APPLICATIONS OF CIRCULANT MATRICES TO DETERMINANTS INVOLVING $k$-TH POWER RESIDUES

HAI-LIANG WU AND LI-YUAN WANG

Abstract. In this paper, by the tools of circulant matrices and hyper-elliptic curves over finite fields, we study some arithmetic properties of certain determinants involving the Legendre symbols and $k$-th residues.

1. Introduction

Let $n$ be an arbitrary positive integer and let $R$ be a commutative ring. For every $n \times n$ matrix $M = [a_{ij}]_{1 \leq i,j \leq n}$ with $a_{ij} \in R$, we use the symbol $\det M$ or $|M|$ to denote the determinant of $M$. Also, given any elements $b_0, b_1, \ldots, b_{n-1} \in R$, the circulant matrix of the $n$-tuple $(b_0, \ldots, b_{n-1})$ is defined by an $n \times n$ matrix over $R$ whose $(i,j)$-entry is $b_{i-j}$, where the indices are cyclic modulo $n$. We also denote this matrix by $C(b_0, b_1, \ldots, b_{n-1})$.

Readers may refer to the survey paper [6] for more results on circulant matrices.

1.1. Circulant Matrices involving The Legendre Symbols. Circulant matrices have many applications in both number theory and combinatorics. Let $p$ be an odd prime and let $\chi(\cdot)$ be a multiplicative character modulo $p$. Carlitz [2] first investigated the following circulant matrix:

$$C(c_0, c_1, \ldots, c_{p-1}) := \begin{bmatrix} \mu + \chi(i-j) \end{bmatrix}_{1 \leq i,j \leq p-1}$$

where $c_i = \mu + \chi(i)$ for $0 \leq i \leq p - 1$. Carlitz [2, Theorem 4] determined the characteristic polynomial of this circulant matrix. In particular, when $\chi(\cdot) = (\cdot)^{p-1}/p$ is the Legendre symbol, the characteristic polynomial of the matrix $[\mu + (\frac{i-j}{p})]_{1 \leq i,j \leq p-1}$ is

$$F_\mu(t) = (t^2 - (1)^{(p-1)/2}p)(t^2 - (p-3)/2(t^2 - (p-1))\mu - (-1)^{(p-1)/2}).$$

Later Chapman [3, 4] and Vsemirnov [16, 17] also studied many variants of Carlitz’s results involving the Legendre symbols.

This research was supported by the National Natural Science Foundation of China (Grant No. 12101321 and Grant No. 11971222).
Let $p = 2n + 1$ be an odd prime. Recently, Sun [11] studied the following determinant:

$$S(d, p) := \det \left[ \left( \frac{i^2 + dj^2}{p} \right) \right]_{1 \leq i, j \leq n},$$

where $d \in \mathbb{Z}$ with $p \nmid d$. Sun [11, Theorem 1.2(iii) and Theorem 1.3(i)] proved that $-S(d, p)$ is a quadratic residue modulo $p$ whenever $(\frac{d}{p}) = 1$. For the recent progress on this topic, readers may refer to [7, 14]. On the other hand, Sun also investigated some global properties of this determinant. Sun conjectured that $-S(1, p)$ is an integral square if $p \equiv 3 \pmod{4}$. Later, by using a sophisticated matrix decomposition, Alekseyev and Krachun proved this conjecture. Also, in the case $p \equiv 1 \pmod{4}$, writing $p = a^2 + 4b^2$ with $a, b \in \mathbb{Z}$ and $a \equiv 1 \pmod{4}$, Cohen, Sun and Vsemirnov (see [11, Remark 4.2]) conjectured that $S(1, p)/a$ is an integral square. This conjecture was later proved by the first author [13, Theorem 3].

It is worth to state here that $S(d, p)$ is indeed a determinant of certain circulant matrix. In fact, fix a primitive root $g$ modulo $p$. Then it is clear that

$$\det \left[ \left( \frac{g^{2i} + dg^{2j}}{p} \right) \right]_{0 \leq i, j \leq n-1} = \det \left[ \left( \frac{g^{2(i-j)} + d}{p} \right) \right]_{0 \leq i, j \leq n-1} = \det C(s_0, s_1, \ldots, s_{n-1}),$$

where $s_i = (\frac{g^{2i} + d}{p})$ for $0 \leq i \leq n - 1$.

Motivated by Sun’s determinant $S(d, p)$, in this paper we study some determinants concerning $k$-th power residues. Let $p$ be an odd prime and let $k \geq 2$ be an integer dividing $p - 1$. Write $p = km + 1$ and let

$$0 < \alpha_1 < \alpha_2 < \cdots < \alpha_m < p$$

be all the $k$-th power residues modulo $p$ in the interval $(0, p)$. We consider the following matrix:

$$W_p(k) := \left[ \left( \frac{\alpha_i + \alpha_j}{p} \right) \right]_{1 \leq i, j \leq m}.$$

To state our results, we first introduce some notations. Let $\mathbb{F}_p$ denote the finite field of $p$ elements. Let $C_{p,k,\psi}$ and $C_{p,k,\phi}$ be the curves over $\mathbb{F}_p$ defined by the equations $y^2 = x^k + 1$ and $y^2 = x(x^k + 1)$ respectively. Also, we define $a_p(k)$ and $b_p(k)$ by

$$p + 1 - a_p(k) = \# \{(x, y) \in \mathbb{F}_p \times \mathbb{F}_p : y^2 = x^k + 1\} \cup \{\infty\},$$

$$(1.2)$$
and
\begin{equation}
    p + 1 - b_p(k) = \# \{(x, y) \in \mathbb{F}_p \times \mathbb{F}_p : \ y^2 = x(x^k + 1)\} \cup \{\infty\},
\end{equation}
where \(\#S\) denotes the cardinality of a set \(S\).

When \(k\) is even, as a generalization of Sun’s determinant \(S(1, p)\), by using the theory of circulant matrices we can obtain the following result:

**Theorem 1.1.** Let \(p\) be an odd prime and let \(k \geq 2\) be an even integer dividing \(p - 1\). Then the following results hold.

(i) If \(m\) is odd, then
\[
    \det W_p(k) = -(a_p(k) + 1)u_p(k)^2 / k
\]
for some \(u_p(k) \in \mathbb{Z}\).

(ii) If \(m\) is even, then
\[
    \det W_p(k) = (a_p(k) + 1)b_p(k)v_p(k)^2 / k^2
\]
for some \(v_p(k) \in \mathbb{Z}\).

**Remark 1.1.** (i) When \(k = 2\) and \(p \equiv 3 \pmod{4}\), it is easy to see that \(a_p(2) = 1\). This implies that \(\det W_p(2) = -S(1, p)\) is an integral square, which also confirms the conjecture of Sun.

(2) When \(k = 2\) and \(p \equiv 1 \pmod{4}\) with \(p = a^2 + 4b^2\), where \(a \equiv 1 \pmod{4}\), it is known that \(a_p(2) = 1\) and \(b_p(2) = 2a\) (cf. [1, Theorem 6.2.9]). This gives that \(\det W_p(2)/a = S(1, p)/a\) is an integral square, which coincides with the result in [13, Theorem 3].

Now we consider the case that \(k\) is odd.

To state our next result, we need to introduce some notations. Fix a primitive root \(g\) modulo \(p\). Let \(E_{p, k, 1}\) and \(E_{p, k, g}\) be the hyperelliptic curves over \(\mathbb{F}_p\) defined by the equations \(y^2 = x(x^{2k} + 1)\) and \(y^2 = x(x^{2k} + g^k)\) respectively. We also define \(c_p(k)\) and \(d_p(k)\) by
\begin{equation}
    p + 1 - c_p(k) := \# \{(x, y) \in \mathbb{F}_p \times \mathbb{F}_p : \ y^2 = x(x^{2k} + 1)\} \cup \{\infty\},
\end{equation}
and
\begin{equation}
    p + 1 - d_p(k) := \# \{(x, y) \in \mathbb{F}_p \times \mathbb{F}_p : \ y^2 = x(x^{2k} + g^k)\} \cup \{\infty\}.
\end{equation}

Now we state our next result.

**Theorem 1.2.** (i) Let \(p \equiv 1 \pmod{4}\) be a prime and let \(k \geq 2\) be an odd integer dividing \(p - 1\). Then we have
\[
    \det W_p(k) = \frac{z_p(k)^2}{4k^2} (c_p(k)^2 + d_p(k)^2)
\]
for some $z_p(k) \in \mathbb{Z}$.

(ii) Let $p \equiv 3 \pmod{4}$ be a prime and let $k \geq 2$ be an odd integer dividing $p - 1$. Then $-\det W_p(k)$ is an integral square.

When $k = 3$ we have the following result:

**Corollary 1.1.** Suppose that $p \equiv 1 \pmod{12}$ is a prime and write $p = c^2 + 9d^2$ with $c,d \in \mathbb{Z}$. Then

(i) $\det W_p(3)/(c^2 + d^2)$ is an integral square.

(ii) Moreover, if $p \nmid \det W_p(3)$, then

$$\left(\frac{\det W_p(3)}{p}\right) = \left(\frac{2}{p}\right).$$

**Remark 1.2.** By our computations, there are primes $p \equiv 1 \pmod{12}$ such that $p \mid \det W_p(3)$. For example, 1117, 1129, 1381, 1597, 1861, 2557, 2749 are all primes $p \equiv 1 \pmod{12}$ less than 3000 such that $p \mid W_p(3)$.

We also have the following corollary:

**Corollary 1.2.** (i) Let $p \equiv 1 \pmod{4}$ be a prime and let $k \geq 2$ be an odd integer dividing $p - 1$. Then $\det W_p(k) \geq 0$.

(ii) Let $p \equiv 3 \pmod{4}$ be a prime and let $k \geq 2$ be an odd integer dividing $p - 1$. Then $\det W_p(k) \leq 0$.

1.2. **Determinants of the form** $\det_{1 \leq i,j \leq m}^{[\frac{1}{\alpha_i + \alpha_j}]}$. Let $p$ be an odd prime. In 2019, Sun [11] also studied the following determinant:

$$A_p := \det \left[ \frac{1}{i^2 + j^2} \right]_{1 \leq i,j \leq (p-1)/2}.$$  

When $p \equiv 3 \pmod{4}$, Sun [11, Theorem 1.4(ii)] showed that

$$A_p \equiv \left(\frac{2}{p}\right) \pmod{p}.$$  

In [11, Remark 1.3] Sun also conjectured that if $p \equiv 2 \pmod{3}$ is odd, then $2B_p$ is a quadratic residue modulo $p$, where

$$B_p := \det \left[ \frac{1}{i^2 - ij + j^2} \right]_{1 \leq i,j \leq p-1}.$$  

This conjecture was later confirmed in [15]. Let the notations be as the above. Inspired by the above work, we consider the matrix:

$$(1.6) \quad I_p(k) := \left[ \frac{1}{\alpha_i + \alpha_j} \right]_{1 \leq i,j \leq m}.$$
As a generalization of Sun’s determinant $\det A_p$, we obtain the following result:

**Theorem 1.3.** Let $p$ be an odd prime and let $k \geq 2$ be an even integer dividing $p-1$. Write $p = km + 1$. Suppose that $-1$ is not a $k$-th power residue modulo $p$. Then we have

$$\det I_p(k) \equiv \frac{(-1)^{\frac{m+1}{2}}}{(2k)^m} \pmod{p}.$$

**Remark 1.3.** When $p \equiv 3 \pmod{4}$ and $k = 2$, by the above theorem

$$\det I_p(2) \equiv \frac{(-1)^{\frac{m+1}{2}}}{(2)^m} = \left(\frac{2}{p}\right) \pmod{p}.$$

This coincides with Sun’s result [11, Theorem 1.4(ii)].

The outline of this paper is as follows. We will prove Theorems 1.1–1.2 and their corollaries in Section 2. The proof of Theorem 1.3 will be given in section 3.

### 2. Proofs of Theorems 1.1–1.2

Recall that $C(a_0, \cdots, a_{n-1})$ denotes the circulant matrix of the $n$-tuple $(a_0, \cdots, a_{n-1})$. We begin with the following lemma which is the key element of our proofs (cf. [14, Lemma 3.4]).

**Lemma 2.1.** Let $R$ be a commutative ring. Let $n$ be a positive integer. Let $a_0, a_1, \cdots, a_{n-1} \in R$ such that

$$a_i = a_{n-i} \quad \text{for each } 1 \leq i \leq n-1.$$

If $n$ is even, then there exists an element $u \in R$ such that

$$\det C(a_0, a_1, \cdots, a_{n-1}) = \left(\sum_{i=0}^{n-1} a_i\right) \left(\sum_{i=0}^{n-1} (-1)^i a_i\right) u^2.$$

If $n$ is odd, then there exists an element $v \in R$ such that

$$\det C(a_0, a_1, \cdots, a_{n-1}) = \left(\sum_{i=0}^{n-1} a_i\right) v^2.$$

**Proof of Theorem 1.1.** Fix a primitive root $g$ modulo $p$. As $k$ is even, we have

$$\det W_p(k) = \det \left[\left(1 + \frac{\alpha_i/\alpha_j}{p}\right)\right]_{1 \leq i, j \leq m} = \det \left[\left(1 + g^{k(i-j)}\right)\right]_{0 \leq i, j \leq m-1} = \det C(e_0, e_1, \cdots, e_{m-1}),$$
where \( e_i = \left( \frac{1+q_i^k}{p} \right) \) for \( 0 \leq i \leq m - 1 \). Clearly \( e_0, \ldots, e_{m-1} \) satisfy the condition (2.7). Moreover,

\[
(2.10) \quad \sum_{i=0}^{m-1} e_i = \frac{1}{k} \sum_{x=1}^{p-1} \left( \frac{1+x^k}{p} \right) = \frac{1}{k} \left( -1 + \sum_{x=0}^{p-1} \left( \frac{1+x^k}{p} \right) \right) = - (1 + a_p(k)) / k
\]

where \( a_p(k) \) is defined by (1.2). Also,

\[
(2.11) \quad \sum_{i=0}^{m-2} (-1)^i e_i = \frac{1}{k} \sum_{x=1}^{p-1} \left( \frac{x^k + 1}{p} \right) \left( \frac{x}{p} \right) = -b_p(k)/k,
\]

where \( b_p(k) \) is defined by (1.3). Combining Lemma 2.1 with (2.10) and (2.11), one can get the desired result.

Now we turn to the proof of Theorem 1.2. We first need the following known result in linear algebra.

**Lemma 2.2.** Let \( M \) be an \( n \times n \) complex matrix. Let \( \lambda_1, \ldots, \lambda_n \) be complex numbers and let \( u_1, \ldots, u_n \) be \( m \)-dimensional column vectors. Suppose that \( M u_i = \lambda_i u_i \) for each \( 1 \leq i \leq n \) and that \( u_1, \ldots, u_n \) are linearly independent. Then \( \lambda_1, \ldots, \lambda_n \) are exactly all the eigenvalues of \( M \) (counting multiplicities).

To state our proof, we introduce the following notations. Let \( \mathbb{F}_p^\times \) denote the cyclic group of all multiplicative characters of \( \mathbb{F}_p \) and let \( \chi_p(\cdot) \) be a generator of \( \mathbb{F}_p^\times \). For any matrix \( M \), we use the symbol \( M^T \) to denote the transpose of \( M \).

Now we are in a position to proof our main result.

**Proof of Theorem 1.2.** Recall that \( k \geq 2 \) is an odd integer dividing \( p - 1 \) and \( p = km + 1 \).

(i) We first consider the case \( p \equiv 1 \pmod{4} \). Clearly the elements \( \alpha_1 \mod p, \ldots, \alpha_m \mod p \) are exactly \( m \) distinct roots of the polynomial \( X^m - 1 \) over \( \mathbb{F}_p = \mathbb{Z}/p\mathbb{Z} \). We therefore have

\[
(2.12) \quad X^m - 1 \equiv \prod_{i=1}^{m} (X - \alpha_i) \pmod{p}.
\]

By (2.12) we obtain

\[
(2.13) \quad \prod_{j=1}^{m} \alpha_j \equiv -1^{m+1} = -1 \pmod{p}.
\]
By (2.13) it is easy to see that \( \det W_p(k) \) is equal to

\[
\left( -\frac{1}{p} \right) \det \left[ \left( \frac{\alpha_i + \alpha_j}{p} \right) \right]_{1 \leq i,j \leq m} = \det \left[ \left( \frac{\alpha_i + \alpha_j}{p} \right) \right]_{1 \leq i,j \leq m}.
\]

Now we first determine all the eigenvalues of the matrix:

\[
W_p^*(k) := \left[ \left( \frac{\alpha_i + \alpha_j}{p} \right) \right]_{1 \leq i,j \leq m}.
\]

For each \( 1 \leq r \leq m \), we have

\[
\sum_{j=1}^{m} \left( \frac{\alpha_i + \alpha_j}{p} \right) \chi_{p}^r(\alpha_j) = \sum_{j=1}^{m} \left( \frac{1 + \alpha_j/\alpha_i}{p} \right) \left( \frac{\alpha_j/\alpha_i}{p} \right) \chi_{p}^r(\alpha_j) = \sum_{j=1}^{m} \left( \frac{1 + \alpha_j}{p} \right) \left( \frac{\alpha_j}{p} \right) \chi_{p}^r(\alpha_j) \chi_{p}^r(\alpha_i).
\]

This implies that for each \( 1 \leq r \leq m \) we have

\[
W_p^*(k) v_r = \lambda_r v_r,
\]

where

\[
\lambda_r = \sum_{j=1}^{m} \left( \frac{1 + \alpha_j}{p} \right) \left( \frac{\alpha_j}{p} \right) \chi_{p}^r(\alpha_j),
\]

and

\[
v_r = (\chi_{p}^r(\alpha_1), \cdots, \chi_{p}^r(\alpha_m))^T.
\]

Note that

\[
\begin{vmatrix}
\chi_{p}^1(\alpha_1) & \chi_{p}^2(\alpha_1) & \cdots & \chi_{p}^m(\alpha_1) \\
\chi_{p}^1(\alpha_2) & \chi_{p}^2(\alpha_2) & \cdots & \chi_{p}^m(\alpha_2) \\
\vdots & \vdots & \ddots & \vdots \\
\chi_{p}^1(\alpha_n) & \chi_{p}^2(\alpha_n) & \cdots & \chi_{p}^m(\alpha_n)
\end{vmatrix} = \pm \prod_{1 \leq i < j \leq m} \left( \chi_{p}^r(\alpha_j) - \chi_{p}^r(\alpha_i) \right) \neq 0.
\]

Hence the vectors \( v_1, \cdots, v_m \) are linearly independent. Now by Lemma 2.2 the numbers \( \lambda_1, \cdots, \lambda_m \) are exactly all the eigenvalues of \( W_p^*(k) \) (counting multiplicities).

When \( r = m \),

\[
\lambda_m = \sum_{j=1}^{m} \left( \frac{1 + \alpha_j}{p} \right) \left( \frac{\alpha_j}{p} \right) = \frac{1}{k} \sum_{x=1}^{p-1} \left( \frac{1 + x^k}{p} \right) \left( \frac{x}{p} \right).
\]

When \( r = m/2 \),

\[
\lambda_{m/2} = \sum_{j=1}^{m} \left( \frac{1 + \alpha_j}{p} \right) = \frac{1}{k} \sum_{x=1}^{p-1} \left( \frac{1 + x^k}{p} \right).
\]
By [1, Proposition 6.1.7] we have

\[(2.17) \quad \lambda_m = \lambda_{m/2}.\]

In addition, when \(1 \leq r \leq m/2 - 1\) it is clear that \(\overline{\lambda_r} = \lambda_{m-r}\), where \(\overline{z}\) denotes the complex conjugation of a complex number \(z\). Combining this with (2.17), we have

\[(2.18) \quad \det W_p(k) = \det W_p^*(k) = \prod_{r=1}^{m} \lambda_r = \lambda_m^2 \prod_{1 \leq r \leq m/2 - 1} \lambda_r \overline{\lambda_r} \geq 0.\]

Let \(i \in \mathbb{C}\) be a 4-th primitive root of unity. Fix a primitive root \(g\) modulo \(p\). Then

\[
\det W_p^*(k) = \det \left[ \left( \frac{\alpha_i + \alpha_j}{p} \right) \left( \frac{\alpha_i}{p} \right) \frac{i^{-j}}{1 \leq i, j \leq m} \right]
= \det \left[ \left( \frac{1 + g^{kr}}{p} \right) \frac{i^{-j}}{0 \leq i, j \leq m-1} \right]
= \det C(\omega_0, \cdots, \omega_{m-1}),
\]

where \(\omega_r = (\frac{1+g^kr}{p})i^r\) for \(0 \leq r \leq m - 1\). One can verify that \(\omega_0, \cdots, \omega_{m-1}\) satisfy the condition (2.7). Fix a multiplicative character \(\psi \in \hat{\mathbb{F}_p}^\times\) of order 4 with \(\psi(g) = i\). Then

\[
\sum_{r=0}^{m-1} \omega_r = \sum_{r=0}^{m-1} \left( \frac{1 + g^{kr}}{p} \right) \psi(g^r) = \frac{1}{k} \sum_{r=0}^{p-2} \left( \frac{1 + g^{kr}}{p} \right) \psi(g^r).
\]

One can also verify the following equalities:

\[
\sum_{r=0}^{p-2} \left( \frac{1 + g^{kr}}{p} \right) \psi(g^r) = \sum_{r=0}^{p-3} \left( \frac{1 + g^{2kr}}{p} \right) \frac{g^r}{p} + i \sum_{r=0}^{p-3} \left( \frac{1 + g^{2kr}g^k}{p} \right) \frac{g^r}{p}
= \frac{1}{2} \sum_{x=1}^{p-1} \left( \frac{1 + x^{2k}}{p} \right) \frac{x}{p} + \frac{1}{2} \sum_{x=1}^{p-1} \left( \frac{1 + x^{2k}g}{p} \right) \frac{x}{p}
= \frac{1}{2} \sum_{x=1}^{p-1} \left( \frac{1 + x^{2k}}{p} \right) \frac{x}{p} + \frac{1}{2} \sum_{x=1}^{p-1} \left( \frac{g^k + x^{2k}}{p} \right) \frac{x}{p}
= - \left( c_p(k) + id_p(k) \right) / 2,
\]

where \(c_p(k)\) and \(d_p(k)\) are defined by (1.4) and (1.5) respectively. Hence

\[(2.19) \quad \sum_{r=0}^{m-1} \omega_r = \frac{-1}{2k} \left( c_p(k) + id_p(k) \right).\]
With essentially the same method, one can also verify that

\[(2.20) \quad \sum_{r=0}^{m-1} (-1)^r \omega_r = \frac{-1}{2k} (c_p(k) - id_p(k)).\]

If \(\det W_p(k) = 0\), then one can get the desired result directly. Suppose now that \(\det W_p(k) \neq 0\). By (2.18) we have \(\det W_p(k) > 0\) under this assumption. Combining Lemma 2.1 with (2.19) and (2.20), there exists an element \(z_p(k) \in \mathbb{Z}[i]\) such that

\[\det W_p(k) = \det W^*_p(k) = z_p(k)^2 \cdot 4k^2 \cdot (c_p(k)^2 + d_p(k)^2).\]

As \(\det W_p(k) \in \mathbb{Z}\) and \(\det W_p(k) > 0\), the number \(z_p(k)\) must be an integer.

This completes the proof of (i).

(ii) We now consider the case \(p \equiv 3 (\text{mod } 4)\). As \(k\) is odd, it is clear that

\[-\alpha_1 \mod p, \ldots, -\alpha_m \mod p\]

is a permutation \(\pi\) of the sequence

\[\alpha_1 \mod p, \ldots, \alpha_m \mod p,\]

and clearly

\[\text{sgn}(\pi) \equiv \prod_{1 \leq i < j \leq m} \frac{-\alpha_j - (-\alpha_i)}{\alpha_j - \alpha_i} = (-1)^{m(m-1)/2} \pmod{p},\]

where \(\text{sgn}(\pi)\) is the sign of \(\pi\). When \(p \equiv 3 (\text{mod } 4)\) and \(k\) is odd, since \(m \equiv 2 (\text{mod } 4)\), the number \(\det W_p(k)\) is equal to

\[\text{sgn}(\pi) \det \left[ \left( \frac{\alpha_i - \alpha_j}{p} \right) \right]_{1 \leq i,j \leq m} = - \det \left[ \left( \frac{\alpha_i - \alpha_j}{p} \right) \right]_{1 \leq i,j \leq m}.\]

Clearly the matrix \(M_p := [(\frac{\alpha_i - \alpha_j}{p})]_{1 \leq i,j \leq m}\) is a skew-symmetric matrix, i.e., \(M^T_p = -M_p\). It is known that the determinant of a skew-symmetric matrix of even order with integer entries is always an integral square (cf. [10, Proposition 2.2]). This implies that \(- \det W_p(k)\) is an integral square.

In view of the above, we have completed the proof. \(\square\)

**Proof of Corollary 1.1.** (i) Let \(k = 3\) and \(p \equiv 1 (\text{mod } 12)\). Write \(p = \alpha^2 + \beta^2\) with \(\alpha, \beta \in \mathbb{Z}\) and \(\alpha \equiv -\left(\frac{2}{p}\right) (\text{mod } 4)\). It is known that (cf. [1, Theorem 6.2.5])

\[c_p(3) \begin{cases} 36\alpha^2 & \text{if } 3 \nmid \alpha, \\ 4\alpha^2 & \text{if } 3 \mid \alpha, \end{cases}, \quad d_p(3) \begin{cases} 4\beta^2 & \text{if } 3 \nmid \alpha, \\ 36\beta^2 & \text{if } 3 \mid \alpha. \end{cases}\]
Hence if we write $p = c^2 + 9d^2$ with $c, d \in \mathbb{Z}$, then one can easily verify that
\[
\frac{c_p(3)^2 + d_p(3)^2}{36} = c^2 + d^2.
\]
By Theorem 1.2 we obtain that $\det W_p(3)/(c^2 + d^2)$ is an integral square if $p \equiv 1 \pmod{12}$.

(ii) If $p \nmid \det W_p(3)$, then
\[
\left( \frac{\det W_p(3)}{p} \right) = \left( \frac{c^2 + d^2}{p} \right) = \left( \frac{8c^2 + p}{p} \right) = \left( \frac{2}{p} \right).
\]
This completes the proof.

3. Proof of Theorem 1.3.

Recall that
\[
I_p(k) = \left[ \frac{1}{\alpha_i + \alpha_j} \right]_{1 \leq i,j \leq m}.
\]
As $-1$ is not a $k$-th power residue modulo $p$, clearly we have $2 \nmid m$. Now we prove our theorem.

**Proof of Theorem 1.3.** By [8, Theorem 12(5.5)] we have
\[
(3.21) \quad \det I_p(k) = \prod_{1 \leq i < j \leq m} (\alpha_i - \alpha_j)^2 \prod_{1 \leq i \leq m} \prod_{1 \leq j \leq m} (\alpha_i + \alpha_j).
\]
We first consider the numerator. One can verify the following equalities:
\[
N_p := \prod_{1 \leq i < j \leq m} (\alpha_i - \alpha_j)^2 = (-1)^{\frac{m(m-1)}{2}} \prod_{1 \leq i \neq j \leq m} (\alpha_i - \alpha_j)
\]
\[
= (-1)^{\frac{m(m-1)}{2}} \prod_{1 \leq j \leq m} \prod_{i \neq j} G'(\alpha_j),
\]
where $G'(X)$ is the derivative of $G(X) = \prod_{1 \leq i \leq m} (X - \alpha_i)$. Observe that
\[
(3.22) \quad G(X) \equiv X^m - 1 \pmod{p}.
\]
Hence $G'(X) \equiv mX^{m-1} \pmod{p}$ and $\prod_{1 \leq i \leq m} \alpha_i \equiv (-1)^{m+1} = 1 \pmod{p}$.

By this we obtain
\[
\prod_{1 \leq i < j \leq m} (\alpha_i - \alpha_j)^2 \equiv (-1)^{\frac{m(m-1)}{2}} \prod_{1 \leq j \leq m} G'(\alpha_j)
\]
\[
\equiv (-1)^{\frac{m(m-1)}{2}} m^m \prod_{1 \leq j \leq m} \alpha_j^{m-1} \equiv (-1)^{\frac{m(m-1)}{2}} m^m \pmod{p}.
\]
Hence
\[
(3.23) \quad N_p \equiv (-1)^{\frac{m(m-1)}{2}} m^m \pmod{p}.
\]
Now we turn to the denominator. One can verify the following equalities:

\[
D_p := \prod_{i=1}^{m} \prod_{j=1}^{m} (\alpha_i + \alpha_j) = \prod_{i=1}^{m} \alpha_i^m \prod_{j=1}^{m} (1 + \alpha_j/\alpha_i) \equiv \prod_{i=1}^{m} \prod_{j=1}^{m} (1 + \alpha_j) \\
= \prod_{j=1}^{m} (1 + \alpha_j)^m \pmod{p}.
\]

Hence by (3.22)

\[
D_p \equiv (-1)^m G(-1)^m \equiv 2^m \pmod{p}.
\]

Combining (3.23) with (3.24), we finally obtain

\[
\det I_p(k) \equiv \frac{(-1)^{m-1} m^m}{2^m} \equiv \frac{(-1)^{m+1}}{(2k)^m} \pmod{p}.
\]

This completes the proof. □
