November 6, 2022

Abstract

This paper proposes a general competing mechanism game of incomplete information where a mechanism allows its designer to send a message to himself at the same time agents send messages. This paper introduces various notions of robust perfect Bayesian equilibrium (PBE). Given the additive separability of each agent's utility function with respect to principals' actions, this paper provides the full characterization of equilibrium allocations in terms of Bayesian incentive compatible (BIC) direct mechanisms for each notion of robust PBE, without reference to the set of arbitrary mechanisms allowed in the game. Szentes' Critique (Szentes (2010)) on the standard competing mechanism game of complete information is valid in a model with incomplete information, regarding the set of allocations supportable in robust PBEs where agents' strategies of communicating with non-deviating principals and their induced BIC direct mechanisms are responsive to market changes.

1 Introduction

The Revelation Principle does not hold when multiple principals compete in the market (Epstein and Peters (1999), McAfee (1992)). When a principal (e.g., a seller) designs

a mechanism, he is aware that agents (e.g., buyers) have not only private information on their payoff types but also market information on mechanisms offered by competing principals, their beliefs on the terms of trade determined in those mechanisms, etc. Therefore, it is generally not enough to ask agents to report their payoff types only.

The literature on competing mechanisms or contractible contracts has explored the big idea that principals can use mechanisms or contractible contracts that involve commitments to punish a competing principal's deviation. Punishment can take place when agents' messages reveal a competing principal's deviation (Epstein and Peters (1999), Yamashita (2010), Xiong (2013)), or it is prescribed in a contractible contract, directly conditional on a deviator's publicly observable contract (Szentes (2015)). This makes it possible for principals to sustain various collusive outcomes.

Epstein and Peters (1999) propose a class of universal mechanisms that allow agents to describe competing principals' mechanisms. However, the message spaces in these universal mechanisms that agents use in describing competing principals' mechanisms are quite complex due to the infinite regress problem: my mechanism depends on the competitor's mechanism, his mechanism depends on mine, and so on ad infinitum. A major contribution by Yamashita (2010) is that any equilibrium allocations can be understood as if a principal offers a recommendation mechanism that delegates a choice of his incentive compatible direct mechanism to agents. The incentive compatible direct mechanism chosen by a majority of agents is implemented. Recommendation mechanisms can be thought of as an extension of menus proposed for common agency (Martimort and Stole (2002), Page and Monterio (2003), and Peters (2001)).

On the other hand, Szentes (2015) studies a bilateral contracting game as in Han (2006), but augmented by contractible contracts (Peters and Szentes (2012)) in which a principal's ordinary contract is directly conditional on a deviator's ordinary contract described by the Gödel language.

1.1 Motivation

The characterization of the equilibrium allocations in the current literature is however tied to the very set of arbitrary mechanisms allowed for each principal in the game. Therefore, the greatest lower bound of a principal's equilibrium utility is not expressed in terms of incentive compatible direct mechanisms.

Further, Szentes (2010) points out a restrictive feature in Yamashita (2010). Mechanisms adopted in Yamashita (2010) delegate a choice of an action to agents in the sense

that agents' messages fully determine an action in a mechanism. This is the restriction imposed on mechanisms in the standard competing mechanism game in the literature. However, a principal may offer a *set-valued mechanism* in which a subset of actions is first determined by agents' messages and the principal subsequently chooses an action that he wants from the subset.

Szentes shows that if such mechanisms are allowed, the greatest lower bound of a principal's (pure-strategy) equilibrium utility in the competing mechanism game of *complete information* can be expressed as his minmax value over actions regardless of the complexity of mechanisms allowed in the game. The reason is that a principal can deviate to a mechanism that leaves the whole set of actions for him regardless of agents' messages. The deviating principal can then choose an action that maximizes his utility given his belief on non-deviators' actions.¹ Therefore, a principal's utility cannot be lower than his minmax value over actions in the case of the complete information. In the standard competing mechanism game, a principal is forced to offer a mechanism that takes away his freedom of choosing an action at a later stage of the game, inducing his maxmin value over actions as a principal's equilibrium utility. Szentes (2010) argues that this is hard to justify on economic grounds.

This paper proposes a general competing mechanism game of *incomplete information* where a principal's general mechanism allows him to send a message to himself at the same time agents send messages and these messages altogether determine an action. A principal does not observe other principals' mechanisms when he sends a message to himself. A principal's mechanism that assigns a subset of actions conditional on agents' messages (Szentes (2010)) is strategically equivalent to a general mechanism. Therefore, the set of mechanisms in Szentes (2010) can be nested into the set of general mechanisms.

In a model with a single principal, the Revelation Principle holds for both set-valued mechanisms in Szentes (2010) and general mechanisms in this paper: For any equilibrium given any set valued mechanism or any general mechanism, there exists an incentive compatible direct mechanism where agents' messages uniquely determine the

¹In Szentes (2010), a principal cannot commit to an action schedule that conditions his action choice directly on action choices made by the other principals (This is the standard approach in the competing mechanism games. If it is possible, a contract is contractible (Peters and Szentes 2012)). Furthermore, a subset of actions determined by agents' messages is not observable by any other principals because messages are private. These imply that it does not matter whether or not a principal's action itself is observable or not given that each principal simultaneously chooses his action from a subset of actions determined by agents' messages to him. A key intuition behind Szentes' critique is that a principal can raise his payoff if he has a freedom to choose an action even after agents send messages.

principal's action and the equilibrium allocation is preserved by a truth-telling equilibrium. Therefore, in a model with a single principal, the mechanism design with set-valued mechanisms in Szentes (2010) or general mechanisms in this paper is no different from the mechanism design with the single-valued mechanisms. Szentes shows that such an equivalence breaks down in a model of complete information with multiple principals.

1.2 Main Results

This paper first identifies the utility environment and various notions of robust PBE under which the set of equilibrium allocations is characterized by incentive compatible direct mechanisms. Further, it clearly shows the types of robust PBE allocations for which Szentes' critique is valid.

We are interested in an allocation that can be supportable in an equilibrium where any principal j cannot gain regardless of a profile of agents' continuation equilibrium strategies of communicating with j upon his deviation to any general mechanism, taking as given a profile of their continuation equilibrium strategies of communicating with non-deviating principals. We call it a *robust perfect Bayesian equilibrium* (PBE).

One interesting variant of robust PBE is that each agent's strategy of communicating with a non-deviating principal does not depend on the other principals' mechanisms. That is, her communication with a non-deviating principal is invariant to market information. If a PBE is robust and invariant to market information, I call it a *market-information invariant robust PBE*.

The notion of robust PBE is stronger than that of PBE because an allocation can be supported in a PBE as long as there exists a continuation equilibrium in which a principal cannot gain upon deviation. However, it is weaker than the notion of strongly robust PBE (Epstein and Peters (1999), Han (2007)) in which a principal cannot gain in all continuation equilibria agents may play upon his deviation. I formulate a notion of *uniquely implementable robust PBE*. A robust PBE is uniquely implementable if any profile of agents' continuation equilibrium strategies of communicating with a non-deviating principal induces the same BIC direct mechanism on the path or off the path following a competing principal's deviation respectively. If a robust PBE is uniquely implementable, the notion of robust PBE *coincides* with that of strongly robust PBE. Once players reach a uniquely implementable robust PBE, not only is there no continuation equilibrium where a principal can gain off the equilibrium path following his

deviation, but every possible continuation equilibrium on the equilibrium path induces the same equilibrium allocation.

If each agent's utility function is additively separable with respect to principals' actions, I can define an individually Bayesian incentive compatible (BIC) direct mechanism for each principal j . Then, a BIC profile of principals' direct mechanisms is a profile of principals' individually BIC direct mechanisms.

I first consider the competing BIC direct mechanism game where a principal is restricted to offer only a BIC direct mechanism. Not only does a (truth-telling) PBE in the competing BIC direct mechanism game exist but it is also robust. Furthermore, the set of market-information invariant robust PBE allocations in any general competing mechanism game is the same as the set of a (truth-telling) PBE allocation, denoted by Π_B^* , in the competing BIC direct mechanism game. Therefore, any (truth-telling) PBE in the competing BIC direct mechanism game is free from Szentes' critique.

Secondly, for the characterization of uniquely implementable robust PBE allocations, I extend the result from Bayesian implementation (Palfrey and Srivastava (2018)). That is, if a profile of direct mechanisms $\pi^* = (\pi_1^*, \dots, \pi_j^*)$ is uniquely implementable in a robust PBE, then (i) π^* is a (truth-telling) PBE allocation in the competing BIC direct mechanism game (i.e., $\pi^* \in \Pi_B^*$) and (ii) each π_j^* satisfies Bayesian monotonicity.² Let Π_{UB}^* be the set of profiles BIC direct mechanisms that satisfies (i) and (ii). I can show Π_{UB}^* is indeed the set of uniquely implementable robust PBE allocations in a general equilibrium when well-established additional conditions are satisfied.³ Furthermore, a uniquely implementable robust PBE is also free from Szentes' critique.

Generally, the set of robust PBE allocations is big. Specifically, it is the set of all profiles of BIC direct mechanisms that induces each principal j 's utility no less than his *minmax* utility value over BIC direct mechanisms (Let's denote it by Π_{RB}^*). Let us explain the key idea. In a general competing mechanism game, principal j can offer a mechanism where the message space for himself is the set that includes all of his BIC direct mechanisms Π_j^B and the message space for each agent is her type space. In this mechanism, principal j chooses his BIC direct mechanism π_j from Π_j^B and agents send type messages to j at the same time and subsequently π_j determines j 's action conditional on agents' messages. The notion of robust PBE makes it possible for j to implement any BIC direct mechanism π_j from Π_j^B . Given j 's belief on BIC direct

²Condition (i) in a single-principal case is just the incentive compatibility of the direct mechanism. See Definition 3.1 for Bayesian monotonicity in Palfrey and Srivastava (2018).

³For the additional conditions, see Palfrey and Srivastava (2018).

mechanisms induced by non-deviators' mechanisms, principal j can then choose his BIC direct mechanism π_j from Π_j^B that maximizes his utility. Therefore, principal j 's utility in a robust PBE of a general competing mechanism game cannot be lower than his minmax values over individually BIC direct mechanisms.

This paper then shows that any profile of BIC direct mechanisms that generates a utility for each principal no less than his minmax value can be supported in a robust PBE where each principal j offers a deviator-reporting mechanism which asks agents to report only the identity of a deviating principal along with their payoff types. If a majority of agents report j , then deviator-reporting mechanisms assign individually BIC direct mechanisms that lead to j 's minmax value: Otherwise, they assign individually BIC direct mechanisms that are supposed to be implemented in an equilibrium.

Note that we have that

$$\Pi_{UB}^* \subset \Pi_B^* \subset \Pi_{RB}^*.$$

All three sets are independent of the set of general mechanisms allowed in competing mechanism games, and they are all specified in terms of BIC direct mechanisms. One may view my paper as one that identifies the notions of PBEs that produce those sets of allocations as the sets of equilibrium allocations in a general competing mechanism game respectively.

For a robust PBE, the standard competing mechanism game is restrictive in the sense that it takes the freedom of choosing any BIC direct mechanism away from a principal at the same time agents send messages to him given his mechanism. In the standard competing mechanism game, a deviating principal's utility can be as low as his *maxmin* value. The reason is that agents' communication with the deviator alone induces a BIC direct mechanism from the deviator's mechanism and non-deviators can choose their BIC direct mechanisms conditional on agents' reports on the deviator's BIC direct mechanism that they induce from the deviator's mechanism.

When random mechanisms are allowed as in our paper and there are only two principals, the restrictive feature of the standard competing mechanism game is not a problem because each principal's minmax value over individually BIC direct mechanisms is equal to his maxmin value. However, the equivalence between the minmax and maxmin values are not extended to the case with three or more principals. My results show that Szentes' critique on the standard competing mechanism game of complete information is also valid in a model of incomplete information, regarding the set of allocations supportable in robust PBEs where agents' strategies of communicating with non-deviating

principals and their induced BIC direct mechanisms are responsive to market changes. However, allocations supportable in market-information invariant robust PBEs are free from Szentes' critique.

Section 1.3 provides the related literature review. Section 2 sets out the model for general competing mechanism games. Section 3 formalizes the three notions of robust PBE. In Section 4, I characterize the set of market-information invariant PBE allocations and the set of uniquely implementable robust PBE allocations. In Section 5, I characterize the set of robust PBE allocations. Section 6 provides discussions related to the results established in this paper.

1.3 Related literature

While this paper imposes the separability on the agent's utility function, it allows for interdependent values of payoff types, an agent's utility depends on actions chosen by all principals, and there are no restrictions on the principal's utility function. In my companion paper (Han (2022)), I considered a particular environment where (i) an agent can choose only one principal for trading and her utility depends on only the action of the principal she chooses and her type (i.e. private value) and (ii) utility functions for all players are linear and there are also no externalities on the principal side. Han (2022) focuses on the specific (but tractable) competition model where a principal's general contract chooses his dominant-strategy incentive compatible direct mechanism as a function of messages sent by all agents before they choose their trading principals; each agent subsequently sends her true type to the principal she chooses.⁴ The focus in Han (2022) is to characterize the equilibrium allocations conditional on truthful type reporting to the trading principal in the specific competition model, show the validity of Szentes' critique based on such equilibria, and provide comparative statics on equilibrium profits and prices in applications.

In common agency (i.e., multiple principals and a single agent), Han (2012), Peters (2003, 2007), and Attar et al. (2008) identify the restrictions on the players' preference ordering with which there is no loss of generality for principals to focus on take-it-or-leave-it offers or incentive-compatible direct mechanisms. The "no externalities" condition imposed in Peters (2003, 2007) focused on games where an agent's payoff type

⁴Extending the DIC-BIC equivalence in Gershkov, et al. (2013), Han (2022) shows that when all the other principals offer such general contracts, a principal has no incentive to deviate to any arbitrary general contract in the sense that there exists a continuation equilibrium that punishes a principal upon his deviation to an arbitrary general contract.

does not affect her preference ordering and it does not allow that a principal’s utility depends on competing principals’ actions. A separability on the agent’s preference ordering is imposed in Attar et al. (2008) for common agency but I impose none of the following restrictions: (i) the no indifference condition in Attar et al. (2008) that an agent is never indifferent between any pair of actions from any principals⁵, (ii) the “no externalities” condition imposed on principals’ preference ordering in Peters (2003, 2007), (iii) the monotonicity condition in Han (2012). In contrast to these papers, I formulate the notion of robust equilibrium such that it is sufficient to impose only the separability on agents’ preference ordering for the characterization of the set of all robust equilibrium allocations in terms of BIC direct mechanisms in general competing mechanism games with multiple principals and multiple agents.

It is worthwhile to mention that mechanism design approaches considered in Szentes (2010) and this paper are different from contracting with limited commitment considered by Bester and Strausz (2000, 2010) and Dorval and Skreta (2018) in a model with a single principal. In Bester and Strausz (2000, 2010), a principal cannot specify the set of the actions that he can choose conditional on agents’ messages. Because of that, the standard Revelation Principle does not hold even with a single principal (Bester and Stausz (2000)). What the principal can design is rather a communication device that generates a publicly observable output message conditional on an agent’s private input message (Bester and Strausz (2010)). While the principal designs a communication device, he observes only the output message and this output message does not restrict the set of actions that the principal can choose. Given the posterior belief conditional on the output message, the principal chooses his action. Dorval and Skreta (2018) applies the limited commitment approach to a model with an agent’s persistent type in multiple periods: The principal’s action choice in the current period is independent of an agent’s output messages observed from previous communication devices.

On the other hand, the class of mechanisms considered in Szentes (2010) and in this paper still allows a principal to commit to a mechanism that specifies a subset of a principal’s actions as a function of agents’ messages sent to him.⁶ As pointed out

⁵We believe that for common agency as in Attar, et al. (2008), only the separability condition is needed for the Revelation Principle for robust equilibrium formulated in our paper without the no indifference condition.

⁶These approaches assume the full commitment. A principal may want to offer a more general mechanism than a standard (single-valued) mechanism even if he can offer any standard mechanism. In fact, the set of standard mechanisms is a strict subset of the set of general mechanisms. On the other hand, the literature on contract design with limited commitment assumes that a principal can offer neither a general mechanism nor a standard mechanism.

in footnote 8, when there is only one principal in a model, the standard Revelation Principle holds for the class of mechanisms considered in Szentes (2010) and my paper. Therefore, for a model with a single principal, the class of mechanisms considered in Szentes (2010) and this paper generates the same set of equilibrium allocations that are generated by the class of standard mechanisms in which agents' messages uniquely determines a principal's action. Szentes (2010) shows that's not the case in a model of complete information with multiple principals by showing that a principal can raise the greatest lower bound of his equilibrium utility by using the class of mechanisms in which agents' messages only determines a subset of actions from which a principal can choose his action. I show that this result can be extended to a model of incomplete information with multiple principals.

2 General Competing Mechanisms

Throughout the paper, I assume that a set is a compact metric space. When a measurable structure is necessary, the corresponding Borel σ algebra is used. For a set Z , $\Delta(Z)$ denotes the set of Borel probability distributions on X . For any mapping L from S into Q , $L(S)$ denotes the image set of L .

There are J principals and I agents. Let $\mathcal{J} = \{1, \dots, J\}$ be the collection of principals and $\mathcal{I} = \{1, \dots, I\}$ the the collection of agents with $J \geq 2$ and $I \geq 3$. Agent i 's payoff type is denoted by $x_i \in X_i$. Let $x = (x_1, \dots, x_I) \in X = X_1 \times \dots \times X_I$ denote a profile of types, which is drawn from a probability distribution $F \in \Delta(X)$. Each principal j takes his action $a_j \in A_j$. Let $a = (a_1, \dots, a_J) \in A = A_1 \times \dots \times A_J$ denote a profile of actions. For all $a \in A$ and all $x \in X$, principal j 's utility is $v_j(a, x)$ and agent i 's utility is $u_i(a, x)$.

Each players's preference relation satisfies the von Neumann-Morgenstern expected utility property. I assume that each agent's utility function is *additively separable* with respect to principals' actions. That is, for all $a \in A$ and all $x \in X$, agent i 's utility takes the form of

$$u_i(a, x) = \sum_{k=1}^J u_{ik}(a_k, x). \quad (1)$$

Notably, (1) allows a quasilinear representation of an agent's preference relation. For example, let $a_j = (y_j, t_j)$, where y_j is a non-monetary (multidimensional) component of principal j 's action and $t_j = (t_{0j}, t_{1j}, \dots, t_{Ij})$ is a profile of monetary transfers with t_{0j}

for principal j himself and t_{ij} for agent i for all $i \in \mathcal{I}$. Then, (1) allows us to express agent i 's utility as $u_i(a, x) = \sum_{k=1}^J h_{ik}(y_k, x) + T_i$ with $T_i = \sum_{k=1}^J t_{ik} + m_i$ for agent i 's initial amount of money $m_i \in \mathbb{R}_+$.

While (1) imposes the separability on the agent's utility function, it is quite general in terms of the nature of actions, how principals' actions affect a player's utility, and how a player's utility depends on all agents' types. The equivalence between dominant-strategy implementation and Bayesian implementation in Gershkov, et al. (2013) is based on the restrictions that (i) agents' utility functions are linear, (ii) each agent's type has only *private value*, and (iii) a principal's action is $a = (n, m)$, where an alternative n belongs to a discrete and finite set $\{1, \dots, N\}$ and m is a vector of monetary transfers, one for each agent. Given that the agent's utility environment in my paper allows for *interdependent values* and generality of a principal's action, working with dominant strategy incentive compatible direct mechanisms for the characterization of equilibrium allocations loses its generality even with linear utility functions and monetary transfers.⁷

For a profile of random actions $(\alpha_1, \dots, \alpha_J) \in \Delta(A_1) \times \dots \times \Delta(A_J)$ and a profile of types $x \in X$, expected utilities for agent i and principal j are

$$\begin{aligned} U_i(\alpha_1, \dots, \alpha_J, x) &:= \int_{A_1} \dots \int_{A_J} u_i(a_1, \dots, a_J, x) d\alpha_J \times \dots \times d\alpha_1, \\ V_j(\alpha_1, \dots, \alpha_J, x) &:= \int_{A_1} \dots \int_{A_J} v_j(a_1, \dots, a_J, x) d\alpha_J \times \dots \times d\alpha_1. \end{aligned}$$

For each $i \in \mathcal{I}$, (1) allows us to express $U_i(\alpha_1, \dots, \alpha_J, x)$ as

$$U_i(\alpha_1, \dots, \alpha_J, x) = \sum_{k=1}^J U_{ik}(\alpha_k, x), \quad (2)$$

where $U_{ik}(\alpha_k, x) := \int_{A_k} u_{ik}(a_k, x) d\alpha_k$. Note that U_i and V_j are both linear in each $\Delta(A_j)$ for all $j \in \mathcal{J}$.

A major departure from the literature on competing mechanisms is to allow a principal to send a message to himself given his mechanism. Specifically, each principal j can offer a *general mechanism* that determines his action contingent on agents' messages and his own message. Let M_{ij} be the set of messages available for agent $i \in \mathcal{I}$. Let M_{0j} be the set of messages available for principal j himself. Let $M_j = \times_{k=0}^I M_{kj}$. A

⁷One may consider ex-post incentive compatible direct mechanisms for the case of interdependent types. However they are generally not equivalent to Bayesian incentive compatible direct mechanisms as shown in Gershkov, et al (2013).

mechanism is then a measurable mapping

$$\gamma_j : M_j \rightarrow \Delta(A_j).$$

Let Γ_j be the set of mechanisms available for principal j . Let $\Gamma = \Gamma_1 \times \cdots \times \Gamma_J$. Note that I allow for *random mechanisms*.

The class of mechanisms proposed in this paper is more general than a standard mechanism that specifies a principal's action contingent on agents' messages only. In terms of our formulation, a standard mechanism is the same as a mechanism $\gamma_j : M_j \rightarrow \Delta(A_j)$ such that for all $m_{0j}, m'_{0j} \in M_{0j}$ and all $(m_{1j}, \dots, m_{Ij}) \in \times_{k \neq 0} M_{kj}$,

$$\gamma_j(m_{0j}, m_{1j}, \dots, m_{Ij}) = \gamma_j(m'_{0j}, m_{1j}, \dots, m_{Ij}). \quad (3)$$

Let $\bar{\Gamma}_j$ be the set of mechanisms satisfying (3) for each $j \in \mathcal{J}$. Clearly $\bar{\Gamma}_j$ is a strict subset of Γ_j . Standard competing mechanism games (e.g., Epstein and Peters (1999), Han (2006), Yamashita (2010) among many) allow principal j to offer only a mechanism in $\bar{\Gamma}_j$. For notational simplicity, I drop the message set M_{0j} for any mechanism in $\bar{\Gamma}_j$ and denote a mechanism in $\bar{\Gamma}_j$ by a measurable mapping from $M_{1j} \times \cdots \times M_{Ij}$ into $\Delta(A_j)$.

Mechanisms in Γ or $\bar{\Gamma}$ are quite general in terms of the degree and nature of communication that they allow. For example, they are sufficiently general that there exists an embedding η_j from the set of individually BIC direct mechanisms for principal j defined in Section 3 into $\bar{\Gamma}_j$. $\bar{\Gamma}$ is also large enough to include mechanisms homeomorphic to deviator-reporting mechanisms and deviator's DM (direct mechanism) reporting mechanisms defined in Sections 4 and 5.

For a contract in Szentes (2010), there exists a strategically equivalent mechanism in Γ_j . Principal j 's contract proposed by Szentes (2010) is a measurable mapping $h_j : M_{1j} \times \cdots \times M_{Ij} \rightarrow \mathcal{P}(\Delta(A_j))$ in our environment, where $\mathcal{P}(\Delta(A_j))$ is the set of all subsets of $\Delta(A_j)$. In this contract, a profile of agents' messages (m_{1j}, \dots, m_{Ij}) first determines $h_j(m_{1j}, \dots, m_{Ij})$, a subset of $\Delta(A_j)$, from which principal j subsequently chooses his action. For such a contract, I can construct a strategically equivalent mechanism $\gamma_j : M_j \rightarrow \Delta(A_j)$. Let m_{0j} be a measurable mapping from $h_j(M_{1j} \times \cdots \times M_{Ij})$ (i.e., the image set of h_j) into $\Delta(A_j)$ with the property that for all $h_j(m_{1j}, \dots, m_{Ij}) \in h_j(M_{1j} \times \cdots \times M_{Ij})$, $m_{0j}(h_j(m_{1j}, \dots, m_{Ij})) \in h_j(m_{1j}, \dots, m_{Ij})$. Let M_{0j} be the set of all such measurable mappings. Let us define a mechanism $\gamma_j : M_j \rightarrow \Delta(A_j)$ such that for a

general contract h_j and all $(m_{0j}, m_{1j}, \dots, m_{Ij}) \in M_j$

$$\gamma_j(m_{0j}, m_{1j}, \dots, m_{Ij}) = m_{0j}(h_j(m_{1j}, \dots, m_{Ij})).$$

In a contract h_j , agents' messages determine a subset of actions and then principal j chooses an action from the subset. In the corresponding mechanism γ_j , principal j reports his contingency plan m_{0j} to himself, at the same time agents send messages to him, as to what action to choose as a function of the subset of actions determined by agents' messages. Therefore, the set of contracts in Szentes (2010) can be nested into Γ .

A general competing mechanism game with Γ starts when principals simultaneously offer their mechanisms from Γ . Given a profile of mechanisms $\gamma = (\gamma_1, \dots, \gamma_J)$, each agent sends a message to every principal and every principal sends a message only to himself at the same time. When principals and agents send messages, each principal j 's mechanism is only observed by agents but not by the other principals. According to each principal j 's mechanism γ_j , a profile of messages $m_j = (m_{0j}, m_{1j}, \dots, m_{Ij})$ determines his random action as $\gamma_j(m_j) \in \Delta(A_j)$. Finally, utilities are realized.

One may consider an alternative game where a principal inputs his message after observing the other principals' mechanisms. In terms of characterizing equilibrium allocations, it does not matter whether or not the other principals' mechanisms are observable by a principal when he inputs his message in his mechanism given three or more agents. The reason is that the message spaces can be sufficiently general that (i) agents are able to describe the other principals' mechanisms with their messages and (ii) a principal can input a message in his mechanism that describes a contingency plan with respect to all possible messages that agents could send, as explained earlier.

3 Notion of Equilibrium

I consider a pure-strategy equilibrium, as in Yamashita (2010), in the sense that principals use pure strategies for their mechanism choices. In this paper, mixed communication strategies are however allowed to such an extent that the existence of an equilibrium can be addressed, whereas Yamashita (2010) considers only pure communication strategies.

Let $c_{ij} : \Gamma \times X_i \rightarrow \Delta(M_{ij})$ denote agent i 's mixed strategy of communicating with principal j . Let $c_{0j} : \Gamma_j \rightarrow \Delta(M_{0j})$ be principal j 's mixed strategy of communicating

with himself. For all $\gamma \in \Gamma$ and all $x \in X$, let

$$g_j(\gamma_j, c_{0j}(\gamma_j), c_{1j}(\gamma, x_1), \dots, c_{Ij}(\gamma, x_I)) \\ := \int_{M_{0j}} \int_{M_{1j}} \cdots \int_{M_{Ij}} \gamma_j(m_{0j}, m_{1j}, \dots, m_{Ij}) dc_{0j}(\gamma_j) dc_{1j}(\gamma, x_1) \cdots dc_{Ij}(\gamma, x_I).$$

Given $\gamma = (\gamma_1, \dots, \gamma_J) \in \Gamma$, $g_j(\gamma_j, c_{0j}(\gamma_j), c_{1j}(\gamma, x_1), \dots, c_{Ij}(\gamma, x_I)) \in \Delta(A_j)$ is the probability distribution over A_j conditional on $x = (x_1, \dots, x_I)$ that is induced by (i) the strategies of communicating with principal j , $c_j(\gamma) = (c_{0j}(\gamma_j), c_{1j}(\gamma, \cdot), \dots, c_{Ij}(\gamma, \cdot))$ and (ii) principal j 's mechanism γ_j . Then,

$$g_j(\gamma_j, c(\gamma)) = g_j(\gamma_j, c_{0j}(\gamma_j), c_{1j}(\gamma, \cdot), \dots, c_{Ij}(\gamma, \cdot)) \quad (4)$$

is a mapping from $X \rightarrow \Delta(A_j)$, which is a *direct mechanism* induced by the communication strategies $c_j(\gamma)$ and principal j 's mechanism γ_j .⁸ Let us denote principal j 's direct mechanism by $\pi_j : X \rightarrow \Delta(A_j)$. Let Π_j be the set of all possible (measurable) mappings $\pi_j : X \rightarrow \Delta(A_j)$.

For $\gamma \in \Gamma$, agent i 's (ex-ante) expected utility is expressed as

$$\mathbb{E}_x [U_i(g_1(\gamma_1, c_1(\gamma, x)), \dots, g_J(\gamma_J, c_J(\gamma, x)), x)] = \sum_{k=1}^J \mathbb{E}_x [U_{ik}(g_k(\gamma_k, c_k(\gamma, x)), x)],$$

where $\mathbb{E}_x [\cdot]$ the expectation operator based on the probability distribution F over X for all $k \in \mathcal{J}$. For $\gamma \in \Gamma$, principal j 's (ex-ante) expected utility is denoted by $\mathbb{E}_x [V_j(g_1(\gamma_1, c_1(\gamma, x)), \dots, g_J(\gamma_J, c_J(\gamma, x)), x)]$.

Definition 1 For all $\gamma \in \Gamma$, $c(\gamma) = (c_1(\gamma), \dots, c_J(\gamma))$ is said to be a continuation equilibrium given γ if

⁸Suppose that there is only one principal in a model. Given a mechanism γ_1 offered by principal 1 (i.e., single principal), a profile of continuation-equilibrium communication strategies $c_1(\gamma_1)$ induces a Bayesian incentive compatible direct mechanism g_1 according to (4) in which only agents send type messages and the principal does not send a message to himself. Therefore, the standard Revelation Principle holds. This implies that in a model of a single principal, the class of mechanisms considered in Szentes (2010) and my paper is no different from the class of standard mechanisms in terms of the set of equilibrium allocations that it generates.

(i) for all $i \in \mathcal{I}$ and all her communication strategies $(c'_{i1}(\gamma, \cdot), \dots, c'_{iJ}(\gamma, \cdot))$

$$\sum_{k=1}^J \mathbb{E}_x [U_{ik}(g_k(\gamma_k, c_{0k}(\gamma_k), c_{1k}(\gamma, x_1), \dots, c_{Ik}(\gamma, x_I)), x)] \geq \sum_{k=1}^J \mathbb{E}_x [U_{ik}(g_k(\gamma_k, c_{0k}(\gamma_k), c'_{ik}(\gamma, x_i), c_{-ik}(\gamma, x_{-i})), x)],$$

where $c_{-ik}(\gamma, x_{-i}) = (c_{\ell k}(\gamma, x_{-\ell}))_{\ell \neq i}$ and

(ii) for all $j \in \mathcal{J}$ and all his communication strategies $c'_{0j}(\gamma)$,

$$\mathbb{E}_x [V_j(g_j(\gamma_j, c_j(\gamma, x)), g_{-j}(\gamma_{-j}, c_{-j}(\gamma, x)), x)] \geq \mathbb{E}_x [V_j(g_j(\gamma_j, c'_{0j}(\gamma), c_{-0,j}(\gamma, x)), g_{-j}(\gamma_{-j}, c_{-j}(\gamma, x)), x)], \quad (5)$$

where $c_{-0,j}(\gamma, x) = (c_{ij}(\gamma, x_i))_{i \in \mathcal{I}}$ and $g_{-j}(\gamma_{-j}, c_{-j}(\gamma, x)) = (g_k(\gamma_k, c_k(\gamma, x)))_{k \neq j}$.

Definition 1 is based on ex-ante expected utilities. Condition (i) in Definition 1 can be equivalently formulated with agents' interim expected utilities as follows: For all $i \in \mathcal{I}$, a.e. $x_i \in X_i$ and all $(\mu_{i1}, \dots, \mu_{iJ}) \in \Delta(M_{i1}) \times \dots \times \Delta(M_{iJ})$,

$$\sum_{k=1}^J \mathbb{E}_{x_{-i}} [U_{ik}(g_k(\gamma_k, c_{0k}(\gamma_k), c_{1k}(\gamma, x_1), \dots, c_{Ik}(\gamma, x_I)), x_{-i}, x_i) | x_i] \geq \sum_{k=1}^J \mathbb{E}_{x_{-i}} [U_{ik}(g_k(\gamma_k, c_{0k}(\gamma_k), \mu_{ik}, c_{-ik}(\gamma, x_{-i})), x_{-i}, x_i) | x_i], \quad (6)$$

where $\mathbb{E}_{x_{-i}}[\cdot | x_i]$ is the expectation operator based on the probability distribution over X_{-i} conditional on $x_i \in X_i$. Let $\mathcal{C}(\gamma)$ be the set of all continuation equilibria given γ . For all $\gamma \in \Gamma$, let $\mathcal{C}_j(\gamma)$ be the projection of $\mathcal{C}(\gamma)$ onto the space of strategies of communicating with principal j . For all $\gamma \in \Gamma$, let $\mathcal{C}_{-j}(\gamma)$ be the projection of $\mathcal{C}(\gamma)$ onto the space of strategies of communicating with principals except for j .

Definition 2 (γ^*, c^*) is a pure-strategy perfect Bayesian equilibrium (henceforth simply PBE) of a general competing mechanism game with Γ if (i) $c^*(\gamma) \in \mathcal{C}(\gamma)$ for all

$\gamma \in \Gamma$ and (ii) for all $j \in \mathcal{J}$ and all $\gamma_j \in \Gamma_j$,

$$\mathbb{E}_x [V_j (g_j (\gamma_j^*, c_j^*(\gamma^*, x)), g_{-j} (\gamma_{-j}^*, c_{-j}^*(\gamma^*, x)), x)] \geq \mathbb{E}_x [V_j (g_j (\gamma_j, c_j^*(\gamma_j, \gamma_{-j}^*, x)), g_{-j} (\gamma_{-j}^*, c_{-j}^*(\gamma_j, \gamma_{-j}^*, x)), x)]. \quad (7)$$

Yamashita (2010) and Xiong (2013) employ the notions of sequential equilibrium and subgame perfect Nash equilibrium respectively with finite types, whereas Szentes (2015) employs the notion of perfect Bayesian equilibrium in the model of contractible contracts. All these notions, including one defined in Definition 2 above, are in fact identical except for the extent to which mixed strategies are allowed. A common requirement of these equilibrium notions is that principals have no incentive to deviate as long as there exists a continuation equilibrium upon deviation where the deviating principal cannot gain.

A strongly robust equilibrium (Epstein and Peters (1999) and Han (2007)) is an alternative notion of equilibrium. In our general competing mechanism game, strongly robust PBE can be defined as follows.

Definition 3 (γ^*, c^*) is a strongly robust PBE of a general competing mechanism game with Γ if (i) it is a PBE and (ii) for all $j \in \mathcal{J}$, all $\gamma_j \in \Gamma_j$, and all $[c_j(\gamma_j, \gamma_{-j}^*), c_{-j}(\gamma_j, \gamma_{-j}^*)] \in \mathcal{C}_j(\gamma_j, \gamma_{-j}^*)$,

$$\mathbb{E}_x [V_j (g_j (\gamma_j^*, c_j^*(\gamma^*, x)), g_{-j} (\gamma_{-j}^*, c_{-j}^*(\gamma^*, x)), x)] \geq \mathbb{E}_x [V_j (g_j (\gamma_j, c_j(\gamma_j, \gamma_{-j}^*, x)), g_{-j} (\gamma_{-j}^*, c_{-j}(\gamma_j, \gamma_{-j}^*, x)), x)]. \quad (8)$$

Condition (ii) in Definition 3 is equivalent to the following condition: For all j and all $\gamma_j \in \Gamma_j$

$$\mathbb{E}_x [V_j (g_j (\gamma_j^*, c_j^*(\gamma^*, x)), g_{-j} (\gamma_{-j}^*, c_{-j}^*(\gamma^*, x)), x)] \geq \sup_{[c_j(\gamma_j, \gamma_{-j}^*), c_{-j}(\gamma_j, \gamma_{-j}^*)] \in \mathcal{C}_j(\gamma_j, \gamma_{-j}^*)} \mathbb{E}_x [V_j (g_j (\gamma_j, c_j(\gamma_j, \gamma_{-j}^*, x)), g_{-j} (\gamma_{-j}^*, c_{-j}(\gamma_j, \gamma_{-j}^*, x)), x)]$$

A principal's equilibrium utility in a strongly robust PBE is compared to his utility based on continuation equilibrium strategies of communicating with all principals that are *best* for him upon his deviation to any mechanism. The literature has not identified the set of strongly robust PBE allocations nor the greatest lower bound of each principal's strongly robust PBE utility even in terms of mechanisms allowed in the game.

I propose a new notion of equilibrium. For all $\gamma \in \Gamma$, all $c_{-j}(\gamma) \in \mathcal{C}_{-j}(\gamma)$, let us define the set of strategies of communicating with principal j as follows

$$\mathcal{C}_j(\gamma|c_{-j}(\gamma)) := \{c_j(\gamma) : (c_j(\gamma), c_{-j}(\gamma)) \in \mathcal{C}(\gamma)\}.$$

Definition 4 (γ^*, c^*) is a robust PBE of a general competing mechanism game with Γ if

- (i) $c^*(\gamma) \in \mathcal{C}(\gamma)$ for all $\gamma \in \Gamma$ and
- (ii) for all $j \in \mathcal{J}$, all $\gamma_j \in \Gamma_j$, and all $c_j(\gamma_j, \gamma_{-j}^*) \in \mathcal{C}_j(\gamma_j, \gamma_{-j}^*|c_{-j}^*(\gamma_j, \gamma_{-j}^*))$,

$$\mathbb{E}_x [V_j(g_j(\gamma_j^*, c_j^*(\gamma_j^*, x)), g_{-j}(\gamma_{-j}^*, c_{-j}^*(\gamma_j^*, x)), x)] \geq \mathbb{E}_x [V_j(g_j(\gamma_j, c_j(\gamma_j, \gamma_{-j}^*, x)), g_{-j}(\gamma_{-j}^*, c_{-j}^*(\gamma_j, \gamma_{-j}^*, x)), x)]. \quad (9)$$

A PBE (γ^*, c^*) is robust if any principal j cannot gain regardless of a profile of agents' continuation equilibrium strategies $c_j(\gamma_j, \gamma_{-j}^*)$ of communicating with j upon his deviation to any general mechanism γ_j , taking as given the profile of their continuation equilibrium strategies $c_{-j}^*(\gamma_j, \gamma_{-j}^*)$ of communicating with non-deviating principals.

One interesting variation of robust PBE is one where an agent's communication with a non-deviating principal does not depend on any other principal's mechanisms. That is,

$$c_j^*(\gamma_j^*, \gamma_{-j}^*) = c_j^*(\gamma_j^*, \gamma'_{-j}) \quad \forall j \in \mathcal{J}, \forall \gamma_{-j}, \gamma'_{-j} \in \Gamma_{-j} \quad (10)$$

given a robust PBE (γ^*, c^*) .

Definition 5 A robust PBE (γ^*, c^*) is a market-information invariant if it satisfies (10).

In a market-information invariant robust PBE, each agent's communication with a non-deviating principal only depends on her type and the principal's equilibrium mechanism.

I also formulate a uniquely implementable robust PBE as follows.

Definition 6 A robust PBE (γ^*, c^*) is uniquely implementable if, for all $j \in \mathcal{J}$, all $k \neq j$ and all $\gamma_j \in \Gamma_j$

$$g_k(\gamma_k^*, c_k(\gamma_j, \gamma_{-j}^*)) = g_k(\gamma_k^*, c'_k(\gamma_j, \gamma_{-j}^*)) \in \Pi_j^B, \quad \forall c_k(\gamma_j, \gamma_{-j}^*), c'_k(\gamma_j, \gamma_{-j}^*) \in \mathcal{C}_k(\gamma_j, \gamma_{-j}^*) \quad (11)$$

Fix a path in the game after principals' mechanism announcement: either equilibrium path $\gamma_j = \gamma_j^*$ or off the equilibrium path following a principal j 's unilateral deviation to an arbitrary general mechanism $\gamma_j \neq \gamma_j^*$. Given such a path, any profile of continuation-equilibrium strategies of communicating with each non-deviating principal k always induces the same BIC direct mechanism for k . This implies that if a robust PBE is uniquely implementable, it is also strongly robust. Furthermore, not only is there no continuation equilibrium where a principal can gain off the equilibrium path following his deviation, but there is a unique equilibrium allocation regardless of a continuation-equilibrium agents play on the equilibrium path.

4 Competing BIC direct mechanisms

In this section, I provide the characterizations of market-information invariant robust PBE allocations and uniquely implementable robust PBE allocations respectively. Let us first define incentive compatible direct mechanisms. A profile of direct mechanisms $\pi = (\pi_1, \dots, \pi_J)$ is *Bayesian incentive compatible* (BIC) if for all $i \in \mathcal{I}$, a.e. $x_i \in X_i$, and all $x_{i1}, \dots, x_{iJ} \in X_i$

$$\mathbb{E}_{x_{-i}} [U_i(\pi_1(x), \dots, \pi_J(x), x_{-i}, x_i) | x_i] \geq \mathbb{E}_{x_{-i}} [U_i(\pi_1(x_{i1}, x_{-i}), \dots, \pi_J(x_{iJ}, x_{-i}), x_{-i}, x_i) | x_i]. \quad (12)$$

Let Π^B be the set of all BIC profiles of direct mechanisms.

Principal j 's direct mechanism is *individually BIC* if for all $i \in \mathcal{I}$, a.e. $x_i \in X_i$, and $x_{ij} \in X_i$,

$$\mathbb{E}_{x_{-i}} [U_{ij}(\pi_j(x_i, x_{-i}), x_{-i}, x_i) | x_i] \geq \mathbb{E}_{x_{-i}} [U_{ij}(\pi_j(x_{ij}, x_{-i}), x_{-i}, x_i) | x_i]. \quad (13)$$

Let Π_j^B be the set of all individually BIC direct mechanisms for principal j . Lemma 1 below shows that the set of BIC profiles of direct mechanisms is the Cartesian product of individually BIC direct mechanisms. This is due to the additive separability of the agent's utility function with respect to principals' actions.

Lemma 1 $\Pi^B = \Pi_1^B \times \dots \times \Pi_J^B$.

Proof. Consider any BIC profile of direct mechanisms $\pi = (\pi_1, \dots, \pi_J) \in \Pi^B$. Because

π is BIC as a whole, I have that for all $j \in \mathcal{J}$, all $i \in \mathcal{I}$, a.e. $x_i \in X_i$, and all $x_{ij} \in X_i$,

$$\sum_{k=1}^J \mathbb{E}_{x_{-i}} [U_{ik}(\pi_k(x), x_{-i}, x_i) | x_i] \geq \mathbb{E}_{x_{-i}} [U_{ij}(\pi_j(x_{ij}, x_i), x_{-i}, x_i) | x_i] + \sum_{k \neq j} \mathbb{E}_{x_{-i}} [U_{ik}(\pi_k(x), x_{-i}, x_i) | x_i],$$

The inequality above implies that for all $i \in \mathcal{I}$, a.e. $x_i \in X_i$, and all $x_{ij} \in X_i$,

$$\mathbb{E}_{x_{-i}} [U_{ij}(\pi_j(x_i, x_{-i}), x_{-i}, x_i) | x_i] \geq \mathbb{E}_{x_{-i}} [U_{ij}(\pi_j(x_{ij}, x_{-i}), x_{-i}, x_i) | x_i].$$

This means that π_j is individually BIC and hence $\pi_j \in \Pi_j^B$ for all $j \in \mathcal{J}$. Therefore, $\pi = (\pi_1, \dots, \pi_J) \in \Pi_1^B \times \dots \times \Pi_J^B$.

It is straightforward to show that any profile of individually BIC direct mechanisms $\pi = (\pi_1, \dots, \pi_J) \in \Pi_1^B \times \dots \times \Pi_J^B$ is also a BIC profile of direct mechanisms, i.e., $\pi = (\pi_1, \dots, \pi_J) \in \Pi^B$. ■

I consider the competing BIC direct mechanism game where each principal is restricted to offer only a BIC direct mechanism in Π_j^B .

Definition 7 $\pi = (\pi_1, \dots, \pi_J) \in \Pi^B$ is a profile of equilibrium BIC direct mechanisms in a (truth-telling) PBE of the competing mechanism game with Π^B if for all $j \in \mathcal{J}$,

$$\mathbb{E}_x [V_j(\pi_j(x), \pi_{-j}(x), x)] \geq \mathbb{E}_x [V_j(\pi'_j(x), \pi_{-j}(x), x)] \quad \forall \pi'_j \in \Pi_j^B \quad (14)$$

Now I show that the strategy space for each principal j in the the competing mechanism game with Π^B is non-empty, convex and compact.

Proposition 1 Π_j^B is non-empty, convex, and compact for all $j \in \mathcal{J}$.

Proof. Π_j^B is non-empty because a constant direct mechanism is BIC. It is also a compact convex set. It is straightforward to show that Π_j^B is a convex set because $\lambda\pi_j + (1 - \lambda)\pi'_j$ is also BIC for all $\pi_j, \pi'_j \in \Pi_j^B$ and all $\lambda \in [0, 1]$.

Π_j^B is compact if and only if it is totally bounded and complete (See Theorem 3.11.2.2 in Kolmogorov and Fomin (1975)). To show that Π_j^B is totally bounded, it is enough to prove that Π_j^B is countably compact (See Theorem 3.11.2.1 in Kolmogorov and Fomin (1975)), i.e., every sequence in Π_j^B has a limit point in Π_j^B . Suppose that Π_j^B is not countably compact so that there is some sequence $\{\pi_j^n\} \in \Pi_j^B$ that has all its limit

point(s) in the complement of Π_j^B . The latter statement is equivalent to the statement that there exists some sequence $\{\pi_j^n\} \in \Pi_j^B$ such that if $\{\pi_j^{n_k}\} \subseteq \{\pi_j^n\}$ is any arbitrary convergent subsequence with limit $\pi_j^* \notin \Pi_j^B$. First, notice that $\{\pi_j^{n_k}\} \in \Pi_j^B$ since $\{\pi_j^{n_k}\} \subseteq \{\pi_j^n\} \in \Pi_j^B$. Now, because $\pi_j^* \notin \Pi_j^B$, there is some $i \in \mathcal{I}$ and some $D_i \subset X_i$ with positive measure such that $\pi_j^* \notin \Pi_j^B$ does not satisfy (13) for all $x_i \in D_i$. Because $\{\pi_j^{n_k}\}$ converges to π_j^* , there exists some $N_o \in \mathbb{N}$ such that $\{\pi_j^{n_k}\}$ also violates (13) for all $x_i \in D_i$ and all $n_k \geq N_o$. This contradicts the fact that $\{\pi_j^{n_k}\} \in \Pi_j^B$. Therefore, Π_j^B must be countably compact, which implies that Π_j^B is totally bounded.

Finally, I show that Π_j^B is complete. Recall that Π_j is the set of all possible (measurable) mappings $\pi_j : X \rightarrow \Delta(A_j)$. Therefore, clearly $\Pi_j^B \subset \Pi_j \subseteq L^p(X)$ with $1 < p < \infty$. Because $L^p(X)$ is complete, it suffices to show that Π_j^B is closed. Π_j^B is closed if and only if every convergent sequence $\{\pi_j^k\}$ in Π_j^B has its limit π_j^* in Π_j^B . On the contrary, suppose that there exists a convergent sequence $\{\pi_j^k\}$ in Π_j^B with $\pi_j^* \notin \Pi_j^B$, that is, for some $i \in \mathcal{I}$ and some $D'_i \in X_i$ with positive measure such that $\{\pi_j^k\}$ violates (13) for all $x_i \in D'_i$. Because $\{\pi_j^k\}$ converges to π_j^* , there exists some $K \in \mathbb{N}$ such that $\{\pi_j^k\}$ also violates (13) for all $x_i \in D'_i$ and all $k \geq K$. This contradicts the fact that $\{\pi_j^k\} \in \Pi_j^B$. Thus, Π_j^B is closed. ■

Given Proposition 1, the existence of a PBE BIC direct mechanisms is straightforward.

Corollary 1 *A (truth-telling) PBE exists in the competing mechanism game with Π^B*

Proof. Because each Π_j^B is non-empty compact convex (Proposition 1) and $\mathbb{E}_x [V_j(\pi(x), x)]$ is linear in each Π_j^B , there exists a PBE in the competing mechanism game with Π^B (Glicksberg 1952, Fudenberg and Tirole 1991). ■

Furthermore, any (truth-telling) PBE in competing BIC direct mechanisms is robust.

Proposition 2 *A (truth-telling) PBE in the competing mechanism game with Π^B is robust.*

Proof. Suppose that principal j deviates to π'_j . Agents choose any arbitrary profile $[c_{1j}(\pi'_j, \pi_j \cdot), \dots, c_{Ij}(\pi'_j, \pi_j \cdot)]$ of continuation equilibrium strategies of communicating with j , given their truthful type reporting to non-deviating principals. Then, $[c_{1j}(\pi'_j, \pi_j \cdot), \dots, c_{Ij}(\pi'_j, \pi_j \cdot)]$ induces a direct mechanism π''_j such that for all $(x_1, \dots, x_I) \in$

X

$$\pi_j''(x_1, \dots, x_I) = \int_{X_1} \cdots \int_{X_I} \pi_j'(x_{1j}, \dots, x_{Ij}) dc_{1j}(\pi_j', \pi_j, x_1) \cdots dc_{Ij}(\pi_j', \pi_j, x_I)$$

and $\pi_j'' \in \Pi_j^B$. Because of (14), I have that

$$\mathbb{E}_x [V_j(\pi_j(x), \pi_{-j}(x), x)] \geq \mathbb{E}_x [V_j(\pi_j''(x), \pi_{-j}(x), x)].$$

■

4.1 Market-information invariant robust PBE allocations

Now I show that the set of market-information invariant robust PBE allocations in a competing mechanism game with Γ is the set of (truthful) PBE allocations in the competing direct mechanism game with Π^B . To establish the equivalence, first recall that given $\gamma \in \Gamma$, a profile of communication strategies $c(\gamma)$ induces a direct mechanism $g_j(\gamma_j, c_{0j}(\gamma_j), c_{1j}(\gamma, \cdot), \dots, c_{Ij}(\gamma, \cdot))$ for each principal $j \in \mathcal{J}$.

Lemma 2 *Given any $\gamma \in \Gamma$ and any $c_j(\gamma) = (c_{0j}(\gamma_j), c_{1j}(\gamma, \cdot), \dots, c_{Ij}(\gamma, \cdot)) \in \mathcal{C}_j(\gamma)$,*

$$g_j(\gamma_j, c_{0j}(\gamma_j), c_{1j}(\gamma, \cdot), \dots, c_{Ij}(\gamma, \cdot)) \in \Pi_j^B \text{ for all } j \in \mathcal{J}$$

Proof. Fix a profile of mechanisms $\gamma \in \Gamma$ and a continuation equilibrium $c_j(\gamma) \in \mathcal{C}_j(\gamma)$. Suppose that $g_j(\gamma_j, c_{0j}(\gamma_j), c_{1j}(\gamma, \cdot), \dots, c_{Ij}(\gamma, \cdot))$ is not individually BIC. That means that for some j , some i , some $B_i \subset X_i$ with $F(B_i, X_{-i}) > 0$, and all $x_i \in B_i$, there exists $x'_i \neq x_i$ such that

$$\begin{aligned} \mathbb{E}_{x_{-i}} [U_{ij}(g_j(\gamma_j, c_{0j}(\gamma_j), c_{-ij}(\gamma, x_{-i}), c_{ij}(\gamma, x'_i)), x_{-i}, x_i) | x_i] > \\ \mathbb{E}_{x_{-i}} [U_{ij}(g_j(\gamma_j, c_{0j}(\gamma_j), c_{-ij}(\gamma, x_{-i}), c_{ij}(\gamma, x_i)), x_{-i}, x_i) | x_i]. \end{aligned}$$

This contradicts that $c_{ij}(\gamma, \cdot)$ is agent i 's continuation-equilibrium strategy of communicating with principal j given γ . Therefore, $g_j(\gamma_j, c_{0j}(\gamma_j), c_{1j}(\gamma, \cdot), \dots, c_{Ij}(\gamma, \cdot))$ must be individually BIC for all $j \in \mathcal{J}$. ■

Let Π_B^* be the set of all equilibrium allocations in (truth-telling) PBEs of the

competing direct mechanism with Π^B :

$$\Pi_B^* := \{ \pi \in \Pi^B : \mathbb{E}_x [V_j(\pi_j(x), \pi_{-j}(x), x)] \geq \mathbb{E}_x [V_j(\pi'_j(x), \pi_{-j}(x), x)] \quad \forall \pi'_j \in \Pi_j^B \}$$

Because of Corollary 1, Π_B^* is non-empty. Let Π_{MR}^* be the set of all market-information invariant robust PBE allocations in a general competing mechanism game with Γ :

$$\Pi_{MR}^* := \left\{ \begin{array}{l} (g_k(\gamma_k^*, c_{01}^*(\gamma_k^*), c_{1k}^*(\gamma^*, \cdot), \dots, c_{Ik}^*(\gamma^*, \cdot)))_{k \in \mathcal{J}} \in \Pi^B : \\ (\gamma^*, c^*) \text{ is a market-information invariant robust PBE.} \end{array} \right\}.$$

Theorem 1 $\Pi_{MR}^* = \Pi_B^*$

Proof. First of all, I prove that $\Pi_{MR}^* \supseteq \Pi_B^*$. Fix $\pi^* = (\pi_1^*, \dots, \pi_J^*) \in \Pi_B^*$. For each j and i , let M_{ij} be homeomorphic to X_i , that is, there is a homeomorphism $\phi_{ij} : X_i \rightarrow M_{ij}$. In a competing general competing mechanism game with Γ , each principal j offers γ_j^* such that $\gamma_j^*(m_{0j}, \phi_{1j}(x_1), \dots, \phi_{Ij}(x_I)) = \pi_j(x_1, \dots, x_I)$ for all $m_{0j} \in M_{0j}$ and all $(x_1, \dots, x_I) \in X$. Because $\pi^* = (\pi_1^*, \dots, \pi_J^*) \in \Pi_B^*$, it is agent i 's continuation-equilibrium strategy to use

$$c_{ij}^*(\gamma_j^*, \gamma_{-j}, x_i) = \phi_{ij}(x_i) \quad (15)$$

for communicating with principal j for all $\gamma_{-j} \in \Gamma_{-j}$ and all $x_i \in X_i$. Since principal j has no role in determining his action in γ_j , I let $c_{0j}^*(\gamma_j^*) = m_{0j}$ for some $m_{0j} \in M_{0j}$. This implies that $\pi^* = (\pi_1^*, \dots, \pi_J^*) \in \Pi^B$ is principal j 's utility on the equilibrium path in a competing general competing mechanism game with Γ .

Suppose that principal j deviates to $\gamma'_j \in \Gamma_j$. Conditional on a profile of strategies of communicating with non-deviating principals $c_{-j}^*(\gamma_{-j}^*, \gamma'_j)$, suppose that agents choose a profile of strategies of communicating with principal j , $c_j(\gamma'_j, \gamma_{-j}^*) \in \mathcal{C}_j(\gamma'_j, \gamma_{-j}^* | c_{-j}^*(\gamma_{-j}^*, \gamma'_j))$. The strategy profile $c_j(\gamma'_j, \gamma_{-j}^*)$ induces a BIC direct mechanism $g_j(\gamma'_j, c_j(\gamma'_j, \gamma_{-j}^*)) \in \Pi_j^B$. Because of (15), the continuation-equilibrium utility for principal j becomes

$$\mathbb{E}_x [V_j(g_j(\gamma'_j, c_j(\gamma'_j, \gamma_{-j}^*), x)), \pi_{-j}^*(x), x)].$$

Because $\pi^* = (\pi_1^*, \dots, \pi_J^*) \in \Pi_B^*$, I have that

$$\begin{aligned} & \mathbb{E}_x [V_j(\pi_j^*(x), \pi_{-j}^*(x), x)] \geq \\ & \mathbb{E}_x [V_j(g_j(\gamma'_j, c_j(\gamma'_j, \gamma_{-j}^*), x)), \pi_{-j}^*(x), x)] \quad \forall c_j(\gamma'_j, \gamma_{-j}^*) \in \mathcal{C}_j(\gamma'_j, \gamma_{-j}^* | c_{-j}^*(\gamma_{-j}^*, \gamma'_j)). \end{aligned} \quad (16)$$

The inequality above show that $\pi^* = (\pi_1^*, \dots, \pi_j^*) \in \Pi_{MR}^*$ because the left-hand side is principal j 's utility on the equilibrium path in the competing general competing mechanism game with Γ given (15).

Second, I prove $\Pi_{MR}^* \subseteq \Pi_B^*$. Fix $\pi^* = (\pi_1^*, \dots, \pi_j^*) \in \Pi_{MR}^*$. Then, (16) is satisfied. For all $\gamma_j \in \Gamma_j$, let

$$G_j(\gamma_j) = \{g_j(\gamma_j, c_j(\gamma_j, \gamma_{-j}^*)) \in \Pi_j^B : c_j(\gamma_j, \gamma_{-j}^*) \in \mathcal{C}_j(\gamma_j, \gamma_{-j}^*)\}.$$

be the set of BIC direct mechanisms that are induced by all possible continuation equilibrium communication strategy profiles. Because of Lemma 2, $\bigcup_{\gamma_j \in \Gamma_j} G_j(\gamma_j) \subseteq \Pi_j^B$. To see

$\bigcup_{\gamma_j \in \Gamma_j} G_j(\gamma_j) \supseteq \Pi_j^B$, pick any $\pi_j \in \Pi_j^B$. Given a homeomorphism $\phi_{ij} : X_i \rightarrow M_{ij}$, I choose a general mechanism $\gamma_j(m_{0j}, \phi_{1j}(x_1), \dots, \phi_{Ij}(x_I)) = \pi_j(x_1, \dots, x_I)$ for all $m_{0j} \in M_{0j}$ and all $(x_1, \dots, x_I) \in X$. Then, $c_j(\gamma_j, \gamma_{-j}^*) = \{c_j(\gamma_j), c_{1j}(\gamma_j, \gamma_{-j}^*), \dots, c_{Ij}(\gamma_j, \gamma_{-j}^*)\} = \{m_{0j}, \phi_{1j}, \dots, \phi_{Ij}\}$ is a profile of continuation-equilibrium strategies of communicating with principal j and $\pi_j = g_j(\gamma_j, c_j(\gamma_j, \gamma_{-j}^*)) \in \bigcup_{\gamma_j \in \Gamma_j} G_j(\gamma_j)$. Therefore, I have

$$\bigcup_{\gamma_j \in \Gamma_j} G_j(\gamma_j) = \Pi_j^B \quad (17)$$

(16) and (17) imply that

$$\mathbb{E}_x [V_j(\pi_j^*(x), \pi_{-j}^*(x), x)] \geq \mathbb{E}_x [V_j(\pi'_j(x), \pi_{-j}^*(x), x)] \quad \forall \pi'_j \in \Pi_j^B,$$

which implies that $\pi^* = (\pi_1^*, \dots, \pi_j^*) \in \Pi_B^*$. ■

As long as our interest is the set of market-information invariant robust PBE allocations, it is enough to focus on equilibrium allocations in (truth-telling) PBEs of the competing BIC direct mechanism game. Such equilibrium allocations are supported when the BIC direct mechanism each non-deviating principal implements does not depend on whether a competing principal deviates or not. Furthermore, equilibrium allocations in (truth-telling) PBEs of the competing BIC direct mechanism game is free from Szentes' critique since $\Pi_{MR}^* = \Pi_B^*$.

4.2 Uniquely implementable robust PBE allocations

Fix a uniquely implementable robust PBE (γ^*, c^*) . $\pi_j^* = g_j(\gamma_j^*, c_j^*(\gamma^*))$ is principal j 's unique BIC direct mechanism on the equilibrium path. Given the additive separability of each agent's utility function, π_j^* is also his unique BIC direct mechanism off the path following a competing principal's deviation. Let Π_{UI}^* be the set of all market-information invariant robust PBE allocations in a general competing mechanism game with Γ :

$$\Pi_{UR}^* := \left\{ \begin{array}{l} (g_k(\gamma_k^*, c_{01}^*(\gamma_k^*), c_{1k}^*(\gamma^*, \cdot), \dots, c_{Ik}^*(\gamma^*, \cdot)))_{k \in \mathcal{J}} \in \Pi^B : \\ (\gamma^*, c^*) \text{ is a uniquely implementable robust PBE.} \end{array} \right\}.$$

Applying the results on Bayesian implementation in the literature, it is easy to see that a uniquely implementable robust PBE allocation $\pi^* = (\pi_1^*, \dots, \pi_J^*)$ in a competing mechanism game with Γ must satisfy

1. for all $j \in \mathcal{J}$, π_j^* satisfies Bayesian monotonicity (Definition 3.1 in Palfrey and Srivastava (2018))
2. π^* is a truth-telling PBE BIC direct mechanisms in the competing mechanism game with Π^B (i.e., $\pi^* \in \Pi_B^*$)

That is,

$$\Pi_{UR}^* \subseteq \Pi_{UB}^*, \tag{18}$$

where

$$\Pi_{UB}^* := \left\{ \begin{array}{l} \pi = (\pi_1, \dots, \pi_J) \in \Pi_B^* : \\ \pi_j \text{ satisfies Bayesian monotonicity } \forall j \in \mathcal{J} \end{array} \right\}$$

(18) is an extension of the necessary conditions for Bayesian implementation in Theorem 3.1 in Palfrey and Srivastava (2018). Furthermore, when additional conditions are satisfied, conditions 1 and 2 are sufficient conditions for a uniquely implementable robust PBE allocation in a competing mechanism game with Γ . That is,

$$\Pi_{UR}^* \supseteq \Pi_{UB}^* \tag{19}$$

These additional conditions are well established in the literature (Theorem 3.2 in Palfrey and Srivastava (2018)). All these results can be adopted seamlessly given the additive separability of each agent's utility function. From (18) and (19), we have

$$\Pi_{UR}^* = \Pi_{UB}^* \tag{20}$$

Note that

$$\Pi_{UB}^* \subset \Pi_B^*. \quad (21)$$

Given $\pi^* = (\pi_1^*, \dots, \pi_j^*)$ that satisfies conditions 1 and 2, each principal j 's equilibrium (indirect) mechanism can be constructed the same way that an indirect mechanism is constructed to implement a BIC direct mechanism with Bayesian monotonicity in a model with a single principal. In such an equilibrium mechanism, a principal does not send a message to himself and agents' messages fully determines his action.

Furthermore, a principal only need to evaluate his continuation-equilibrium payoff upon deviation to a BIC direct mechanism for a profitable deviation even if a deviation to a general mechanism is possible. Therefore, a uniquely implementable robust PBE is free from Szentes' critique.

5 Robust PBE allocations

Not every robust PBE allocation is market-information invariant. Some of them can be supported only when agents play a continuation equilibrium upon a principal's deviation that make non-deviating principals change their BIC direct mechanisms. In this section, I fully characterize the set of robust PBE allocations in the general competing mechanism game. The greatest lower bound of each principals' robust PBE utility in the general competing mechanism game is greater than that in the standard competing mechanism game. The same thing can be shown for the notion of PBE. One advantage of the notion of robust PBE is that the incentive compatibility alone is sufficient to characterize the set of robust equilibrium allocations given the additive separability of agents' utility functions. This point is explained in details in Section 6.

Let Π_R^* be the set of all robust PBE allocations of a general competing mechanism game with Γ :

$$\Pi_R^* := \left\{ (g_k(\gamma_k^*, c_{01}^*(\gamma_k^*), c_{1k}^*(\gamma^*, \cdot), \dots, c_{Ik}^*(\gamma^*, \cdot)))_{k \in \mathcal{J}} \in \Pi^B : (\gamma^*, c^*) \text{ is a robust PBE.} \right\}.$$

Our main result is that Π_R^* is characterized by only BIC direct mechanisms without reference to Γ . For all $j \in \mathcal{J}$, let

$$\underline{V}_j = \min_{\pi_{-j} \in \Pi_{-j}^B} \max_{\pi_j \in \Pi_j^B} \mathbb{E}_x [V_j(\pi_j(x), \pi_{-j}(x), x)]. \quad (22)$$

For $\pi = (\pi_1, \dots, \pi_J) \in \Pi^B$, principal j 's expected utility $\mathbb{E}_x [V_j(\pi_1(x), \dots, \pi_J(x), x)]$ and it is linear in each Π_j^B . Because each Π_j^B is compact according to Proposition 1, I can then apply Berge's Maximum Theorem (Aliprantis and Border (1999)) to show that $\min_{\pi_{-j} \in \Pi_{-j}^B} \max_{\pi_j \in \Pi_j^B} \mathbb{E}_x [V_j(\pi_j(x), \pi_{-j}(x), x)]$ is well defined.

Define

$$\Pi_{RB}^* := \{ \pi \in \Pi^B : \mathbb{E}_x [V_j(\pi(x), x)] \geq \underline{V}_j \text{ for all } j \in \mathcal{J} \}$$

Theorem 2

$$\Pi_R^* = \Pi_{RB}^*. \quad (23)$$

Proof. I first show that any robust PBE allocation must generate a utility no less than \underline{V}_j for all $j \in \mathcal{J}$. Fix a robust PBE (γ^*, c^*) . On contrary, suppose that for some $j \in \mathcal{J}$

$$\mathbb{E}_x [V_j (g_j (\gamma_j^*, c_j^*(\gamma^*, x)), g_{-j} (\gamma_{-j}^*, c_{-j}^*(\gamma^*, x)), x)] < \underline{V}_j. \quad (24)$$

Suppose that principal j unilaterally deviates to $\gamma'_j : M_j \rightarrow \Delta(A_j)$ such that, with a slight abuse of notation, (i) $M_{0j} = \Pi_j^B$, (ii) $M_{ij} = X_i$ for all $i \in \mathcal{I}$, (iii) for all $\pi_j \in M_{0j}$ and all $x_{ij} \in X_i$ for all $i \in \mathcal{I}$,

$$\gamma'_j (\pi_j, x_{1j}, \dots, x_{Ij}) = \pi_j (x_{1j}, \dots, x_{Ij}). \quad (25)$$

This is a general mechanism where principal j chooses his direct mechanism from Π_j^B and agents send their type messages at the same time.⁹

Now I can construct continuation-equilibrium strategies of communicating with principal j that provides a higher utility for principal j than his PBE utility, *given* continuation-equilibrium strategies $c_{-j}^*(\gamma'_j, \gamma_{-j}^*)$ of communicating with non-deviating principals. For this, I first show that I can keep continuation-equilibrium strategies $c_{-j}^*(\gamma'_j, \gamma_{-j}^*)$ of communicating with non-deviating principals regardless of continuation-equilibrium strategies of communicating with principal j .

Note that principal j 's deviation to γ'_j is not observable by non-deviating principals so that they do not change their messages to themselves, i.e., $c_{0k}(\gamma_k^*) = c_{0k}^*(\gamma_k^*)$ for all $k \neq j$. Now consider agents' communication with every principal $k \neq j$. Because $c^*(\gamma'_j, \gamma_{-j}^*)$ is a continuation equilibrium, I have that for all $k \neq j$, all $i \in \mathcal{I}$, a.e. $x_i \in X_i$

⁹A precise formulation of such a mechanism $\gamma'_j : M_j \rightarrow A_j$ can be given as follows. M_{ij} is homeomorphic to X_i , there exists a homeomorphism $\xi_{ij} : X_i \rightarrow M_{ij}$ and M_{0j} is homeomorphic to $\eta_j(\Pi_j^B)$, that is, there exists an homeomorphism $\varrho_{0j} : \eta_j(\Pi_j^B) \rightarrow M_{0j}$, where η_j is an embedding $\eta_j : \Pi_j^B \rightarrow \bar{\Gamma}_j$.

and all $\mu_{ik} \in \Delta(M_{ik})$,

$$\begin{aligned} \mathbb{E}_{x_{-i}} [U_{ik} (g_k (\gamma_k^*, c_{0k}^*(\gamma_k^*), c_{1k}^*(\gamma'_j, \gamma_{-j}^*, x_1), \dots, c_{Ik}^*(\gamma'_j, \gamma_{-j}^*, x_I)), x_{-i}, x_i) | x_i] \geq \\ \mathbb{E}_{x_{-i}} [U_{ik} (g_k (\gamma_k^*, c_{0k}^*(\gamma_k^*), \mu_{ik}, c_{-ik}^*(\gamma'_j, \gamma_{-j}^*, x_{-i})), x_{-i}, x_i) | x_i]. \end{aligned}$$

This implies that I can also keep each agent i 's strategy $c_{ik}^*(\gamma'_j, \gamma_{-j}^*, \cdot)$ of communicating with each non-deviating principal k for continuation-equilibrium strategies of communicating with principal j at $(\gamma'_j, \gamma_{-j}^*)$. Therefore, I fix

$$c_{-j}^*(\gamma'_j, \gamma_{-j}^*). \quad (26)$$

for continuation-equilibrium strategies of communicating with non-deviating principals regardless of continuation-equilibrium strategies of communicating with principal j .

Now consider how to construct continuation-equilibrium strategies of communicating with principal j that are best for principal j upon his deviation to γ'_j . Note that $g_k(\gamma_k^*, c_k^*(\gamma'_j, \gamma_{-j}^*))$ is individually BIC for all $k \neq j$ by Lemma 2. Then, with a slight abuse of notation, let principal j choose a degenerate probability distribution $c_{0j}(\gamma'_j) \in M_{0j} = \Pi_j^B$ satisfying

$$c_{0j}(\gamma'_j) \in \arg \max_{\pi_j \in \Pi_j^B} \mathbb{E}_x [V_j (\pi_j(x), g_{-j} (\gamma_{-j}^*, c_{-j}^*(\gamma'_j, \gamma_{-j}^*, x)), x)], \quad (27)$$

and let each agent choose a non-degenerate probability distribution that chooses her true type with probability one and send it to principal j , i.e., for all $i \in \mathcal{I}$ and a.e. $x_i \in X_i$

$$c_{ij}(\gamma'_j, \gamma_{-j}^*, x_i) = x_i. \quad (28)$$

Principal j takes $g_k(\gamma_k^*, c_k^*(\gamma'_j, \gamma_{-j}^*, \cdot))$ for all $k \neq j$ as given. Given agents' truthful type reporting to him, $c_{0j}(\gamma'_j)$ satisfying (27) is clearly principal j 's optimal choice of a direct mechanism in $M_{0j} = \Pi_j^B$. Given principal j 's choice of a BIC direct mechanism $\pi_j = c_{0j}(\gamma'_j)$, truthful type reporting (i.e., (28)) is also optimal for every agent i of a.e. $x_i \in X_i$. Therefore, (26), (27) and (28) constitute a *continuation equilibrium* at $(\gamma'_j, \gamma_{-j}^*)$.

Because $g_{-j}(\gamma_{-j}^*, c_{-j}^*(\gamma'_j, \gamma_{-j}^*)) \in \Pi_{-j}^B$, principal j 's utility in this continuation equi-

librium upon deviation to γ'_j is no less than \underline{V}_j :

$$\max_{\pi_j \in \Pi_j^B} \mathbb{E}_x [V_j(\pi_j(x), g_{-j}(\gamma_{-j}^*, c_{-j}^*(\gamma'_j, \gamma_{-j}^*, x)), x)] \geq \underline{V}_j \quad (29)$$

(24) and (29) show that

$$\begin{aligned} \max_{\pi_j \in \Pi_j^B} \mathbb{E}_x [V_j(\pi_j(x), g_{-j}(\gamma_{-j}^*, c_{-j}^*(\gamma'_j, \gamma_{-j}^*, x)), x)] > \\ \mathbb{E}_x [V_j(g_j(\gamma_j^*, c_j^*(\gamma^*, x)), g_{-j}(\gamma_{-j}^*, c_{-j}^*(\gamma^*, x)), x)] \end{aligned}$$

and hence principal j 's utility in this continuation equilibrium is greater than his equilibrium utility. Because this continuation equilibrium upon deviation to γ'_j is constructed with (26), (9) in the definition of a robust PBE is violated. Therefore, any robust PBE allocation must be in the set on the right hand side of (23)

To complete the proof, I need to show how to construct a robust PBE to support an allocation in the set on the right hand side of (23). Consider an allocation $\pi^* = (\pi_1^*, \dots, \pi_J^*)$ in the set on the right hand side of (23). For each $k \in \mathcal{J}$, I consider the following *deviator-reporting mechanism* $\gamma_k^\star : M_{1k} \times \dots \times M_{Ik} \rightarrow \Delta(A_k)$, where, with a slight abuse of notation, $M_{ik} = \{1, \dots, J\} \times X_i$ (precisely, M_{ik} is homeomorphic to $\{1, \dots, J\} \times X_i$, that is there exists a homeomorphism $\vartheta_{ik} : \{1, \dots, J\} \times X_i \rightarrow M_{ik}$). Note that a deviator-reporting mechanism is a standard mechanism in $\bar{\Gamma}_k$ where the principal does not send a message to himself. In this deviator-reporting mechanism, each agent sends a message on who the deviator is, if any, and her type. If more than a half of agents report $j \neq k$ as the deviator, principal k assigns a BIC direct mechanism π_k^j that punishes principal k . Otherwise, he assigns π_k^* . I choose the following BIC direct mechanism for π_k^j . For all $j \in \mathcal{J}$, then π_k^j is principal k 's BIC direct mechanism in π_{-j}^j satisfying

$$\pi_{-j}^j = (\pi_k^j)_{k \neq j} \in \arg \min_{\pi_{-j} \in \Pi_{-j}^B} \left[\max_{\pi_j \in \Pi_j^B} \mathbb{E}_x [V_j(\pi_j(x), \pi_{-j}(x), x)] \right]. \quad (30)$$

(30) implies that

$$\mathbb{E}_x [V_j(\pi^*(x), x)] \geq \max_{\pi_j \in \Pi_j^B} \mathbb{E}_x [V_j(\pi_j(x), \pi_{-j}^j(x), x)] = \underline{V}_j \quad (31)$$

because $\pi^* = (\pi_1^*, \dots, \pi_J^*)$ in the set on the right hand side of (23).

Principal k 's deviator-reporting mechanism is constructed as follows. For all $((\ell_{1k},$

$x_{1k}), \dots, (\ell_{Ik}, x_{Ik})) \in \times_{i \in \mathcal{I}} M_{ik}$,

$$\gamma_k^\star((\ell_{1k}, x_{1k}), \dots, (\ell_{Ik}, x_{Ik})) = \begin{cases} \pi_k^j(x_{1k}, \dots, x_{Ik}) & \text{if } \#\{\ell_{ik} = j \text{ for } j \neq k\} > I/2 \\ \pi_k^*(x_{1k}, \dots, x_{Ik}) & \text{otherwise} \end{cases}. \quad (32)$$

Every principal k offers the mechanism γ_k^\star specified in (32). Suppose that no principal deviates. Then, each agent i of a.e. $x_i \in X_i$ truthfully reports x_i to every principal k along with the message $\ell_{ik} = k$. Then γ_k^\star implements $\pi_k^*(x_1, \dots, x_I)$. Since there are three or more agents, any single agent i 's deviation from $\ell_{ik} = k$ does not prevent principal k from implementing $\pi_k^*(x_1, \dots, x_I)$. Because π_k^* is individually BIC, such communication behavior constitutes a continuation equilibrium and each principal k receives the utility of $\mathbb{E}_x [V_k(\pi^*(x), x)]$.

Suppose that principal j deviates to a general mechanism $\gamma_j : M_j \rightarrow \Delta(A_j)$. Then, each agent i of a.e. $x_i \in X_i$ truthfully reports x_i to every principal $k \neq j$ along with the message $\ell_{ik} = j$. Then, γ_k^\star implements $\pi_k^j(x_1, \dots, x_I)$. Because π_k^j is individually BIC, I can fix such communication behavior for a continuation equilibrium upon principal j 's deviation to γ_j . Let $(c_{0j}(\gamma_j), c_{1j}(\gamma_j, \gamma_{-j}^\star, \cdot), \dots, c_{Ij}(\gamma_j, \gamma_{-j}^\star, \cdot))$ be arbitrary continuation-equilibrium strategies of communicating with principal j upon j 's deviation to γ_j . Then, it is clear that

$$g_j(\gamma_j, c_{0j}(\gamma_j), c_{1j}(\gamma_j, \gamma_{-j}^\star, \cdot), \dots, c_{Ij}(\gamma_j, \gamma_{-j}^\star, \cdot)) \in \Pi_j^B. \quad (33)$$

Because of (33), I have that

$$\max_{\pi_j \in \Pi_j^B} \mathbb{E}_x [V_j(\pi_j(x), \pi_{-j}^j(x), x)] \geq \mathbb{E}_x [V_j(g_j(\gamma_j, c_j(\gamma_j, \gamma_{-j}^\star, x)), \pi_{-j}^j(x), x)] \quad (34)$$

where $c_j(\gamma_j, \gamma_{-j}^\star, x) = (c_{0j}(\gamma_j), c_{1j}(\gamma_j, \gamma_{-j}^\star, x_1), \dots, c_{Ij}(\gamma_j, \gamma_{-j}^\star, x_I))$. Note that the expression on the right hand side of (34) is principal j 's utility in a continuation equilibrium upon deviation to γ_j . Combining (31) and (34) yields

$$\mathbb{E}_x [V_j(\pi^*(x), x)] \geq \mathbb{E}_x [V_j(g_j(\gamma_j, c_j(\gamma_j, \gamma_{-j}^\star, x)), \pi_{-j}^j(x), x)], \quad (35)$$

which shows that principal j cannot gain upon deviation to γ_j . (35) implies that $\pi^* = (\pi_1^*, \dots, \pi_J^*)$ is supported as a robust PBE allocation because the first argument $g_j(\gamma_j, c_j(\gamma_j, \gamma_{-j}^\star, x))$ on the right-hand side of (35) is derived with any continuation-

equilibrium strategies of communicating with principal j , $\left(c_{0j}(\gamma_j), c_{1j}(\gamma_j, \gamma_{-j}^\star, \cdot), \dots, c_{Ij}(\gamma_j, \gamma_{-j}^\star, \cdot)\right)$, given agents' truth telling to non-deviating principals. ■

The proof of Theorem 2 first establishes that a principal's utility in a robust PBE (γ^\star, c^\star) cannot be lower than his minmax value over BIC direct mechanisms. Given continuation-equilibrium strategies c_{-j}^\star of communicating with non-deviating principals, principal j can deviate to a general mechanism γ'_j where he can choose any BIC direct mechanism from Π_j^B and agents send their type messages to principal j at the same time. Given the robustness of PBE, principal j can implement the BIC direct mechanism from Π_j^B that maximizes his utility, taking $g_{-j}(\gamma_{-j}^\star, c_{-j}^\star(\gamma'_j, \gamma_{-j}^\star)) \in \Pi_{-j}^B$ as given. This directly implies that principal j 's robust PBE utility cannot be lower than his minmax value over BIC direct mechanisms.

The proof of Theorem 2 is completed by constructing the deviator-reporting mechanism to show how to support any profile of BIC direct mechanisms that provides every principal a utility no less than his minmax value over BIC direct mechanisms as a robust PBE allocation.

The existence of a robust PBE with deviator-reporting mechanisms can be addressed. First consider a continuation equilibrium upon principal j 's deviation to a general mechanism γ_j . If principal j deviates, the truth-telling continuation equilibrium that implements π_{-j}^j is also well established and exists when it comes to communicating with non-deviating principals.

One may wonder if there is a (mixed-strategy) continuation equilibrium

$$\left(c_{0j}(\gamma_j), c_{1j}(\gamma_j, \gamma_{-j}^\star, \cdot), \dots, c_{Ij}(\gamma_j, \gamma_{-j}^\star, \cdot)\right)$$

exists for communicating with deviating principal j upon his deviation to a general mechanism γ_j . When agents and principal j send messages to principal j given his mechanism γ_j , they take π_{-j}^j as given. For all $(m_{0j}, m_{1j}, \dots, m_{Ij}) \in M_j$ and all $x \in X$, principal j 's utility for the subgame defined by γ_j follows

$$\mathcal{V}_j(m_{0j}, m_{1j}, \dots, m_{Ij}, x) := V_j(\gamma_j(m_{0j}, m_{1j}, \dots, m_{Ij}), \pi_{-j}^j(x), x). \quad (36)$$

Because the agent's utility function is additively separable with respect to principals' actions, the agent's relevant utility for the subgame defined by γ_j is

$$\mathcal{U}_{ij}(m_{0j}, m_{1j}, \dots, m_{Ij}, x) := U_{ij}(\gamma_j(m_{0j}, m_{1j}, \dots, m_{Ij}), x). \quad (37)$$

If \mathcal{V}_j and \mathcal{U}_{ij} and the information structure satisfy the sufficient conditions for the existence of a Bayesian equilibrium with continuous actions identified in the literature (Balder (1988), Hellman and Levy (2017), Milgrom and Weber (1985), etc.), then a continuation equilibrium for the subgame defined by γ_j exists.¹⁰

Because any (mixed) continuation-equilibrium strategies

$$\left(c_{0j}(\gamma_j), c_{1j}(\gamma_j, \gamma_{-j}^\star, \cdot), \dots, c_{Ij}(\gamma_j, \gamma_{-j}^\star, \cdot) \right)$$

upon deviation to any mechanism γ_j induces a BIC direct mechanism

$$g_j \left(\gamma_j, c_{0j}(\gamma_j), c_{1j}(\gamma_j, \gamma_{-j}^\star, \cdot), \dots, c_{Ij}(\gamma_j, \gamma_{-j}^\star, \cdot) \right) \in \Pi_j^B, \quad (38)$$

the notion of robustness makes it possible for principal j to focus on any BIC direct mechanism in Π_j^B for his deviation.

Finally, note that a deviator-reporting mechanism γ_k^\star can be viewed as one of mechanisms in Γ_k for all k and each principal j receives a utility no higher than \underline{V}_j upon deviation to any $\gamma_j \in \Gamma_j$ in a continuation equilibrium where agents report the identity of a deviator and their types truthfully to non-deviating principals whose mechanisms are deviator-reporting mechanisms. Given the structure of a deviator-reporting mechanism and (38), this implies that a robust PBE of a general competing mechanism game with Γ exists if (i) $\Pi_{RB}^* = \{ \pi \in \Pi^B : \mathbb{E}_x [V_j(\pi(x), x)] \geq \underline{V}_j \text{ for all } j \in \mathcal{J} \}$ is non-empty¹¹ and (ii) \mathcal{V}_j and \mathcal{U}_{ij} defined for any given γ_j ((36) and (37)), and the information structure satisfy the sufficient conditions for the existence of a Bayesian equilibrium with continuous actions identified in the literature (Balder (1988), Hellman and Levy (2017), Milgrom and Weber (1985), etc.).

Note that it is clear that $\Pi_B^* \subset \Pi_{RB}^*$. Applying (21), we have that

$$\Pi_{UB}^* \subset \Pi_B^* \subset \Pi_{RB}^*.$$

All three sets are independent of the set of general mechanisms allowed in competing mechanism games and they are all specified in terms of BIC direct mechanisms. My

¹⁰For example, \mathcal{V}_j and \mathcal{U}_{ij} are uniformly continuous and the information structure is absolutely continuous (Milgrom and Weber (1985)), then a (mixed-strategy) continuation equilibrium exists. However, the existence of a (mixed-strategy) continuation equilibrium for communicating with principal j upon his deviation should come naturally. When principal j deviates, he will certainly deviate to a mechanism that guarantees the existence of a (mixed-strategy) continuation equilibrium for communicating with him.

¹¹ Π_R^* is non-empty because $\Pi_B^* \subset \Pi_R^*$ and Π_B^* is non-empty because of Corollary 1.

paper identifies the notions of PBEs that produce those sets of allocations as the sets of equilibrium allocations in general competing mechanism games respectively.

6 Discussion

For a robust equilibrium, the standard competing mechanism game is restrictive in the sense that it takes the freedom of choosing any BIC direct mechanism away from a principal at the same time agents send messages to him given his mechanism. In the standard competing mechanism game, a deviating principal's utility can be as low as his maxmin value over BIC direct mechanisms:

$$\max_{\pi_j \in \Pi_j^B} \min_{\pi_{-j} \in \Pi_{-j}^B} \mathbb{E}_x [V_j(\pi_j(x), \pi_{-j}(x), x)]$$

The reason is that agents' communication with the deviator alone induces a BIC direct mechanism from the deviator's mechanism and non-deviators can choose their BIC direct mechanisms conditional on agents' reports on the deviator's BIC direct mechanism that they induce from the deviator's mechanism.

When random mechanisms are allowed as in our paper and there are only two principals, the restrictive feature of the standard competing mechanism game is not a problem. To see this, I use Sion's minimax theorem.

Theorem 3 (Sion's minimax theorem (1958)) *Let Y and Z be convex, compact spaces. If the real-valued function f on $Y \times Z$ is quasi-concave and upper semi-continuous in Y and quasi-convex and lower semi-continuous in Z ,*

$$\inf_{y \in Y} \sup_{z \in Z} f(y, z) = \sup_{z \in Z} \inf_{y \in Y} f(y, z).$$

For the case of $J = 2$, it is easily shown that

$$\min_{\pi_{-j} \in \Pi_{-j}^B} \max_{\pi_j \in \Pi_j^B} \mathbb{E}_x [V_j(\pi_j(x), \pi_{-j}(x), x)] = \max_{\pi_j \in \Pi_j^B} \min_{\pi_{-j} \in \Pi_{-j}^B} \mathbb{E}_x [V_j(\pi_j(x), \pi_{-j}(x), x)] \quad (39)$$

Since Π_k^B is a compact convex set for all $k \in \mathcal{J}$, the properties of the domain of the functions in Sion's Minimax Theorem (1958) are satisfied. Since $\mathbb{E}_x [V_j(\pi_j(x), \pi_{-j}(x), x)]$ is linear in each Π_k^B I can apply Sion's Minimax Theorem to establish (39).

In the case of $J \geq 3$, one cannot swap the max and min in (39). To see this reason, interpret Π_{-j}^B as the set of degenerate probability distributions that put probability one

on a profile of individually BIC direct mechanisms for principals except for j . A convex combination between two such degenerate probability distributions creates correlation between two profiles of individually BIC direct mechanisms and such correlation is not feasible if I only focus on degenerate probability distributions that put probability one on a profile of individually BIC direct mechanisms. Therefore, Π_{-j}^B is not a convex set in terms of the probability measure space and hence one cannot apply Sion's Minimax Theorem (1958). Therefore, Szentes' critique is valid in a model with incomplete information as to the set of allocations supportable in robust PBEs where agents' strategies of communicating with non-deviating principals and their induced BIC direct mechanisms are responsive to market changes. However, allocations supportable in market-information invariant robust PBEs are free from Szentes' critique as shown in Section 4.

Robust PBE vs. PBE It can be also shown that Szentes' critique is generally valid for PBE as well. However, the set of PBE allocations cannot be characterized by incentive compatibility alone for PBE or robust PBE. To see this point, let $\mathcal{C}_j^*(\pi_{-j}, \gamma_j)$ be the set of all continuation equilibrium strategies of communicating with principal j conditional on truth telling type reporting to the other principals given $(\pi_{-j}, \gamma_j) \in \Pi_{-j}^B \times \Gamma_j$. Using recommendation mechanisms for non-deviators' equilibrium mechanisms (Yamashita (2010)), I can show that the greatest lower bound of principal j 's PBE utility is

$$\begin{aligned} \underline{V}_j^P &\equiv \min_{\pi_{-j} \in \Pi_{-j}^B} \max_{\gamma_j \in \Gamma_j} \min_{c_j(\pi_{-j}, \gamma_j) \in \mathcal{C}_j^*(\pi_{-j}, \gamma_j)} \mathbb{E}_x [V_j(\gamma_j(c_j(\pi_{-j}, \gamma_j, x)), \pi_{-j}(x), x)] \\ &= \min_{\pi_{-j} \in \Pi_{-j}^B} \max_{\pi_j \in \hat{\Pi}_j^B(\Gamma_j)} \mathbb{E}_x [V_j(\pi_j(x)), \pi_{-j}(x), x)], \end{aligned}$$

where

$$\hat{\Pi}_j^B(\Gamma_j) \equiv \left\{ \begin{array}{l} \gamma_j(c_j(\pi_{-j}, \gamma_j, \cdot)) \in \Pi_j^B : \\ \text{(i) } \gamma_j \in \Gamma_j, \text{ (ii) } c_j(\pi_{-j}, \gamma_j) \in \mathcal{C}_j^*(\pi_{-j}, \gamma_j), \\ \text{(iii) } \mathbb{E}_x [V_j(\gamma_j(c_j(\pi_{-j}, \gamma_j, x)), \pi_{-j}(x), x)] \leq \\ \mathbb{E}_x [V_j(\gamma_j(c'_j(\pi_{-j}, \gamma_j, x)), \pi_{-j}(x), x)] \quad \forall c'_j(\pi_{-j}, \gamma_j) \in \mathcal{C}_j^*(\pi_{-j}, \gamma_j) \end{array} \right\}$$

It is clear that $\hat{\Pi}_j^B(\Gamma_j) \subset \Pi_j^B$ but generally $\hat{\Pi}_j^B(\Gamma_j)$ is not equal to Π_j^B . The reason is that given the other principals' BIC direct mechanisms $\pi_{-j} \in \Pi_{-j}^B$, some direct mechanisms in Π_j^B may not be induced by the worst continuation equilibrium regardless of

his deviation to any mechanism in Γ_j .

Identifying the set of strongly robust equilibrium is challenging even in the standard competing mechanism game. It is not known how to characterize the greatest lower bound of each principal's strongly robust PBE utility even in terms of mechanisms allowed in the game just like Yamashita (2010) does for the greatest lower bound of each principal's PBE equilibrium utility.

Together with the separability assumption on agents' utility function, the notion of robust PBE allows us to focus on the incentive compatibility alone to identify the set of equilibrium allocations because Π_k^B is defined only with the incentive compatibility respectively for each $k \in \mathcal{J}$.

Mixed strategies for principals I have not considered mixed strategies for principals. This can be done easily. Consider the general competing mechanism game. When principal j deviates given that the other principals employ mixed strategies for their mechanism choice, he can deviate to a general mechanism where he asks agents not only about their types but also the BIC direct mechanisms π_{-j} induced from the other principals' mechanisms. Principal j 's message in this general mechanism is a mapping from Π_{-j}^B into Π_j^B , which specifies his choice of a BIC direct mechanism as a function of agents' reports on the other principals' BIC direct mechanisms. In this way, even in a mixed-strategy robust PBE, a deviating principal can always implement a BIC direct mechanism that maximizes his utility conditional on BIC direct mechanisms induced by the other principals' mechanisms. Therefore, the greatest lower bound of principal j 's mixed-strategy robust PBE utility is the same as the greatest lower bound of his pure-strategy robust PBE utility, that is, his minmax value \underline{V}_j over BIC direct mechanisms. For all j , let

$$\Phi_j(\sigma_1, \dots, \sigma_J) := \int_{\Pi_1^B} \cdots \int_{\Pi_J^B} \mathbb{E}_x [V_j(\pi_1(x), \dots, \pi_J(x), x)] d\sigma_1 \cdots d\sigma_J,$$

where $(\sigma_1, \dots, \sigma_J) \in \Delta(\Pi_1^B) \times \cdots \times \Delta(\Pi_J^B)$. Then, the set of mixed-strategy robust PBE allocations of a general competing mechanism game with Γ is

$$\{(\sigma_1, \dots, \sigma_J) \in \Delta(\Pi_1^B) \times \cdots \times \Delta(\Pi_J^B) : \Phi_j(\sigma_1, \dots, \sigma_J) \geq \underline{V}_j \text{ for all } j \in \mathcal{J}\}.$$
