MAXIMAL SUBGROUPS OF GENERALISED BASILICA GROUPS

KARTHIKA RAJEEV AND ANITHA THILLAISSUNDARAM

Abstract. The Basilica group is a well-known 2-generated weakly branch, but not branch, group acting on the binary rooted tree. Recently a more general form of the Basilica group has been investigated by Petschick and Rajeev, which is an $s$-generated weakly branch, but not branch, group that acts on the $m$-adic tree, for $s, m \geq 2$. With the new developments by Francoeur, the study of the existence of maximal subgroups of infinite index has been extended from branch groups to weakly branch groups. Here we show that generalised Basilica groups have maximal subgroups only of finite index.

1. Introduction

Groups acting on rooted trees have drawn a great deal of attention over the last couple of decades because they exhibit prominent features and solve several long-standing problems in group theory. The initial examples studied were Grigorchuk’s groups of intermediate word growth ([10]; answering Milnor’s question) and Gupta and Sidki’s examples of finitely generated infinite torsion $p$-groups ([12]; providing an explicit family of 2-generated counterexamples to the general Burnside problem). Ever since, attempts have been made to characterise and generalise the groups of automorphisms of rooted trees. Today, the Grigorchuk groups and the Gupta–Sidki groups are known as the first examples of groups in the family of branch groups. Branch groups are groups acting spherically transitively on a spherically homogeneous rooted tree $T$ and having subnormal subgroups similar to that of the full automorphism group $\text{Aut} T$ of the tree $T$, see Section 2 for definitions. The groups studied in this paper belong to a more general class of groups, the weakly branch groups, obtained by weakening some of the algebraic properties of the branch groups; cf. [2].

The Basilica group is a 2-generated weakly branch, but not branch, group acting on the binary rooted tree, which was introduced by Grigorchuk and Żuk in [13] and [14]. It is the first known example of an amenable [3] but not sub-exponentially amenable group [14]. In contrast to the Grigorchuk and the Gupta–Sidki groups, the Basilica group is torsion-free and has exponential word growth [14]. Moreover, it is the iterated monodromy group of the complex polynomial $z^2 - 1$; see [16, Section 6.12.1]. The generators of the Basilica group are recursively defined as follows:

$$a = (1, b) \quad \text{and} \quad b = (1, a)\sigma,$$

where $\sigma$ is the cyclic permutation which swaps the subtrees rooted at the first level of the binary rooted tree, and $(x, y)$ represents the independent action on the two maximal subtrees, where $x, y \in \text{Aut} T$. Recently, Petschick and Rajeev [18] introduced a construction which relates the Basilica group and the one-generated dyadic odometer $O_2$ (also known as the adding machine).
Let \( m, s \geq 2 \) be integers and let \( G \) be a subgroup of the automorphism group \( \text{Aut} \, T \) of the \( m \)-adic tree \( T \). The \( s \)th Basilica group of \( G \) is given by \( \text{Bas}_s(G) = \langle \beta_i^s(g) \mid g \in G, i \in \{0,1,\ldots, s-1\} \rangle \), where \( \beta_i^s : \text{Aut} \, T \to \text{Aut} \, T \) are monomorphisms given by

\[
\beta_i^s(g) = (1,\ldots,1,\beta_{i-1}^s(g)) \quad \text{for } i \in \{1,\ldots, s-1\},
\]

where \( g_x \) is the restriction of \( g \) to the subtree rooted at a first-level vertex \( x \in \{0,\ldots, m-1\} \), and \( g^x \) is the local action of the element \( g \) at the root of \( T \) (in [18] the generators \( \beta_i^s(g) \), for \( i \in \{1,\ldots, s-1\} \), are defined along the leftmost spine and the element \( g^x \) is acting from the left, which is equivalent to the definition above). We obtain the classical Basilica group by applying the operator \( \text{Bas}_2 \) to the dyadic odometer as follows: let \( c = (1, c) \sigma \) be the automorphism of the binary rooted tree generating the dyadic odometer. Then the generators of the Basilica group are given by

\[
a = \beta_1^2(c) \quad \text{and} \quad b = \beta_0^2(c).
\]

This gives a natural generalisation of the Basilica group given by \( \text{Bas}_s(\mathcal{O}_m) \) for every pair of integers \( m, s \geq 2 \). Here \( \mathcal{O}_m \) is the \( m \)-adic odometer, which is an embedding of the infinite cyclic group into the automorphism group of the \( m \)-adic tree \( T \), and is generated by

\[
c = (1, \beta_{m-1}^s, 1, c) \sigma
\]

where \( \sigma = (0 \ 1 \ \cdots \ m-1) \) is the \( m \)-cycle that cyclically permutes the \( m \) subtrees rooted at the first level of \( T \). The generalised Basilica groups \( \text{Bas}_s(\mathcal{O}_m) \) resemble the classical Basilica group, as they are weakly branch, not branch, torsion-free groups of exponential word growth [18, Theorem 1.6]. They are also weakly regular branch over their derived subgroup.

In this paper, we study the maximal subgroups of the generalised Basilica groups \( \text{Bas}_s(\mathcal{O}_m) \). The study of maximal subgroups of branch groups was initiated by Pervova [17], where she proved that the torsion Grigorchuk groups do not contain maximal subgroups of infinite index. Thenceforth, attempts have been made to generalise the results and techniques from [17], for instance see [1], [15], and [7]. Among which, our interest lies in the work of Francoeur [7] (or see [6, Section 8.4]), who provided a strategy to study the maximal subgroups of weakly branch groups. In particular, he proved that the classical Basilica group does not contain maximal subgroups of infinite index. Following this technique we prove that the generalised Basilica groups \( \text{Bas}_s(\mathcal{O}_m) \) do not admit maximal subgroups of infinite index.

**Theorem 1.1.** Let \( m \) and \( s \) be positive integers such that \( m, s \geq 2 \). Then the generalised Basilica group \( \text{Bas}_s(\mathcal{O}_m) \) does not admit a maximal subgroup of infinite index.

Since we are considering generalised Basilica groups \( \text{Bas}_s(\mathcal{O}_m) \) for an arbitrary \( s \geq 2 \), the final stages of our proof differ from previously seen results; compare Proposition 4.5. In particular, we work with a product of the distinct \( s \) generators of the group, and all cyclic permutations of this product. This is also the first time that maximal subgroups of a weakly branch, but not branch, group \( G \) have been considered for a group \( G \) with more than 2 generators.

It is interesting to note that there are currently no examples of finitely generated weakly branch, but not branch, groups with maximal subgroups of infinite index. There are only examples of finitely generated branch groups with maximal subgroups of infinite index; see [4] and [8]. It remains to be seen whether being a finitely generated weakly branch group with maximal subgroups of infinite index implies the group is branch.

Furthermore, in all known examples of finitely generated weakly branch, but not branch, groups with maximal subgroups only of finite index, these groups have maximal subgroups that are not normal; compare Remark 4.6 and [9, 5]. Therefore it is also natural to ask if there exists
a finitely generated weakly branch, but not branch, group with all maximal subgroups of finite index and normal.

**Organisation.** Section 2 contains preliminary material on groups acting on the $m$-adic tree. In Section 3, we record some length reducing properties of generalised Basilica groups, and in Section 4 we prove Theorem 1.1.

2. Preliminaries

By $\mathbb{N}$ we denote the set of positive integers, and by $\mathbb{N}_0$ the set of non-negative integers.

Let $m \in \mathbb{N}_{\geq 2}$ and let $T = T_m$ be the $m$-adic tree, that is, a rooted tree where all vertices have $m$ children. Using the alphabet $X = \{0, 1, \ldots, m - 1\}$, the vertices $u_\omega$ of $T$ are labelled bijectively by the elements $\omega$ of the free monoid $X^*$ in the following natural way: the root of $T$ is labelled by the empty word, and is denoted by $\epsilon$, and for each word $\omega \in X^*$ and letter $x \in X$ there is an edge connecting $u_\omega$ to $u_{\omega x}$. More generally, we say that $u_\omega$ precedes $u_\lambda$ whenever $\omega$ is a prefix of $\lambda$.

There is a natural length function on $X^*$, which is defined as follows: the words $\omega$ of length $|\omega| = n$, representing vertices $u_\omega$, that are at distance $n$ from the root, are the $n$th level vertices and constitute the $n$th layer of the tree.

We denote by $T_u$ the full rooted subtree of $T$ that has its root at a vertex $u$ and includes all vertices succeeding $u$. For any two vertices $u = u_\omega$ and $v = u_\lambda$, the map $u_\omega \mapsto u_{\lambda \tau}$, induced by replacing the prefix $\omega$ by $\lambda$, yields an isomorphism between the subtrees $T_u$ and $T_v$.

Now each $f \in \text{Aut} T$ fixes the root, and the orbits of $\text{Aut} T$ on the vertices of the tree $T$ are the layers of the tree $T$. The image of a vertex $u$ under $f$ will be denoted by $f(u)$. The automorphism $f$ induces a faithful action on $X^*$ given by $f(u_\omega) = u_{f(\omega)}$. For $\omega \in X^*$ and $x \in X$ we have $f(\omega x) = f(\omega)x'$, for $x' \in X$ uniquely determined by $\omega$ and $f$. This induces a permutation $f^\omega$ of $X$ which satisfies

$$f(\omega x) = f(\omega)f^\omega(x), \quad \text{and consequently} \quad f(u_{\omega x}) = u_{f(\omega)f^\omega(x)}.$$

More generally, for an automorphism $f$ of $T$, since the layers are invariant under $f$, for $u, v \in X^*$, the equation

$$f(uv) = f(u)f(v)$$

defines a unique automorphism $f_u$ of $T$ called the section of $f$ at $u$. This automorphism can be viewed as the automorphism of $T$ induced by $f$ upon identifying the rooted subtrees of $T$ at the vertices $u$ and $f(u)$ with the tree $T$. As seen here, we often do not differentiate between $X^*$ and vertices of $T$.

2.1. Subgroups of $\text{Aut} T$. Let $G$ be a subgroup of $\text{Aut} T$ acting spherically transitively, that is, transitively on every layer of $T$. The vertex stabiliser $\text{st}_G(u)$ is the subgroup consisting of elements in $G$ that fix the vertex $u$. For $n \in \mathbb{N}$, the $n$th level stabiliser $\text{St}_G(n) = \bigcap_{|\omega| = n} \text{st}_G(u_\omega)$ is the subgroup of automorphisms that fix all vertices at level $n$.

Each $g \in \text{St}_{\text{Aut} T}(n)$ can be completely determined in terms of its restrictions $g_1, \ldots, g_m$ to the subtrees rooted at vertices at level $n$. There is a natural isomorphism

$$\psi_n: \text{St}_{\text{Aut} T}(n) \rightarrow \prod_{|\omega| = n} \text{Aut} T_{u_\omega} \cong \text{Aut} T \times \cdots \times \text{Aut} T$$
defined by sending $g \in \text{St}_{\text{Aut} T}(n)$ to its tuple of sections $(g_1, \ldots, g_m)$. For conciseness, we will omit the use of $\psi_1$, and simply write $g = (g_1, \ldots, g_m)$ for $g \in \text{St}_{\text{Aut} T}(1)$.

Let $\omega \in X^n$ be of length $n$. We further define

$$\varphi_\omega: \text{st}_{\text{Aut} T}(u_\omega) \rightarrow \text{Aut} T_{u_\omega} \cong \text{Aut} T$$
to be the map sending $f \in \text{st}_{\text{Aut} T}(u_\omega)$ to the section $f_{u_\omega}$.
A group \( G \leq \text{Aut} T \) is said to be self-similar if for all \( f \in G \) and all \( \omega \in X^* \) the section \( f_{u_\omega} \) belongs to \( G \). We will denote \( G_\omega \) to be the subgroup \( \varphi_\omega(\text{st}_G(\omega)) \).

Let \( G \) be a subgroup of \( \text{Aut} T \) acting spherically transitively. Here the vertex stabilisers at every level are conjugate under \( G \). We say that the group \( G \) is fractal if \( G_\omega = \varphi_\omega(\text{st}_G(\omega)) = G \) for every \( \omega \in X^* \), after the natural identification of subtrees.

The rigid vertex stabiliser of \( u \) in \( G \) is the subgroup \( \text{rist}_G(u) \) consisting of all automorphisms in \( G \) that fix all vertices of \( T \) not succeeding \( u \). The rigid nth level stabiliser is the direct product of the rigid vertex stabilisers of the vertices at level \( n \):

\[
\text{Rist}_G(n) = \prod_{|\omega|=n} \text{rist}_G(\omega) \leq G.
\]

We recall that a spherically transitive group \( G \) is a branch group if \( \text{Rist}_G(n) \) has finite index in \( G \) for every \( n \in \mathbb{N} \); and \( G \) is weakly branch if \( \text{Rist}_G(n) \) is non-trivial for every \( n \in \mathbb{N} \). If, in addition, the group \( G \) is self-similar and there exists a subgroup \( 1 \neq K \leq G \) with \( K \times \cdots \times K \subseteq \psi(K \cap \text{St}_G(1)) \) and \(|G : K| < \infty \), then \( G \) is said to be regular branch over \( K \). If in the previous definition the condition \(|G : K| < \infty \) is omitted, then \( G \) is said to be weakly regular branch over \( K \).

2.2. A basic result. Here we record a general result that will be useful in the sequel. For \( g \in \text{Aut} T \), recall that \( g^e \) denotes the action induced by \( g \) at the root of \( T \).

**Lemma 2.1.** For \( G \leq \text{Aut} T \), let \( z = (z_0, \ldots, z_{m-1})z^e \in G^e \). Then \( z_0 \cdots z_{m-1} \in G^e \).

**Proof.** It suffices to prove the result for a basic commutator \([g, h]\) where \( g, h \in G \). Write \( g = (g_0, \ldots, g_{m-1})g^e \) and \( h = (h_0, \ldots, h_{m-1})h^e \). For notational convenience, let us write \( \tau = (g^e)^{-1} \) and \( \kappa = (h^e)^{-1} \), and for \( \alpha \in \text{Sym}(X) \) and \( x \in X \) we write \( x^\alpha \) for \( \alpha(x) \). As

\[
[g, h] = \tau(g_0^{-1}, \ldots, g_{m-1}^{-1})\kappa(h_0^{-1}, \ldots, h_{m-1}^{-1})(g_0, \ldots, g_{m-1})g^e(h_0, \ldots, h_{m-1})h^e
\]

\[
= (g_0^{-1}, \ldots, g_{m-1}^{-1})\tau(g_0, \ldots, g_{m-1})(h_0, \ldots, h_{m-1})\kappa(\tau^{-1}g^e, \ldots, \tau^{-1}g_{m-1}^e)\tau\kappa g^e h^e,
\]

the result follows. \( \square \)

3. Length reducing properties

For any two integers \( i, j \), let \( [i, j] \) denote the set \( \{i, i+1, \ldots, j-1, j\} \). In the following sections, we fix \( m, s \in \mathbb{N}_{\geq 2} \). For convenience, write \( G = \text{Bas}_s(\mathcal{O}_m) \) for the remainder of this paper. Then \( G \) is generated by the elements

\[
\beta^s_0(c) = (1, m^{-1}, 1, \beta_{s-1}(c))\sigma,
\]

\[
\beta^s_i(c) = (1, m^{-1}, 1, \beta_0(c)),
\]

\[
\vdots
\]

\[
\beta^s_{s-1}(c) = (1, m^{-1}, 1, \beta_{s-2}(c)),
\]

where \( c = (1, m^{-1}, 1, c)\sigma \) is the generator of the \( m \)-adic odometer \( \mathcal{O}_m \) acting on the \( m \)-adic tree \( T \) and \( \sigma \) is the permutation which cyclically permutes the subtrees rooted at the first level of \( T \). We refer the reader to [18] for a detailed study of these groups.

Denote by \( \beta^s_i(c) = a_i \), for every \( i \in [0, s-1] \). We shall adopt the convention that the subscripts of \( a_i \)'s are taken modulo \( s \). Set \( S = \{a_i^{\pm 1} \mid i \in [0, s-1] \} \) and then \( G = \langle S \rangle \). For each word \( w \in S^* \), the length of \( |w| \) is the usual word length of \( w \) over the alphabet \( S \). If \( g \in G \) then \( |g| \) denotes the minimal length of all words in the alphabet \( S \) representing \( g \). A word \( w \in S^* \) is called a geodesic word if \( |w| = |g| \), where \( g \) is the image of the word \( w \) in \( G \). Notice that for
Lemma 3.1. Let $g = (g_0, \ldots, g_{m-1})\sigma_g \in G$. Then $\sum_{k=0}^{m-1} |g_k| \leq |g|$.

Proof. The proof proceeds by induction on the length of $g$. Clearly, the result is true if $|g| = 0$ and $|g| = 1$. Assume that $|g| > 1$. Let $w \in S^*$ be a geodesic word representing $g$. The word $w$ can be written as $w = xw'$ for some $x \in S$ and $w' \in S^*$ such that $w'$ is reduced. Then $|w'| < |w|$ and $w'$ does not represent $g$ in $G$. Denote by $g'$ the corresponding element in $G$. Then $|g'| \leq |w'| < |w| = |g|$. We obtain,

\[
(g_0, \ldots, g_{m-1})\sigma_g = g = xg' = (x_0, \ldots, x_{m-1})\sigma_x(g_0', \ldots, g'_{m-1})\sigma_{g'}
\]

which implies $g_k = x_kg'_k$ for all $k \in [0, m - 1]$. It follows by induction that,

\[
\sum_{k=0}^{m-1} |g_k| = \sum_{k=0}^{m-1} |x_kg'_k| \leq \sum_{k=0}^{m-1} |x_k| + \sum_{k=0}^{m-1} |g'_k| \leq |x| + |g'| \leq |x| + |w| = |w| = |g|.
\]

\[
\square
\]

Lemma 3.2. Let $g = (g_0, \ldots, g_{m-1})\sigma_g \in G$ with $\sigma_g = \sigma^i$ for some $i \in [1, m - 1]$ such that $\gcd(i, m) = 1$. Let $\alpha_0, \ldots, \alpha_{m-1} \in G$ be such that $g^m = (\alpha_0, \ldots, \alpha_{m-1})$. Then $|\alpha_k| \leq \sum_{l=0}^{m-1} |g_l| \leq |g|$ for all $k \in [0, m - 1]$.

Proof. Observe that,

\[
g^m = (g_0\sigma^i g_0\sigma^{2i} \cdots g_0\sigma^{(m-1)i}, \ldots, g_{m-1}\sigma g_{m-1}\sigma^{2i} \cdots g_{m-1}\sigma^{(m-1)i})
\]

By setting $\alpha_k = g_k g_k^{\sigma^i} \cdots g_k^{\sigma^{(m-1)i}}$, for each $k \in [0, m - 1]$, we obtain

\[
|\alpha_k| = |g_k g_k^{\sigma^i} \cdots g_k^{\sigma^{(m-1)i}}| \leq \sum_{l=0}^{m-1} |g_l| \leq |g|
\]

where the last inequality follows from Lemma 3.1. \square

For a subset $J \subseteq [0, s - 1]$, write $S_J$ for the symmetric set $\{a_0^{\pm 1}, \ldots, a_s^{\pm 1}\}\backslash\{a_j^{\pm 1} \mid j \in J\}$. When $J = \{j\}$, we simply write $S_j$.

Lemma 3.3. Let $g = (g_0, \ldots, g_{m-1})\sigma_g \in G$ and let $x_1 \cdots x_{\ell} \in S^*$ be a geodesic word representing $g$. If there exist $1 \leq r < r' \leq \ell$ such that $x_r = a_0$, $x_{r'} = a_0^{-1}$, then $\sum_{k=0}^{m-1} |g_k| < |g|$.

Proof. By assumption, the word $x_1 \cdots x_{\ell}$ contains a subword of the form $a_0w_0a_0^{-1}$, where $w$ is a non-trivial reduced word in the alphabet $S$. We assume, without loss of generality, that $w$ is a reduced word in the alphabet $S_0$. Let $w$ represents an element $h$ in $G$. Since $x_1 \cdots x_{\ell} \in S^*$ is a geodesic word, the word $w$ is also geodesic and so $|h| = |w|$. Notice that $|a_0w_0a_0^{-1}| = |w| + 2$. Realising the word $a_0w_0a_0^{-1}$ in $G$ gives

\[
a_0w_0a_0^{-1} = (1, \ldots, 1, \varphi_{m-1}(h), 1).
\]

Here $|\varphi_{m-1}(h)| = |h| = |w|$, which follows from the fact that $a_i$‘s in $h$ are simply replaced by $a_{i-1}$‘s in $\varphi_{m-1}(h)$. Therefore we conclude that

\[
\sum_{k=0}^{m-1} |g_k| \leq |g| - 2 < |g|.
\]

\[
\square
\]
4. Maximal subgroups

Recall that we write $G = \text{Bas}_s(O_m)$. It follows from Proposition 4.1 below together with [7, Proposition 2.21] that the group $G$ admits maximal subgroups of infinite index if and only if it admits a proper subgroup $H < G$ such that $HN = G$ for every non-trivial normal subgroup $N \triangleleft G$. A subgroup $H \triangleleft G$ satisfying the above condition is called a \textit{prodense subgroup}. As seen below, we prove that $G$ does not admit any proper prodense subgroup, which proves Theorem 1.1.

**Proposition 4.1.** The group $G$ is just non-(virtually nilpotent). Hence, maximal subgroups of proper quotients of $G$ are of finite index.

**Proof.** As $G$ has exponential word growth, it follows from the celebrated theorem of Gromov, see [11], that $G$ is not virtually nilpotent. To see that every proper quotient of $G$ is virtually nilpotent, by [7, Theorem 4.10], it suffices to prove that $G/G''$ is virtually nilpotent. Set $N = \psi^{-1}(\gamma_3(G) \times \cdots \times \gamma_3(G))$. From [18, Lemma 7.3], we have $N \triangleleft G'' < \text{St}_G(1) < G$. Therefore $\psi_1$ induces a homomorphism

$$\tilde{\psi} : \text{St}_G(1)/N \rightarrow G/\gamma_3(G) \times \cdots \times G/\gamma_3(G).$$

Since $\tilde{\psi}_1$ is injective and $\tilde{\psi}_1(\text{St}_G(1)/N)$ is nilpotent (being a subgroup of a nilpotent group), we obtain that $\text{St}_G(1)/N$ is nilpotent. This implies that $\text{St}_G(1)/G''$ is nilpotent as it is a quotient of $\text{St}_G(1)/N$. As the subgroup $\text{St}_G(1)$ has finite index in $G$, the group $\text{St}_G(1)/G''$ has finite index in $G/G''$ and hence $G/G''$ is virtually nilpotent. The last part of the result follows from [6, Corollary 5.1.3].

Hereafter, for $g, h \in G$, the equivalence $g \equiv h \mod G'$ will simply be denoted by $g \equiv h$. Notice that for every $z \in G'$, we have $\sigma_z = 1$ and $G' \triangleleft \text{St}_G(1)$.

**Lemma 4.2.** Let $g \in G$ be such that $g \equiv a_{s-1} \cdots a_0 \mod G'$. If $g^m = (g_0, \ldots, g_{m-1})$ then $g_k \equiv a_{s-1} \cdots a_0$ for all $k \in [0, m-1]$.

**Proof.** Since $g \equiv a_{s-1} \cdots a_0$, there exists an element $(z_0, \ldots, z_{m-1}) = z \in G'$ such that $g = a_{s-1} \cdots a_0 z$. We have

$$(g_0, \ldots, g_{m-1}) = g^m = (a_{s-1} \cdots a_0 z)^m = ((z_1, \ldots, z_{m-1}, a_{s-2} \cdots a_0 a_{s-1} a_0) \sigma)^m = (z_1 z_2 \cdots z_{m-1} a_{s-2} \cdots a_0 a_{s-1} a_0, \ldots, a_{s-2} \cdots a_0 a_{s-1} a_0 z_2 \cdots z_{m-1}).$$

Therefore $g_k \equiv a_{s-1} \cdots a_0$ for all $k \in [0, m-1]$, since $z_0 \cdots z_{m-1} \in G'$ by Lemma 2.1. □

We recall that $H_u$ denotes the subgroup $\varphi_u(\text{st}_H(u))$ for a vertex $u \in X^*$. By [18, Theorem 1.6(ii)], the group $G$ is fractal, so $G_u = G$ for all $u \in X^*$. In the following, we denote by $\text{Sym}(s)$ the symmetric group on $\{0, 1, \ldots, s-1\}$.

**Lemma 4.3.** Let $H$ be a subgroup of $G$. Assume that $a_{(s-1)^\pi} \cdots a_0^\pi \in H$ for some $\pi \in \text{Sym}(s)$.

Then for every vertex $u$ of level $ns$, for each $n \in \mathbb{N}$, the subgroup $H_u$ contains all elements obtained by cyclic permutations of the word $a_{(s-1)^\pi} \cdots a_0^\pi$.

**Proof.** Let $g = a_{(s-1)^\pi} \cdots a_0^\pi \in H$. Then $0 = i^\pi$ for some $i \in [0, s-1]$, and $g = a_{(s-1)^\pi} \cdots a_{(i+1)^\pi} a_0 a_{(i-1)^\pi} \cdots a_0^\pi$.

By taking the $m$th power of the element $g$ we get

$$g^m = (\ast, \ldots, \ast, a_{(s-1)^\pi-1} \cdots a_{(i+1)^\pi-1} a_{(s-1)^\pi-1} \cdots a_0^\pi),$$

where $\ast = a_{(i-1)^\pi-1} \cdots a_0^\pi a_{(s-1)^\pi-1} a_{(i+1)^\pi-1} a_{(s-1)^\pi-1} \cdots a_0^\pi$. By repeating the process of taking powers we get that $\psi_s(g^m_\ast) = (g_0, \ldots, g_{m^\pi-1})$ with $g_{m^\pi-1} = g$ and $g_k$ is a cyclic permutation of the word $a_{(s-1)^\pi} \cdots a_0^\pi$ for $k \in [0, m^\pi - 2]$. Furthermore, we see all cyclic permutations of
Lemma 4.2, we suppose that there exist distinct \( a \) as a component of \( g^{m^s} \). If \( v = (m - 1) \cdot \ldots \cdot (m - 1) \) is the rightmost vertex at the \( s \)th level, then \( g \in H_v \).

Now, notice that each \( a_1 \) acts locally as an \( m \)-cycle at different levels and these actions do not cancel each other. Therefore the element \( g \) acts as an \( m^s \)-cycle on the set of vertices at level \( s \). Hence, the cyclic group generated by \( g \) acts transitively on this set of vertices. Denote by \( u \) a vertex at the level \( s \). There exists \( \ell \in \mathbb{N} \) such that \( g^\ell(v) = u \). Recalling that the action on the tree is on the right, we get

\[
H_v = (H_v)^{g^\ell} = (H^{g^\ell})_{g^\ell(v)} = H_u,
\]

and hence, for every vertex \( u \) of level \( s \), the subgroup \( H_u \) contains all the elements obtained by cyclic permutations of the word \( a_{(s-1)}^\ast \ldots a_0^\ast \). Now, by an inductive argument one can see that the result holds for every vertex of level \( ns \).

\[\square\]

**Proposition 4.4.** Let \( g \in G \) be such that \( g = a_{s-1} \ldots a_0 \). Then there exists a vertex \( u \) in \( T \) and an element \( g' \in \text{st}(g)(u) \) such that \( \varphi_u(g') = a_{(s-1)}^\ast \ldots a_0^\ast \) for some \( \pi \in \text{Sym}(s) \).

**Proof.** The proof proceeds by induction on the length of \( g \). If \( g \) is equivalent to \( a_{s-1} \ldots a_0 \) then \(|g| > s - 1\). Assume that \(|g| = s\). Then \( g \in \{a_{(s-1)}^\ast \ldots a_0^\ast \mid \pi \in \text{Sym}(s)\} \) and the result follows trivially by choosing \( u \) as the root vertex. Now, assume that \(|g| > s\). Since the exponent sum of \( a_0 \) in any word representing \( g \) is 1, we can write \( g = (g_0, \ldots, g_{m-1})\sigma \) with \( g_0, \ldots, g_{m-1} \in G \). Set

\[
(\alpha_0, \ldots, \alpha_{m-1}) = g^m = (g_0 \cdot g_1 \cdot \ldots \cdot g_{m-1} \cdot g_{m-1} \cdot g_{m-2} \cdot \ldots \cdot g_0).
\]

It follows from Lemma 4.2 that \( \alpha_k = a_{s-1} \ldots a_0 \) for all \( k \in [0, m - 1] \). Furthermore \(|\alpha_k| \leq |g|\) for all \( k \in [0, m - 1] \) by Lemma 3.2. If there exists \( k \in [0, m - 1] \) such that \(|\alpha_k| < |g|\), then the result follows by induction.

Assume that \(|\alpha_k| = |g|\) for all \( k \in [0, m - 1] \). Let \( w_g \in S^* \) be a geodesic word representing \( g \). Since for each \( i \in [0, s - 1] \) the element \( a_i \) contributes \( a_{i-1} \) in exactly one component, we can obtain the geodesic words \( w_{g_k} \) representing \( g_k \) by substituting \( a_i \) in \( w_g \) with \( a_{i-1} \) in the appropriate component. Set \( w_{\alpha_k} = w_{g_k}w_{g_{k+1}} \ldots w_{g_{k+m-1}} \). Clearly \( w_{\alpha_k} \) represents \( \alpha_k \). Therefore \(|\alpha_k| \leq |w_{\alpha_k}|\). Furthermore,

\[
|w_{\alpha_k}| \leq |w_{g_k}| + \ldots + |w_{g_{k+m-1}}| = \sum_{k=0}^{m-1} |g_k| = |g| = |\alpha_k|.
\]

Thus \(|\alpha_k| = |w_{\alpha_k}|\) and \( w_{\alpha_k} \) is a geodesic word.

Now, we claim that in order to prove the result, it suffices to consider the situation in which for every \( i \in [0, s - 1] \) there exists a unique \( k \in [0, m - 1] \) such that \( w_{g_k} \) contains a non-trivial power of \( a_i \). First we consider the case when \( i = 0 \). Assume to the contrary that there exist distinct \( k_1, k_2 \in [0, m - 1] \) such that \( w_{g_{k_1}} \) and \( w_{g_{k_2}} \) contain non-trivial powers of \( a_0 \). We can reduce to the following two cases.

**Case 1:** Suppose that there exist distinct \( k_1, k_2 \in [0, m - 1] \) such that \( w_{g_{k_1}} \) and \( w_{g_{k_2}} \) contain \( a_0 \) and \( a_0^{-1} \) respectively. Then for some \( k \in [0, m - 1] \), the word \( w_{\alpha_k} \) contains a subword of the form \( a_0 w a_0^{-1} \) with \( w \in S^* \). If \( \alpha_k^m = (\beta_0, \ldots, \beta_{m-1}) \) then, by Lemma 3.2 and Lemma 3.3, we obtain that \(|\beta| < |\alpha|\) for every \( \ell \in [0, m - 1] \). Again, the result follows by induction.

**Case 2:** Suppose there exist distinct \( k_1, k_2 \in [0, m - 1] \) such that \( w_{g_{k_1}} \) and \( w_{g_{k_2}} \) contain \( a_0 \). As the exponent sum of \( a_1 \) in any word representing \( g \) is 1, the exponent sum of \( a_0 \) in \( w_{\alpha_k} \) should be equal to 1 for all \( k \in [0, m - 1] \). This implies that there exists \( k_3 \in [0, m - 1] \) such that \( w_{g_{k_3}} \) contains \( a_0^{-1} \), and we are in the previous case. Analogously, the same argument works if both \( w_{g_{k_1}} \) and \( w_{g_{k_2}} \) contain \( a_0^{-1} \).
We reduce to the case such that there exists a unique \( k \in [0, m - 1] \) such that \( w_{g_k} \) contains a non-trivial power of \( a_0 \). By inducting on \( i \in [0, s - 1] \), assume that there exist a unique \( k \in [0, m - 1] \) such that \( w_{g_k} \) contains a non-trivial power of \( a_{i-1} \). Suppose that there exist distinct \( k_1, k_2 \in [0, m - 1] \) such that \( w_{g_{k_1}} \) and \( w_{g_{k_2}} \) contain non-trivial powers of \( a_i \). We can find \( k_3 \in [0, m - 1] \) such that \( w_{\alpha_{k_3}} \) contains a subword of the form \( a_i^{\ell_1} w_i^{\ell_2} \), where \( \ell_1, \ell_2 \in \mathbb{Z}\setminus\{0\} \) and \( w \in S^* \) with exponent sum of \( a_0 \) in \( w \) is not equal to \( 0 \mod m \). Thanks to Lemma 4.2, we may replace \( w \) with \( \alpha_{k_3} \). Then we find more than one \( w_{g_k} \) containing non-trivial powers of \( a_{i-1} \), contradicting the assumption and hence proving the claim.

Thus, we reduce to the situation in which for every \( i \in [0, s - 1] \) there exists a unique \( k \in [0, m - 1] \) such that \( w_{g_k} \) contains a non-trivial power of \( a_i \). An easy computation yields that \( w_g \) does not contain a subword of the form \( a_i^{\ell_1} w_i^{\ell_2} \), for some \( i \in [0, s - 1] \) where \( \ell_1, \ell_2 \in \mathbb{Z}\setminus\{0\} \) and \( w \in S^* \) with the exponent sum of \( a_0 \) in \( w \) is not equal to \( 0 \mod m \). Hence, we conclude that \( w_g \) must be of the form

\[
w_1(a_{i_1}, \ldots, a_{i_r})a_0 w_2(a_{i_{r+1}}, \ldots, a_{i_{s-1}}),
\]

where \( w_1 \) and \( w_2 \) are words in the given elements, and \( \{i_1, \ldots, i_r, i_{r+1}, \ldots, i_{s-1}\} = [1, s - 1] \) such that the intersection \( \{i_1, \ldots, i_r\} \cap \{i_{r+1}, \ldots, i_{s-1}\} \) is empty. Consider the element \( \alpha_{m-1} \) obtained from the element \( g \) above. Then the corresponding \( \omega_{\alpha_{k_n}} \) has the form

\[
w_1(a_{i_1}, \ldots, a_{i_r})a_0 w_2(a_{i_{r+1}}, \ldots, a_{i_{s-1}}),
\]

and continuing the above procedure with this word, yields the element \( a_{(s-1)^{e}} \cdots a_{0^{e}} \in H_u \) for some \( u \in T \).

**Proposition 4.5.** If \( H \) is a prodense subgroup of \( G \) then \( H = G \).

**Proof.** Note that \( HG' = G \) as \( H \) is a prodense subgroup. Therefore there exists an element \( h \in H \) and \( z \in G' \) such that \( hz = a_{s-1} \cdots a_0 \). By an application of Proposition 4.4 followed by Lemma 4.3, we can find \( u \in T \) such that \( H_u \) contains all cyclic conjugates of \( a_{(s-1)^{e}} \cdots a_{0^{e}} \) for some \( \pi \in \text{Sym}(s) \). Thanks to [7, Lemma 3.1], the subgroup \( H_u \) is again a prodense subgroup of \( G \). We replace \( H \) with \( H_u \). Let \( c_i = a_{\ell_{i_1}} \cdots a_{\ell_{i_s}}, a_i \) be a cyclic conjugate of \( a_{(s-1)^{e}} \cdots a_{0^{e}} \) with \( \{\ell_{i_1}, \ldots, \ell_{i_{s-1}}\} = [0, s - 1] \setminus \{i\} \). For each \( n \in \mathbb{N}_0 \), let \( v_n = (m-1)^n (m-1) \) denote the rightmost vertex at level \( n \). It follows from Lemma 4.3 that the set \( \{c_0, \ldots, c_{s-1}\} \) is contained in \( H_n \) for all \( n \in \mathbb{N}_0 \). Observe that, for all \( j \in [0, s - 1] \), we have \( \varphi_{v_j}(c_j^{m'}) = a_{(\ell_1,1)} \cdots a_{(\ell_{s-1},s)}a_0 \) where we write \( a_{(\ell_{i})} \) instead of \( a_i \) for readability. For each \( j \in [0, s - 1] \), set \( e_j = \varphi_{v_j}(c_j^{m'}). \) Now let \( \ell \in \mathbb{N}_0 \), and we write \( \ell = ns + j \) where \( n \in \mathbb{N}_0 \) and \( j \in [0, s - 1] \). Then \( \varphi_{v_{\ell}}(c_{\ell}^{m'}) = e_{\ell} \) and thus \( e_{\ell} \in H_{v_{\ell}} \).

Further, for every \( i \in [0, m - 1] \), let \( e_{j,i} \) denote the \( i \)th section of \( e_j \). Now, \( e_0 = e_0 = a_{t_{0,1}} \cdots a_{t_{0,s-1}}a_0 \in H \). We have

\[
e_0^m = (e_{0,m-1}, \ldots, e_{0,0}),
\]

and so \( e_{0,m-1} \in H_{v_1} \). Therefore \( e_{0,m-1}e_1^{-1} \in H_{v_1} \). From the definition of \( e_0 \), we know that \( e_{0,m-1} = a_{(t_{0,1}-1)} \cdots a_{(t_{0,s-1}-1)}a_{s-1} \). Suppose \( e_{0,i} = 1 \), for some \( i \in [1, s - 1] \). Then

\[
e_{0,m-1}e_1^{-1} = a_{(t_{0,1}-1)} \cdots a_{(t_{0,s-1}-1)}a_0 a_{(t_{0,1}+1)} \cdots a_{(t_{0,s-1}+1)}a_{s-1}e_1^{-1} = (1, \ldots, 1, a_{(t_{0,1}+1)} \cdots a_{(t_{0,s-1}+1)}a_0 a_{(t_{0,s-1}+1)} \cdots a_{(t_{0,s-1}+1)}a_{s-2}),
\]

and

\[
(a_{(t_{0,1}-1)} \cdots a_{(t_{0,s-1}-1)}a_{s-1}e_1^{-1})e_1 = (e_{1,m-1}, 1, \ldots, 1, a_{(t_{0,1}+1)} \cdots a_{(t_{0,s-1}+1)}a_0 a_{(t_{0,s-1}+1)} \cdots a_{(t_{0,s-1}+1)}a_{s-2}).
\]
where $* = a_{(t_0,1-2)} \cdots a_{(t_0,i-1-2)}a_{s-1}^{-1}$. Hence $a_{(t_0,i+1-2)} \cdots a_{(t_0,s-1-2)}a_{s-2} \in H_{v_2}$ and
\[
|a_{(t_0,i+1-2)} \cdots a_{(t_0,s-1-2)}a_{s-2}| < |e_0,m| = |e_0|.
\]
Now, let $j \in [2, s]$ be minimal such that $a_{(t_0,i+1-j)} \cdots a_{(t_0,s-1-j)}a_{s-j} \notin st_G(v_j)$. If $j = s$, then again from the definition of $e_0$ it follows that $a_{(t_0,i+1-2)} \cdots a_{(t_0,s-1-2)} = 1$. Hence, we get $a_0 \in H_{v_s}$. So we may assume that $j \in [2, s-1]$. Since $a_{(t_0,i+1-j)} \cdots a_{(t_0,s-1-j)}a_{s-j}$ does not stabilise the vertex $v_j$, there exists $k \in [i+1, s-1]$ such that $t_0,k = j$. We have
\[
a_{(t_0,i+1-j)} \cdots a_{(t_0,s-1-j)}a_{s-j}^{-1} = a_{(t_0,i+1-j)} \cdots a_{(t_0,k-1-j)}a_0 \cdots a_{(t_0,s-1-j)}a_{s-j}^{-1} = (1, \ldots, 1, a_{(t_0,k+1-j-1)} \cdots a_{(t_0,s-1-j-1)}a_{s-j-1}, *)
\]
where $* = a_{(t_0,i+1-j-1)} \cdots a_{(t_0,k-1-j-1)}a_{s-1}^{-1}$. Hence $a_{(t_0,k+1-j-1)} \cdots a_{(t_0,s-1-j-1)}a_{s-j-1} \in H_{v_{j+1}}$ and
\[
|a_{(t_0,k+1-j-1)} \cdots a_{(t_0,s-1-j-1)}a_{s-j-1}| < |a_{(t_0,i+1-j)} \cdots a_{(t_0,s-1-j)}a_{s-j}|.
\]
Continuing in this manner, we see that $a_0 \in H_{v_s}$.

Now we repeat the above process, restarting with $a_0 \in H$. Writing
\[
c_1 = a_{t_1,1} \cdots a_{t_{1,i-1}}a_0 a_{t_{1,i+1}} \cdots a_{t_{1,s-1}}a_1,
\]
for some $i \in [1, s-1]$ where $\{t_1,1, \ldots, t_{1,i-1}, t_{1,i+1}, \ldots, t_{1,s-1}\} = [2, s-2]$, we have
\[
c_1e_0 = (1, \ldots, 1, a_{(t_1,i+1-1)} \cdots a_{(t_1,s-1-1)}a_0, *)
\]
where $* = a_{(t_1,i-1)} \cdots a_{(t_1,s-1-1)}a_{s-1}^{-1}$. Hence $a_{(t_1,i+1-1)} \cdots a_{(t_1,s-1-1)}a_0 \in H_{v_1}$ and
\[
|a_{(t_1,i+1-1)} \cdots a_{(t_1,s-1-1)}a_0| < |c_1|.
\]
Now, continuing with $a_{(t_1,i+1-1)} \cdots a_{(t_1,s-1-1)}a_0$ as above, we see that $a_1 \in H_{v_s}$.

Now repeat the process with $c_i$ for all $i \in [1, s-1]$, we see that $\{a_0, \ldots, a_{s-1}\} \subseteq H_{v}$ for some $v \in X^*$. Hence $H_v = G$.

**Remark 4.6.** Akin to [5, Proposition 6.6], one can show that the group $G$ has a non-normal maximal subgroup of index $q$, for infinitely many primes $q$. Indeed, the group $G$ has a proper quotient isomorphic to $W_m(\mathbb{Z})$, where for $G$ a group and $m \in \mathbb{N}_{\geq 2}$, we write $W_m(G)$ for the wreath product of $G$ with a cyclic group of order $m$. Writing $L = \psi^{-1}(G \times \cdots \times G')$ and $N = L(a_0^n) \cong G$, analogous to [5, Lemma 6.4] we have that $G/N \cong W_m(\mathbb{Z}^{s-1})$, which has $W_m(\mathbb{Z})$ as a quotient group; compare also [18, Theorem 1.6(iv)].
