(e^2, 2e) \cong \pi_0 \text{GW}(\mathbb{F}_\ell) \to \pi_0 S_{K(1)} \cong \mathbb{Z}_2[\varepsilon]/(\varepsilon^2, 2\varepsilon) \]
of Theorem 4.0.1 sends \( e \) to \( \varepsilon \).

Proof. By Theorem 4.0.1, the map exhibits the target as the 2-completion of the source. Since \( e \) is the only nilpotent element in \( \mathbb{Z}[e]/(e^2, 2e) \) and \( \varepsilon \) is the only nilpotent element of \( \mathbb{Z}_2[\varepsilon]/(\varepsilon^2, 2\varepsilon) \), we deduce that this homomorphism must take \( e \) to \( \varepsilon \).

\[ \square \]

5 Computations in the \( K(1) \)-local sphere

Let \( p = 2 \) and let \( \ell \) be a prime congruent to 3 or 5 modulo 8. The fact that the 2-typical 1-commutative monoid \( S^{(-)}_{K(1)} \) is the \( K(1) \)-localization of the 1-commutative pre-monoid \( GW^{(-)}(\mathbb{F}_\ell) \) allows us to deduce facts about the \( K(1) \)-local sphere from more concrete computations in symmetric bilinear forms over the finite field \( \mathbb{F}_\ell \). We shall demonstrate this method by computing the cardinalities of 2-typical \( \pi \)-finite spaces in \( \pi_0 S_{K(1)} \) (Theorem A) in Section 5.1, and deducing various natural power operations for \( \text{Sp}_{K(1)} \) (Theorems 1.2.5 and 1.2.6) in Section 5.2.

5.1 Cardinalities

Recall that, for a \( \pi \)-finite space \( A \), one can associate an element \( |A| \in \pi_0 S_{K(1)} \), known as the \( (K(1)\)-local) cardinality of \( A \) (cf. Definition 2.1.12). In this section we explain how to compute these cardinalities for every 2-typical \( \pi \)-finite space \( A \). Since \( \text{Sp}_{K(1)} \) is 2-local of semiadditive height 1 (see [CSY20, Theorem 4.4.5]), the most interesting case is when \( A \) is a 2-typical \( \pi \)-finite groupoid.

5.1.1 \( K(1) \)-local cardinalities of 2-typical \( \pi \)-finite spaces

Let \( A \) be a 2-typical \( \pi \)-finite space. Recall that if \( A = \sqcup_i A_i \) then \( |A| = \sum_i |A_i| \) and so the computation of cardinalities reduces immediately to the case where \( A \) is connected. For connected \( A \), we shall express the result in terms of its homotopy cardinality, defined by the formula
\[ |A|_0 := \prod_{i\in \mathbb{N}} |\pi_i A|^{(-1)^i}. \]

We have the following relationship between the homotopy cardinality of \( A \) and its \( K(1) \)-local cardinality:

Theorem 5.1.1. Let \( S_{K(1)} \) denote the \( K(1) \)-local sphere at the prime 2, and let \( A \) be a connected 2-typical \( \pi \)-finite space. Then we have
\[ |A| = 1 + \log_2(|A|_0) \cdot \varepsilon \in \pi_0 S_{K(1)}. \]

In particular,
\[ |BC_2| = 1 + \varepsilon. \]

33
Proof. We first reduce the general case to the case $A = BC_2$. Let $A \to B \to C$ be a principal fiber sequence of 2-typical $\pi$-finite spaces such that $A$ is connected. Then, since $Sp_{K(1)}$ is of semiadditive height 1, we have by [CSY20, Proposition 2.3.3, Proposition 3.2.3] that

$$|B| = |A| \cdot |C| \in \pi_0 S_{K(1)}.$$ 

On the other hand, since (for the same reason) we have $|B|_0 = |A|_0 |C|_0$, and since $\varepsilon^2 = 0$, we deduce that

$$1 + \log_2(|B|_0) \varepsilon = 1 + \log_2(|A|_0) \varepsilon + \log_2(|C|_0) \varepsilon = (1 + \log_2(|A|_0) \varepsilon) \cdot (1 + \log_2(|C|_0) \varepsilon).$$

Hence, both the left hand side and the right hand side in the proposed identity (5) are multiplicative in principal fiber sequences with connected fiber.

Note that every connected 2-typical $\pi$-finite space $A$ is nilpotent, and hence participates in a sequence of principal fibrations

$$A = A_0 \to A_1 \to \ldots \to A_k = \text{pt}$$

such that, for every $0 \leq i \leq k - 1$, the fiber of the map $A_i \to A_{i+1}$ is of the form $B^\ell C_2$ for some $\ell_i > 0$. Hence, the claim for general $A$ follows from the cases $A = B^\ell C_2$. Moreover, since we have principal fiber sequences

$$B^{\ell - 1} C_2 \to \text{pt} \to B^\ell C_2,$$

we may further reduce these cases to the single case $A = BC_2$.

We now prove the claim for $BC_2$. By the results of Section 4, we have a (unital) map $GW(F_{\ell}) \to S_{K(1)}$ in $\text{PMon}_{(2)}(\text{Sp})$. Thus, by definition of the cardinality, the map $\pi_0 GW(F_{\ell}) \to \pi_0 S_{K(1)}$ carries the element $|BC_2| \in \pi_0 GW(F_{\ell})$ to the element $|BC_2| \in \pi_0 S_{K(1)}$. Therefore, it is enough to compute $|BC_2|$ in $\pi_0 GW(F_{\ell})$. Moreover, since (by Lemma 4.1.5) the map $\pi_0 GW(F_{\ell}) \to \pi_0 S_{K(1)}$ sends $e$ to $\varepsilon$, it suffices to see that

$$|BC_2| = 1 + e \in \pi_0 GW(F_{\ell}).$$

Let $\pi : BC_2 \to \text{pt}$ denote the terminal map. By definition, $|BC_2| \in \pi_0 GW(F_{\ell})$ is given by $\int_{\pi^* 1}$, where $1 \in \pi_0 GW(F_{\ell})$ is represented by the symmetric bilinear form $[1] \in \mathcal{Q} F(F_{\ell})$. Under $\pi^* : GW(F_{\ell}) \to GW^{BC_2}(F_{\ell})$, the element $1 \in \pi_0 GW(F_{\ell})$ is sent to the element $1 \in \pi_0 GW^{BC_2}(F_{\ell})$ represented by the symmetric bilinear form $[1] \in \mathcal{Q} F(F_{\ell})$, thought of as a $C_2$-equivariant form via the trivial $C_2$-action on $F_{\ell}$. Thus, by Corollary 3.2.14 we have

$$|BC_2| = \int_{BC_2} [1] = [C_2] \cdot 1 = [2] = [1] + ([2] - [1]) \in \pi_0 GW(F_{\ell}).$$

Finally, since $l = 3, 5 \pmod{8}$ by assumption, 2 is not a square in $F_{\ell}^\times$, and so $[2] - [1]$ is a representative for $\varepsilon$ in $GW_0(F_{\ell})$ and the result follows. \qed

34
5.2 Power operations

Using the multiplicative nature of the $K(1)$-local equivalence $GW(\mathbb{F}_\ell) \to S(\mathbb{F}_\ell)$, we can compute power operations in $\pi_\ast S_{K(1)}$ using multiplicative operations on symmetric bilinear forms over $\mathbb{F}_\ell$. In this section, we will compute two closely related operations on $\pi_0 S_{K(1)}$: the $\theta$-operation (originally due to McClure, cf. [BMMS86, Hop14]), and the canonical $p$-derivation $\delta_p$, used in the proof of the higher semiadditivity of $Sp_{T(n)}$ in [CSY18]. It turns out that both operations can be deduced from a third operation $\alpha_p$ (studied in [CSY18]), which we start by computing.

5.2.1 The operation $\alpha$

Let $C$ be a symmetric monoidal $\infty$-category and let $R \in CAlg(C)$. Then, the total $p$-power operation determines a map of sets $P_p : \pi_0(R) \to \pi_0(R^{B\Sigma_p})$, where $\Sigma_p$ is the group of permutations on $p$ letters. This map can be thought of as taking $x \in \pi_0(R)$ to the canonical $B\Sigma_p$-family of $p$-th powers of $x$. If $C$ is $p$-typically 1-semiadditive, then one can integrate $P_p$ over the classifying space $BC_p$ of the $p$-Sylow subgroup $C_p \subset \Sigma_p$, to obtain a self map of $\pi_0(R)$. Let $i : BC_p \hookrightarrow B\Sigma_p$ be the map induced by the inclusion of a $p$-Sylow subgroup of $\Sigma_p$.

**Definition 5.2.1 ([CSY18] §4.2).** Let $C \in CAlg(Cat^{\Sigma_p^{-1}}_\infty)$. For $R \in CAlg(C)$, we define the map $\alpha_p : \pi_0(R) \to \pi_0(R)$ by the composite

\[ \alpha_p : \pi_0(R) \xrightarrow{P_p} \pi_0(R^{B\Sigma_p}) \xrightarrow{i^*} \pi_0(R^{BC_p}) \xrightarrow{\int_{BC_p}} \pi_0(R), \]

Informally, we have $\alpha_p(x) = \int_{BC_p} x^p$.

**Remark 5.2.2.** Morally, $\alpha_p$ is supposed to resemble the function $\frac{x^p}{p}$. For example, one can show [CSY18, §4.2] that $\alpha_p$ satisfies the functional equation

\[ \alpha_p(x + y) - \alpha_p(x) - \alpha_p(y) = \frac{(x + y)^p - x^p - y^p}{p}. \] (6)

Here, the right hand side does not actually involve division by $p$, and hence makes sense in every ring.

**Remark 5.2.3.** The operation $\alpha_p$ has a simple interaction with cardinalities, namely that

\[ \alpha_p(|A|) = |A \wr C_p| = |(A \times C_p)_{hC_p}|, \]

where $C_p$ acts on $A \times C_p$ by permuting the factors [CSY18, Theorem 4.2.12].

When combined with the functional equation from Remark 5.2.2, this fact gives a computation of $\alpha_p$ on $\mathbb{Z}_p = \pi_0 S_{K(1)}$. 

35
Theorem 5.2.4. Let $K(1)$ denote a Morava K-theory of height one at the prime $p$, and for $p = 2$
let $\varepsilon = \eta \cdot \zeta \in \pi_0 S_{K(1)}$. For an odd prime $p$, we have
\[
\alpha_p(x) = \frac{x^p + (p-1)x}{p} \in \pi_0 S_{K(1)}.
\]
For $p = 2$, we have
\[
\alpha_2(r + d\varepsilon) = \frac{r^2 + r}{2} + (rd + r + d)\varepsilon \in \pi_0 S_{K(1)}.
\]

Proof. First, a direct computation shows that the proposed formulas for $\alpha_p$ satisfy the functional
equation in Remark 5.2.2. Note that every two functions which satisfy this equation differ by an
additive function. Hence, we may a priori write $\alpha_p$ as a sum of the proposed formula and an additive
term.

At an odd prime, since every additive function on $\mathbb{Z}_p$ is given by multiplication by an element of
$\mathbb{Z}_p$, we may write $\alpha_p(x) = \frac{x^p}{p} + ax$ for some $a \in \mathbb{Z}_p$. Using the fact that $|BC_p| = 1$ for odd $p,$
and that $\alpha_p(1) = |BC_p| = 1$ (see Remark 5.2.3), we deduce that $a = 1$, as required.

For $p = 2$, since every additive function $\mathbb{Z}_2[\varepsilon] \to \mathbb{Z}_2[\varepsilon]$ is of the form
\[
r + d\varepsilon \mapsto ru + dv
\]
for some $u, v \in \mathbb{Z}_2[\varepsilon]$, we may write
\[
\alpha_2(r + d\varepsilon) = \frac{r^2 + r}{2} + (rd + r + d)\varepsilon + ru + dv.
\]

Combining our formula of $K(1)$-local cardinalities (Theorem A) and the interaction of $\alpha_2$ with
 cardinalities (Remark 5.2.3), we deduce that
\[
1 + \varepsilon + u = \alpha_2(1) = |BC_2| = 1 + \varepsilon,
\]
while
\[
1 + \varepsilon + u + v = \alpha_2(1 + \varepsilon) = \alpha_2(|BC_2|) = |B(C_2 \wr C_2)| = (1 + \varepsilon)^3 = 1 + \varepsilon.
\]
This implies that $u = v = 0$ and the result follows.

5.2.2 $\alpha$ and symmetric bilinear forms

The determination of $\alpha_2$ in Theorem 5.2.4 is based on the “coincidence” that $|BC_2| = 1 + \varepsilon$.
Indeed, if it happened that $|BC_2| = 1$, the above method (of using the functional equation) would
not have sufficed to determine $\alpha_2$. We now present a theoretically more involved yet more systematic
approach to the computation of $\alpha_2$, based on the multiplicative aspects of our higher semiadditive
Grothendieck-Witt theory.

We shall first compute the operation $\alpha_2$ on $\mathcal{Q}F(\mathbb{F}_\ell)$ for an odd prime $\ell$. 

36
Proposition 5.2.5. The total power map \( \mathbb{P}_2: \pi_0 \mathcal{QF}(\mathbb{F}_\ell) \to \pi_0 \mathcal{QF}^{BC_2}(\mathbb{F}_\ell) \) is given by

\[
\mathbb{P}_2(V, b) = (V \otimes V, b \otimes b).
\]

Here, \( C_2 \) acts on \( V \otimes V \) by permuting the tensor factors.

Proof. The space \( \mathcal{QF}(\mathbb{F}_\ell) \) is 1-truncated and hence, for \( (V, b) \in \pi_0 \mathcal{QF}(\mathbb{F}_\ell) \) the map

\[
\mathbb{P}_2(V, b) : BC_2 \to QF(\mathbb{F}_\ell)
\]

is completely determined by its restriction to the 1-skeleton \( \mathbb{R}P^1 \simeq S^1 \) of \( BC_2 \). The restriction of the total power \( \mathbb{P}_2(x) \) of an element \( x \) in a commutative ring \( R \) to the 1-skeleton of \( BC_2 \) is described as follows: it takes the basepoint of \( S^1 \) to the square \( x^2 \) and the 1-cell of the circle to the symmetry that swaps the two \( x \)-factors using the commutativity of the ring \( R \).

In the special case \( x = (V, b) \in \pi_0 \mathcal{QF}(\mathbb{F}_\ell) \), we see that the basepoint of \( S^1 \) goes to \( (V \otimes V, b \otimes b) \) and the 1-cell to the involution \( \sigma(v \otimes u) = u \otimes v \), by the definition of the commutative ring structure of \( \mathcal{QF}(\mathbb{F}_\ell) \). This gives us the desired formula for \( \mathbb{P}_2(V, b) \).

Using the above, we may now write

\[
\alpha_2(V, b) = ((V \otimes V)_{C_2}, f_{BC_2}(b \otimes b)) = (\text{Sym}^2(V), f_{BC_2}(b \otimes b))
\]

where, by Proposition 3.2.12, we have the formula

\[
f_{BC_2}(b \otimes b)(u \otimes v, u' \otimes v') = b(u, u')b(v, v') + b(u, v')b(u', v).
\]

Recall that a symmetric bilinear form \( b \) over \( \mathbb{F}_\ell \) is completely determined by its rank and determinant (cf. Example 2.2.3). Hence, to describe \( f_{BC_2}(b \otimes b) \) is sufficient to compute its rank and determinant. For this, we have:

Proposition 5.2.6. Let \( \ell \) be an odd prime, let \( (V, b) \) be a symmetric bilinear form over \( \mathbb{F}_\ell \), and let \( r = \text{dim}(V) \). Then,

\[
\text{rank}(\alpha_2(V, b)) = \binom{r+1}{2}
\]

and

\[
\text{det}(\alpha_2(V, b)) = 2^r \cdot \text{det}(V, b)^{r-1} \in \mathbb{F}_\ell^\times / (\mathbb{F}_\ell^\times)^2
\]

Proof. The first statement amounts to the fact that the rank of \( \alpha_2(V, b) \) is the dimension of \( \text{Sym}^2(V) \) which equals \( \binom{r+1}{2} \). It remains to compute the determinant of \( f_{BC_2} b \otimes b \). Choose a basis \( e_1, ..., e_r \) of \( V \) which is orthogonal with respect to \( b \), and set \( b(e_i, e_i) = \lambda_i \). Then, \( \text{Sym}^2(V) \) has a basis given by \( \{e_i \cdot e_j\}_{i \leq j} \). By the formula (7), we immediately see that these basis elements \( e_i \cdot e_j \) are pairwise orthogonal. Moreover, we have

\[
f_{BC_2}(b \otimes b)(e_i \cdot e_j, e_i \cdot e_j) = \begin{cases} 
\lambda_i \lambda_j & \text{if } i \neq j \\
2\lambda_i^2 & \text{if } i = j.
\end{cases}
\]

37
Consequently, we have

\[
\det(\alpha_2(V, b)) = 2\prod_{i=1}^{r} 2\lambda_i^2 \cdot \prod_{i < j} \lambda_i \lambda_j = 2^r \prod_{i=1}^{r} \lambda_i^{r-1} = 2^r \det(V, b)^{r-1} \in \mathbb{F}_\ell^2 / (\mathbb{F}_\ell^2)^2
\]

We can now present an alternative proof for the formula of \(\alpha_2\).

**Proof of Theorem 5.2.4 at \(p = 2\).** Choose a prime \(\ell \equiv 3, 5 \pmod{8}\) and consider the diagram

\[
\begin{array}{cccccc}
\pi_0 QF(F_\ell) & \longrightarrow & \pi_0 GW(F_\ell) & \xrightarrow{L_{K(1)}} & \pi_0 S_{K(1)} \\
\downarrow \varphi_2 & & \downarrow \varphi_2 & & \downarrow \varphi_2 \\
\pi_0 QF^{BC_2}(F_\ell) & \longrightarrow & \pi_0 GW(F_\ell)^{BC_2} & \xrightarrow{L_{K(1)}} & \pi_0 S_{BC_2}^{K(1)} \\
\downarrow \varphi_{BC_2} & & \downarrow \varphi_{BC_2} & & \downarrow \varphi_{BC_2} \\
\pi_0 QF(F_\ell) & \longrightarrow & \pi_0 GW(F_\ell) & \xrightarrow{L_{K(1)}} & \pi_0 S_{K(1)}
\end{array}
\]

The upper squares commute because the horizontal maps, given by group completion \(QF(F_\ell) \to \Omega_{\infty} GW(F_\ell)\) and \(K(1)\)-localization, induce maps of commutative semi-rings in \(\mathcal{S}\), and hence intertwine the total power map. The lower squares commute because the maps are maps of 2-typical 1-commutative pre-monoids (cf. Theorem 4.0.1). We deduce that the outer square commutes, or in other words, that we have a commutative square

\[
\begin{array}{ccc}
\pi_0 QF(F_\ell) & \longrightarrow & \pi_0 S_{K(1)} \\
\downarrow \alpha_2 & & \downarrow \alpha_2 \\
\pi_0 QF(F_\ell) & \longrightarrow & \pi_0 S_{K(1)}
\end{array}
\]

Now, let \((V, b)\) be an \(r\)-dimensional vector space over \(F_\ell\) with a symmetric bilinear form \(b\) of determinant \(2^d\). Then, since 2 is not a quadratic residue mod \(\ell\), the horizontal maps (which we have labeled \(\nu\)) take \((V, b)\) to \(r + d\varepsilon\). Using our formula for the determinant and rank of \(\alpha_2(V, b)\) we now get:

\[
\alpha_2(r + d\varepsilon) = \alpha_2(\nu(V, b)) = \nu(\alpha_2(V, b)) = \left(\frac{r + 1}{2}\right) + ((r - 1)d + r)\varepsilon = \frac{r^2 + r}{2} + (r + d + rd)\varepsilon,
\]

for elements of the sub-semiring \(\mathbb{N}[\varepsilon] \subseteq \mathbb{Z}_2[\varepsilon]\). Using the functional equation satisfied by \(\alpha_2\) (Remark 5.2.2), we see that \(\alpha_2\) is continuous with respect to the 2-adic topology on \(\mathbb{Z}_2[\varepsilon]\); thus, because \(\mathbb{N}[\varepsilon]\) is dense in \(\mathbb{Z}_2[\varepsilon]\), we conclude that our formula must hold everywhere in \(\mathbb{Z}_2[\varepsilon]\).
5.2.3 The operations $\theta$ and $\delta_p$

The operation $\alpha_p$ has two closely related cousins: the operation $\delta_p$, which is defined in any symmetric monoidally higher semiadditive category [CSY18], and the operation $\theta$, which was introduced by McClure for any $K(1)$-local $E_\infty$-ring [BMMS86, Hop14]. Our aim is to clarify the relationship between these operations and compute them in the $K(1)$-local sphere. We start by reviewing the definition of these operations.

Definition 5.2.7 (Definition 4.3.1 [CSY18]). Let $\mathcal{C}$ be a symmetric monoidally 1-semiadditive, additive $\infty$-category. For $R \in \mathcal{C}\text{Alg}(\mathcal{C})$, let $\delta_p : \pi_0(R) \to \pi_0(R)$ be defined by the equation

$$\delta_p(x) = |BC_p|x - \alpha_p(x).$$

To define and compute the operation $\theta$, we need to introduce some notation.

Notation 5.2.8.

- Let $\Sigma_p$ be the group of permutations on $p$ letters and let $e : \text{pt} \to B\Sigma_p$ and $\pi : B\Sigma_p \to \text{pt}$ be the inclusion of the basepoint of $B\Sigma_p$ and the projection to the point, respectively.
- For an object $X$ of a stable $\infty$-category $\mathcal{C}$, the above induce maps $\pi : X[B\Sigma_p] \to X$ and $e : X \to X[B\Sigma_p]$, and corresponding restrictions $\pi^* : X \to X^{B\Sigma_p}$ and $e^* : X^{B\Sigma_p} \to X$. Here, $X[B\Sigma_p]$ is the tensoring of $X$ with the space $B\Sigma_p$ in the category of $K(1)$-local spectra; i.e.,

$$X[B\Sigma_p] = L_{K(1)}(X \otimes \Sigma^\infty_+ B\Sigma_p).$$

- Since $\mathcal{C}$ is stable (therefore semiadditive), we also have transfer maps $\text{Tr}_e : X[B\Sigma_p] \to X$ and $\int_e : X \to X^{B\Sigma_p}$.

In the special case where $\mathcal{C} = \text{Sp}_{K(1)}$, we have:

Proposition 5.2.9 ([Hop14], Lemma 3). Let $X \in \text{Sp}_{K(1)}$. Then the map

$$(\pi, \text{Tr}_e) : X[B\Sigma_p] \to X \oplus X$$

is an equivalence in $\text{Sp}_{K(1)}$.

Consequently, for $R \in \mathcal{C}\text{Alg}(\text{Sp}_{K(1)})$, we can specify an element $x \in \pi_0 R[B\Sigma_p]$ by specifying its composites with $\pi$ and $\text{Tr}_e$, which will be elements $\pi(x), \text{Tr}_e(x) \in \pi_0(R)$.

Definition 5.2.10 ([Hop14], §3). Let $R \in \mathcal{C}\text{Alg}(\text{Sp}_{K(1)})$. Define the element $\theta \in \pi_0 R[B\Sigma_p]$ by the requirements:

$$\text{Tr}_e(\theta) = -(p - 1)! \in \pi_0(R)$$
$$\pi(\theta) = 0 \in \pi_0(R).$$

\[\text{We note that the first requirement differs from [Hop14]; the formula given there contains a typo, as can be seen from its inconsistency with the formula relating it to the Adams operation.}\]
Our next goal is to compare $\theta$ with $\alpha$, culminating in Corollary 5.2.13.

**Remark 5.2.11.** For our comparison, it will be convenient to think about the dual situation: namely, by linear duality, we have maps

$$
\text{Hom}_R(R, R[B\Sigma_p]) \to \text{Hom}_R(R^{B\Sigma_p}, R)
$$

$$
\text{Hom}_R(R[B\Sigma_p], R) \to \text{Hom}_R(R, R^{B\Sigma_p})
$$

which we will denote by $f \mapsto f^t$. Here, $\text{Hom}_R$ denotes maps in $K(1)$-local $R$-modules, and these maps are equivalences because $B\Sigma_p$ is $K(1)$-locally dualizable. This duality acts as follows for the maps described in Notation 5.2.8:

- We have $e^t = e^* : R^{B\Sigma_p} \to R$ and $\pi^t = \pi^* : R \to R^{B\Sigma_p}$.

- We may write $\text{Tr}_e$ as the composite

$$
R[B\Sigma_p] \xrightarrow{\text{Nm}_{B\Sigma_p}} R^{B\Sigma_p} \xrightarrow{e^*} R.
$$

Here, $\text{Nm}_{B\Sigma_p}$ denotes the additive norm map for the group $\Sigma_p$; note that since it comes from a symmetric pairing $R[B\Sigma_p \times B\Sigma_p] \to R$, it is linearly self-dual. Therefore, $(\text{Tr}_e)^t$ is given by the composite:

$$
R \xrightarrow{e} R[B\Sigma_p] \xrightarrow{\text{Nm}_{B\Sigma_p}} R^{B\Sigma_p}
$$

which is, by definition, $\int_e$.

We proceed by rewriting $\theta^t$ in terms of maps more closely related to $\alpha$ and $\delta_p$. Recall that $i : BC_p \to B\Sigma_p$ is induced by the inclusion of a $p$-Sylow, and let $i^* : R^{B\Sigma_p} \to R^{BC_p}$ denote the corresponding restriction.

**Proposition 5.2.12.** Let $R \in \text{CAlg}(Sp_{K(1)})$. Then we have

$$
\theta^t \overset{\text{def}}{=} \frac{\int_{BC_p} i^* \pi^* - |BC_p| e^*}{p - 1} \in \text{Map}(R^{B\Sigma_p}, R).^3
$$

**Proof.** Combining Remark 5.2.11 and Proposition 5.2.9, it suffices to check this equation after precomposition with $\pi^t = \pi^*$ and $(\text{Tr}_e)^t = \int_e$. Thus, by definition of $\theta$, it is enough to verify the pair of identities:

$$
\frac{\int_{BC_p} i^* \pi^* - |BC_p| e^* \pi^*}{p - 1} = 0,
$$

and

$$
\frac{\int_{BC_p} i^* \int_e - |BC_p| e^* \int_e}{p - 1} = -(p - 1)!.\n$$

Now, we claim that

---

^3Note that this formula diverges slightly from the one proposed without proof in [CSY18, Remark 5.2.3]. However, the two agree for odd primes.
(1) $\int_{BC_p} i^* \pi^* = |BC_p|$. This follows from the fact that $i^* \pi^*$ is restriction along the terminal map $BC_p \to pt$ and the definition of the cardinality.

(2) $e^* \pi^* = 1$. This follows from the fact that $\pi \circ e = \text{Id}_{pt}$.

(3) $\int_{BC_p} i^* f_e = |\Sigma_p/C_p| = (p - 1)!$. This follows from the base-change formula for integrals (see [CSY18, Proposition 3.1.13]) applied to the pullback square

\[
\begin{array}{ccc}
\Sigma_p/C_p & \rightarrow & pt \\
\downarrow \downarrow & & \downarrow e \\
BC_p & \rightarrow & B\Sigma_p.
\end{array}
\]

Indeed, from this pullback square we deduce that $i^* f_e = |\Sigma_p/C_p| f_{e'}$ where $e'$ is the inclusion of the basepoint of $BC_p$. The claim then follows because

$$|\Sigma_p/C_p| \int_{BC_p} f_{e'} = |\Sigma_p/C_p|$$

by the Fubini Theorem for integration (see [CSY18, Proposition 2.1.15]).

(4) $\int_{BC_p} i^* f_e = |\Sigma_p| = p!$. This again follows from base-change of integration along the pullback square

\[
\begin{array}{ccc}
\Sigma_p & \rightarrow & pt \\
\downarrow \downarrow & & \downarrow \\
pt & \rightarrow & B\Sigma_p.
\end{array}
\]

Using (1) – (4) above and the fact that $p|BC_p| = p$ for all primes $p$ (which follows directly from our computation of $|BC_p|$), we see that

$$\frac{\int_{BC_p} i^* \pi^* - |BC_p| e^* \pi^*}{p - 1} = \frac{|BC_p| - |BC_p|}{p - 1} = 0$$

and

$$\frac{\int_{BC_p} i^* f_e - |BC_p| e^* f_e}{p - 1} = \frac{(p - 1)! - |BC_p| \cdot p!}{p - 1} = \frac{(p - 1)! - p!}{p - 1} = -(p - 1)!$$

as we wanted to show.

We can use the map $\theta^t$ to define a power operation by the composition $\theta^t \circ \mathbb{P}_p$. We shall abuse notation and denote the resulting power operation by $\theta$.

Corollary 5.2.13. As a power operation for $K(1)$-local $\mathbb{E}_\infty$-rings, we have

$$\theta(x) = \frac{\alpha_p(x) - |BC_p| x^p}{p - 1}.$$
Proof. Recall that $\alpha_p(x) = \int_{BC_p} i^*P_p(x)$ (Definition 5.2.1). Thus, by Proposition 5.2.12,

$$\theta(x) = \frac{\int_{BC_p} i^*P_p(x) - |BC_p|e^*P_p(x)}{p-1} = \frac{\alpha_p(x) - |BC_p|x^p}{p-1}.$$ 

\[\square\]

As a result, we can now compute both the operations $\delta_p$ and $\theta$ for the $K(1)$-local sphere, as they are expressed in terms of $\alpha_p$ and $|BC_p|$. We remark that the computations are elementary and well-known for odd primes, and may also be known to experts in general; we state it for all primes for the sake of completeness:

**Theorem 5.2.14.** For $p$ an odd prime, the power operations $\delta_p$ and $\theta$ are given on $\pi_0S_{K(1)} \simeq \mathbb{Z}_p$ by

$$\delta_p(x) = \theta(x) = \frac{x - x^p}{p}.$$

For $p = 2$, these power operations act on $\pi_0S_{K(1)}$ by

$$\delta_2(r + d\varepsilon) = \frac{r - r^2}{2} + rd\varepsilon$$

and

$$\theta(r + d\varepsilon) = \frac{r - r^2}{2} + (r - 1)d\varepsilon.$$

Proof. At an odd prime, we have $\alpha_p(x) = \frac{x^p - x}{p} + x$ (Theorem 5.2.4) and $|BC_p| = 1$. Hence, we get

$$\delta_p(x) = x - \alpha_p(x) = \frac{x - x^p}{p}$$

and

$$\theta(x) = \frac{\frac{x^p - x}{p} + x - x^p}{p - 1} = \frac{x - x^p}{p}.$$ 

At the prime 2 we have $\alpha(r + d\varepsilon) = \frac{r^2 + r}{2} + (r + d + rd)d\varepsilon$ (Theorem 5.2.4) and $|BC_2| = 1 + \varepsilon$. Hence, we get

$$\delta_2(r + d\varepsilon) = (1 + \varepsilon)(r + d\varepsilon) - \left(\frac{r^2 + r}{2} + (r + d + rd)d\varepsilon\right) = \frac{r - r^2}{2} + rd\varepsilon.$$ 

Here, we used the facts that $2\varepsilon = \varepsilon^2 = 0$. Similarly, we get

$$\theta(r + d\varepsilon) = \left(\frac{r^2 + r}{2} + (r + d + rd)d\varepsilon\right) - (1 + \varepsilon)(r + d\varepsilon)^2 =$$

$$= \frac{r - r^2}{2} + (r + r^2 + (r - 1)d)d\varepsilon.$$ 

Since $r + r^2 \equiv 0 \pmod{2}$ for every $r \in \mathbb{Z}_2$, we see that this is exactly $\frac{r - r^2}{2} + (r - 1)d\varepsilon$, as we wanted to show. \[\square\]
5.2.4 The Rezk logarithm

For a \( K(n) \)-local \( \mathbb{E}_\infty \)-ring \( R \), let \( R^{\times} \) (sometimes denoted \( \text{gl}_1(R) \)) denote the connective spectrum of units in \( R \). In [Rez06], Rezk defined a “logarithmic power operation”

\[
\log_{K(n)} : R^{\times} \to R,
\]

which arises as the composite of the \( K(n) \)-localization map \( R^{\times} \to L_{K(n)}R^{\times} \) with a certain equivalence \( L_{K(n)}R^{\times} \simeq L_{K(n)}R \) supplied by the Bousfield-Kuhn functor (we refer the reader to [Rez06] for a more extensive discussion). In addition to defining this logarithmic operation, Rezk computes it (on \( \pi_0 \)) for Morava \( E \)-theory of any height, and for any \( K(1) \)-local \( \mathbb{E}_\infty \)-ring spectrum \( R \) satisfying the technical condition that the kernel of the unit map \( \pi_0S_{K(1)} \to \pi_0R \) contains the torsion subgroup of \( \pi_0S_{K(1)} \) (which is automatically satisfied for odd \( p \)).

Here, we refine this computation by computing the map

\[
\log_{K(1)} : \pi_0S_{K(1)}^{\times} \to \pi_0S_{K(1)}
\]
in the case \( p = 2 \). For the sake of completeness, we state the result at all primes \( p \):

**Theorem 5.2.15** (Rezk [Rez06] for \( p \) odd). Let \( \log_p : 1 + p\mathbb{Z}_p \to \mathbb{Z}_p \) denote the \( p \)-adic logarithm.

- For an odd prime \( p \), the Rezk logarithm is given on \( \pi_0S_{K(1)}^{\times} \simeq \mathbb{Z}_p^{\times} \) by the formula
  
  \[
  \log_{K(1)}(x) = \frac{1}{p} \log_p(x^{p-1}).
  \]

- For \( p = 2 \), the Rezk logarithm is given on \( \pi_0S_{K(1)}^{\times} \simeq \mathbb{Z}_2^{\times} \oplus \mathbb{Z}_2\varepsilon \) by
  
  \[
  \log_{K(1)}(r + d\varepsilon) = \frac{1}{2} \log_2(r) + \frac{r - 1}{2}\varepsilon.
  \]

We note that when \( p = 2 \), most of this computation is carried out by Clausen in [Cla17, Proposition 1.10]; namely, one has an isomorphism

\[
\pi_0S_{K(1)}^{\times} \simeq (\mathbb{Z}_2[\varepsilon]/(2\varepsilon, \varepsilon^2))^{\times} \simeq \mathbb{Z}_2^{\times} \oplus \mathbb{Z}/2\mathbb{Z}\varepsilon,
\]

and Clausen computes \( \log_{K(1)} \) on the \( \mathbb{Z}_2^{\times} \) component. In this section, we extend the computation to \( \mathbb{Z}/2\mathbb{Z}\varepsilon \)-component by showing that the logarithm vanishes on \( |B\mathcal{C}_2| = 1 + \varepsilon \).

**Definition 5.2.16.** Let \( R \) be an \( \mathbb{E}_\infty \)-ring. A **strict unit** in \( R \) is a map of connective spectra \( \mathbb{Z} \to R^{\times} \).

By abuse of language, we will say a unit \( x \in \pi_0R^{\times} \) is a strict unit if there is a strict unit \( \alpha : \mathbb{Z} \to R^{\times} \) such that \( x = \alpha(1) \).

**Lemma 5.2.17.** Let \( n \geq 1 \) and let \( R \) be a \( K(n) \)-local \( \mathbb{E}_\infty \)-ring. Then the map

\[
\log_{K(n)} : \pi_0R^{\times} \to \pi_0R
\]

vanishes on strict units.
Proof. Let $\alpha : \mathbb{Z} \to R^\times$ be a strict unit. To show that $\log_{K(n)}(\alpha(1)) = 0$, it would suffice to show that the composite $\log_{K(n)} \circ \alpha$ vanishes in $\operatorname{Map}_{\mathbb{P}}(\mathbb{Z}, R)$. But $R$ is $K(n)$-local and $\mathbb{Z}$ is $K(n)$-acyclic, so there are no nonzero spectrum maps $\mathbb{Z} \to R$. 

In view of this lemma, to show that $\log_{K(n)}(\big|BC_2\big|) = 0$, it would suffice to show that $|BC_2|$ is a strict unit. In fact, this follows from the following general phenomenon, which we learned from Tomer Schlank:

**Proposition 5.2.18** (T. Schlank). Let $p$ be a prime and let $K(n)$ be a Morava $K$-theory of height $n$ at the prime $p$. Then the cardinality $|B^nC_p|^\tau_{K(n)} \in \pi_0S_{K(n)}$ is a strict unit.

**Proof.** If $n = 0$ then $S_{K(0)} \simeq \mathbb{Q}$ and every unit is a strict unit. Assume from now on that $n \geq 1$. Since $S_{K(n)}$ is an $n$-commutative monoid in $\mathbb{P}_{K(n)}$, we have a canonical map of semirings

$$\langle - \rangle : S_{K(n)} \to \Omega^\infty S_{K(n)}$$

taking an $n$-truncated $\pi$-finite space $A$ to the $K(n)$-local cardinality of $A$ (here, $S_n$ denotes the $\infty$-category of $n$-truncated $\pi$-finite spaces). We also have a map of commutative monoids

$$B^n : \mathbb{P}_{K(n)} \to (S_n)\simeq$$

taking a finite dimensional $\mathbb{F}_p$-vector space $V$ to the space $B^nV$, where the monoid operation on the source is direct sum of vector spaces and on the target the Cartesian product. The composite

$$\langle B^n(-) \rangle : \mathbb{P}_{K(n)} \to (S_n)\simeq \Omega^\infty S_{K(n)}$$

is hence again a morphism of commutative monoids, where the commutative monoid structure on $\Omega^\infty S_{K(n)}$ is given by multiplication. Since $\mathbb{P}_{K(n)}$ is an $\infty$-category of semiadditive height $n$ (in the sense of [CSY20]), the cardinality $|B^nV|$ is invertible for every $V \in \mathbb{P}_{\mathbb{F}_p}$ (cf. [CSY20, Theorem 4.4.5]) and so (8) determines a map of spectra

$$K(\mathbb{F}_p) := (\mathbb{P}_{\mathbb{F}_p})^{\mathbb{P}} \to S_{K(n)}^\infty,$$

which we denote again by $\langle B^n(-) \rangle_S_{K(n)}$.

To show that $|B^nC_p|$ is a strict unit, it would suffice to show that $\langle B^n(-) \rangle_S_{K(n)}$ factors through the 0-truncation map $K(\mathbb{F}_p) \to \pi_0K(\mathbb{F}_p) \simeq \mathbb{Z}$. For this, it is enough to show that $\operatorname{Map}(\tau_{\geq 1}K(\mathbb{F}_p), S_{K(n)}^\infty)$ is contractible. Note that

$$\operatorname{Map}(\tau_{\geq 1}K(\mathbb{F}_p), S_{K(n)}^\infty) \simeq \operatorname{Map}(\tau_{\geq 1}K(\mathbb{F}_p), \tau_{\geq 1}S_{K(n)}^\infty).$$

In the source, $p$ acts invertibly by Quillen’s computation of the higher $K$-groups of $\mathbb{F}_p$ [Qui72]. On the other hand, we claim the target is $p$-complete. Recall that a spectrum is $p$-complete if and only if each homotopy group is derived $p$-complete [Bou79, Proposition 2.5]. Thus, since $S_{K(n)}$ is $p$-complete for $n \geq 1$ and $\pi_iS_{K(n)} \simeq \pi_nS_{K(n)}^\infty$ for $i \geq 1$, it follows that $\tau_{\geq 1}S_{K(n)}^\infty$ is also a $p$-complete spectrum. Together, these facts imply that the mapping space (9) is contractible and the result follows.

\[\square\]
As a corollary, we have

**Corollary 5.2.19.** At the prime 2, the element \(1 + \varepsilon \in \pi_0S_{K(1)}\) is a strict unit.

**Proof.** By Theorem 5.1.1, we have \(1 + \varepsilon = |BC_2|\), and so the result follows from Proposition 5.2.18.

We are now ready to complete the computation of \(\log_{K(1)}\) for \(\pi_0S_{K(1)}\) at \(p = 2\):

**Proof of Theorem 5.2.15.** If \(p\) is odd, this is [Rez06, Theorem 1.9], and if \(p = 2\) and \(d = 0\) this formula is shown in [Cla17, Proposition 1.10]. Hence, it remains to show that \(\log(r + \varepsilon) = \log(r)\) for \(r + \varepsilon \in \pi_0(S_{K(1)})^\times\). Note that the invertibility of \(r + \varepsilon\) implies that \(r\) is odd. Hence, we have

\[(1 + \varepsilon)(r + \varepsilon) = r + (r + 1)\varepsilon = r.\]

This, together with Corollary 5.2.19 implies that

\[\log_{K(1)}(r) = \log_{K(1)}((1 + \varepsilon)(r + \varepsilon)) = \log_{K(1)}(1 + \varepsilon) + \log_{K(1)}(r + \varepsilon) = \log_{K(1)}(r + \varepsilon).\]
